`SELECT ... FOR SHARE` is a replacement for `SELECT ... LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility. The statements are equivalent. However, `FOR SHARE` supports `OF table_name`, `NOWAIT`, and `SKIP LOCKED` options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

- `SELECT ... FOR UPDATE`

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... FOR SHARE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by `FOR SHARE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

Note

Locking reads are only possible when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0).

A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table `t2`.

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
```

To lock rows in table `t2`, add a locking read clause to the subquery:

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
```

Locking Read Examples

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `FOR SHARE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' FOR SHARE;
```

After the `FOR SHARE` query returns the parent `'Jones'`, you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `FOR SHARE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locking Read Concurrency with `NOWAIT` and `SKIP LOCKED`

If a row is locked by a transaction, a `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` transaction that requests the same locked row must wait until the blocking transaction releases the row lock. This behavior prevents transactions from updating or deleting rows that are queried for updates by other transactions. However, waiting for a row lock to be released is not necessary if you want the query to return immediately when a requested row is locked, or if excluding locked rows from the result set is acceptable.

To avoid waiting for other transactions to release row locks, `NO WAIT` and `SKIP LOCKED` options may be used with `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` locking read statements.

- `NOWAIT`

A locking read that uses `NOWAIT` never waits to acquire a row lock. The query executes immediately, failing with an error if a requested row is locked.

- `SKIP LOCKED`

A locking read that uses `SKIP LOCKED` never waits to acquire a row lock. The query executes immediately, removing locked rows from the result set.

Note

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`NO WAIT` and `SKIP LOCKED` only apply to row-level locks.

Statements that use `NO WAIT` or `SKIP LOCKED` are unsafe for statement based replication.

The following example demonstrates `NOWAIT` and `SKIP LOCKED`. Session 1 starts a transaction that takes a row lock on a single record. Session 2 attempts a locking read on the same record using the `NOWAIT` option. Because the requested row is locked by Session 1, the locking read returns immediately with an error. In Session 3, the locking read with `SKIP LOCKED` returns the requested rows except for the row that is locked by Session 1.

```
# Session 1:

mysql> CREATE TABLE t (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;

mysql> INSERT INTO t (i) VALUES(1),(2),(3);

mysql> START TRANSACTION;

mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE;
+----+
| i  |
+----+
| 2  |
+----+

# Session 2:
```

```
mysql> START TRANSACTION;

mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE NOWAIT;
ERROR 3572 (HY000): Do not wait for lock.

# Session 3:

mysql> START TRANSACTION;

mysql> SELECT * FROM t FOR UPDATE SKIP LOCKED;
+----+
| i  |
+----+
| 1  |
| 3  |
+----+
```

15.5.3 Locks Set by Different SQL Statements in InnoDB

A [locking read](#), an [UPDATE](#), or a [DELETE](#) generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are [WHERE](#) conditions in the statement that would exclude the row. [InnoDB](#) does not remember the exact [WHERE](#) condition, but only knows which index ranges were scanned. The locks are normally [next-key locks](#) that also block inserts into the “gap” immediately before the record. However, [gap locking](#) can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 15.5.1, “InnoDB Locking”](#). The transaction isolation level also can affect which locks are set; see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

If a secondary index is used in a search and index record locks to be set are exclusive, [InnoDB](#) also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

[InnoDB](#) sets specific types of locks as follows.

- [SELECT ... FROM](#) is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to [SERIALIZABLE](#). For [SERIALIZABLE](#) level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- [SELECT ... FOR UPDATE](#) and [SELECT ... FOR SHARE](#) statements that use a unique index acquire locks for scanned rows, and release the locks for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the [WHERE](#) clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a [UNION](#), scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.
- For [locking reads](#) ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#), and [DELETE](#) statements, the locks that are taken depend on whether the statement uses a unique index with a unique search condition, or a range-type search condition.
 - For a unique index with a unique search condition, [InnoDB](#) locks only the index record found, not the [gap](#) before it.

- For other search conditions, and for non-unique indexes, [InnoDB](#) locks the index range scanned, using [gap locks](#) or [next-key locks](#) to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 15.5.1, “InnoDB Locking”](#).
- For index records the search encounters, `SELECT ... FOR UPDATE` blocks other sessions from doing `SELECT ... FOR SHARE` or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an [InnoDB](#) table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
```

```
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.
- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, InnoDB does the search on `S` as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from `S`. InnoDB has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 15.5.2, “InnoDB Transaction Model”](#).

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks.

Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). See also [Section 15.8.1.7, “Limits on InnoDB Tables”](#).

15.5.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the

index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When `InnoDB` scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by `InnoDB` include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 15.5.1, “InnoDB Locking”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

15.5.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see [Section 15.5.5.1, “An InnoDB Deadlock Example”](#).

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see [Section 15.5.5.3, “How to Minimize and Handle Deadlocks”](#).

When deadlock detection is enabled (the default) and a deadlock does occur, `InnoDB` detects the condition and rolls back one of the transactions (the victim). If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, `InnoDB` relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock. Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an `InnoDB` user transaction, use the `SHOW ENGINE INNODB STATUS` command. If frequent deadlocks highlight a problem with transaction structure or application error handling, run with the `innodb_print_all_deadlocks` setting enabled to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

15.5.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an `S` lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 FOR SHARE;
+-----+
| i     |
+-----+
| 1     |
+-----+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

15.5.5.2 Deadlock Detection and Rollback

When [deadlock detection](#) is enabled (the default), InnoDB automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back.

If the `LATEST DETECTED DEADLOCK` section of InnoDB Monitor output includes a message stating, “TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,” this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

15.5.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the `SHOW ENGINE INNODB STATUS` command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you use [locking reads](#) (`SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or

call stored routines, rather than coding multiple similar sequences of [INSERT](#), [UPDATE](#), and [DELETE](#) statements in different places.

- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use [EXPLAIN SELECT](#) to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a [SELECT](#) to return data from an old snapshot, do not add the clause [FOR UPDATE](#) or [FOR SHARE](#) to it. Using the [READ COMMITTED](#) isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use [LOCK TABLES](#) with transactional tables, such as [InnoDB](#) tables, is to begin a transaction with [SET autocommit = 0](#) (not [START TRANSACTION](#)) followed by [LOCK TABLES](#), and to not call [UNLOCK TABLES](#) until you commit the transaction explicitly. For example, if you need to write to table [t1](#) and read from table [t2](#), you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the [InnoDB](#) instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

15.6 InnoDB Configuration

This section provides configuration information and procedures for [InnoDB](#) initialization, startup, and various components and features of the [InnoDB](#) storage engine. For information about optimizing database operations for [InnoDB](#) tables, see [Section 8.5, “Optimizing for InnoDB Tables”](#).

15.6.1 InnoDB Startup Configuration

The first decisions to make about [InnoDB](#) configuration involve the configuration of data files, log files, page size, and memory buffers. It is recommended that you define data file, log file, and page size configuration before creating the [InnoDB](#) instance. Modifying data file or log file configuration after the [InnoDB](#) instance is created may involve a non-trivial procedure, and page size can only be defined when the [InnoDB](#) instance is first initialized.

In addition to these topics, this section provides information about specifying [InnoDB](#) options in a configuration file, viewing [InnoDB](#) initialization information, and important storage considerations.

- [Specifying Options in a MySQL Configuration File](#)
- [Viewing InnoDB Initialization Information](#)
- [Important Storage Considerations](#)
- [System Tablespace Data File Configuration](#)
- [InnoDB Log File Configuration](#)

- [InnoDB Undo Tablespace Configuration](#)
- [InnoDB Temporary Tablespace Configuration](#)
- [InnoDB Page Size Configuration](#)
- [InnoDB Memory Configuration](#)

Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size configuration settings to initialize the [InnoDB](#) instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing [InnoDB](#) for the first time. [InnoDB](#) is initialized when the MySQL server is started, and the first initialization of [InnoDB](#) normally occurs the first time you start the MySQL server.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in [Section 4.2.7, “Using Option Files”](#).

To make sure that `mysqld` reads options only from a specific file (and `mysqld-auto.cnf`), use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

Viewing InnoDB Initialization Information

To view [InnoDB](#) initialization information during startup, start `mysqld` from a command prompt. When `mysqld` is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 8.0\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
shell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information [InnoDB](#) printed during the startup process.

For information about starting MySQL using other methods, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).

Note

[InnoDB](#) does not open all user tables and associated data files at startup. However, [InnoDB](#) does check for the existence of tablespace files (`*.ibd` files) that are referenced in the data dictionary. If a tablespace file is not found, [InnoDB](#) logs an error and continues the startup sequence. Tablespace files that are referenced in the redo log may be opened during crash recovery for redo application.

Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example,

you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See [Section 15.7.3, “Using Raw Disk Partitions for the System Tablespace”](#).

- InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and higher, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see [Section 15.11.1, “InnoDB Disk I/O”](#).
- Before using NFS with InnoDB, review potential issues outlined in [Using NFS with MySQL](#).

System Tablespace Data File Configuration

The `innodb_data_file_path` configuration option defines the name, size, and attributes of InnoDB system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

To specify more than one data file, separate them by semicolon (;) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

The following setting configures a single 12MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

File size is specified using `K`, `M`, or `G` suffix letters to indicate units of KB, MB, or GB. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 12MB.

A minimum file size is enforced for the *first* system tablespace data file to ensure that there is enough space for doublewrite buffer pages:

- For an `innodb_page_size` value of 16KB or less, the minimum file size is 3MB.
- For an `innodb_page_size` value of 32KB, the minimum file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum file size is 12MB.

A system tablespace with a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, file size, and optional `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the data file that is specified last in the `innodb_data_file_path` setting.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The `autoextend` increment is 64MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For instructions, see [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly causing the server to exit. The following configuration permits `ibdata1` to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

InnoDB creates system tablespace files in the MySQL data directory by default (`datadir`). To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to create two files named `ibdata1` and `ibdata2` in a directory named `myibdata`, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note

A trailing slash is required when specifying a value for `innodb_data_home_dir`.

InnoDB does not create directories, so make sure that the `myibdata` directory exists before you start the server. Use the Unix or DOS `mkdir` command to create directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If the `innodb_data_home_dir` option is not specified,

the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/path/to/myibdata/ibdata1:50M:/path/to/myibdata/ibdata2:50M:autoextend
```

InnoDB Log File Configuration

By default, **InnoDB** creates two 48MB log files in the MySQL data directory (`datadir`) named `ib_logfile0` and `ib_logfile1`.

The following options can be used to modify the default configuration:

- `innodb_log_group_home_dir` defines directory path to the **InnoDB** log files (the redo logs). If this option is not configured, **InnoDB** log files are created in the MySQL data directory (`datadir`).

You might use this option to place **InnoDB** log files in a different physical storage location than **InnoDB** data files to avoid potential I/O resource conflicts. For example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

Note

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- `innodb_log_files_in_group` defines the number of log files in the log group. The default and recommended value is 2.
- `innodb_log_file_size` defines the size in bytes of each log file in the log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

InnoDB Undo Tablespace Configuration

By default, undo logs reside in two [undo tablespaces](#). The I/O patterns for undo logs make undo tablespaces good candidates for [SSD](#) storage. Because undo logs can become large during long-running transactions, having undo logs in multiple undo tablespaces reduces the maximum size of any one undo tablespace.

The `innodb_undo_directory` configuration option defines the path where **InnoDB** creates tablespaces for the undo logs. If a path is not specified for `innodb_undo_directory`, undo tablespaces are created

in the MySQL data directory, as defined by `datadir`. The `innodb_undo_directory` option is non-dynamic. Configuring it requires restarting the server.

**Note**

`innodb_undo_tablespaces` is deprecated and will be removed in a future release.

For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

InnoDB Temporary Tablespace Configuration

By default, InnoDB creates a single auto-extending temporary tablespace data file named `ibtmp1` that is slightly larger than 12MB in the `innodb_data_home_dir` directory. The default temporary tablespace data file configuration can be modified at startup using the `innodb_temp_data_file_path` configuration option.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending K, M, or G to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

The `innodb_data_home_dir` default value is the MySQL data directory (`datadir`).

An autoextending temporary tablespace data file can become large in environments that use large temporary tables or that use temporary tables extensively. A large data file can also result from long running queries that use temporary tables. To prevent the temporary data file from becoming too large, configure the `innodb_temp_data_file_path` option to specify a maximum data file size. For more information see [Managing Temporary Tablespace Data File Size](#).

InnoDB Page Size Configuration

The `innodb_page_size` option specifies the page size for all InnoDB tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64KB, 32KB, 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default page size of 16KB is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

InnoDB Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for InnoDB, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use MyISAM tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

Buffers specific to InnoDB are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for InnoDB tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size`

is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see [Section 8.12.3.1, “How MySQL Uses Memory”](#). For information about how to configure InnoDB buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#). Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the by `innodb_buffer_pool_instances` option. By default, InnoDB creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).

- `innodb_log_buffer_size` defines the size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default size is 16MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. `glibc` may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size` + `read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See [Section 8.12.3.2, “Enabling Large Page Support”](#).

15.6.2 Configuring InnoDB for Read-Only Operation

You can now query InnoDB tables where the MySQL data directory is on read-only media, by enabling the `--innodb-read-only` configuration option at server startup.

How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is [flushed](#) to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a [slow shutdown](#).

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`
- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`
- `--innodb_temp_data_file_path`. This option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The default setting is `ibtmp1:12M:autoextend`, which creates the `ibtmp1` temporary tablespace data file in the data directory. To prepare an instance for read-only operation, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory; for example:

```
--innodb_temp_data_file_path=../../tmp/ibtmp1:12M:autoextend
```

As of MySQL 8.0, enabling `innodb_read_only` prevents table creation and drop operations for all storage engines. These operations modify data dictionary tables in the `mysql` system database, but those tables use the InnoDB storage engine and cannot be modified when `innodb_read_only` is enabled. The same restriction applies to any operation that modifies data dictionary tables, such as `ANALYZE TABLE` and `ALTER TABLE tbl_name ENGINE=engine_name`.

In addition, other tables in the `mysql` system database use the InnoDB storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. For example, `CREATE USER`, `GRANT`, `REVOKE`, and `INSTALL PLUGIN` operations are not permitted in read-only mode.

Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.
- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid [bottlenecks](#) that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.
- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No [change buffering](#) is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a [slow shutdown](#) first.
- There is no [crash recovery](#) phase at startup. The instance must have performed a [slow shutdown](#) before being put into the read-only state.

- Because the [redo log](#) is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.
- All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any [deadlock](#).
- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.
- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.
- The [MVCC](#) processing to enforce [isolation levels](#) is turned off. All queries read the latest version of a record, because update and deletes are not possible.
- The [undo log](#) is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

15.6.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the [InnoDB](#) buffer pool.

15.6.3.1 The InnoDB Buffer Pool

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning. For information about how the [InnoDB](#) buffer pool works, see [InnoDB Buffer Pool LRU Algorithm](#).

You can configure the various aspects of the [InnoDB](#) buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more [InnoDB](#) acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).
- With 64-bit systems with large memory sizes, you can split the buffer pool into multiple parts, to minimize contention for the memory structures among concurrent operations. For details, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).
- You can keep frequently accessed data in memory despite sudden spikes of activity for operations such as backups or reporting. For details, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#).
- You can control when and how [InnoDB](#) performs read-ahead requests to prefetch pages into the buffer pool asynchronously, in anticipation that the pages will be needed soon. For details, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- You can control when background flushing of dirty pages occurs and whether or not [InnoDB](#) dynamically adjusts the rate of flushing based on workload. For details, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).
- You can fine-tune aspects of [InnoDB](#) buffer pool flushing behavior to improve performance. For details, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).
- You can configure how [InnoDB](#) preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. You can also save the current buffer pool state while the server is running. For details, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

InnoDB Buffer Pool LRU Algorithm

InnoDB manages the buffer pool as a list, using a variation of the least recently used (LRU) algorithm. When room is needed to add a new page to the pool, InnoDB evicts the least recently used page and adds the new page to the middle of the list. This “midpoint insertion strategy” treats the list as two sublists:

- At the head, a sublist of “new” (or “young”) pages that were accessed recently.
- At the tail, a sublist of “old” pages that were accessed less recently.

This algorithm keeps pages that are heavily used by queries in the new sublist. The old sublist contains less-used pages; these pages are candidates for [eviction](#).

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When InnoDB reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read in because it is required for a user-specified operation such as an SQL query, or as part of a [read-ahead](#) operation performed automatically by InnoDB.
- Accessing a page in the old sublist makes it “young”, moving it to the head of the buffer pool (the head of the new sublist). If the page was read in because it was required, the first access occurs immediately and the page is made young. If the page was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the page is evicted).
- As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused for long enough reaches the tail of the old sublist and is evicted.

By default, pages read by queries immediately move into the new sublist, meaning they stay in the buffer pool longer. A table scan (such as performed for a [mysqldump](#) operation, or a [SELECT](#) statement with no [WHERE](#) clause) can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and then accessed only once move to the head of the new list. These situations can push frequently used pages to the old sublist, where they become subject to eviction. For information about optimizing this behavior, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#), and [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

InnoDB Standard Monitor output contains several fields in the [BUFFER POOL AND MEMORY](#) section that pertain to operation of the buffer pool LRU algorithm. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

InnoDB Buffer Pool Configuration Options

Several configuration options affect different aspects of the InnoDB buffer pool.

- [innodb_buffer_pool_size](#)

Specifies the size of the buffer pool. If the buffer pool is small and you have sufficient memory, making the buffer pool larger can improve performance by reducing the amount of disk I/O needed as queries access InnoDB tables. The [innodb_buffer_pool_size](#) option is dynamic, which allows you to configure buffer pool size without restarting the server. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- [innodb_buffer_pool_chunk_size](#)

Defines the chunk size for InnoDB buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_instances`

Divides the buffer pool into a user-specified number of separate regions, each with its own LRU list and related data structures, to reduce contention during concurrent memory read and write operations. This option only takes effect when you set `innodb_buffer_pool_size` to a value of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte. See [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#) for more information.

- `innodb_old_blocks_pct`

Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_old_blocks_time`

Specifies how long in milliseconds (ms) a page inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a page inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, pages remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes pages to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

Setting `innodb_old_blocks_time` greater than 0 prevents one-time table scans from flooding the new sublist with pages used only for the scan. Rows in a page read in for a scan are accessed many times in rapid succession, but the page is unused after that. If `innodb_old_blocks_time` is set to a value greater than time to process the page, the page remains in the “old” sublist and ages to the tail of the list to be evicted quickly. This way, pages used only for a one-time scan do not act to the detriment of heavily used pages in the new sublist.

`innodb_old_blocks_time` can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps:

```
SET GLOBAL innodb_old_blocks_time = 1000;  
... perform queries that scan tables ...  
SET GLOBAL innodb_old_blocks_time = 0;
```

This strategy does not apply if your intent is to “warm up” the buffer pool by filling it with a table's content. For example, benchmark tests often perform a table or index scan at server startup, because that data would normally be in the buffer pool after a period of normal use. In this case, leave `innodb_old_blocks_time` set to 0, at least until the warmup phase is complete.

See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_read_ahead_threshold`

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#).

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_random_read_ahead`

Enables random [read-ahead](#) technique for prefetching pages into the buffer pool. Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. `innodb_random_read_ahead` is disabled by default.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_adaptive_flushing`

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the buffer pool based on workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_adaptive_flushing_lwm`

Low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flush_neighbors`

Specifies whether [flushing](#) a page from the buffer pool also flushes other [dirty pages](#) in the same [extent](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flushing_avg_loops`

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_lru_scan_depth`

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the `page_cleaner` thread scans looking for [dirty pages](#) to flush.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct`

InnoDB tries to [flush](#) data from the buffer pool so that the percentage of [dirty pages](#) does not exceed this value. Specify an integer in the range from 0 to 99.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct_lwm`

Low water mark representing percentage of [dirty pages](#) where preflushing is enabled to control the dirty page ratio. A value of 0 disables the pre-flushing behavior entirely.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_buffer_pool_filename`

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

Specifies whether to record the pages cached in the buffer pool when the MySQL server is shut down, to shorten the `warmup` process at the next restart.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_at_startup`

Specifies that, on MySQL server startup, the buffer pool is automatically `warmed up` by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_now`

Immediately records the pages cached in the buffer pool.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_now`

Immediately `warms up` the buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance. Typically used with `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_pct`

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_abort`

Interrupts the process of restoring `buffer pool` contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

15.6.3.2 Configuring InnoDB Buffer Pool Size

You can configure `InnoDB` buffer pool size offline (at startup) or online, while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see [Configuring InnoDB Buffer Pool Size Online](#).

When increasing or decreasing `innodb_buffer_pool_size`, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option, which has a default of `128M`. For more information, see [Configuring InnoDB Buffer Pool Chunk Size](#).

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`. If you configure `innodb_buffer_pool_size` to a value that is not equal to or a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`, buffer pool size is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`.

In the following example, `innodb_buffer_pool_size` is set to 8G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value.

8G is a valid `innodb_buffer_pool_size` value because 8G is a multiple of `innodb_buffer_pool_instances=16` * `innodb_buffer_pool_chunk_size=128M`, which is 2G.

```
shell> mysqld --innodb_buffer_pool_size=8G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
| 8.000000000000000 |
+-----+
```

In this example, `innodb_buffer_pool_size` is set to 9G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value. In this case, 9G is not a multiple of `innodb_buffer_pool_instances=16` * `innodb_buffer_pool_chunk_size=128M`, so `innodb_buffer_pool_size` is adjusted to 10G, which is a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`.

```
shell> mysqld --innodb_buffer_pool_size=9G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
| 10.000000000000000 |
+-----+
```

Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

Command line:

```
shell> mysqld --innodb_buffer_pool_chunk_size=134217728
```

Configuration file:

```
[mysqld]
innodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- If the new `innodb_buffer_pool_chunk_size` value * `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized,

`innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of **2GB** (2147483648 bytes), **4** buffer pool instances, and a chunk size of **1GB** (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
shell> mysqld --innodb_buffer_pool_size=2147483648 --innodb_buffer_pool_instances=4
--innodb_buffer_pool_chunk_size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                2147483648 |
+-----+

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                        4 |
+-----+

# Chunk size was set to 1GB (1073741824 bytes) on startup but was
# truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                536870912 |
+-----+
```

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```
# The buffer pool has a default size of 128MB (134217728 bytes)
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                134217728 |
+-----+
```

```
# The chunk size is also 128MB (134217728 bytes)
```

```
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                134217728 |
+-----+
```

```
# There is a single buffer pool instance
```

```
mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
```

```

| @@innodb_buffer_pool_instances |
+-----+
| 1 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):

shell> mysql --innodb_buffer_pool_chunk_size=133169152

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 133169152 |
+-----+

# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 266338304 |
+-----+

```

This example demonstrates the same behavior but with multiple buffer pool instances:

```

# The buffer pool has a default size of 2GB (2147483648 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 2147483648 |
+-----+

# The chunk size is .5 GB (536870912 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 536870912 |
+-----+

# There are 4 buffer pool instances

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 4 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (536870912 - 1048576 = 535822336):

shell> mysql --innodb_buffer_pool_chunk_size=535822336

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+

```

```

| 535822336 |
+-----+
# Buffer pool size increases from 2147483648 to 4286578688
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 4286578688 |
+-----+

```

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

Note

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

Configuring InnoDB Buffer Pool Size Online

The `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

Note

Nested transactions could fail if initiated after the buffer pool resizing operation begins.

Monitoring Online Buffer Pool Resizing Progress

The `Innodb_buffer_pool_resize_status` reports buffer pool resizing progress. For example:

```

mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables. |
+-----+-----+

```

Buffer pool resizing progress is also logged in the server error log. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages.
(253952/253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in **chunks** (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in **chunks** (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

15.6.3.3 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a **buffer pool** size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the **InnoDB** buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool. Prior to MySQL

8.0, each buffer pool was protected by its own buffer pool mutex. In MySQL 8.0 and later, the buffer pool mutex was replaced by several list and hash protecting mutexes, to reduce contention.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

For information about modifying InnoDB buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

15.6.3.4 Making the Buffer Pool Scan Resistant

Rather than using a strict LRU algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as [read-ahead](#) and [full table scans](#) bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is $3/8$ from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and specifics about the LRU algorithm, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the LRU list and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of $3/8$. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

15.6.3.5 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A **read-ahead** request is an I/O request to prefetch multiple pages in the **buffer pool** asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one **extent**. **InnoDB** uses two read-ahead algorithms to improve I/O performance:

Linear read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when **InnoDB** performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, **InnoDB** would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive **InnoDB** is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, **InnoDB** initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, **InnoDB** triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, **InnoDB** triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL **configuration file**, or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, **InnoDB** asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`
- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#) and [Section 8.12.1, “Optimizing Disk I/O”](#).

15.6.3.6 Configuring InnoDB Buffer Pool Flushing

InnoDB performs certain tasks in the background, including [flushing](#) of [dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#).

InnoDB starts flushing buffer pool pages when the percentage of dirty pages in the buffer pool reaches the low water mark setting defined by `innodb_max_dirty_pages_pct_lwm`. This option is intended to control the ratio of dirty pages in the buffer pool and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. If the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`, InnoDB begins to aggressively flush buffer pool pages.

InnoDB uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even if `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in workload.

Internal benchmarking has shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is `ON`, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

For information about fine-tuning InnoDB buffer pool flushing behavior, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.3.7 Fine-tuning InnoDB Buffer Pool Flushing

The configuration options `innodb_flush_neighbors` and `innodb_lru_scan_depth` let you fine-tune aspects of the [flushing](#) process for the [InnoDB buffer pool](#).

- `innodb_flush_neighbors`

Specifies whether flushing a page from the buffer pool also flushes other dirty pages in the same extent. When the table data is stored on a traditional [HDD](#) storage device, flushing neighbor pages in one

operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on [SSD](#), seek time is not a significant factor and you can disable this setting to spread out write operations.

- `innodb_lru_scan_depth`

Specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

These options primarily help write-intensive [workloads](#). With heavy [DML](#) activity, flushing can fall behind if it is not aggressive enough, resulting in excessive memory use in the buffer pool; or, disk writes due to flushing can saturate your I/O capacity if that mechanism is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

For systems with constant heavy [workloads](#), or workloads that fluctuate widely, several configuration options let you fine-tune the [flushing](#) behavior for [InnoDB](#) tables:

- `innodb_adaptive_flushing_lwm`
- `innodb_max_dirty_pages_pct_lwm`
- `innodb_io_capacity_max`
- `innodb_flushing_avg_loops`

These options feed into the formula used by the `innodb_adaptive_flushing` option.

The `innodb_adaptive_flushing`, `innodb_io_capacity` and `innodb_max_dirty_pages_pct` options are limited or extended by the following options:

- `innodb_adaptive_flushing_lwm`
- `innodb_io_capacity_max`
- `innodb_max_dirty_pages_pct_lwm`

The [InnoDB adaptive flushing](#) mechanism is not appropriate in all cases. It gives the most benefit when the [redo log](#) is in danger of filling up. The `innodb_adaptive_flushing_lwm` option specifies a “low water mark” percentage of redo log capacity; when that threshold is crossed, [InnoDB](#) turns on adaptive flushing even if not specified by the `innodb_adaptive_flushing` option.

If flushing activity falls far behind, [InnoDB](#) can flush more aggressively than specified by `innodb_io_capacity`. `innodb_io_capacity_max` represents an upper limit on the I/O capacity used in such emergency situations, so that the spike in I/O does not consume all the capacity of the server.

[InnoDB](#) tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed the value of `innodb_max_dirty_pages_pct`. The default value for `innodb_max_dirty_pages_pct` is 75.

Note

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

The `innodb_max_dirty_pages_pct_lwm` option specifies a “low water mark” value that represents the percentage of dirty pages where pre-flushing is enabled to control the dirty page ratio and ideally

prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. A value of `innodb_max_dirty_pages_pct_lwm=0` disables the “pre-flushing” behavior.

Most of the options referenced above are most applicable to servers that run write-heavy workloads for long periods of time and have little reduced load time to catch up with changes waiting to be written to disk.

`innodb_flushing_avg_loops` defines the number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, which controls how quickly adaptive flushing responds to foreground load changes. Setting a high value for `innodb_flushing_avg_loops` means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. A high value also reduces positive feedback between foreground and background work, but when setting a high value it is important to ensure that InnoDB redo log utilization does not reach 75% (the hardcoded limit at which async flushing starts) and that the `innodb_max_dirty_pages_pct` setting keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large `innodb_log_file_size`, and small spikes that do not reach 75% redo log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, consider a smaller `innodb_flushing_avg_loops` value. A smaller value allows flushing to closely track the load and helps avoid reaching 75% redo log space utilization.

15.6.3.8 Saving and Restoring the Buffer Pool State

To reduce the `warmup` period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_pct` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU_INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the InnoDB data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because

uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- [Configuring the Dump Percentage for Buffer Pool Pages](#)
- [Saving the Buffer Pool State at Shutdown and Restoring it at Startup](#)
- [Saving and Restoring the Buffer Pool State Online](#)
- [Displaying Buffer Pool Dump Progress](#)
- [Displaying Buffer Pool Load Progress](#)
- [Aborting a Buffer Pool Load Operation](#)
- [Monitoring Buffer Pool Load Progress Using Performance Schema](#)

Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the `innodb_buffer_pool_dump_pct` option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value is 25 (dump 25% of most-recently-used pages).

Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default.

To restore the buffer pool state at server startup, specify the `--innodb_buffer_pool_load_at_startup` option when starting the server:

```
mysqld --innodb_buffer_pool_load_at_startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default.

Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

Monitoring Buffer Pool Load Progress Using Performance Schema

You can monitor buffer pool load progress using [Performance Schema](#).

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#). For information about Performance Schema stage event instruments and related consumers, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
      WHERE NAME LIKE 'stage/innodb/buffer%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%stages%';
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
***** 1. row *****
Variable_name: Innodb_buffer_pool_dump_status
Value: Buffer pool(s) dump completed at 150202 16:38:58
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_current;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/buffer pool load	5353	7167

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_history;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/buffer pool load	7167	7167

Note

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must be enabled at startup. For more information, see [Section 25.3, “Performance Schema Startup Configuration”](#).

15.6.3.9 Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics that pertain to operation of the InnoDB buffer pool. Buffer pool metrics are located in the `BUFFER POOL AND MEMORY` section of InnoDB Standard Monitor output and appear similar to the following:

```
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 2198863872
Dictionary memory allocated 776332
Buffer pool size 131072
```

```

Free buffers      124908
Database pages    5720
Old database pages 2071
Modified db pages  910
Pending reads     0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young  4, not young 0
0.10 youngs/s, 0.00 non-youngs/s
Pages read 197, created 5523, written 5060
0.00 reads/s, 190.89 creates/s, 244.94 writes/s
Buffer pool hit rate 1000 / 1000, young-making rate 0 / 1000 not
0 / 1000
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read
ahead 0.00/s
LRU len: 5720, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]

```

The following table describes [InnoDB](#) buffer pool metrics reported by the [InnoDB](#) Standard Monitor.

Note

Per second averages provided in [InnoDB](#) Standard Monitor output are based on the elapsed time since [InnoDB](#) Standard Monitor output was last printed.

Table 15.2 InnoDB Buffer Pool Metrics

Name	Description
Total memory allocated	The total memory allocated for the buffer pool in bytes.
Dictionary memory allocated	The total memory allocated for the InnoDB data dictionary in bytes.
Buffer pool size	The total size in pages allocated to the buffer pool.
Free buffers	The total size in pages of the buffer pool free list.
Database pages	The total size in pages of the buffer pool LRU list.
Old database pages	The total size in pages of the buffer pool old LRU sublist.
Modified db pages	The current number of pages modified in the buffer pool.
Pending reads	The number of buffer pool pages waiting to be read in to the buffer pool.
Pending writes LRU	The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.
Pending writes flush list	The number of buffer pool pages to be flushed during checkpointing.
Pending writes single page	The number of pending independent page writes within the buffer pool.
Pages made young	The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).
Pages made not young	The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).
youngs/s	The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.
non-youngs/s	The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information.

Name	Description
Pages read	The total number of pages read from the buffer pool.
Pages created	The total number of pages created within the buffer pool.
Pages written	The total number of pages written from the buffer pool.
reads/s	The per second average number of buffer pool page reads per second.
creates/s	The per second average number of buffer pool pages created per second.
writes/s	The per second average number of buffer pool page writes per second.
Buffer pool hit rate	The buffer pool page hit rate for pages read from the buffer pool memory vs from disk storage.
young-making rate	The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.
not (young-making rate)	The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information.
Pages read ahead	The per second average of read ahead operations.
Pages evicted without access	The per second average of the pages evicted without being accessed from the buffer pool.
Random read ahead	The per second average of random read ahead operations.
LRU len	The total size in pages of the buffer pool LRU list.
unzip_LRU len	The total size in pages of the buffer pool unzip_LRU list.
I/O sum	The total number of buffer pool LRU list pages accessed, for the last 50 seconds.
I/O cur	The total number of buffer pool LRU list pages accessed.
I/O unzip sum	The total number of buffer pool unzip_LRU list pages accessed.
I/O unzip cur	The total number of buffer pool unzip_LRU list pages accessed.

Notes:

- The `young/s` metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you see very low `young/s` values when there are no large scans occurring, you might need to reduce the delay time or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so pages in that sublist take longer to move to the tail and to be evicted. This increases the likelihood that the pages will be accessed again and be made young.
- The `non-young/s` metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you do not see a lot of `non-young/s` when you are doing large table scans (and lots of `young/s`), increase the delay value.
- The `young-making` rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist. The `young-making` rate and `not` rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

- `not (young-making rate)` is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist.

InnoDB buffer pool [server status variables](#) and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information about the `INNODB_BUFFER_POOL_STATS` table, see [Example 15.10, “Querying the INNODB_BUFFER_POOL_STATS Table”](#).

15.6.4 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has a [change buffer](#) that caches changes to secondary index entries when the relevant [page](#) is not in the [buffer pool](#), thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a [slow shutdown](#).

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working set fits entirely within the buffer, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs change buffering using the `innodb_change_buffering` configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- `all`

The default value: buffer inserts, delete-marking operations, and purges.

- `none`

Do not buffer any operations.

- `inserts`

Buffer insert operations.

- `deletes`

Buffer delete-marking operations.

- `changes`

Buffer both inserts and delete-marking operations.

- **purges**

Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#). Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For related information, see [Section 15.4.2, “Change Buffer”](#). For information about configuring change buffer size, see [Section 15.6.4.1, “Configuring the Change Buffer Maximum Size”](#).

15.6.4.1 Configuring the Change Buffer Maximum Size

The `innodb_change_buffer_max_size` configuration option allows you to configure the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

You might consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

You might consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space that is shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` setting is dynamic, which allows you modify the setting without restarting the server.

15.6.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts

`innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see [Section 8.12.4.1, “How MySQL Uses Threads for Client Connections”](#).

15.6.6 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1–64.

The purpose of these configuration options to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is [read-ahead](#) requests. InnoDB tries to balance the load of incoming requests in such way that most background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than $64 \times \text{innodb_read_io_threads}$ pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, [InnoDB](#) uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that [InnoDB](#) background threads service these types of I/O requests. For more information, see [Section 15.6.7, “Using Asynchronous I/O on Linux”](#).

For more information about [InnoDB](#) I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.7 Using Asynchronous I/O on Linux

[InnoDB](#) uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, [InnoDB](#) uses synchronous I/O only. Historically, [InnoDB](#) only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and [InnoDB](#) background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the [InnoDB](#) background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is n , where n is the number of [InnoDB](#) background threads. The number of [InnoDB](#) background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See [Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”](#).

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. [InnoDB](#) background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents [InnoDB](#) from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if [InnoDB](#) detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

15.6.8 Configuring the InnoDB Master Thread I/O Rate

The [master thread](#) in [InnoDB](#) is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, [InnoDB](#) has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to [InnoDB](#). This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to `100` reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is 200, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The `innodb_io_capacity` setting is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances. For more information, see the `innodb_io_capacity` system variable description.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The `innodb_flush_sync` configuration option causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

In earlier MySQL releases, the InnoDB master thread also performed any needed `purge` operations. Those I/O operations are now performed by other background threads, whose number is controlled by the `innodb_purge_threads` configuration option.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.9 Configuring Spin Lock Polling

Many InnoDB `mutexes` and `rw-locks` are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, which results in processors invalidating portions of each other's cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the `innodb_spin_wait_delay` system variable. The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of `innodb_spin_wait_delay` is 6. The spin wait delay is a dynamic, global parameter that you can specify in the MySQL option file (`my.cnf` or `my.ini`) or change at runtime with the `SET GLOBAL innodb_spin_wait_delay=delay` statement, where `delay` is the desired maximum delay. Changing the setting at runtime requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

For performance considerations for InnoDB locking operations, see [Section 8.11, “Optimizing Locking Operations”](#).

15.6.10 Configuring InnoDB Purge Scheduling

The `purge` operations (a type of garbage collection) that InnoDB performs automatically may be performed by one or more separate threads rather than as part of the `master thread`. The use of separate threads improves scalability by allowing the main database operations to run independently from maintenance work happening in the background.

To control this feature, increase the value of the configuration option `innodb_purge_threads`. If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. Its maximum is 32. `innodb_purge_threads` is a non-dynamic configuration option, which means it cannot be configured at runtime.

There is another related configuration option, `innodb_purge_batch_size` with a default value of 300 and maximum value of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for `InnoDB` tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater [plan stability](#) and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

15.6.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves [plan stability](#) by storing statistics to disk and making them persistent across server restarts so that the [optimizer](#) is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are created or altered with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared on each server restart and after some other operations, and recomputed on the next table access. Consequently, different estimates could be produced when

recalculating statistics, leading to different choices in query execution plans and thus variations in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables, as described in [InnoDB Persistent Statistics Tables](#).

To revert to using non-persistent optimizer statistics, you can modify tables using an `ALTER TABLE tbl_name STATS_PERSISTENT=0` statement. For related information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#)

Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` configuration option, which is enabled by default, determines whether statistics are calculated automatically whenever a table undergoes substantial changes (to more than 10% of the rows). You can also configure automatic statistics recalculation for individual tables using a `STATS_AUTO_RECALC` clause in a `CREATE TABLE` or `ALTER TABLE` statement. `innodb_stats_auto_recalc` is enabled by default.

Because of the asynchronous nature of automatic statistics recalculation (which occurs in the background), statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. In some cases, statistics recalculation may be delayed by a few seconds. If up-to-date statistics are required immediately after changing significant portions of a table, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, ensure the accuracy of optimizer statistics by issuing the `ANALYZE TABLE` statement for each applicable table after making substantial changes to indexed columns. You might run this statement in your setup scripts after representative data has been loaded into the table, and run it periodically after DML operations significantly change the contents of indexed columns, or on a schedule at times of low activity. When a new index is added to an existing table, or a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

Caution

To ensure statistics are gathered when a new index is created, either enable the `innodb_stats_auto_recalc` option, or run `ANALYZE TABLE` after creating each new index when the persistent statistics mode is enabled.

Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global configuration options. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table.
- `STATS_AUTO_RECALC` specifies whether to automatically recalculate [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated

when 10% of the data in the table has changed. The value 0 prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table.

- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY (`id`),
  INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
  STATS_PERSISTENT=1,
  STATS_AUTO_RECALC=1,
  STATS_SAMPLE_PAGES=25;
```

Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Operations such as `ANALYZE TABLE` cause [InnoDB](#) to sample random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_persistent_sample_pages`, which can be set at runtime.

`innodb_stats_persistent_sample_pages` has a default value of 20. As a general guideline, consider modifying this parameter when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown by `EXPLAIN` output. The accuracy of statistics can be checked by comparing the actual cardinality of an index (as returned by running `SELECT DISTINCT` on the index columns) with the estimates provided in the `mysql.innodb_index_stats` persistent statistics table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *`ANALYZE TABLE` is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each nonunique index.

For related information, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

Table 15.3 Columns of `innodb_table_stats`

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row
<code>n_rows</code>	The number of rows in the table
<code>clustered_index_size</code>	The size of the primary index, in pages
<code>sum_of_other_index_sizes</code>	The total size of other (non-primary) indexes, in pages

Table 15.4 Columns of `innodb_index_stats`

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>index_name</code>	Index name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row
<code>stat_name</code>	The name of the statistic, whose value is reported in the <code>stat_value</code> column
<code>stat_value</code>	The value of the statistic that is named in <code>stat_name</code> column
<code>sample_size</code>	The number of pages sampled for the estimate provided in the <code>stat_value</code> column
<code>stat_description</code>	Description of the statistic that is named in the <code>stat_name</code> column

Both the `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column showing when InnoDB last updated index statistics, as shown in the following example:

```
mysql> SELECT * FROM innodb_table_stats \G
***** 1. row *****
      database_name: sakila
      table_name: actor
```

```

        last_update: 2014-05-28 16:16:44
        n_rows: 200
        clustered_index_size: 1
        sum_of_other_index_sizes: 1
        ...
    
```

```

mysql> SELECT * FROM innodb_index_stats \G
***** 1. row *****
  database_name: sakila
    table_name: actor
    index_name: PRIMARY
  last_update: 2014-05-28 16:16:44
    stat_name: n_diff_pfx01
    stat_value: 200
  sample_size: 1
  ...
    
```

The `innodb_table_stats` and `innodb_index_stats` tables are ordinary tables and can be updated manually. The ability to update statistics manually makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, issue the `FLUSH TABLE tbl_name` command to make MySQL reload the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The `innodb_table_stats` and `innodb_index_stats` tables are therefore not replicated when automatic statistics recalculation takes place. If you run `ANALYZE TABLE` to initiate a synchronous recalculation of statistics, this statement is replicated (unless you suppressed logging for it), and recalculation takes place on the replication slaves.

InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row per table. The data collected is demonstrated in the following example.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```

CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
    
```

After inserting five rows of sample data, the table appears as follows:

```

mysql> SELECT * FROM t1;
+----+-----+-----+-----+-----+-----+
| a  | b  | c  | d  | e  | f  |
+----+-----+-----+-----+-----+-----+
| 1  | 1  | 10 | 11 | 100 | 101 |
| 1  | 2  | 10 | 11 | 200 | 102 |
| 1  | 3  | 10 | 11 | 100 | 103 |
| 1  | 4  | 10 | 12 | 200 | 104 |
| 1  | 5  | 10 | 12 | 100 | 105 |
+----+-----+-----+-----+-----+-----+
    
```

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```

mysql> ANALYZE TABLE t1;
    
```

Table	Op	Msg_type	Msg_text
test.t1	analyze	status	OK

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
***** 1. row *****
      database_name: test
        table_name: t1
      last_update: 2014-03-14 14:36:34
          n_rows: 5
  clustered_index_size: 1
sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
       FROM mysql.innodb_index_stats WHERE table_name like 't1';
```

index_name	stat_name	stat_value	stat_description
PRIMARY	n_diff_pfx01	1	a
PRIMARY	n_diff_pfx02	5	a,b
PRIMARY	n_leaf_pages	1	Number of leaf pages in the index
PRIMARY	size	1	Number of pages in the index
i1	n_diff_pfx01	1	c
i1	n_diff_pfx02	2	c,d
i1	n_diff_pfx03	2	c,d,a
i1	n_diff_pfx04	5	c,d,a,b
i1	n_leaf_pages	1	Number of leaf pages in the index
i1	size	1	Number of pages in the index
i2uniq	n_diff_pfx01	2	e
i2uniq	n_diff_pfx02	5	e,f
i2uniq	n_leaf_pages	1	Number of leaf pages in the index
i2uniq	size	1	Number of pages in the index

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.
- `n_leaf_pages`: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.
- `n_diff_pfxNN`: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Additionally, where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a, b`), a secondary index (columns `c, d`), and a unique index (columns `e, f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+-----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+-----+-----+-----+-----+-----+-----+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description` where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats
WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+-----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+-----+-----+-----+-----+
| PRIMARY   | n_diff_pfx01 | 1 | a |
| PRIMARY   | n_diff_pfx02 | 5 | a,b |
| i1        | n_diff_pfx01 | 1 | c |
| i1        | n_diff_pfx02 | 2 | c,d |
| i1        | n_diff_pfx03 | 2 | c,d,a |
| i1        | n_diff_pfx04 | 5 | c,d,a,b |
| i2uniq    | n_diff_pfx01 | 2 | e |
| i2uniq    | n_diff_pfx02 | 5 | e,f |
+-----+-----+-----+-----+
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

Note

For nonunique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (`a`) is shown in the `stat_description` column of the result set.
- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a,b`). The number of distinct values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`, in which there are five distinct values: (1,1), (1,2), (1,3), (1,4) and (1,5). The counted columns (`a,b`) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c,d`) but there are four `n_diff%` rows for the secondary index because InnoDB suffixes

all nonunique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c,d`) and the primary key columns (`a,b`).

- Where `index_name=i1` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: (10). The counted column (`c`) is shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c,d`). The number of distinct values in columns `c` and `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: (10,11) and (10,12). The counted columns (`c,d`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c,d,a`). The number of distinct values in columns `c`, `d`, and `a` is confirmed by viewing the data in column `c`, `d`, and `a` in table `t1`, in which there are two distinct values: (10,11,1) and (10,12,1). The counted columns (`c,d,a`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c,d,a,b`). The number of distinct values in columns `c`, `d`, `a` and `b` is confirmed by viewing the data in columns `c`, `d`, `a`, and `b` in table `t1`, in which there are five distinct values: (10,11,1,1), (10,11,1,2), (10,11,1,3), (10,12,1,4) and (10,12,1,5). The counted columns (`c,d,a,b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct values in column `e` is confirmed by viewing the data in column `e` in table `t1`, in which there are two distinct values: (100) and (200). The counted column (`e`) is shown in the `stat_description` column of the result set.
- Where `index_name=i2uniq` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`e,f`). The number of distinct values in columns `e` and `f` is confirmed by viewing the data in columns `e` and `f` in table `t1`, in which there are five distinct values: (100,101), (200,102), (100,103), (200,104) and (100,105). The counted columns (`e,f`) are shown in the `stat_description` column of the result set.

Retrieving Index Size Using the `innodb_index_stats` Table

The size of indexes for tables, partitions, or subpartitions can be retrieved using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see [InnoDB Persistent Statistics Tables Example](#).

```
mysql> SELECT SUM(stat_value) pages, index_name,
SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name='t1'
AND stat_name = 'size' GROUP BY index_name;
```

pages	index_name	size
1	PRIMARY	16384
1	i1	16384
1	i2uniq	16384

For partitions or subpartitions, the same query with a modified `WHERE` clause can be used to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
      SUM(stat_value)*@@innodb_page_size size
      FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
      AND stat_name = 'size' GROUP BY index_name;
```

15.6.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` is `OFF`. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

Note

`innodb_stats_on_metadata` only applies when optimizer [statistics](#) are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
- InnoDB detects that 1 / 16 of table has been modified since the last time statistics were updated.

Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. When InnoDB updates optimizer statistics, it

samples random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter [innodb_stats_transient_sample_pages](#). The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue. See [Section 8.2.1.21, “Avoiding Full Table Scans”](#) for tips on tuning such queries. [innodb_stats_transient_sample_pages](#) is a global parameter that can be set at runtime.

The value of [innodb_stats_transient_sample_pages](#) affects the index sampling for all InnoDB tables and indexes when [innodb_stats_persistent](#)=0. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the [innodb_stats_transient_sample_pages](#) value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute [SHOW TABLE STATUS](#).
- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of [innodb_stats_transient_sample_pages](#) works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of [ANALYZE TABLE](#), it does not make sense to increase the index sample size, run [ANALYZE TABLE](#), then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for [innodb_stats_transient_sample_pages](#) than if you have mostly smaller tables.

15.6.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

[ANALYZE TABLE](#) complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by [innodb_stats_persistent_sample_pages](#).
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating [ANALYZE TABLE](#) complexity would be:

The value of [innodb_stats_persistent_sample_pages](#) * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for [ANALYZE TABLE](#).

Note

[innodb_stats_persistent_sample_pages](#) defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the [STATS_SAMPLE_PAGES](#) option with [CREATE TABLE](#) or [ALTER](#)

TABLE. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
  * (n_cols_in_uniq_i
    + n_cols_in_non_uniq_i
    + n_cols_in_pk * (1 + n_non_uniq_i))
  * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all nonunique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- `n_non_uniq_i` is the number of nonunique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
  UNIQUE KEY iluniq (c, d),
  KEY i2nonuniq (e, f),
  KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the nonunique indexes, the primary key columns (a,b) are counted in addition to the user defined columns.

**Note**

For additional information about the [InnoDB](#) persistent statistics tables, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#)

```
mysql> SELECT index_name, stat_name, stat_description
FROM mysql.innodb_index_stats WHERE
database_name='test' AND
table_name='t' AND
stat_name like 'n_diff_pfx%';
```

index_name	stat_name	stat_description
PRIMARY	n_diff_pfx01	a
PRIMARY	n_diff_pfx02	a,b
iluniq	n_diff_pfx01	c
iluniq	n_diff_pfx02	c,d
i2nonuniq	n_diff_pfx01	e
i2nonuniq	n_diff_pfx02	e,f
i2nonuniq	n_diff_pfx03	e,f,a
i2nonuniq	n_diff_pfx04	e,f,a,b
i3nonuniq	n_diff_pfx01	g
i3nonuniq	n_diff_pfx02	g,h
i3nonuniq	n_diff_pfx03	g,h,a
i3nonuniq	n_diff_pfx04	g,h,a,b

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (`c` and `d`)
- `n_cols_in_non_uniq_i`, the total number of all columns in all nonunique indexes, is 4 (`e`, `f`, `g` and `h`)
- `n_cols_in_pk`, the number of columns in the primary key, is 2 (`a` and `b`)
- `n_non_uniq_i`, the number of nonunique indexes in the table, is 2 (`i2nonuniq` and `i3nonuniq`)
- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages * (2 + 4 + 2 * (1 + 2)) * 1` to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 KiB (`innodb_page_size=16384`), you can then estimate that `20 * 12 * 16384 bytes` are read for table `t`, or about 4 MiB.

**Note**

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

15.6.12 Configuring the Merge Threshold for Index Pages

You can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, [InnoDB](#) attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, `InnoDB` attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that `InnoDB` attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

Setting `MERGE_THRESHOLD` for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (  
  id INT,  
  KEY id_index (id)  
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (  
  id INT,  
  KEY id_index (id)  
);  
  
ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

Setting `MERGE_THRESHOLD` for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (  
  id INT,  
  KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'  
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (  
  id INT,  
  KEY id_index (id)  
);  
  
ALTER TABLE t1 DROP KEY id_index;  
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

Note

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by InnoDB when an InnoDB table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

Querying the `MERGE_THRESHOLD` Value for an Index

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE NAME='id_index' \G
***** 1. row *****
      INDEX_ID: 91
        NAME: id_index
      TABLE_ID: 68
         TYPE: 0
      N_FIELDS: 1
      PAGE_NO: 4
        SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```
mysql> SHOW CREATE TABLE t2 \G
***** 1. row *****
      Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

Note

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```
mysql> SHOW INDEX FROM t2 \G
***** 1. row *****
      Table: t2
    Non_unique: 1
      Key_name: id_index
    Seq_in_index: 1
    Column_name: id
    Collation: A
    Cardinality: 0
      Sub_part: NULL
        Packed: NULL
         Null: YES
    Index_type: BTREE
```

```
Comment:
Index_comment: MERGE_THRESHOLD=40
```

Measuring the Effect of MERGE_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
       WHERE NAME like '%index_page_merge%';
```

NAME	COMMENT
index_page_merge_attempts	Number of index page merge attempts
index_page_merge_successful	Number of successful index page merges

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

15.6.13 Enabling Automatic Configuration for a Dedicated MySQL Server

When `innodb_dedicated_server` is enabled, `InnoDB` automatically configures the following options according to the amount of memory detected on the server:

- `innodb_buffer_pool_size`

Table 15.5 Automatically Configured Buffer Pool Size

Detected Server Memory	Buffer Pool Size
< 1G	128MiB (the <code>innodb_buffer_pool_size</code> default)
<= 4G	Detected server memory * 0.5
> 4G	Detected server memory * 0.75

- `innodb_log_file_size`

Table 15.6 Automatically Configured Log File Size

Detected Server Memory	Log File Size
< 1GB	48MiB (the <code>innodb_log_file_size</code> default)
<= 4GB	128MiB
<= 8GB	512MiB
<= 16GB	1024MiB
> 16GB	2048MiB

- `innodb_flush_method`

The flush method is set to `O_DIRECT_NO_FSYNC` when `innodb_dedicated_server` is enabled. If the `O_DIRECT_NO_FSYNC` setting is not available, the default `innodb_flush_method` setting is used.

Warning

The `O_DIRECT_NO_FSYNC` setting is currently not recommended for use on Linux systems. It may cause the operating system to hang when data files change size.

Only consider enabling this option if your MySQL instance runs on a dedicated server where the MySQL server is able to consume all available system resources. Enabling this option is not recommended if your MySQL instance shares system resources with other applications.

If an automatically configured option is configured explicitly in an option file or elsewhere, the explicitly specified setting is used and a startup warning similar to this is printed to `stderr`:

```
[Warning] [000000] InnoDB: Option innodb_dedicated_server is ignored for
innodb_buffer_pool_size because innodb_buffer_pool_size=134217728 is specified
explicitly.
```

Explicit configuration of one option does not prevent the automatic configuration of other options. For example, if `innodb_dedicated_server` is enabled and `innodb_buffer_pool_size` is configured explicitly in an option file, `innodb_log_file_size` and `innodb_flush_method` are still subject to automatic configuration.

Automatically configured settings are reevaluated according to the amount of detected server memory each time the MySQL server is started. If the amount of detected server memory changes, the automatically configured settings are adjusted accordingly.

15.7 InnoDB Tablespaces

This section covers topics related to `InnoDB` tablespaces.

15.7.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the `InnoDB` system tablespace.

Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the `InnoDB` system tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then `InnoDB` increases the size of that file automatically in 64MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword `autoextend`, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024×1024 bytes (= 1MB), and specify this rounded size explicitly in `innodb_data_file_path`.

3. Add a new data file to the end of `innodb_data_file_path`, optionally making that file auto-extending. Only the last data file in the `innodb_data_file_path` can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. **InnoDB** creates and initializes the file when you restart the server.

Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all your **InnoDB** tables, including **InnoDB** tables located in the MySQL database.

```
mysql> SELECT TABLE_NAME from INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='mysql' and ENGINE='InnoDB';
+-----+
| TABLE_NAME |
+-----+
| columns_priv |
| component    |
| db           |
| default_roles |
| engine_cost  |
| func         |
| global_grants |
| gtid_executed |
| help_category |
| help_keyword  |
| help_relation |
| help_topic    |
| innodb_dynamic_metadata |
| innodb_index_stats |
| innodb_table_stats |
| plugin       |
| procs_priv   |
| proxies_priv |
| role_edges   |
| server_cost  |
| servers      |
| slave_master_info |
| slave_relay_log_info |
| slave_worker_info |
| tables_priv  |
| time_zone    |
| time_zone_leap_second |
| time_zone_name |
```

```
| time_zone_transition |
| time_zone_transition_type |
| user |
+-----+
```

2. Stop the server.
3. Remove all the existing tablespace files (*.ibd), including the `ibdata` and `ib_log` files. Do not forget to remove *.ibd files for tables located in the MySQL database.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

Note

If your databases only use the [InnoDB](#) engine, it may be simpler to dump **all** databases, stop the server, remove all databases and [InnoDB](#) log files, restart the server, and import the dump files.

15.7.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your [InnoDB redo log](#) files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If [InnoDB](#) detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

15.7.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the [InnoDB system tablespace](#). This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see [Section 4.2.7, “Using Option Files”](#).

Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you

specify. Note that 1MB in [InnoDB](#) is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

2. Restart the server. [InnoDB](#) notices the [newraw](#) keyword and initializes the new partition. However, do not create or change any [InnoDB](#) tables yet. Otherwise, when you next restart the server, [InnoDB](#) reinitializes the partition and your changes are lost. (As a safety measure [InnoDB](#) prevents users from modifying data when any partition with [newraw](#) is specified.)
3. After [InnoDB](#) has initialized the new partition, stop the server, change [newraw](#) in the data file specification to [raw](#):

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw:/dev/hdd2:2Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the [innodb_data_file_path](#) setting differs slightly on Windows.

1. When you create a new data file, specify the keyword [newraw](#) immediately after the data file size for the [innodb_data_file_path](#) option:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. [InnoDB](#) notices the [newraw](#) keyword and initializes the new partition.
3. After [InnoDB](#) has initialized the new partition, stop the server, change [newraw](#) in the data file specification to [raw](#):

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

15.7.4 InnoDB File-Per-Table Tablespaces

Historically, all [InnoDB](#) tables and indexes were stored in the [system tablespace](#). This monolithic approach was targeted at machines dedicated entirely to database processing, with carefully planned data growth, where any disk storage allocated to MySQL would never be needed for other purposes. [InnoDB](#)'s [file-per-table tablespace](#) feature provides a more flexible alternative, where each [InnoDB](#) table and its indexes are stored in a separate `.ibd` data file. Each such `.ibd` data file represents an individual [tablespace](#). This feature is controlled by the [innodb_file_per_table](#) configuration option, which is enabled by default.

Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the shared [system tablespace](#) creates free space internally in the system tablespace data files ([ibdata files](#)) which can only be used for new [InnoDB](#) data.

Similarly, a table-copying [ALTER TABLE](#) operation on table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. The additional space required for the table-copying [ALTER TABLE](#) operation is not released back to the operating system as it is for file-per-table tablespaces.

- The [TRUNCATE TABLE](#) operation is faster when run on tables stored in file-per-table tablespaces.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes by specifying the location of each table using the syntax [CREATE TABLE ... DATA DIRECTORY = absolute_path_to_directory](#), as explained in [Section 15.7.5, “Creating a Tablespace Outside of the Data Directory”](#).
- You can run [OPTIMIZE TABLE](#) to compact or recreate a file-per-table tablespace. When you run an [OPTIMIZE TABLE](#), [InnoDB](#) creates a new [.ibd](#) file with a temporary name, using only the space required to store actual data. When the optimization is complete, [InnoDB](#) removes the old [.ibd](#) file and replaces it with the new one. If the previous [.ibd](#) file grew significantly but the actual data only accounted for a portion of its size, running [OPTIMIZE TABLE](#) can reclaim the unused space.
- You can move individual [InnoDB](#) tables rather than entire databases.
- You can copy individual [InnoDB](#) tables from one MySQL instance to another (known as the [transportable tablespace](#) feature).
- Tables created in file-per-table tablespaces support features associated with [compressed](#) and [dynamic row formats](#).
- You can enable more efficient storage for tables with large [BLOB](#) or [TEXT](#) columns using the [dynamic row format](#).
- File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.
- You can back up or restore individual tables quickly using the MySQL Enterprise Backup product, without interrupting the use of other [InnoDB](#) tables. This is beneficial if you have tables that require backup less frequently or on a different backup schedule. See [Making a Partial Backup](#) for details.
- File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.
- You can monitor table size at a file system level without accessing MySQL.
- Common Linux file systems do not permit concurrent writes to a single file when [innodb_flush_method](#) is set to [O_DIRECT](#). As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with [innodb_flush_method](#).
- The system tablespace stores the data dictionary and undo logs, and is limited in size by [InnoDB](#) tablespace size limits. See [Section 15.8.1.7, “Limits on InnoDB Tables”](#). With file-per-table tablespaces, each table has its own tablespace, which provides room for growth.

Potential Disadvantages of File-Per-Table Tablespaces

- With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.

- `fsync` operations must run on each open table rather than on a single file. Because there is a separate `fsync` operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of `fsync` operations.
- `mysqld` must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.
- More file descriptors are used.
- `innodb_file_per_table` is enabled by default. You may consider disabling it if backward compatibility with MySQL 5.5 or earlier is a concern. Disabling `innodb_file_per_table` prevents `ALTER TABLE` from moving an InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`).

For example, when restructuring the clustered index for an InnoDB table, the table is re-created using the current setting for `innodb_file_per_table`. This behavior does not apply when adding or dropping InnoDB secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting. This behavior also does not apply to tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax. These tables are not affected by the `innodb_file_per_table` setting.

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.
- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

15.7.4.1 Enabling and Disabling File-Per-Table Tablespaces

The `innodb_file_per_table` option is enabled by default.

To set the `innodb_file_per_table` option at startup, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

You can also set `innodb_file_per_table` dynamically, while the server is running:

```
mysql> SET GLOBAL innodb_file_per_table=1;
```

With `innodb_file_per_table` enabled, you can store InnoDB tables in a `tbl_name.ibd` file. Unlike the MyISAM storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file.

If you disable `innodb_file_per_table` in your startup options and restart the server, or disable it with the `SET GLOBAL` command, InnoDB creates new tables inside the system tablespace unless you have

explicitly placed the table in file-per-table tablespace or general tablespace using the `CREATE TABLE ... TABLESPACE` option.

You can always read and write any `InnoDB` tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
mysql> SET GLOBAL innodb_file_per_table=1;
mysql> ALTER TABLE table_name ENGINE=InnoDB;
```

Tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. To move these tables from the system tablespace to a file-per-table tablespace, they must be moved explicitly using `ALTER TABLE ... TABLESPACE` syntax.

Note

`InnoDB` always needs the system tablespace because it puts its internal `data dictionary` and `undo logs` there. The `.ibd` files are not sufficient for `InnoDB` to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new `InnoDB` data, but is not reclaimed for use by the operating system. When moving large `InnoDB` tables out of the system tablespace, where disk space is limited, you may prefer to enable `innodb_file_per_table` and recreate the entire instance using the `mysqldump` command. As mentioned above, tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. These tables must be moved individually.

15.7.5 Creating a Tablespace Outside of the Data Directory

The `CREATE TABLE ... DATA DIRECTORY` clause permits creating a `file-per-table` tablespace outside of the data directory. For example, you can use the `DATA DIRECTORY` clause to create a tablespace on a separate storage device with particular performance or capacity characteristics, such as a fast `SSD` or a high-capacity `HDD`.

Be sure of the location that you choose. The `DATA DIRECTORY` clause cannot be used with `ALTER TABLE` to change the location later.

The tablespace data file is created in the specified directory, within in a subdirectory named for the schema to which the table belongs.

The following example demonstrates creating a file-per-table tablespace outside of the data directory. It is assumed that the `innodb_file_per_table` variable is enabled.

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/remote/directory';

# MySQL creates the tablespace file in a subdirectory that is named
# for the schema to which the table belongs
```

```
shell> cd /remote/directory/test
shell> ls
t1.ibd
```

When creating a tablespace outside of the data directory, ensure that the directory is known to [InnoDB](#). Otherwise, if the server halts unexpectedly before tablespace data file pages are fully flushed, startup fails when the tablespace is not found during the pre-recovery discovery phase that searches known directories for tablespace data files. To make a directory known, add it to the [innodb_directories](#) argument value. [innodb_directories](#) is a read-only startup option that defines directories to scan at startup for tablespace data files. Configuring it requires restarting the server.

[CREATE TABLE ... TABLESPACE](#) syntax can also be used in combination with the [DATA DIRECTORY](#) clause to create a file-per-table tablespace outside of the data directory. To do so, specify [innodb_file_per_table](#) as the tablespace name.

```
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
      DATA DIRECTORY = '/remote/directory';
```

The [innodb_file_per_table](#) variable does not need to be enabled when using this method.

Usage Notes:

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the table if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated tablespace data file is missing causes a serious error that requires a server restart.

A server restart issues errors and warnings if the tablespace data file is not at the expected path. In this case, you can restore the tablespace data file from a backup or drop the table to remove the information about it from the [data dictionary](#).

- Before placing a tablespace on an NFS-mounted volume, review potential issues outlined in [Using NFS with MySQL](#).
- If using an LVM snapshot, file copy, or other file-based mechanism to back up the tablespace data file, always use the [FLUSH TABLES ... FOR EXPORT](#) statement first to ensure that all changes buffered in memory are [flushed](#) to disk before the backup occurs.
- Using the [DATA DIRECTORY](#) clause is an alternative to [using symbolic links](#), which is not supported.

15.7.6 Copying File-Per-Table Tablespaces to Another Instance

This section describes how to copy a [file-per-table](#) tablespaces from one MySQL instance to another, otherwise known as the [Transportable Tablespaces](#) feature. This feature also supports partitioned [InnoDB](#) tables and individual [InnoDB](#) table partitions and subpartitions.

For information about other [InnoDB](#) table copying methods, see [Section 15.8.1.3, “Moving or Copying InnoDB Tables”](#).

There are many reasons why you might copy an [InnoDB file-per-table](#) tablespace to a different instance:

- To run reports without putting extra load on a production server.
- To set up identical data for a table on a new [slave server](#).
- To restore a backed-up version of a table or partition after a problem or mistake.

- As a faster way of moving data around than importing the results of a `mysqldump` command. The data is available immediately, rather than having to be re-inserted and the indexes rebuilt.
- To move a [file-per-table](#) tablespace to a server with storage medium that better suits system requirements. For example, you may want to have busy tables on an [SSD](#) device, or large tables on a high-capacity [HDD](#) device.

Limitations and Usage Notes

- The tablespace copy procedure is only possible when `innodb_file_per_table` is enabled, which is the default setting. Tables residing in the shared system tablespace cannot be quiesced.
- When a table is quiesced, only read-only transactions are allowed on the affected table.
- When importing a tablespace, the page size must match the page size of the importing instance.
- `ALTER TABLE ... DISCARD TABLESPACE` is supported for partitioned [InnoDB](#) tables, and `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is supported for [InnoDB](#) table partitions.
- `DISCARD TABLESPACE` is not supported for tablespaces with a parent-child (primary key-foreign key) relationship when `foreign_key_checks` is set to `1`. Before discarding a tablespace for parent-child tables, set `foreign_key_checks=0`. Partitioned [InnoDB](#) tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. Partitioned [InnoDB](#) tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` do not require a `.cfg` metadata file to import a tablespace. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

The ability to import without a `.cfg` file may be more convenient when no schema mismatches are expected. Additionally, the ability to import without a `.cfg` file could be useful in crash recovery scenarios in which metadata cannot be collected from an `.ibd` file.

If no `.cfg` file is used, [InnoDB](#) uses the equivalent of a `SELECT MAX(ai_col) FROM table_name FOR UPDATE` statement to initialize the in-memory auto-increment counter that is used in assigning values for to an `AUTO_INCREMENT` column. Otherwise, the current maximum auto-increment counter value is read from the `.cfg` metadata file. For related information, see [InnoDB AUTO_INCREMENT Counter Initialization](#).

- Due to a `.cfg` metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing tablespace files for partitioned tables. Column differences are reported.
- When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.
- Importing a tablespace file from another MySQL server instance works if both instances have GA (General Availability) status and the server instance into which the file is imported is at the same or higher release level within the same release series. Importing a tablespace file into a server instance running an earlier release of MySQL is not supported.

- In replication scenarios, `innodb_file_per_table` must be set to `ON` on both the master and slave.
- On Windows, `InnoDB` stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and UNIX, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

Note

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported with tables that belong to an `InnoDB` general tablespace. For more information, see `CREATE TABLESPACE`.
- The default row format for `InnoDB` tables is configurable using the `innodb_default_row_format` configuration option. Attempting to import a table that does not explicitly define a row format (`ROW_FORMAT`), or that uses `ROW_FORMAT=DEFAULT`, could result in a schema mismatch error if the `innodb_default_row_format` setting on the source instance differs from the setting on the destination instance. For related information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).
- When exporting a tablespace that is encrypted using the `InnoDB` tablespace encryption feature, `InnoDB` generates a `.cfp` file in addition to a `.cfg` metadata file. The `.cfp` file must be copied to the destination instance together with the `.cfg` file and tablespace file before performing the `ALTER TABLE ... IMPORT TABLESPACE` operation on the destination instance. The `.cfp` file contains a transfer key and an encrypted tablespace key. On import, `InnoDB` uses the transfer key to decrypt the tablespace key. For related information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#).
- `FLUSH TABLES ... FOR EXPORT` is not supported on tables that have a `FULLTEXT` index. Full-text search auxiliary tables are not flushed. After importing a table with a `FULLTEXT` index, run `OPTIMIZE TABLE` to rebuild the `FULLTEXT` indexes. Alternatively, drop `FULLTEXT` indexes before the export operation and recreate them after importing the table on the destination instance.

15.7.6.1 Transportable Tablespace Examples

Note

If you are transporting tables that are encrypted using the `InnoDB` tablespace encryption, see [Limitations and Usage Notes](#) before you begin for additional procedural information.

Example 1: Copying an InnoDB Table to Another Instance

This procedure demonstrates how to copy a regular `InnoDB` table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full table restore on the same instance.

1. On the source instance, create a table if one does not exist:

```
mysql> USE test;
```

```
mysql> CREATE TABLE t(c1 INT) ENGINE=InnoDB;
```

2. On the destination instance, create a table if one does not exist:

```
mysql> USE test;  
mysql> CREATE TABLE t(c1 INT) ENGINE=InnoDB;
```

3. On the destination instance, discard the existing tablespace. (Before a tablespace can be imported, [InnoDB](#) must discard the tablespace that is attached to the receiving table.)

```
mysql> ALTER TABLE t DISCARD TABLESPACE;
```

4. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table and create the `.cfg` metadata file:

```
mysql> USE test;  
mysql> FLUSH TABLES t FOR EXPORT;
```

The metadata (`.cfg`) is created in the [InnoDB](#) data directory.

Note

The `FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that a binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, [InnoDB](#) produces a `.cfg` file in the same database directory as the table. The `.cfg` file contains metadata used for schema verification when importing the tablespace file.

5. Copy the `.ibd` file and `.cfg` metadata file from the source instance to the destination instance. For example:

```
shell> scp /path/to/datadir/test/t.{ibd,cfg} destination-server:/path/to/datadir/test
```

Note

The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

6. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> USE test;  
mysql> UNLOCK TABLES;
```

7. On the destination instance, import the tablespace:

```
mysql> USE test;  
mysql> ALTER TABLE t IMPORT TABLESPACE;
```

Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time.

In this case you would stop updating the tables, commit all transactions, acquire shared locks on the tables, and then perform the export operation.

Example 2: Copying an InnoDB Partitioned Table to Another Instance

This procedure demonstrates how to copy a partitioned InnoDB table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full restore of a partitioned InnoDB table on the same instance.

1. On the source instance, create a partitioned table if one does not exist. In the following example, a table with three partitions (p0, p1, p2) is created:

```
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

2. On the destination instance, create the same partitioned table:

```
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

3. On the destination instance, discard the tablespace for the partitioned table. (Before the tablespace can be imported on the destination instance, the tablespace that is attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three `.ibd` files that make up the tablespace for the partitioned table are discarded from the `/datadir/test` directory.

4. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files:

```
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

Metadata (`.cfg`) files, one for each tablespace (`.ibd`) file, are created in the `/datadir/test` directory on the source instance:

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
t1#P#p0.cfg t1#P#p1.cfg t1#P#p2.cfg
```

**Note**

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

5. Copy the `.ibd` and `.cfg` files from the source instance database directory to the destination instance database directory. For example:

```
shell>scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test
```

**Note**

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

6. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> USE test;
mysql> UNLOCK TABLES;
```

7. On the destination instance, import the tablespace for the partitioned table:

```
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

Example 3: Copying InnoDB Table Partitions to Another Instance

This procedure demonstrates how to copy InnoDB table partitions from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a restore of InnoDB table partitions on the same instance. In the following example, a partitioned table with four partitions (p0, p1, p2, p3) is created on the source instance. Two of the partitions (p2 and p3) are copied to the destination instance.

1. On the source instance, create a partitioned table if one does not exist. In the following example, a table with four partitions (p0, p1, p2, p3) is created:

```
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

2. On the destination instance, create the same partitioned table:

```
mysql> USE test;
```

```
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

3. On the destination instance, discard the tablespace partitions that you plan to import from the source instance. (Before tablespace partitions can be imported on the destination instance, the corresponding partitions that are attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The `.ibd` files for the two discarded partitions are removed from the `/datadir/test` directory on the destination instance, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd
```

Note

When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

4. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files.

```
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

The metadata files (`.cfg` files) are created in the `/datadir/test` directory on the source instance. There is a `.cfg` file for each tablespace (`.ibd`) file.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
t1#P#p0.cfg t1#P#p1.cfg t1#P#p2.cfg t1#P#p3.cfg
```

Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

5. Copy the `.ibd` and `.cfg` files from the source instance database directory to the destination instance database directory. In this example, only the `.ibd` and `.cfg` files for partition 2 (p2) and partition 3 (p3) are copied to the `data` directory on the destination instance. Partition 0 (p0) and partition 1 (p1) remain on the source instance.

```
shell> scp t1#P#p2.ibd t1#P#p2.cfg t1#P#p3.ibd t1#P#p3.cfg destination-server:/path/to/datadir/test
```

Note

The `.ibd` files and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

6. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> USE test;
mysql> UNLOCK TABLES;
```

7. On the destination instance, import the tablespace partitions (p2 and p3):

```
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

Note

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

15.7.6.2 Transportable Tablespace Internals

The following information describes internals and error log messaging for the transportable tablespaces copy procedure for a regular `InnoDB` table.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
2013-09-24T13:10:19.903526Z 2 [Note] InnoDB: Sync to disk of '"test"."t"' started.
2013-09-24T13:10:19.903586Z 2 [Note] InnoDB: Stopping purge
2013-09-24T13:10:19.903725Z 2 [Note] InnoDB: Writing table metadata to './test/t.cfg'
2013-09-24T13:10:19.904014Z 2 [Note] InnoDB: Table '"test"."t"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary .cfg file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
2013-09-24T13:10:21.181104Z 2 [Note] InnoDB: Deleting the meta-data file './test/t.cfg'
2013-09-24T13:10:21.181180Z 2 [Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
2013-07-18 15:15:01 34960 [Note] InnoDB: Importing tablespace for table 'test/t' that was exported from ho
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase I - Update all pages
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk - done!
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase III - Flush changes to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase IV - Flush complete
```

Note

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing .ibd file:

```
2013-07-18 15:14:38 34960 [Warning] InnoDB: Table "test"."t" tablespace is set as discard
2013-07-18 15:14:38 7f34d9a37700 InnoDB: cannot calculate statistics for table "test"."t"
because the .ibd file is missing. For help, please refer to
http://dev.mysql.com/doc/refman/8.0/en/innodb-troubleshooting.html
```

15.7.7 Moving Tablespace Files While the Server is Offline

The `innodb_directories` option, which defines directories to scan at startup for tablespace files, supports moving or restoring tablespace files to a new location while the server is offline. During startup, discovered tablespace files are used instead those referenced in the data dictionary, and the data dictionary is updated to reference the relocated files. If duplicate tablespace files are discovered by the scan, startup fails with an error indicating that multiple files were found for the same tablespace ID.

The directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` configuration options are automatically appended to the `innodb_directories` argument value. These directories are scanned at startup regardless of whether the `innodb_directories` option is specified explicitly. The implicit addition of these directories permits moving system tablespace files, the data directory, or undo tablespace files without configuring the `innodb_directories` setting. However,

settings must be updated when directories change. For example, after relocating the data directory, you must update the `--datadir` setting before restarting the server.

The `innodb_directories` option may be specified in a startup command or MySQL option file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_directories="directory_path_1;directory_path_2"
```

The following procedure is applicable to moving individual [file-per-table](#) and [general tablespace](#) files, [system tablespace](#) files, [undo tablespace](#) files, or the data directory. Before moving files or directories, review the usage notes that follow.

1. Stop the server.
2. Move the tablespace files or directories.
3. Make the new directory known to [InnoDB](#).
 - If moving individual [file-per-table](#) or [general tablespace](#) files, add unknown directories to the `innodb_directories` value.
 - The directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` configuration options are automatically appended to the `innodb_directories` argument value, so you need not specify these.
 - A file-per-table tablespace file can only be moved to a directory with same name as the schema. For example, if the `actor` table belongs to the `sakila` schema, then the `actor.ibd` data file can only be moved to a directory named `sakila`.
 - General tablespace files cannot be moved to the data directory or a subdirectory of the data directory.
 - If moving system tablespace files, undo tablespaces, or the data directory, update the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` settings, as necessary.
4. Restart the server.

Usage Notes

- Wildcard expressions cannot be used in the `innodb_directories` argument value.
- The `innodb_directories` scan also traverses subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.
- The `innodb_directories` option only supports moving [InnoDB](#) tablespace files. Moving files that belong to a storage engine other than [InnoDB](#) is not supported. This restriction also applies when moving the entire data directory.

- The `innodb_directories` option supports renaming of tablespace files when moving files to a scanned directory. It also supports moving tablespaces files to other supported operating systems.
- When moving tablespace files to a different operating system, ensure that tablespace file names do not include prohibited characters or characters with a special meaning on the destination system.
- When moving a data directory from a Windows operating system to a Linux operating system, modify the binary log file paths in the binary log index file to use backward slashes instead of forward slashes. By default, the binary log index file has the same base name as the binary log file, with the extension `'.index'`. The location of the binary log index file is defined by `--log-bin`. The default location is the data directory.
- If moving tablespace files to a different operating system introduces cross-platform replication, it is the responsibility of the Database Administrator to ensure proper replication of DDL statements that contain platform-specific directories. Statements that permit specifying directories include `CREATE TABLE ... DATA DIRECTORY` and `CREATE TABLESPACE ... ADD DATAFILE`.
- The directory of file-per-table and general tablespace files created with an absolute path or in a location outside of the data directory should be added to the `innodb_directories` argument value. Otherwise, InnoDB is not able to locate these files during recovery. `CREATE TABLE ... DATA DIRECTORY` and `CREATE TABLESPACE ... ADD DATAFILE` permit creation of tablespace files with absolute paths. `CREATE TABLESPACE ... ADD DATAFILE` also permits tablespace file directories that are relative to the data directory. To view tablespace file locations, query the `INFORMATION_SCHEMA.FILES` table:

```
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES \G
```

- `CREATE TABLESPACE ... ADD DATAFILE` requires that the target directory exists and is known to InnoDB. Known directories include those implicitly and explicitly defined by the `innodb_directories` option.

15.7.8 Configuring Undo Tablespaces

By default, `undo logs` reside in two `undo tablespaces`. The I/O patterns for undo logs make undo tablespaces good candidates for `SSD` storage. Because undo logs can become large during long-running transactions, having undo logs in multiple undo tablespaces reduces the maximum size of any one undo tablespace.

Configuring the Number of Undo Tablespaces

The `innodb_undo_tablespaces` configuration option defines the number of undo tablespaces used by InnoDB. The default and minimum value is 2. You can configure `innodb_undo_tablespaces` at startup or while the server is running.

Note

`innodb_undo_tablespaces` is deprecated and will be removed in a future release.

Increasing the `innodb_undo_tablespaces` setting creates the specified number of undo tablespaces and adds them to the list of active undo tablespaces. Decreasing the `innodb_undo_tablespaces` setting removes undo tablespaces from the list of active undo tablespaces. However, undo tablespaces that are removed from the active list remain active until they are no longer used by existing transactions. Undo tablespaces are made inactive rather than removed so that the number of active undo tablespaces can easily be increased again.

Undo tablespaces or individual [segments](#) inside those tablespaces cannot be dropped. However, undo logs stored in undo tablespaces can be truncated. For more information, see [Section 15.7.9, “Truncating Undo Tablespaces”](#).

Configuring the Location of Undo Tablespaces

Undo tablespace files are created in the location defined by the `innodb_undo_directory` configuration option. This option is typically used to place undo logs on a different storage device. If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`. The `innodb_undo_directory` option is non-dynamic. Configuring it requires restarting the server.

At startup, the directories defined by the `innodb_directories` variable are scanned for undo tablespace files. Directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are automatically appended to the `innodb_directories` argument value, regardless of whether the `innodb_directories` variable is defined explicitly. The `innodb_directories` scan also traverses subdirectories.

Undo tablespace file names are in the form of `undo_###`, where `###` is an undo space number between 1 and 127. The undo space number and undo space ID are related as follows:

- undo space number = $0xFFFFFFFF0 - \text{undo space ID}$
- undo space ID = $0xFFFFFFFF0 - \text{undo space number}$

The default size of an undo tablespace file is 10MiB.

Configuring the Number of Rollback Segments

The `innodb_rollback_segments` configuration option defines the number of [rollback segments](#) allocated to each undo tablespace. This option can be configured at startup or while the server is running.

The `innodb_rollback_segments` configuration option also defines the number of rollback segments assigned to the [temporary tablespace](#).

The default setting for `innodb_rollback_segments` is 128, which is also the maximum value. Each rollback segment can support a maximum of 1023 data-modifying transactions.

15.7.9 Truncating Undo Tablespaces

To truncate [undo tablespaces](#), the MySQL instance must be configured with a minimum of two undo tablespaces, which is the default and minimum value in MySQL 8.0. A minimum of two undo tablespaces ensures that one undo tablespace remains active while the other is taken offline to be truncated. The number of undo tablespaces is defined by the `innodb_undo_tablespaces` option. Use this statement to check the value of `innodb_undo_tablespaces`:

```
mysql> SELECT @@innodb_undo_tablespaces;
+-----+
| @@innodb_undo_tablespaces |
+-----+
|                2         |
+-----+
```

Note

`innodb_undo_tablespaces` is deprecated and will be removed in a future release.

For information about configuring undo tablespaces, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

Enabling Truncation of Undo Tablespaces

To truncate undo tablespaces, enable `innodb_undo_log_truncate`.

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When `innodb_undo_log_truncate` is enabled, undo tablespace files that exceed the size limit defined by `innodb_max_undo_log_size` are marked for truncation. `innodb_max_undo_log_size` is a dynamic global variable with a default value of 1024 MiB (1073741824 bytes).

```
mysql> SELECT @@innodb_max_undo_log_size;
+-----+
| @@innodb_max_undo_log_size |
+-----+
| 1073741824 |
+-----+
```

You can configure `innodb_max_undo_log_size` using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_max_undo_log_size=2147483648;
```

When `innodb_undo_log_truncate` is enabled:

1. Undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a circular fashion to avoid truncating the same undo tablespace each time.
2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not assigned to new transactions. Existing transactions that are currently using rollback segments are allowed to complete.
3. The `purge` system frees rollback segments that are no longer needed.
4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and the undo tablespace is truncated to its initial size. The initial size of an undo tablespace file depends on the `innodb_page_size` value. For the default 16KB InnoDB page size, the initial undo tablespace file size is 10MiB. For 4KB, 8KB, 32KB, and 64KB page sizes, the initial undo tablespace files sizes are 7MiB, 8MiB, 20MiB, and 40MiB, respectively.

The size of an undo tablespace after a truncate operation may be larger than the initial size due to immediate use following the completion of the operation.

The `innodb_undo_directory` option defines the location of undo tablespace files. The default value of “.” represents the directory where InnoDB creates other log files by default.

```
mysql> SELECT @@innodb_undo_directory;
+-----+
| @@innodb_undo_directory |
+-----+
| . |
+-----+
```

5. The rollback segments are reactivated so that they can be assigned to new transactions.

Expediting Truncation of Undo Tablespace Files

An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. To expedite the truncation of undo tablespaces, use the `innodb_purge_rseg_truncate_frequency` option to temporarily increase the frequency with which the purge system frees rollback segments. The default `innodb_purge_rseg_truncate_frequency` setting is 128, which is also the maximum value.

```
mysql> SELECT @@innodb_purge_rseg_truncate_frequency;
+-----+
| @@innodb_purge_rseg_truncate_frequency |
+-----+
|                                     128 |
+-----+
```

To increase the frequency with which the purge thread frees rollback segments, decrease the value of `innodb_purge_rseg_truncate_frequency`. For example:

```
mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;
```

Performance Impact of Truncating Undo Tablespace Files Online

While an undo tablespace is truncated, rollback segments in that tablespace are temporarily deactivated. The remaining active rollback segments in the other undo tablespaces assume responsibility for the entire system load, which may result in a slight performance degradation. The degree of performance degradation depends on a number of factors including:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

15.7.10 InnoDB General Tablespaces

A general tablespace is a shared InnoDB tablespace that is created using `CREATE TABLESPACE` syntax. General tablespace capabilities and features are described under the following topics in this section:

- [General Tablespace Capabilities](#)
- [Creating a General Tablespace](#)
- [Adding Tables to a General Tablespace](#)
- [General Tablespace Row Format Support](#)
- [Moving Tables Between Tablespaces Using ALTER TABLE](#)
- [Renaming a General Tablespace](#)
- [Dropping a General Tablespace](#)

- [General Tablespace Limitations](#)

General Tablespace Capabilities

The general tablespace feature provides the following capabilities:

- Similar to the system tablespace, general tablespaces are shared tablespaces that can store data for multiple tables.
- General tablespaces have a potential memory advantage over [file-per-table tablespaces](#). The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.
- General tablespace data files may be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of [file-per-table tablespaces](#). As with file-per-table tablespaces, the ability to place data files outside of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.
- General tablespaces support both Antelope and Barracuda file formats, and therefore support all table row formats and associated features. With support for both file formats, general tablespaces have no dependence on [innodb_file_format](#) or [innodb_file_per_table](#) settings, nor do these variables have any effect on general tablespaces.
- The [TABLESPACE](#) option can be used with [CREATE TABLE](#) to create tables in a general tablespaces, file-per-table tablespace, or in the system tablespace.
- The [TABLESPACE](#) option can be used with [ALTER TABLE](#) to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace. Previously, it was not possible to move a table from a file-per-table tablespace to the system tablespace. With the general tablespace feature, you can now do so.

Creating a General Tablespace

General tablespaces are created using [CREATE TABLESPACE](#) syntax.

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

A general tablespace may be created in the MySQL data directory or in a directory outside of the MySQL data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist and must be known to [InnoDB](#) prior to creating the tablespace. To make an unknown directory known to [InnoDB](#), add the directory to the [innodb_directories](#) argument value. [innodb_directories](#) is a read-only startup option. Configuring it requires restarting the server.

Examples:

Creating a general tablespace in the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
```

Creating a general tablespace in a directory outside of the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;
```

You can specify a path that is relative to the MySQL data directory as long as the tablespace directory is not under the MySQL data directory. In this example, the `my_tablespace` directory is at the same level as the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;
```

Note

The `ENGINE = InnoDB` clause must be defined as part of the `CREATE TABLESPACE` statement or `InnoDB` must be defined as the default storage engine (`default_storage_engine=InnoDB`).

Adding Tables to a General Tablespace

After creating an InnoDB general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace, as shown in the following examples:

CREATE TABLE:

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1;
```

ALTER TABLE:

```
mysql> ALTER TABLE t2 TABLESPACE ts1;
```

Note

Support for adding table partitions to shared tablespaces was deprecated in MySQL 5.7.24 and removed in MySQL 8.0.13. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

For detailed syntax information, see `CREATE TABLE` and `ALTER TABLE`.

General Tablespace Row Format Support

General tablespaces support all table row formats (`REDUNDANT`, `COMPACT`, `DYNAMIC`, `COMPRESSED`) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables (`ROW_FORMAT=COMPRESSED`), `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16KB` and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8.

The following table shows permitted `innodb_page_size`, `FILE_BLOCK_SIZE`, and `KEY_BLOCK_SIZE` combinations. `FILE_BLOCK_SIZE` values may also be specified in bytes. To determine a valid `KEY_BLOCK_SIZE` value for a given `FILE_BLOCK_SIZE`, divide the `FILE_BLOCK_SIZE` value by 1024.

Table compression is not support for 32K and 64K [InnoDB](#) page sizes. For more information about [KEY_BLOCK_SIZE](#), see [CREATE TABLE](#), and [Section 15.9.1.2, “Creating Compressed Tables”](#).

Table 15.7 Permitted Page Size, FILE_BLOCK_SIZE, and KEY_BLOCK_SIZE Combinations for Compressed Tables

InnoDB Page Size (innodb_page_size)	Permitted FILE_BLOCK_SIZE Value	Permitted KEY_BLOCK_SIZE Value
64KB	64K (65536)	Compression is not supported
32KB	32K (32768)	Compression is not supported
16KB	16K (16384)	N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE , the tablespace cannot contain a compressed table.
16KB	8K (8192)	8
16KB	4K (4096)	4
16KB	2K (2048)	2
16KB	1K (1024)	1
8KB	8K (8192)	N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE , the tablespace cannot contain a compressed table.
8KB	4K (4096)	4
8KB	2K (2048)	2
8KB	1K (1024)	1
4KB	4K (4096)	N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE , the tablespace cannot contain a compressed table.
4KB	2K (2048)	2
4KB	1K (1024)	1

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default [innodb_page_size](#) of 16KB. The [FILE_BLOCK_SIZE](#) of 8192 requires that the compressed table have a [KEY_BLOCK_SIZE](#) of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

If you do not specify [FILE_BLOCK_SIZE](#) when creating a general tablespace, [FILE_BLOCK_SIZE](#) defaults to [innodb_page_size](#). When [FILE_BLOCK_SIZE](#) is equal to [innodb_page_size](#), the tablespace may only contain tables with an uncompressed row format ([COMPACT](#), [REDUNDANT](#), and [DYNAMIC](#) row formats).

Moving Tables Between Tablespaces Using ALTER TABLE

You can use [ALTER TABLE](#) with the [TABLESPACE](#) option to move a table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

**Note**

Support for placing table partitions in shared tablespaces was deprecated in MySQL 5.7.24 and removed MySQL 8.0.13. Shared tablespaces include the [InnoDB](#) system tablespace and general tablespaces.

To move a table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See [CREATE TABLESPACE](#) for more information.

```
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name;
```

To move a table from a general tablespace or file-per-table tablespace to the system tablespace, specify [innodb_system](#) as the tablespace name.

```
ALTER TABLE tbl_name TABLESPACE [=] innodb_system;
```

To move a table from the system tablespace or a general tablespace to a file-per-table tablespace, specify [innodb_file_per_table](#) as the tablespace name.

```
ALTER TABLE tbl_name TABLESPACE [=] innodb_file_per_table;
```

[ALTER TABLE ... TABLESPACE](#) operations always cause a full table rebuild, even if the [TABLESPACE](#) attribute has not changed from its previous value.

[ALTER TABLE ... TABLESPACE](#) syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The [DATA DIRECTORY](#) clause is permitted with [CREATE TABLE ... TABLESPACE=innodb_file_per_table](#) but is otherwise not supported for use in combination with the [TABLESPACE](#) option.

Restrictions apply when moving tables from encrypted tablespaces. See [InnoDB Tablespace Encryption Limitations](#).

Renaming a General Tablespace

Renaming a general tablespace is supported using [ALTER TABLESPACE ... RENAME TO](#) syntax.

```
ALTER TABLESPACE s1 RENAME TO s2;
```

The [CREATE TABLESPACE](#) privilege is required to rename a general tablespace.

[RENAME TO](#) operations are implicitly performed in [autocommit](#) mode, regardless of the [autocommit](#) setting.

A [RENAME TO](#) operation cannot be performed while [LOCK TABLES](#) or [FLUSH TABLES WITH READ LOCK](#) is in effect for tables that reside in the tablespace.

Exclusive [metadata locks](#) are taken on tables within a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

Dropping a General Tablespace

The [DROP TABLESPACE](#) statement is used to drop an [InnoDB](#) general tablespace.

All tables must be dropped from the tablespace prior to a [DROP TABLESPACE](#) operation. If the tablespace is not empty, [DROP TABLESPACE](#) returns an error.

Use a query similar to the following to identify tables in a general tablespace.

```
mysql> SELECT a.NAME AS space_name, b.NAME AS table_name FROM INFORMATION_SCHEMA.INNODB_TABLESPACES a,
        INFORMATION_SCHEMA.INNODB_TABLES b WHERE a.SPACE=b.SPACE AND a.NAME LIKE 'ts1';
```

space_name	table_name
ts1	test/t1
ts1	test/t2
ts1	test/t3

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

A general tablespace does not belong to any particular database. A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the `DROP DATABASE` operation drops all tables that belong to the tablespace. A general tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a `DROP TABLE` operation.

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts10 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

Note

`tablespace_name` is a case-sensitive identifier in MySQL.

General Tablespace Limitations

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is for `file-per-table` tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- Support for placing table partitions in general tablespaces was deprecated in MySQL 5.7.24 and removed in MySQL 8.0.13.

15.7.11 InnoDB Tablespace Encryption

The `InnoDB` tablespace encryption feature provides at-rest data encryption for [file-per-table](#) and [general](#) tablespace data files. Support for general tablespaces was introduced in MySQL 8.0.13.

About InnoDB Tablespace Encryption

Tablespace encryption uses a two tier encryption key architecture, consisting of a master encryption key and tablespace keys. When a tablespace is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted tablespace data, `InnoDB` uses a master encryption key to decrypt the tablespace key. The decrypted version of a tablespace key never changes, but the master encryption key can be changed as required. This action is referred to as *master key rotation*.

The tablespace encryption feature relies on a keyring plugin for master encryption key management.

All MySQL editions provide a `keyring_file` plugin, which stores keyring data in a file local to the server host.

MySQL Enterprise Edition offers additional keyring plugins:

- The `keyring_encrypted_file` plugin, which stores keyring data in an encrypted file local to the server host.

- The `keyring_okv` plugin, which includes a KMIP client (KMIP 1.1) that uses a KMIP-compatible product as a back end for keyring storage. Supported KMIP-compatible products include centralized key management solutions such as Oracle Key Vault, Gemalto KeySecure, Thales Vormetric key management server, and Fornetix Key Orchestration.
- The `keyring_aws` plugin, which communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage.

Warning

The `keyring_file` and `keyring_encrypted_file` plugins are not intended as regulatory compliance solutions. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

A secure and robust encryption key management solution is critical for security and for compliance with various security standards. When the tablespace encryption feature uses a centralized key management solution, the feature is referred to as “MySQL Enterprise Transparent Data Encryption (TDE)”.

Tablespace encryption supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

For frequently asked questions about the tablespace encryption feature, see [Section A.16, “MySQL 8.0 FAQ: InnoDB Tablespace Encryption”](#).

InnoDB Tablespace Encryption Prerequisites

- A keyring plugin must be installed and configured. Keyring plugin installation is performed at startup using the `early-plugin-load` option. Early loading ensures that the plugin is available prior to initialization of the InnoDB storage engine. For keyring plugin installation and configuration instructions, see [Section 6.5.4, “The MySQL Keyring”](#).

Only one keyring plugin can be enabled at a time. Enabling multiple keyring plugins is not supported.

Important

Once encrypted tablespaces are created in a MySQL instance, the keyring plugin that was loaded when creating the encrypted tablespace must continue to be loaded at startup using the `early-plugin-load` option. Failing to do so results in errors when starting the server and during InnoDB recovery.

To verify that a keyring plugin is active, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table. For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |
+-----+-----+
```

- Encryption is supported for file-per-table and general tablespaces. To create a table in a file-per-table tablespace, ensure that `innodb_file_per_table` is enabled (the default) before executing a `CREATE TABLE` statement. Alternatively, use the `TABLESPACE='innodb_file_per_table'` clause in `CREATE`

`TABLE` statements. There is no similar prerequisite associated with creation of general tablespaces, which are created using `CREATE TABLESPACE` syntax.

- When encrypting production data, ensure that you take steps to prevent loss of the master encryption key. *If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable.* If you use the `keyring_file` or `keyring_encrypted_file` plugin, create a backup of the keyring data file immediately after creating the first encrypted tablespace, before master key rotation, and after master key rotation. The `keyring_file_data` configuration option defines the keyring data file location for the `keyring_file` plugin. The `keyring_encrypted_file_data` configuration option defines the keyring data file location for the `keyring_encrypted_file` plugin. If you use the `keyring_okv` or `keyring_aws` plugin, ensure that you have performed the necessary configuration. For instructions, see [Section 6.5.4, “The MySQL Keyring”](#).

Enabling and Disabling File-Per-Table Tablespace Encryption

To enable encryption for a new file-per-table tablespace, specify the `ENCRYPTION` option in a `CREATE TABLE` statement.

```
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION='Y';
```

To enable encryption for an existing file-per-table tablespace, specify the `ENCRYPTION` option in an `ALTER TABLE` statement.

```
mysql> ALTER TABLE t1 ENCRYPTION='Y';
```

To disable encryption for a file-per-table tablespace, set `ENCRYPTION='N'` using `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ENCRYPTION='N';
```

Enabling and Disabling General Tablespace Encryption

To enable encryption for a new general tablespace, specify the `ENCRYPTION` option in a `CREATE TABLESPACE` statement.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENCRYPTION = 'Y' Engine=InnoDB;
```

To enable encryption for an existing general tablespace, specify the `ENCRYPTION` option in an `ALTER TABLESPACE` statement.

```
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
```

To disable encryption for general tablespace, set `ENCRYPTION='N'` using `ALTER TABLESPACE`.

```
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'N';
```

Redo Log Data Encryption

Redo log data encryption is enabled using the `innodb_redo_log_encrypt` configuration option. Redo log encryption is disabled by default.

As with tablespace data, redo log data encryption occurs when redo log data is written to disk, and decryption occurs when redo log data is read from disk. Once redo log data is read into memory, it is in unencrypted form. Redo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_redo_log_encrypt` is enabled, unencrypted redo log pages that are present on disk remain unencrypted, and new redo log pages are written to disk in encrypted form. Likewise, when `innodb_redo_log_encrypt` is disabled, encrypted redo log pages that are present on disk remain encrypted, and new redo log pages are written to disk in unencrypted form.

Redo log encryption metadata, including the tablespace encryption key, is stored in the header of the first redo log file (`ib_logfile0`). If this file is removed, redo log encryption is disabled.

Once redo log encryption is enabled, a normal restart without the keyring plugin or without the encryption key is not possible, as InnoDB must be able to scan redo pages during startup, which is not possible if redo log pages are encrypted. Without the keyring plugin or the encryption key, only a forced startup without the redo logs (`SRV_FORCE_NO_LOG_REDO`) is possible. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Undo Log Data Encryption

Undo log data encryption is enabled using the `innodb_undo_log_encrypt` configuration option. Undo log encryption applies to undo logs that reside in [undo tablespaces](#). See [Section 15.7.8, “Configuring Undo Tablespaces”](#). Undo log data encryption is disabled by default.

As with tablespace data, undo log data encryption occurs when undo log data is written to disk, and decryption occurs when undo log data is read from disk. Once undo log data is read into memory, it is in unencrypted form. Undo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_undo_log_encrypt` is enabled, unencrypted undo log pages that are present on disk remain unencrypted, and new undo log pages are written to disk in encrypted form. Likewise, when `innodb_undo_log_encrypt` is disabled, encrypted undo log pages that are present on disk remain encrypted, and new undo log pages are written to disk in unencrypted form.

Undo log encryption metadata, including the tablespace encryption key, is stored in the header of the undo log file (`undoN.ibd`, where *N* is the space ID).

InnoDB Tablespace Encryption and Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key has been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, InnoDB rolls the operation forward on server restart. For more information, see [InnoDB Tablespace Encryption and Recovery](#).

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.

Rotating the master encryption key requires the `ENCRYPTION_KEY_ADMIN` or `SUPER` privilege.

To rotate the master encryption key, run:

```
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with tablespace encryption operations, and locks are taken to prevent conflicts that could arise

from concurrent execution. If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation is running, it must finish before a tablespace encryption operation can proceed, and vice versa.

InnoDB Tablespace Encryption and Recovery

If a server failure occurs during an encryption operation, the operation is rolled forward when the server is restarted. For general tablespaces, the encryption operation is resumed in a background thread from the last processed page.

If a server failure occurs during master key rotation, [InnoDB](#) continues the operation on server restart.

The keyring plugin must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before [InnoDB](#) initialization and recovery activities access tablespace data. (See [InnoDB Tablespace Encryption Prerequisites](#).)

When [InnoDB](#) initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespace keys may already be encrypted using the new master encryption key. [InnoDB](#) reads the encryption data from each tablespace header, and if the data indicates that the tablespace key is encrypted using the old master encryption key, [InnoDB](#) retrieves the old key from the keyring and uses it to decrypt the tablespace key. [InnoDB](#) then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

Exporting Encrypted Tablespaces

Tablespace export is only supported for file-per-table tablespaces.

When an encrypted tablespace is exported, [InnoDB](#) generates a *transfer key* that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, [InnoDB](#) uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

InnoDB Tablespace Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the master and slaves run a version of MySQL that supports tablespace encryption.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on slaves.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on slaves.
- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring plugin is installed on the master but not on the slave.
- If the `keyring_file` or `keyring_encrypted_file` plugin is installed on both the master and a slave but the slave does not have a keyring data file, the replicated `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement creates the keyring data file on the slave, assuming the keyring file data is not cached in memory. `ALTER INSTANCE ROTATE INNODB MASTER KEY` uses keyring file data that is cached in memory, if available.

Identifying Encrypted Tablespaces

The `INFORMATION_SCHEMA.INNODB_TABLESPACES` table, introduced in MySQL 8.0.13, includes an `ENCRYPTION` column that can be used to identify encrypted tablespaces.

```
mysql> SELECT SPACE, NAME, SPACE_TYPE, ENCRYPTION FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
       WHERE ENCRYPTION='Y'\G
***** 1. row *****
      SPACE: 2
      NAME: ts1
SPACE_TYPE: General
ENCRYPTION: Y
***** 2. row *****
      SPACE: 3
      NAME: test/t1
SPACE_TYPE: Single
ENCRYPTION: Y
```

When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` column of `INFORMATION_SCHEMA.TABLES`. This column can be queried to identify tables that reside in encrypted file-per-table tablespaces.

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
       WHERE CREATE_OPTIONS LIKE '%ENCRYPTION="Y"%';
+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | CREATE_OPTIONS |
+-----+-----+-----+
| test         | t1          | ENCRYPTION="Y" |
+-----+-----+-----+
```

Query `INFORMATION_SCHEMA.INNODB_TABLESPACES` to retrieve information about the tablespace associated with a particular schema and table.

```
mysql> SELECT SPACE, NAME, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='test/t1';
+-----+-----+-----+
| SPACE | NAME   | SPACE_TYPE |
+-----+-----+-----+
| 3     | test/t1 | Single     |
+-----+-----+-----+
```

Monitoring Tablespace Encryption Progress

You can monitor general tablespace encryption progress using [Performance Schema](#).

The `stage/innodb/alter tablespace (encryption)` stage event instrument reports `WORK_ESTIMATED` and `WORK_COMPLETED` information for general tablespace encryption operations.

The following example demonstrates how to enable the `stage/innodb/alter tablespace (encryption)` stage event instrument and related consumer tables to monitor general tablespace encryption progress. For information about Performance Schema stage event instruments and related consumers, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter tablespace (encryption)` instrument:

```
mysql> USE performance_schema;
mysql> UPDATE setup_instruments SET ENABLED = 'YES'
       WHERE NAME LIKE 'stage/innodb/alter tablespace (encryption)';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
```

- Run a general tablespace encryption operation.

```
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
```

- Check the progress of the encryption operation by querying the Performance Schema `events_stages_current` table. `WORK_ESTIMATED` reports the total number of pages in the tablespace. `WORK_COMPLETED` reports the number of pages processed.

```
mysql> SELECT EVENT_NAME, WORK_ESTIMATED, WORK_COMPLETED FROM events_stages_current;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/alter tablespace (encryption)	1056	1407

The `events_stages_current` table returns an empty set if the encryption operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/alter tablespace (encryption)	1407	1407

InnoDB Tablespace Encryption Usage Notes

- Plan appropriately when altering an existing file-per-table tablespace with the `ENCRYPTION` option. Tables residing in file-per-table tablespaces are rebuilt using the `COPY` algorithm. The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the general tablespace. Concurrent DDL is blocked.
- When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted general tablespace is encrypted.
- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.
- The first master encryption key is generated when the first new or existing tablespace is encrypted.
- Master key rotation re-encrypts tablespaces keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable encryption. For file-per-table tablespaces, re-encrypting the tablespace is an `ALGORITHM=COPY` operation that rebuilds the table. For general tablespaces, it is an `ALGORITHM=INPLACE` operation, which does not require rebuilding tables that reside in the tablespace.
- If a table is created with both the `COMPRESSION` and `ENCRYPTION` options, compression is performed before tablespace data is encrypted.
- If a keyring data file (the file named by `keyring_file_data` or `keyring_encrypted_file_data`) is empty or missing, the first execution of `ALTER INSTANCE ROTATE INNODB MASTER KEY` creates a master encryption key.
- Uninstalling the `keyring_file` or `keyring_encrypted_file` plugin does not remove an existing keyring data file.

- It is recommended that you not place a keyring data file under the same directory as tablespace data files.
- Modifying the `keyring_file_data` or `keyring_encrypted_file_data` setting at runtime or when restarting the server can cause previously encrypted tablespaces to become inaccessible, resulting in lost data.

InnoDB Tablespace Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. InnoDB tablespace encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.
- Encryption is only supported for `file-per-table` and `general` tablespaces. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption is not supported for other tablespace types including the `system tablespace`.
- You cannot move or copy a table from an encrypted `file-per-table` tablespace or `general` tablespace to a tablespace type that does not support encryption.
- You cannot move or copy a table from an encrypted tablespace to an unencrypted tablespace. However, moving a table from an unencrypted tablespace to an encrypted one is permitted. For example, you can move or copy a table from a unencrypted `file-per-table` or `general` tablespace to an encrypted general tablespace.
- By default, tablespace encryption only applies to data in the tablespace. Redo log and undo log data can be encrypted by enabling `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt`. See [Redo Log Data Encryption](#), and [Undo Log Data Encryption](#). Binary log data is not encrypted.
- It is not permitted to change the storage engine of a table that resides or previously resided in an encrypted tablespace.

15.8 InnoDB Tables and Indexes

This section covers topics related to InnoDB tables and indexes.

15.8.1 InnoDB Tables

This section covers topics related to InnoDB tables.

15.8.1.1 Creating InnoDB Tables

To create an InnoDB table, use the `CREATE TABLE` statement.

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

You do not need to specify the `ENGINE=InnoDB` clause if InnoDB is defined as the default storage engine, which it is by default. To check the default storage engine, issue the following statement:

```
mysql> SELECT @@default_storage_engine;
+-----+
| @@default_storage_engine |
+-----+
| InnoDB                   |
+-----+
```

```
+-----+
```

You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not `InnoDB`.

An `InnoDB` table and its indexes can be created in the `system tablespace`, in a `file-per-table` tablespace, or in a `general tablespace`. When `innodb_file_per_table` is enabled, which is the default, an `InnoDB` table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an `InnoDB` table is implicitly created in the `InnoDB` system tablespace. To create a table in a general tablespace, use `CREATE TABLE ... TABLESPACE` syntax. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

When you create a table in a file-per-table tablespace, MySQL creates an `.ibd` tablespace file in a database directory under the MySQL data directory, by default. A table created in the `InnoDB` system tablespace is created in an existing `ibdata file`, which resides in the MySQL data directory. A table created in a general tablespace is created in an existing general tablespace `.ibd file`. General tablespace files can be created inside or outside of the MySQL data directory. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

Internally, `InnoDB` adds an entry for each table to the data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry for the database name is `'test/t1'`. This means you can create a table of the same name (`t1`) in a different database, and the table names do not collide inside `InnoDB`.

InnoDB Tables and Row Formats

The default row format for `InnoDB` tables is defined by the `innodb_default_row_format` configuration option, which has a default value of `DYNAMIC`. `Dynamic` and `Compressed` row format allow you to take advantage of `InnoDB` features such as table compression and efficient off-page storage of long column values. To use these row formats, `innodb_file_per_table` must be enabled (the default).

```
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=DYNAMIC;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=COMPRESSED;
```

Alternatively, you can use `CREATE TABLE ... TABLESPACE` syntax to create an `InnoDB` table in a general tablespace. General tablespaces support all row formats. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

`CREATE TABLE ... TABLESPACE` syntax can also be used to create `InnoDB` tables with a `Dynamic` row format in the system tablespace, alongside tables with a `Compact` or `Redundant` row format.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE = innodb_system ROW_FORMAT=DYNAMIC;
```

For more information about `InnoDB` row formats, see [Section 15.10, “InnoDB Row Storage and Row Formats”](#). For how to determine the row format of an `InnoDB` table and the physical characteristics of `InnoDB` row formats, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

InnoDB Tables and Primary Keys

Always define a `primary key` for an `InnoDB` table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on `(firstname, lastname)` because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

# The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.

Viewing InnoDB Table Properties

To view the properties of an [InnoDB](#) table, issue a `SHOW TABLE STATUS` statement:

```
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
        Rows: 0
  Avg_row_length: 0
    Data_length: 16384
  Max_data_length: 0
    Index_length: 0
      Data_free: 0
  Auto_increment: NULL
    Create_time: 2015-03-16 15:13:31
    Update_time: NULL
    Check_time: NULL
  Collation: utf8mb4_0900_ai_ci
    Checksum: NULL
  Create_options:
    Comment:
```

For information about `SHOW TABLE STATUS` output, see [Section 13.7.6.36, “SHOW TABLE STATUS Syntax”](#).

[InnoDB](#) table properties may also be queried using the [InnoDB](#) Information Schema system tables:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test/t1' \G
```

```
***** 1. row *****
TABLE_ID: 45
NAME: test/t1
FLAG: 1
N_COLS: 5
SPACE: 35
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
```

For more information, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

15.8.1.2 The Physical Row Structure of an InnoDB Table

The physical row structure of an [InnoDB](#) table depends on the row format specified when the table is created. If a row format is not specified, the default row format is used. The default row format for [InnoDB](#) tables is defined by the `innodb_default_row_format` configuration option, which has a default value of `DYNAMIC`.

The following sections describe the characteristics of [InnoDB](#) row formats.

- [Determining the Row Format of an InnoDB Table](#)
- [Redundant Row Format Characteristics](#)
- [COMPACT Row Format Characteristics](#)
- [DYNAMIC and COMPRESSED Row Format Characteristics](#)

For more information about [InnoDB](#) row formats, see [Section 15.10, “InnoDB Row Storage and Row Formats”](#).

Determining the Row Format of an InnoDB Table

To determine the row format of an [InnoDB](#) table, you can use `SHOW TABLE STATUS`. For example:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2016-09-14 16:29:38
      Update_time: NULL
      Check_time: NULL
      Collation: utf8mb4_0900_ai_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also determine the row format of an [InnoDB](#) table by querying `INFORMATION_SCHEMA.INNODB_TABLES`.

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test1/t1';
```

NAME	ROW_FORMAT
test1/t1	Dynamic

Redundant Row Format Characteristics

The **REDUNDANT** format is available to retain compatibility with older versions of MySQL.

Rows in **InnoDB** tables that use **REDUNDANT** row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, **InnoDB** stores fixed-length character columns such as **CHAR(10)** in a fixed-length format. **InnoDB** does not truncate trailing spaces from **VARCHAR** columns.
- **InnoDB** encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with **utf8mb4**.
- An SQL **NULL** value reserves one or two bytes in the record directory. Besides that, an SQL **NULL** value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for **NULL** values enables an update of the column from **NULL** to a non-**NULL** value to be done in place without causing fragmentation of the index page.

COMPACT Row Format Characteristics

The **COMPACT** row format decreases row storage space by about 20% compared to the **REDUNDANT** format at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, **COMPACT** format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in **InnoDB** tables that use **COMPACT** row format have the following characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating **NULL** columns. If the number of columns in the index that can be **NULL** is *N*, the bit vector occupies **CEILING(N/8)** bytes. (For example, if there are anywhere from 9 to 16 columns that can be **NULL**, the bit vector uses two bytes.) Columns that are **NULL** do not occupy space other than the bit in this vector. The variable-length

part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.

- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-`NULL` columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, for nonvariable-length character sets, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format.

InnoDB does not truncate trailing spaces from `VARCHAR` columns.

- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, InnoDB attempts to store `CHAR(N)` in `N` bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds `N` bytes, InnoDB trims trailing spaces to a minimum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length $\times N$.

InnoDB reserves a minimum of `N` bytes for `CHAR(N)`. Reserving the minimum space `N` in many cases enables column updates to be done in place without causing fragmentation of the index page. By comparison, for `ROW_FORMAT=REDUNDANT`, `CHAR(N)` columns occupy the maximum character byte length $\times N$.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

`ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`.

DYNAMIC and COMPRESSED Row Format Characteristics

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format. For information about these row formats, see [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#).

15.8.1.3 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, [InnoDB](#) always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

**Note**

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.

Techniques for moving or copying [InnoDB](#) tables include:

- [Transportable Tablespaces](#)
- [MySQL Enterprise Backup](#)
- [Copying Data Files \(Cold Backup Method\)](#)
- [Export and Import \(mysqldump\)](#)

Transportable Tablespaces

The transportable tablespaces feature uses `FLUSH TABLES ... FOR EXPORT` to ready [InnoDB](#) tables for copying from one server instance to another. To use this feature, [InnoDB](#) tables must be created with `innodb_file_per_table` set to `ON` so that each [InnoDB](#) table has its own tablespace. For usage information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).

Copying Data Files (Cold Backup Method)

You can move an [InnoDB](#) database simply by copying all the relevant files listed under “Cold Backups” in [Section 15.17.1, “InnoDB Backup”](#).

[InnoDB](#) data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy file-per-table `.ibd` files, the database directory name must be the same on the source and destination systems. The table definition stored in the [InnoDB](#) shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.
2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.
4. Issue this `ALTER TABLE` statement to tell InnoDB to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

One way to increase the performance of this method is to switch off [autocommit](#) mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

15.8.1.4 Converting Tables from MyISAM to InnoDB

If you have [MyISAM](#) tables that you want to convert to [InnoDB](#) for better reliability and scalability, review the following guidelines and tips before converting.

Note

Partitioned [MyISAM](#) tables created in previous versions of MySQL are not compatible with MySQL 8.0. Such tables must be prepared prior to upgrade, either by removing the partitioning, or by converting them to [InnoDB](#). See [Section 22.6.2](#), “[Partitioning Limitations Relating to Storage Engines](#)”, for more information.

- [Adjusting Memory Usage for MyISAM and InnoDB](#)
- [Handling Too-Long Or Too-Short Transactions](#)
- [Handling Deadlocks](#)
- [Planning the Storage Layout](#)
- [Converting an Existing Table](#)
- [Cloning the Structure of a Table](#)
- [Transferring Existing Data](#)
- [Storage Requirements](#)
- [Defining a PRIMARY KEY for Each Table](#)
- [Application Performance Considerations](#)
- [Understanding Files Associated with InnoDB Tables](#)

Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from [MyISAM](#) tables, lower the value of the [key_buffer_size](#) configuration option to free memory no longer needed for caching results. Increase the value of the [innodb_buffer_pool_size](#) configuration option, which performs a similar role of allocating cache memory for [InnoDB](#) tables. The [InnoDB buffer pool](#) caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see [Section 8.12.3.1](#), “[How MySQL Uses Memory](#)”.

Handling Too-Long Or Too-Short Transactions

Because [MyISAM](#) tables do not support [transactions](#), you might not have paid much attention to the [autocommit](#) configuration option and the [COMMIT](#) and [ROLLBACK](#) statements. These keywords are important to allow multiple sessions to read and write [InnoDB](#) tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.
- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to InnoDB tables prior to the `COMMIT`, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using `TRUNCATE TABLE`) and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.
- The time when `autocommit=1` is suitable for InnoDB tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and InnoDB can *automatically optimize the read-only workload*.
- If you make a series of related changes, finalize all the changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a *deadlock* is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. When *deadlock detection* is enabled (the default), MySQL immediately detects this condition and cancels (*rolls back*) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

Planning the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table` and `innodb_page_size` configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default, new InnoDB tables are implicitly created in `file-per-table` tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support `DYNAMIC` and `COMPRESSED` row formats and associated features such as table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

You can also store InnoDB tables in a shared general tablespace, which support multiple tables and all row formats. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using `ALTER TABLE` to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `SHOW CREATE TABLE table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;  
... import operation ...  
SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its [change buffer](#) to write secondary index records as a batch. Be certain that the data contains no duplicate keys. [unique_checks](#) permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable  
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the [InnoDB](#) buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the size of [InnoDB](#) log files.

Storage Requirements

If you intend to make several temporary copies of your data in [InnoDB](#) tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the [innodb_file_per_table](#) configuration option is enabled (the default), newly created [InnoDB](#) tables are implicitly created in file-per-table tablespaces.

Whether you convert the [MyISAM](#) table directly or create a cloned [InnoDB](#) table, make sure that you have sufficient disk space to hold both the old and new tables during the process. **InnoDB tables require more disk space than MyISAM tables.** If an [ALTER TABLE](#) operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, [InnoDB](#) uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Defining a PRIMARY KEY for Each Table

The [PRIMARY KEY](#) clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a [PRIMARY KEY](#) for each table. Typically, it is the most important column that you refer to in [WHERE](#) clauses when looking up a single row.
- Declare the [PRIMARY KEY](#) clause in the original [CREATE TABLE](#) statement, rather than adding it later through an [ALTER TABLE](#) statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a [primary key](#) to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any [secondary indexes](#), because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the [buffer pool](#), speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a [VARCHAR](#), consider adding a new unsigned [AUTO_INCREMENT](#) column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as [UNIQUE NOT NULL](#) to enforce the same constraints as the [PRIMARY KEY](#) clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the [PRIMARY KEY](#) clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

Application Performance Considerations

The reliability and scalability features of [InnoDB](#) require more disk storage than equivalent [MyISAM](#) tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for [join](#) queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned [INT](#) column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#).

Understanding Files Associated with InnoDB Tables

[InnoDB](#) files require more care and planning than [MyISAM](#) files do.

- You must not delete the [ibdata files](#) that represent the [InnoDB system tablespace](#).
- Methods of moving or copying [InnoDB](#) tables to a different server are described in [Section 15.8.1.3, “Moving or Copying InnoDB Tables”](#).

15.8.1.5 AUTO_INCREMENT Handling in InnoDB

InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. To use the `AUTO_INCREMENT` mechanism with an InnoDB table, an `AUTO_INCREMENT` column must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of `AUTO_INCREMENT` lock modes, usage implications for different `AUTO_INCREMENT` lock mode settings, and how InnoDB initializes the `AUTO_INCREMENT` counter.

- [InnoDB AUTO_INCREMENT Lock Modes](#)
- [InnoDB AUTO_INCREMENT Lock Mode Usage Implications](#)
- [InnoDB AUTO_INCREMENT Counter Initialization](#)

InnoDB AUTO_INCREMENT Lock Modes

This section describes the behavior of `AUTO_INCREMENT` lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “`INSERT`-like” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. As of MySQL

8.0, interleaved lock mode (`innodb_autoinc_lock_mode=2`) is the default setting. Prior to MySQL 8.0, consecutive lock mode is the default (`innodb_autoinc_lock_mode=1`).

The default setting of interleaved lock mode in MySQL 8.0 reflects the change from statement-based replication to row based replication as the default replication type. Statement-based replication requires the consecutive auto-increment lock mode to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement are consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 are either smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements

using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, InnoDB can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time. If the source table of the bulk insert operation is different from the target table, the `AUTO-INC` lock on the target table is taken after a shared lock is taken on the first row selected from the source table. If the source and target of the bulk insert operation are the same table, the `AUTO-INC` lock is taken after shared locks are taken on all selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “[INSERT](#)-like” statements use the table-level [AUTO-INC](#) lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “[INSERT](#)-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

InnoDB [AUTO_INCREMENT](#) Lock Mode Usage Implications

- Using auto-increment with replication

If you are using statement-based replication, set [innodb_autoinc_lock_mode](#) to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use [innodb_autoinc_lock_mode](#) = 2 (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “[INSERT](#)-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an [AUTO_INCREMENT](#) column of a table.

- Specifying NULL or 0 for the [AUTO_INCREMENT](#) column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the [AUTO_INCREMENT](#) column in an [INSERT](#), InnoDB treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the [AUTO_INCREMENT](#) column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the [AUTO_INCREMENT](#) column.

- If the [AUTO_INCREMENT](#) value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “`INSERT`-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

```
mysql> CREATE TABLE t1 (
-> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> c2 CHAR(1)
-> ) ENGINE = INNODB;
```

Now, consider the following “mixed-mode insert” statement:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

c1	c2
1	a
101	b
5	c
102	d

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows are also:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

c1	c2
1	a
101	b
5	c
102	d

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “[INSERT](#)-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

c1	c2
1	a
<i>x</i>	b
5	c
<i>y</i>	d

The values of *x* and *y* are unique and larger than any previously generated rows. However, the specific values of *x* and *y* depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number is 100:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (101,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 101 is allocated for the row (NULL, 'b') and insertion of the row (101, 'c') fails.

- Modifying `AUTO_INCREMENT` column values in the middle of a sequence of `INSERT` statements

In MySQL 5.7 and earlier, modifying an `AUTO_INCREMENT` column value in the middle of a sequence of `INSERT` statements could lead to “Duplicate entry” errors. For example, if you performed an `UPDATE` operation that changed an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent `INSERT` operations that did not specify an unused auto-increment value could encounter “Duplicate entry” errors. In MySQL 8.0 and later, if you modify an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, the new value is persisted, and subsequent `INSERT` operations allocate auto-increment values starting from the new, larger value. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 (
-> c1 INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (c1)
-> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
```

c1
1
2
3

```
mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;
```

```
mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
+-----+

mysql> INSERT INTO t1 VALUES(0);

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
```

InnoDB AUTO_INCREMENT Counter Initialization

This section describes how InnoDB initializes `AUTO_INCREMENT` counters.

If you specify an `AUTO_INCREMENT` column for an InnoDB table, the in-memory table object contains a special counter called the auto-increment counter that is used when assigning new values for the column.

In MySQL 5.7 and earlier, the auto-increment counter is stored only in main memory, not on disk. To initialize an auto-increment counter after a server restart, InnoDB would execute the equivalent of the following statement on the first insert into a table containing an `AUTO_INCREMENT` column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

In MySQL 8.0, this behavior is changed. The current maximum auto-increment counter value is written to the redo log each time it changes and is saved to an engine-private system table on each checkpoint. These changes make the current maximum auto-increment counter value persistent across server restarts.

On a server restart following a normal shutdown, InnoDB initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary system table.

On a server restart during crash recovery, InnoDB initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary system table and scans the redo log for auto-increment counter values written since the last checkpoint. If a redo-logged value is greater than the in-memory counter value, the redo-logged value is applied. However, in the case of a server crash, reuse of a previously allocated auto-increment value cannot be guaranteed. Each time the current maximum auto-increment value is changed due to an `INSERT` or `UPDATE` operation, the new value is written to the redo log, but if the crash occurs before the redo log is flushed to disk, the previously allocated value could be reused when the auto-increment counter is initialized after the server is restarted.

The only circumstance in which InnoDB uses the equivalent of a `SELECT MAX(ai_col) FROM table_name FOR UPDATE` statement in MySQL 8.0 and later to initialize an auto-increment counter is when importing a tablespace without a `.cfg` metadata file. Otherwise, the current maximum auto-increment counter value is read from the `.cfg` metadata file.

In MySQL 5.7 and earlier, a server restart cancels the effect of the `AUTO_INCREMENT = N` table option, which may be used in a `CREATE TABLE` or `ALTER TABLE` statement to set an initial counter value or alter the existing counter value, respectively. In MySQL 8.0, a server restart does not cancel the effect of the `AUTO_INCREMENT = N` table option. If you initialize the auto-increment counter to a specific value, or

if you alter the auto-increment counter value to a larger value, the new value is persisted across server restarts.

**Note**

`ALTER TABLE ... AUTO_INCREMENT = N` can only change the auto-increment counter value to a value larger than the current maximum.

In MySQL 5.7 and earlier, a server restart immediately following a [ROLLBACK](#) operation could result in the reuse of auto-increment values that were previously allocated to the rolled-back transaction, effectively rolling back the current maximum auto-increment value. In MySQL 8.0, the current maximum auto-increment value is persisted, preventing the reuse of previously allocated values.

If a `SHOW TABLE STATUS` statement examines a table before the auto-increment counter is initialized, [InnoDB](#) opens the table and initializes the counter value using the current maximum auto-increment value that is stored in the data dictionary system table. The value is stored in memory for use by later inserts or updates. Initialization of the counter value uses a normal exclusive-locking read on the table which lasts to the end of the transaction. [InnoDB](#) follows the same procedure when initializing the auto-increment counter for a newly created table that has a user-specified auto-increment value that is greater than 0.

After the auto-increment counter is initialized, if you do not explicitly specify an auto-increment value when inserting a row, [InnoDB](#) implicitly increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies an auto-increment column value, and the value is greater than the current maximum counter value, the counter is set to the specified value.

[InnoDB](#) uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, [InnoDB](#) reinitializes the auto-increment counter, as described earlier.

The `auto_increment_offset` configuration option determines the starting point for the `AUTO_INCREMENT` column value. The default setting is 1.

The `auto_increment_increment` configuration option controls the interval between successive column values. The default setting is 1.

15.8.1.6 InnoDB and FOREIGN KEY Constraints

How the [InnoDB](#) storage engine handles foreign key constraints is described under the following topics in this section:

- [Foreign Key Definitions](#)
- [Referential Actions](#)
- [Foreign Key Restrictions for Generated Columns and Virtual Indexes](#)

For foreign key usage information and examples, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#).

Foreign Key Definitions

Foreign key definitions for [InnoDB](#) tables are subject to the following conditions:

- [InnoDB](#) permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- [InnoDB](#) does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned [InnoDB](#) table may contain foreign key references or columns referenced by foreign keys.

- [InnoDB](#) allows a foreign key constraint to reference a nonunique key. *This is an [InnoDB](#) extension to standard SQL.*

Referential Actions

Referential actions for foreign keys of [InnoDB](#) tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by [InnoDB](#). `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for InnoDB tables.
- If there are several rows in the parent table that have the same referenced key value, [InnoDB](#) acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, [InnoDB](#) does not permit the deletion of any of those parent rows.
- [InnoDB](#) performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, [InnoDB](#) checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records it has to look at. [InnoDB](#) checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until [InnoDB](#) implements deferred constraint checking, some things are impossible, such as deleting a record that refers to itself using a foreign key.

Foreign Key Restrictions for Generated Columns and Virtual Indexes

- A foreign key constraint on a [stored generated column](#) cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.
- A foreign key constraint cannot reference a [virtual generated column](#).
- Prior to MySQL 8.0, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.

15.8.1.7 Limits on InnoDB Tables

Limits on [InnoDB](#) tables are described under the following topics in this section:

- [Maximums and Minimums](#)
- [Restrictions on InnoDB Tables](#)
- [Locking and Transactions](#)

Warning

Before using NFS with [InnoDB](#), review potential issues outlined in [Using NFS with MySQL](#).

Maximums and Minimums

- A table can contain a maximum of 1017 columns. Virtual generated columns are included in this limit.
- A table can contain a maximum of 64 [secondary indexes](#).
- The index key prefix length limit is 3072 bytes for [InnoDB](#) tables that use [DYNAMIC](#) or [COMPRESSED](#) row format.

The index key prefix length limit is 767 bytes for [InnoDB](#) tables that use [REDUNDANT](#) or [COMPACT](#) row format. For example, you might hit this limit with a [column prefix](#) index of more than 191 characters on a [TEXT](#) or [VARCHAR](#) column, assuming a [utf8mb4](#) character set and the maximum of 4 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error.

The limits that apply to index key prefixes also apply to full-column index keys.

- If you reduce the [InnoDB page size](#) to 8KB or 4KB by specifying the [innodb_page_size](#) option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.
- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

```
ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
```

- The maximum row length, except for variable-length columns ([VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), is slightly less than half of a page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row length for the default [innodb_page_size](#) of 16KB is about 8000 bytes. For an [InnoDB](#) page size of 64KB, the maximum row length is about 16000 bytes. [LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 15.11.2, “File Space Management”](#).

- Although [InnoDB](#) supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of [InnoDB](#) itself, but if you require a large tablespace, configure it using several smaller data files rather than one large data file.
- The combined size of the [InnoDB](#) log files can be up to 512GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the [InnoDB](#) page size.

Table 15.8 InnoDB Maximum Tablespace Size

InnoDB Page Size	Maximum Tablespace Size
4KB	16TB
8KB	32TB
16KB	64TB
32KB	128TB
64KB	256TB

The maximum tablespace size is also the maximum size for a table.

- The default page size in InnoDB is 16KB. You can increase or decrease the page size by configuring the `innodb_page_size` option when creating the MySQL instance.

32KB and 64KB page sizes are supported, but `ROW_FORMAT=COMPRESSED` is unsupported for page sizes greater than 16KB. For both 32KB and 64KB page sizes, the maximum record size is 16KB. For `innodb_page_size=32KB`, extent size is 2MB. For `innodb_page_size=64KB`, extent size is 4MB.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

Restrictions on InnoDB Tables

- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by performing `random dives` on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the `statistics` collected by `ANALYZE TABLE` more precise and more stable by turning on the `innodb_stats_persistent` configuration option, as explained in [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#). When that setting is enabled, it is important to run `ANALYZE TABLE` after major changes to indexed column data, because the statistics are not recalculated periodically (such as after a server restart).

If the persistent statistics setting is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If the persistent statistics setting is disabled, modify the `innodb_stats_transient_sample_pages` system variable instead.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section B.5.5, “Optimizer-Related Issues”](#).

- If statements or transactions are running on a table, and `ANALYZE TABLE` is run on the same table followed by a second `ANALYZE TABLE` operation, the second `ANALYZE TABLE` operation is blocked until the statements or transactions are completed. This behavior occurs because `ANALYZE TABLE` marks the currently loaded table definition as obsolete when `ANALYZE TABLE` is finished running. New statements or transactions (including a second `ANALYZE TABLE` statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.

- `SHOW TABLE STATUS` does not give accurate statistics on InnoDB tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

For information about how InnoDB processes `SELECT COUNT(*)` statements, refer to the `COUNT()` description in [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.
- An `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.
- InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). This restriction applies to use of the names in any letter case.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;  
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

Locking and Transactions

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Versions of MySQL before 4.1.2 did not acquire InnoDB table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no InnoDB table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

In MySQL 8.0, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All [InnoDB](#) locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on [InnoDB](#) tables in `autocommit=1` mode because the acquired [InnoDB](#) table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.
- The limit on data-modifying transactions is $96 * 1023$ concurrent transactions that generate undo records. 32 of 128 rollback segments are assigned to non-redo logs for transactions that modify temporary tables and related objects. This means that the maximum number of concurrent data-modifying transactions is 96K. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the limit is 32K concurrent transactions.

15.8.2 InnoDB Indexes

This section covers topics related to [InnoDB](#) indexes.

15.8.2.1 Clustered and Secondary Indexes

Every [InnoDB](#) table has a special index called the [clustered index](#) where the data for the rows is stored. Typically, the clustered index is synonymous with the [primary key](#). To get the best performance from queries, inserts, and other database operations, you must understand how [InnoDB](#) uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a [PRIMARY KEY](#) on your table, [InnoDB](#) uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new [auto-increment](#) column, whose values are filled in automatically.
- If you do not define a [PRIMARY KEY](#) for your table, MySQL locates the first [UNIQUE](#) index where all the key columns are `NOT NULL` and [InnoDB](#) uses it as the clustered index.
- If the table has no [PRIMARY KEY](#) or suitable [UNIQUE](#) index, [InnoDB](#) internally generates a hidden clustered index named `GEN_CLUST_INDEX` on a synthetic column containing row ID values. The rows are ordered by the ID that [InnoDB](#) assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record.

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as [secondary indexes](#). In [InnoDB](#), each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. [InnoDB](#) uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of [InnoDB](#) clustered and secondary indexes, see [Section 8.3](#), “[Optimization and Indexes](#)”.

15.8.2.2 The Physical Structure of an InnoDB Index

With the exception of spatial indexes, InnoDB indexes are B-tree data structures. Spatial indexes use R-trees, which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB.

When new records are inserted into an InnoDB clustered index, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.

InnoDB performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. The `innodb_fill_factor` configuration option defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see [Section 15.8.2.3, “Sorted Index Builds”](#). An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an InnoDB index page drops below the `MERGE_THRESHOLD`, which is 50% by default if not specified, InnoDB tries to contract the index tree to free the page. The `MERGE_THRESHOLD` setting applies to both B-tree and R-tree indexes. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

You can define the page size for all InnoDB tablespaces in a MySQL instance by setting the `innodb_page_size` configuration option prior to initializing the MySQL instance. Once the page size for an instance is defined, you cannot change it without reinitializing the instance. Supported sizes are 64KB, 32KB, 16KB (default), 8KB, and 4KB.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

15.8.2.3 Sorted Index Builds

InnoDB performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the clustered index is scanned, and index entries are generated and added to the sort buffer. When the sort buffer becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the B-tree.

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree cursor to find the insert position and then inserting entries into a B-tree page using an optimistic insert. If an insert failed due to a page being full, a pessimistic insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down” method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a “bottom-up” approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the `innodb_fill_factor` configuration option to reserve a percentage of B-tree page space. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries. The amount of space that is reserved may not be exactly as configured, as the `innodb_fill_factor` value is interpreted as a hint rather than a hard limit.

Sorted Index Builds and Full-Text Index Support

Sorted index builds are supported for [fulltext indexes](#). Previously, SQL was used to insert entries into a fulltext index.

Sorted Index Builds and Compressed Tables

For [compressed tables](#), the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page) became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For more information about compression of B-Tree pages, see [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#).

Sorted Index Builds and Redo Logging

[Redo logging](#) is disabled during a sorted index build. Instead, there is a [checkpoint](#) to ensure that the index build can withstand a crash or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the [page cleaner](#) thread is signaled periodically to flush [dirty pages](#) to ensure that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are flushed promptly to reduce checkpoint overhead and to parallelize I/O and CPU activity.

Sorted Index Builds and Optimizer Statistics

Sorted index builds may result in [optimizer](#) statistics that differ from those generated by the previous method of index creation. The difference in statistics, which is not expected to affect workload performance, is due to the different algorithm used to populate the index.

15.8.2.4 InnoDB FULLTEXT Indexes

[FULLTEXT](#) indexes are created on text-based columns (`CHAR`, `VARCHAR`, or `TEXT` columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A [FULLTEXT](#) index is defined as part of a `CREATE TABLE` statement or added to an existing table using `ALTER TABLE` or `CREATE INDEX`.

Full-text search is performed using `MATCH() . . . AGAINST` syntax. For usage information, see [Section 12.9, “Full-Text Search Functions”](#).

[InnoDB FULLTEXT](#) indexes are described under the following topics in this section:

- [InnoDB Full-Text Index Design](#)
- [InnoDB Full-Text Index Tables](#)

- [InnoDB Full-Text Index Cache](#)
- [InnoDB Full-Text Index Document ID and FTS_DOC_ID Column](#)
- [InnoDB Full-Text Index Deletion Handling](#)
- [InnoDB Full-Text Index Transaction Handling](#)
- [Monitoring InnoDB Full-Text Indexes](#)

InnoDB Full-Text Index Design

[InnoDB FULLTEXT](#) indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

InnoDB Full-Text Index Tables

When creating an [InnoDB FULLTEXT](#) index, a set of index tables is created, as shown in the following example:

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;
```

```
mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_TABLES
WHERE name LIKE 'test/%';
```

table_id	name	space
333	test/fts_0000000000000147_0000000000001c9_index_1	289
334	test/fts_0000000000000147_0000000000001c9_index_2	290
335	test/fts_0000000000000147_0000000000001c9_index_3	291
336	test/fts_0000000000000147_0000000000001c9_index_4	292
337	test/fts_0000000000000147_0000000000001c9_index_5	293
338	test/fts_0000000000000147_0000000000001c9_index_6	294
330	test/fts_0000000000000147_being_deleted	286
331	test/fts_0000000000000147_being_deleted_cache	287
332	test/fts_0000000000000147_config	288
328	test/fts_0000000000000147_deleted	284
329	test/fts_0000000000000147_deleted_cache	285
327	test/opening_lines	283

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID ([DOC_ID](#)). The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word's first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the [innodb_ft_sort_pll_degree](#) option. Consider increasing the number of threads when creating [FULLTEXT](#) indexes on large tables.

Auxiliary index table names are prefixed with [fts_](#) and postfixed with [index_*](#). Each index table is associated with the indexed table by a hex value in the index table name that matches the [table_id](#)

of the indexed table. For example, the `table_id` of the `test/opening_lines` table is `327`, for which the hex value is `0x147`. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the `FULLTEXT` index also appears in auxiliary index table names. For example, in the auxiliary table name `test/fts_00000000000000147_000000000000001c9_index_1`, the hex value `1c9` has a decimal value of `457`. The index defined on the `opening_lines` table (`idx`) can be identified by querying the `INFORMATION_SCHEMA.INNODB_INDEXES` table for this value (`457`).

```
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_INDEXES
        WHERE index_id=457;
```

index_id	name	table_id	space
457	idx	327	283

Index tables are stored in their own tablespace if the primary table is created in a `file-per-table` tablespace.

The other index tables shown in the preceding example are referred to as common index tables and are used for deletion handling and storing the internal state of `FULLTEXT` indexes. Unlike the inverted index tables, which are created for each full-text index, this set of tables is common to all full-text indexes created on a particular table.

Common auxiliary tables are retained even if full-text indexes are dropped. When a full-text index is dropped, the `FTS_DOC_ID` column that was created for the index is retained, as removing the `FTS_DOC_ID` column would require rebuilding the table. Common auxiliary tables are required to manage the `FTS_DOC_ID` column.

- `fts_*_deleted` and `fts_*_deleted_cache`

Contain the document IDs (`DOC_ID`) for documents that are deleted but whose data is not yet removed from the full-text index. The `fts_*_deleted_cache` is the in-memory version of the `fts_*_deleted` table.

- `fts_*_being_deleted` and `fts_*_being_deleted_cache`

Contain the document IDs (`DOC_ID`) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `fts_*_being_deleted_cache` table is the in-memory version of the `fts_*_being_deleted` table.

- `fts_*_config`

Stores information about the internal state of the `FULLTEXT` index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the `FULLTEXT` index cache. To view the data in this table, query the `INFORMATION_SCHEMA.INNODB_FT_CONFIG` table.

InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the `FULLTEXT` index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, `InnoDB` uses a `FULLTEXT` index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the

cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

InnoDB Full-Text Index Document ID and FTS_DOC_ID Column

InnoDB uses a unique document identifier referred to as a Document ID (`DOC_ID`) to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, InnoDB automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
mysql> CREATE TABLE opening_lines (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200)
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that InnoDB is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0 Duplicates: 0 Warnings: 1

mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	124	InnoDB rebuilding table to add column FTS_DOC_ID

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, InnoDB adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior

to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have InnoDB create it for you. InnoDB creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all upper case), as in the following example:

Note

The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column, but `AUTO_INCREMENT` could make loading data easier.

```
mysql> CREATE TABLE opening_lines (
    FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200)
) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all upper case) on the `FTS_DOC_ID` column.

```
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

Note

`FTS_DOC_ID_INDEX` cannot be defined as a descending index because the InnoDB SQL parser does not use descending indexes.

The permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 65535.

To avoid rebuilding the table, the `FTS_DOC_ID` column is retained when dropping a full-text index.

InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

InnoDB Full-Text Index Transaction Handling

InnoDB `FULLTEXT` indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The

following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> BEGIN;

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         0 |
+-----+

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         1 |
+-----+
```

Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of `InnoDB FULLTEXT` indexes by querying the following `INFORMATION_SCHEMA` tables:

- `INNODB_FT_CONFIG`
- `INNODB_FT_INDEX_TABLE`
- `INNODB_FT_INDEX_CACHE`
- `INNODB_FT_DEFAULT_STOPWORD`
- `INNODB_FT_DELETED`
- `INNODB_FT_BEING_DELETED`

You can also view basic information for `FULLTEXT` indexes and tables by querying `INNODB_INDEXES` and `INNODB_TABLES`.

For more information, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

15.9 InnoDB Table and Page Compression

This section provides information about the [InnoDB](#) table compression and [InnoDB](#) page compression features. The page compression feature is also referred to as [transparent page compression](#).

Using the compression features of [InnoDB](#), you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

15.9.1 InnoDB Table Compression

This section describes [InnoDB](#) table compression, which is supported with [InnoDB](#) tables that reside in [file_per_table](#) tablespaces or [general tablespaces](#). Table compression is enabled using the [ROW_FORMAT=COMPRESSED](#) attribute with [CREATE TABLE](#) or [ALTER TABLE](#).

15.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An [InnoDB](#) table created with [ROW_FORMAT=COMPRESSED](#) can use a smaller [page size](#) on disk than the configured [innodb_page_size](#) value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The compressed page size is specified through the [CREATE TABLE](#) or [ALTER TABLE KEY_BLOCK_SIZE](#) parameter. The different page size requires that the table be placed in a [file-per-table](#) tablespace or [general tablespace](#) rather than in the [system tablespace](#), as the system tablespace cannot store compressed tables. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#), and [Section 15.7.10, “InnoDB General Tablespaces”](#).

The level of compression is the same regardless of the [KEY_BLOCK_SIZE](#) value. As you specify smaller values for [KEY_BLOCK_SIZE](#), you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small [KEY_BLOCK_SIZE](#) can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the [CREATE TABLE](#) or [ALTER TABLE](#) statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the [KEY_BLOCK_SIZE](#) value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

15.9.1.2 Creating Compressed Tables

Compressed tables can be created in [file-per-table](#) tablespaces or in [general tablespaces](#). Table compression is not available for the [InnoDB system tablespace](#). The system tablespace (space 0, the [.ibdata files](#)) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, `innodb_file_per_table` must be enabled (the default). You can set this parameter in the MySQL configuration file (`my.cnf` or `my.ini`) or dynamically, using a `SET` statement.

After the `innodb_file_per_table` option is configured, specify the `ROW_FORMAT=COMPRESSED` clause or `KEY_BLOCK_SIZE` clause, or both, in a `CREATE TABLE` or `ALTER TABLE` statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t1
  (c1 INT PRIMARY KEY)
  ROW_FORMAT=COMPRESSED
  KEY_BLOCK_SIZE=8;
```

Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, `FILE_BLOCK_SIZE` must be defined for the general tablespace, which is specified when the tablespace is created. The `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value, and the page size of the compressed table, defined by the `CREATE TABLE` or `ALTER TABLE KEY_BLOCK_SIZE` clause, must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16384` and `FILE_BLOCK_SIZE=8192`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 15.7.10, “InnoDB General Tablespace”](#).

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

Notes

- As of MySQL 8.0, the tablespace file for a compressed table is created using the physical page size instead of the `InnoDB` page size, which makes the initial size of a tablespace file for an empty compressed table smaller than in previous MySQL releases.
- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the `KEY_BLOCK_SIZE` setting defaults to half the `innodb_page_size` value.
- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#). For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace `.ibd` file, nor does it return disk space to the operating system. For more information, see [Section 15.7.10, “InnoDB General Tablespace”](#).
- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by `InnoDB` if necessary. For file-per-table tablespaces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size`

value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablespaces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablespace. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

- InnoDB supports 32KB and 64KB page sizes but these page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.
- The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (`.ibd` file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
- When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer overflow pages as described in [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#). For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).
- All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they will appear in the output of the `SHOW CREATE TABLE` statement).
- For performance-related configuration options, see [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#).

Restrictions on Compressed Tables

- Compressed tables cannot be stored in the InnoDB system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.
- InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns errors if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The same restrictions apply to `ALTER TABLE` operations on temporary tables.

15.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.

- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a [file-per-table](#) tablespace and look at the size of the resulting [.ibd file](#). For example:

```
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL autocommit=0;

-- Create an uncompressed table with a million or two rows.
```

```

CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;

SHOW CREATE TABLE big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

CREATE TABLE key_block_size_4 LIKE big_table;
ALTER TABLE key_block_size_4 key_block_size=4 row_format=compressed;

INSERT INTO key_block_size_4 SELECT * FROM big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd

```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```

-rw-rw----  1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw----  1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd

```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the [INFORMATION_SCHEMA.INNODB_CMP](#) table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the [INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX](#) table. Because the statistics in the [INNODB_CMP_PER_INDEX](#) table are expensive to collect, you must enable the configuration option [innodb_cmp_per_index_enabled](#) before querying that table, and you might restrict such testing to a development server or a non-critical [slave server](#).
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the [INFORMATION_SCHEMA.INNODB_CMP](#) or [INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX](#) table, and comparing [COMPRESS_OPS](#) to [COMPRESS_OPS_OK](#).
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust [innodb_compression_level](#), [innodb_compression_failure_threshold_pct](#), and [innodb_compression_pad_pct_max](#) options as described in [Section 15.9.1.6, “Compression for OLTP Workloads”](#), and try further tests.

Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as [LIKE](#), and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing [BLOBs](#) or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are [INSERTs](#) that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, [DELETE](#) operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

15.9.1.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 15.1, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each [InnoDB](#) table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different [workloads](#), data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization,

you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of [INSERT](#), [UPDATE](#) and [DELETE](#) operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations ([COMPRESS_OPS_OK](#)) is a high percentage of the total number of compression operations ([COMPRESS_OPS](#)), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase [KEY_BLOCK_SIZE](#) for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

15.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Note

InnoDB supports the [zlib](#) library up to version 1.2.11, which is the version bundled with MySQL 8.0.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) [.idb](#) files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the [innodb_compression_level](#) configuration option.

InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the [innodb_compression_failure_threshold_pct](#), and [innodb_compression_pad_pct_max](#) configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If [innodb_strict_mode](#) is [ON](#), MySQL checks the maximum row size during [CREATE TABLE](#) or [CREATE INDEX](#). If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when [innodb_strict_mode](#) is [OFF](#), and a subsequent [INSERT](#) or [UPDATE](#) statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with [ALTER TABLE](#) and select a larger compressed page size ([KEY_BLOCK_SIZE](#)), shorten any column prefix indexes, or disable compression entirely with [ROW_FORMAT=DYNAMIC](#) or [ROW_FORMAT=COMPACT](#).

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.19, “CREATE TABLESPACE Syntax”](#).

Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables that use `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT` store the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size (`KEY_BLOCK_SIZE`). For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used ([LRU](#)) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

To create a compressed table in a file-per-table tablespace, [innodb_file_per_table](#) must be enabled. There is no dependence on the [innodb_file_per_table](#) setting when creating a compressed table in a general tablespace. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

15.9.1.6 Compression for OLTP Workloads

Traditionally, the [InnoDB compression](#) feature was recommended primarily for read-only or read-mostly [workloads](#), such as in a [data warehouse](#) configuration. The rise of [SSD](#) storage devices, which are fast but relatively small and expensive, makes compression attractive also for [OLTP](#) workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second ([IOPS](#)) by using compressed tables with applications that do frequent [INSERT](#), [UPDATE](#), and [DELETE](#) operations.

These configuration options let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- [innodb_compression_level](#) lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.
- [innodb_compression_failure_threshold_pct](#) specifies a cutoff point for [compression failures](#) during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by [innodb_compression_pad_pct_max](#)
- [innodb_compression_pad_pct_max](#) lets you adjust the maximum amount of space reserved within each [page](#) to record changes to compressed rows, without needing to compress the entire page again.

The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

- `innodb_log_compressed_pages` lets you disable writing of images of [re-compressed pages](#) to the [redo log](#). Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

15.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with [file-per-table](#) tablespaces and [general tablespaces](#).

SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled.

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	1478	InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=4.
Warning	1478	InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.
Warning	1478	InnoDB: assuming ROW_FORMAT=DYNAMIC.

Note

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=DYNAMIC` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper setting for the `innodb_file_per_table` configuration parameter.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 15.9, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

Table 15.9 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options

Option	Usage Notes	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>		Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>		Compresses the table and indexes using zlib
<code>KEY_BLOCK_SIZE=n</code>		Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code> . For general tablespaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted.

Table 15.10, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
```

```
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;

ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.     |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+
```

Table 15.10 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	<code>REDUNDANT</code>
<code>ROW_FORMAT=COMPACT</code>	None	<code>COMPACT</code>
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified	Ignored for file-per-table tablespaces unless <code>innodb_file_per_table</code> is enabled. General tablespaces support all row formats. See Section 15.7.10, “InnoDB General Tablespaces” .	the default row format for file-per-table tablespaces; the specified row format for general tablespaces
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the specified row format, or the default row format
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used	<code>COMPRESSED</code>
<code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format	<code>KEY_BLOCK_SIZE</code> is ignored	<code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code>
<code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code>	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	the default row format or N/A

When `innodb_strict_mode` is `ON`, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. Strict mode is `ON` by default. When `innodb_strict_mode` is `OFF`, MySQL issues warnings instead of errors for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED
```

```
KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid `KEY_BLOCK_SIZE` to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
      KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot
contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot
contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.19, “CREATE TABLESPACE Syntax”](#).

For more information about using compressed tables with general tablespaces, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

15.9.2 InnoDB Page Compression

InnoDB supports page-level compression for tables that reside in [file-per-table](#) tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include `Zlib` and `LZ4`.

Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x

- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher

**Note**

All of the available file systems for a given Linux distribution may not support hole punching.

How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

Table 15.11 Windows NTFS Cluster Size and Compression Units

Cluster Size	Compression Unit
512 Bytes	8 KB
1 KB	16 KB
2 KB	32 KB
4 KB	64 KB

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4KB, for which the compression unit size is 64KB. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64KB.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an `innodb_page_size` value of 16K or greater.

Enabling Page Compression

To enable page compression, specify the `COMPRESSION` attribute in the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an `ALTER TABLE` statement. However, `ALTER TABLE ... COMPRESSION` only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using `OPTIMIZE TABLE`.

```
ALTER TABLE t1 COMPRESSION="zlib";
OPTIMIZE TABLE t1;
```

Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

Page Compression Metadata

Page compression metadata is found in the `INFORMATION_SCHEMA.INNODB_TABLESPACES` table, in the following columns:

- `FS_BLOCK_SIZE`: The file system block size, which is the unit size used for hole punching.
- `FILE_SIZE`: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- `ALLOCATED_SIZE`: The actual size of the file, which is the amount of space allocated on disk.

Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`Zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the employees table is retrieved from the `INFORMATION_SCHEMA.INNODB_TABLESPACES` table.

```
# Create the employees table with Zlib page compression

CREATE TABLE employees (
  emp_no      INT          NOT NULL,
  birth_date  DATE         NOT NULL,
  first_name  VARCHAR(14)  NOT NULL,
  last_name   VARCHAR(16)  NOT NULL,
  gender      ENUM ('M','F') NOT NULL,
  hire_date   DATE         NOT NULL,
  PRIMARY KEY (emp_no)
) COMPRESSION="zlib";

# Insert data (not shown)
```

```
# Query page compression metadata in INFORMATION_SCHEMA.INNODB_TABLESPACES

mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM
        INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='employees/employees'\G
***** 1. row *****
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040
```

Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) * 2 > [innodb_page_size](#).
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, temporary tablespaces, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables ([ROW_FORMAT=COMPRESSED](#)) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run [ALTER TABLE ... COMPRESSION=None](#) and [OPTIMIZE TABLE](#).
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large [InnoDB](#) page size and relatively small file system block size could result in write amplification. For example, a maximum [InnoDB](#) page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

15.10 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#), off-page storage of long variable-length column values, and large index key prefixes are controlled by the row format of an [InnoDB](#) table. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

15.10.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature and large index key prefix support.

15.10.2 Specifying the Row Format for a Table

The default row format is defined by [innodb_default_row_format](#), which has a default value of [DYNAMIC](#). The default row format is used when the [ROW_FORMAT](#) table option is not defined explicitly or when [ROW_FORMAT=DEFAULT](#) is specified.

The row format of a table can be defined explicitly using the [ROW_FORMAT](#) table option in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined [ROW_FORMAT](#) setting overrides the implicit default. Specifying [ROW_FORMAT=DEFAULT](#) is equivalent to using the implicit default.

The [innodb_default_row_format](#) option can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid [innodb_default_row_format](#) options include [DYNAMIC](#), [COMPACT](#), and [REDUNDANT](#). The [COMPRESSED](#) row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. Attempting to set [innodb_default_row_format](#) to [COMPRESSED](#) returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by [innodb_default_row_format](#) when a [ROW_FORMAT](#) option is not specified explicitly or when [ROW_FORMAT=DEFAULT](#) is used. For example, the following [CREATE TABLE](#) statements use the row format defined by [innodb_default_row_format](#).

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` and `ALTER TABLE` operations that use `ALGORITHM=INPLACE` where table rebuilding is required. See [Section 15.12.1, “Online DDL Operations”](#) for more information. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic                      |
+-----+

mysql> CREATE TABLE t1 (c1 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 54
        NAME: test/t1
        FLAG: 33
       N_COLS: 4
        SPACE: 35
   ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;

mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 55
        NAME: test/t1
        FLAG: 1
       N_COLS: 5
        SPACE: 36
   ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from `REDUNDANT` or `COMPACT` to `DYNAMIC`.

- The `REDUNDANT` and `COMPACT` row format supports a maximum index key prefix length of 767 bytes whereas `DYNAMIC` and `COMPRESSED` row formats support an index key prefix length of 3072 bytes. In a replication environment, if `innodb_default_row_format` is set to `DYNAMIC` on the master and set to `COMPACT` on the slave, the following DDL statement, which does not explicitly define a row format, succeeds on the master but fails on the slave:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 15.8.1.7, “Limits on InnoDB Tables”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, refer to the limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

To view the row format of a table, issue a `SHOW TABLE STATUS` statement or query `INFORMATION_SCHEMA.TABLES`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
```

The row format of an `InnoDB` table determines its physical row structure. See [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#) for more information.

15.10.3 DYNAMIC and COMPRESSED Row Formats

When a table is created with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `InnoDB` can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. `InnoDB` also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, `InnoDB` chooses the longest columns for off-page storage until the clustered index record fits on the `B-tree` page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 15.9, “InnoDB Table and Page Compression”](#).

Both `DYNAMIC` and `COMPRESSED` row formats support index key prefixes up to 3072 bytes.

Tables that use the `COMPRESSED` row format can be created in `file-per-table` tablespaces or `general tablespaces`. The system tablespace does not support the `COMPRESSED` row format. To store a `COMPRESSED` table in a file-per-table tablespace, `innodb_file_per_table` must be enabled. The `innodb_file_per_table` configuration options is not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information about general tablespaces, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

`DYNAMIC` tables can be stored in file-per-table tablespaces, general tablespaces, and the system tablespace. To store `DYNAMIC` tables in the system tablespace, you can either disable `innodb_file_per_table` and use a regular `CREATE TABLE` or `ALTER TABLE` statement, or you can

use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` without having to alter your `innodb_file_per_table` setting. The `innodb_file_per_table` configuration option is not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format and therefore handle `CHAR` storage in the same way as the `COMPACT` row format. For more information, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

15.10.4 COMPACT and REDUNDANT Row Formats

InnoDB tables that use the `COMPACT` or `REDUNDANT` row format store up to the first 768 bytes of variable-length columns (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the `B-tree` node, with the remainder stored on the overflow pages. InnoDB also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

For `COMPACT` or `REDUNDANT` row formats, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short `BLOBs`, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

The default row format is `DYNAMIC`, as defined by the `innodb_default_row_format` configuration option. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#) for more information.

For information about the physical row structure of tables that use the `REDUNDANT` or `COMPACT` row format, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

15.11 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The `ACID` design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as `InnoDB` tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

15.11.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default in most cases (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

If system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

15.11.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the [InnoDB system tablespace](#). The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, InnoDB allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating

system rather than still being reserved by InnoDB within the system tablespace. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

You can also store tables in [general tablespaces](#). General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database [pages](#). Every tablespace in a MySQL instance has the same [page size](#). By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance. You can also increase the page size to 32KB or 64KB. For more information, refer to the `innodb_page_size` documentation.

The pages are grouped into [extents](#) of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called [segments](#) in InnoDB. (These segments are different from the [rollback segment](#), which actually contains many tablespace segments.)

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it one at a time. After that, InnoDB starts to allocate whole extents to the segment. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in InnoDB. One is for nonleaf nodes of the [B-tree](#), the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 15.3, “InnoDB Multi-Versioning”](#).)

How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, [variable-length columns](#) are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list

of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 15.10.4, “COMPACT and REDUNDANT Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#).

`LOBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `LOBLOB` and `TEXT` columns, must be less than 4GB.

15.11.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger.

How Checkpoint Processing Works

InnoDB implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

15.11.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.

Both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 15.12, “InnoDB and Online DDL”](#).

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filesystem management algorithm guarantees that fragmentation in the index does not occur.

15.11.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an InnoDB table, the table must be stored in its own `.ibd` file. For a table to be stored in its own `.ibd` file, `innodb_file_per_table` must be enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the InnoDB system tablespace (tables created when `innodb_file_per_table=OFF`) and tables stored in shared general tablespaces, where only InnoDB can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tablespace.

15.12 InnoDB and Online DDL

The online DDL feature provides support for instant and in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- For in-place operations, the ability to adjust the balance between performance and concurrency during DDL operations using the `LOCK` clause. See [The LOCK clause](#).
- Less disk space usage and I/O overhead than the table-copy method.

Note

`ALGORITHM=INSTANT` support is available for `ADD COLUMN` and other operations in MySQL 8.0.12.

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation instantly or in place, as permitted, with as little locking as possible.

You can control aspects of a DDL operation using the `ALGORITHM` and `LOCK` clauses of the `ALTER TABLE` statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

The `LOCK` clause may be used for operations that are performed in place and is useful for fine-tuning the degree of concurrent access to the table during operations. Only `LOCK=DEFAULT` is supported for operations that are performed instantly. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, during an in-place [ALTER TABLE](#) operation, specify a clause on the [ALTER TABLE](#) statement such as [LOCK=NONE](#) (permit reads and writes) or [LOCK=SHARED](#) (permit reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance between algorithms, run a statement with [ALGORITHM=INSTANT](#), [ALGORITHM=INPLACE](#) and [ALGORITHM=COPY](#). You can also run a statement with the [old_alter_table](#) configuration option enabled to force the use of [ALGORITHM=COPY](#).
- To avoid tying up the server with an [ALTER TABLE](#) operation that copies the table, include [ALGORITHM=INSTANT](#) or [ALGORITHM=INPLACE](#). The statement halts immediately if it cannot use the specified algorithm.

15.12.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

- [Index Operations](#)
- [Primary Key Operations](#)
- [Column Operations](#)
- [Generated Column Operations](#)
- [Foreign Key Operations](#)
- [Table Operations](#)
- [Tablespace Operations](#)
- [Partitioning Operations](#)

Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

Table 15.12 Online DDL Support for Index Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Creating or adding a secondary index	No	Yes	No	Yes	No
Dropping an index	No	Yes	No	Yes	Yes
Renaming an index	No	Yes	No	Yes	Yes
Adding a FULLTEXT index	No	Yes*	No*	No	No
Adding a SPATIAL index	No	Yes	No	No	No

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Changing the index type	Yes	Yes	No	Yes	Yes

Syntax and Usage Notes

- Creating or adding a secondary index

```
CREATE INDEX name ON table (col_list);
```

```
ALTER TABLE tbl_name ADD INDEX name (col_list);
```

The table remains available for read and write operations while the index is being created. The [CREATE INDEX](#) statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

A newly created secondary index contains only the committed data in the table at the time the [CREATE INDEX](#) or [ALTER TABLE](#) statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Some factors affect the performance, space usage, and semantics of this operation. For details, see [Section 15.12.6, “Online DDL Limitations”](#).

- Dropping an index

```
DROP INDEX name ON table;
```

```
ALTER TABLE tbl_name DROP INDEX name;
```

The table remains available for read and write operations while the index is being dropped. The [DROP INDEX](#) statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

- Renaming an index

```
ALTER TABLE tbl_name RENAME INDEX old_index_name TO new_index_name, ALGORITHM=INPLACE, LOCK=NONE;
```

- Adding a [FULLTEXT](#) index

```
CREATE FULLTEXT INDEX name ON table(column);
```

Adding the first [FULLTEXT](#) index rebuilds the table if there is no user-defined [FTS_DOC_ID](#) column. Additional [FULLTEXT](#) indexes may be added without rebuilding the table.

- Adding a [SPATIAL](#) index

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
```

```
ALTER TABLE geom ADD SPATIAL INDEX(g), ALGORITHM=INPLACE, LOCK=SHARED;
```

Adding the first `FULLTEXT` index rebuilds the table if there is no user-defined `FTS_DOC_ID` column. Additional `FULLTEXT` indexes may be added without rebuilding the table.

- Changing the index type (`USING {BTREE | HASH}`)

```
ALTER TABLE tbl_name DROP INDEX i1, ADD INDEX i1(key_part,...) USING BTREE, ALGORITHM=INSTANT;
```

Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See [Syntax and Usage Notes](#).

Table 15.13 Online DDL Support for Primary Key Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a primary key	No	Yes*	Yes*	Yes	No
Dropping a primary key	No	No	Yes	No	No
Dropping a primary key and adding another	No	Yes	Yes	Yes	No

Syntax and Usage Notes

- Adding a primary key

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. `ALGORITHM=INPLACE` is not permitted under certain conditions if columns have to be converted to `NOT NULL`.

Restructuring the [clustered index](#) always requires copying of table data. Thus, it is best to define the [primary key](#) when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later.

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL converts `NULL` values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only permitted when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ALGORITHM=INPLACE` is permitted, but the statement can still fail if the requested primary key columns contain `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

If you create a table without a primary key, `InnoDB` chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid uncertainty and the potential

space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a `clustered index` organized based on the `primary key`, forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.
- Dropping a primary key

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ALGORITHM=COPY;
```

Only `ALGORITHM=COPY` supports dropping a primary key without adding a new one in the same `ALTER TABLE` statement.

- Dropping a primary key and adding another

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

Table 15.14 Online DDL Support for Column Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a column	Yes*	Yes	Yes	Yes*	No
Dropping a column	No	Yes	Yes	Yes	No
Renaming a column	No	Yes	No	Yes*	Yes

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Reordering columns	No	Yes	Yes	Yes	No
Setting a column default value	Yes	Yes	No	Yes	Yes
Changing the column data type	No	No	Yes	No	No
Extending <code>VARCHAR</code> column size	No	Yes	No	Yes	Yes
Dropping the column default value	Yes	Yes	No	Yes	Yes
Changing the auto-increment value	No	Yes	No	Yes	No*
Making a column <code>NULL</code>	No	Yes	Yes*	Yes	No
Making a column <code>NOT NULL</code>	No	Yes*	Yes*	Yes	No
Modifying the definition of an <code>ENUM</code> or <code>SET</code> column	Yes	Yes	No	Yes	Yes

Syntax and Usage Notes

- Adding a column

```
ALTER TABLE tbl_name ADD COLUMN column_name column_definition, ALGORITHM=INSTANT;
```

Concurrent DML is not permitted when adding an `auto-increment` column. Data is reorganized substantially, making it an expensive operation. At a minimum, `ALGORITHM=INPLACE`, `LOCK=SHARED` is required.

The following limitations apply when the `INSTANT` algorithm is used to add a column:

- Adding a column cannot be combined in the same statement with other `ALTER TABLE` actions that do not support `ALGORITHM=INSTANT`.
- A column can only be added as the last column of the table. Adding a column to any other position among other columns is not supported.
- Columns cannot be added to tables that use `ROW_FORMAT=COMPRESSED`.
- Columns cannot be added to tables that include a `FULLTEXT` index.

- Columns cannot be added to temporary tables. Temporary tables only support `ALGORITHM=COPY`.
- Columns cannot be added to tables that reside in the data dictionary tablespace.
- Row size limits are not evaluated when adding a column. However, row size limits are checked during DML operations that insert and update rows in the table.

Multiple columns may be added in the same `ALTER TABLE` statement. For example:

```
ALTER TABLE t1 ADD COLUMN c2 INT, ADD COLUMN c3 INT, ALGORITHM=INSTANT;
```

`INFORMATION_SCHEMA.INNODB_TABLES` and `INFORMATION_SCHEMA.INNODB_COLUMNS` provide metadata for instantly added columns. `INFORMATION_SCHEMA.INNODB_TABLES.INSTANT_COLS` shows number of columns in the table prior to adding the first instant column. `INFORMATION_SCHEMA.INNODB_COLUMNS.HAS_DEFAULT` and `DEFAULT_VALUE` provide metadata about default values for instantly added columns.

- Dropping a column

```
ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Renaming a column

```
ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INPLACE, LOCK=NONE;
```

To permit concurrent DML, keep the same data type and only change the column name.

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, the operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with `ALGORITHM=INPLACE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement fails.

`ALGORITHM=INPLACE` is not supported for renaming a [generated column](#).

- Reordering columns

To reorder columns, use `FIRST` or `AFTER` in `CHANGE` or `MODIFY` operations.

```
ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Changing the column data type

```
ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
```

Changing the column data type is only supported with `ALGORITHM=COPY`.

- Extending `VARCHAR` column size

```
ALTER TABLE tbl_name CHANGE COLUMN c1 c1 VARCHAR(255), ALGORITHM=INPLACE, LOCK=NONE;
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` columns of 0 to 255 bytes in size, one length byte is required to encode the value. For `VARCHAR` columns of 256 bytes in size or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` column size from 0 to 255 bytes, or from 256 bytes to a greater size. In-place `ALTER TABLE` does not support increasing the size of a `VARCHAR` column from less than 256 bytes to a size equal to or greater than 256 bytes. In this case, the number of required length bytes changes from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size for a single byte character set from `VARCHAR(255)` to `VARCHAR(256)` using in-place `ALTER TABLE` returns this error:

```
ALTER TABLE tbl_name ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

Note

The byte length of a `VARCHAR` column is dependant on the byte length of the character set.

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

- Setting a column default value

```
ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INSTANT;
```

Only modifies table metadata. Default column values are stored in the [data dictionary](#).

- Dropping a column default value

```
ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INSTANT;
```

- Changing the auto-increment value

```
ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
```

Modifies a value stored in memory, not the data file.

In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- Making a column `NULL`

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- Making a column `NOT NULL`

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. [STRICT_ALL_TABLES](#) or [STRICT_TRANS_TABLES SQL_MODE](#) is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See [Section 13.1.8, “ALTER TABLE Syntax”](#). Data is reorganized substantially, making it an expensive operation.

- Modifying the definition of an [ENUM](#) or [SET](#) column

```
CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INSTANT;
```

Modifying the definition of an [ENUM](#) or [SET](#) column by adding new enumeration or set members to the *end* of the list of valid member values may be performed instantly or in place, as long as the storage size of the data type does not change. For example, adding a member to a [SET](#) column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

Generated Column Operations

The following table provides an overview of online DDL support for generated column operations. For details, see [Syntax and Usage Notes](#).

Table 15.15 Online DDL Support for Generated Column Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a STORED column	No	No	Yes	No	No
Modifying STORED column order	No	No	Yes	No	No
Dropping a STORED column	No	Yes	Yes	Yes	No
Adding a VIRTUAL column	Yes	Yes	No	Yes	Yes
Modifying VIRTUAL column order	No	No	Yes	No	No
Dropping a VIRTUAL column	Yes	Yes	No	Yes	Yes

Syntax and Usage Notes

- Adding a [STORED](#) column

```
ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) STORED), ALGORITHM=COPY;
```

ADD COLUMN is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server.

- Modifying **STORED** column order

```
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED FIRST, ALGORITHM=COPY;
```

Rebuilds the table in place.

- Dropping a **STORED** column

```
ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place.

- Adding a **VIRTUAL** column

```
ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL), ALGORITHM=INSTANT;
```

Adding a virtual column can be performed instantly or in place for non-partitioned tables.

Adding a **VIRTUAL** is not an in-place operation for partitioned tables.

- Modifying **VIRTUAL** column order

```
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL FIRST, ALGORITHM=COPY;
```

- Dropping a **VIRTUAL** column

```
ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INSTANT;
```

Dropping a **VIRTUAL** column can be performed instantly or in place for non-partitioned tables.

Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

Table 15.16 Online DDL Support for Foreign Key Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a foreign key constraint	No	Yes*	No	Yes	Yes
Dropping a foreign key constraint	No	Yes	No	Yes	Yes

Syntax and Usage Notes

- Adding a foreign key constraint

The `INPLACE` algorithm is supported when `foreign_key_checks` is disabled. Otherwise, only the `COPY` algorithm is supported.

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
REFERENCES tbl2(col2) referential_actions;
```

- Dropping a foreign key constraint

```
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
SHOW CREATE TABLE table\G
```

Or, query the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` table and use the `CONSTRAINT_NAME` and `CONSTRAINT_TYPE` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

Note

If **foreign keys** are already present in the table being altered (that is, it is a **child table** containing a `FOREIGN KEY ... REFERENCE` clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.
- In the same way, if a table is the **parent table** in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement causes an `ON UPDATE` or `ON DELETE` action in the child table.

Table Operations

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

Table 15.17 Online DDL Support for Table Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Changing the <code>ROW_FORMAT</code>	No	Yes	Yes	Yes	No

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Changing the KEY_BLOCK_SIZE	No	Yes	Yes	Yes	No
Setting persistent table statistics	No	Yes	No	Yes	Yes
Specifying a character set	No	Yes	Yes*	No	No
Converting a character set	No	No	Yes*	No	No
Optimizing a table	No	Yes*	Yes	Yes	No
Rebuilding with the FORCE option	No	Yes*	Yes	Yes	No
Performing a null rebuild	No	Yes*	Yes	Yes	No
Renaming a table	Yes	Yes	No	Yes	Yes

Syntax and Usage Notes

- Changing the [ROW_FORMAT](#)

```
ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

For additional information about the [ROW_FORMAT](#) option, see [Table Options](#).

- Changing the [KEY_BLOCK_SIZE](#)

```
ALTER TABLE tbl_name KEY_BLOCK_SIZE = value, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

For additional information about the [KEY_BLOCK_SIZE](#) option, see [Table Options](#).

- Setting persistent table statistics options

```
ALTER TABLE tbl_name STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE, LOCK=NONE;
```

Only modifies table metadata.

Persistent statistics include [STATS_PERSISTENT](#), [STATS_AUTO_RECALC](#), and [STATS_SAMPLE_PAGES](#). For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- Specifying a character set

```
ALTER TABLE tbl_name CHARACTER SET = charset_name, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table if the new character encoding is different.

- Converting a character set

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name, ALGORITHM=COPY;
```

Rebuilds the table if the new character encoding is different.

- Optimizing a table

```
OPTIMIZE TABLE tbl_name;
```

In-place operation is not supported for tables with `FULLTEXT` indexes. The operation uses the `INPLACE` algorithm, but `ALGORITHM` and `LOCK` syntax is not permitted.

- Rebuilding a table with the `FORCE` option

```
ALTER TABLE tbl_name FORCE, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Performing a "null" rebuild

```
ALTER TABLE tbl_name ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Renaming a table

```
ALTER TABLE old_tbl_name RENAME TO new_tbl_name, ALGORITHM=INSTANT;
```

Renaming a table can be performed instantly or in place. MySQL renames files that correspond to the table *tbl_name* without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 13.1.33, “RENAME TABLE Syntax”](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

Tablespace Operations

The following table provides an overview of online DDL support for tablespace operations. For details, see [Syntax and Usage Notes](#).

Table 15.18 Online DDL Support for Tablespace Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Renaming a general tablespace	No	Yes	No	Yes	Yes

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Enabling or disabling general tablespace encryption	No	Yes	No	Yes	No
Enabling or disabling file-per-table tablespace encryption	No	No	Yes	No	No

Syntax and Usage Notes

- Renaming a general tablespace

```
ALTER TABLESPACE tablespace_name RENAME TO new_tablespace_name;
```

`ALTER TABLESPACE ... RENAME TO` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

- Enabling or disabling general tablespace encryption

```
ALTER TABLESPACE tablespace_name ENCRYPTION='Y';
```

`ALTER TABLESPACE ... ENCRYPTION` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

For related information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#).

- Enabling or disabling file-per-table tablespace encryption

```
ALTER TABLE tbl_name ENCRYPTION='Y', ALGORITHM=COPY;
```

For related information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#).

Partitioning Operations

With the exception of some `ALTER TABLE` partitioning clauses, online DDL operations for partitioned `InnoDB` tables follow the same rules that apply to regular `InnoDB` tables.

Some `ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned `InnoDB` tables. As a result, online support for `ALTER TABLE` partitioning clauses varies.

The following table shows the online status for each `ALTER TABLE` partitioning statement. Regardless of the online DDL API that is used, MySQL attempts to minimize data copying and locking where possible.

`ALTER TABLE` partitioning options that use `ALGORITHM=COPY` or that only permit “`ALGORITHM=DEFAULT, LOCK=DEFAULT`”, repartition the table using the `COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the `ALTER TABLE` statement, and table data is copied into the new table structure.

Table 15.19 Online DDL Support for Partitioning Operations

Partitioning Clause	Instant	In Place	Permits DML	Notes
<code>PARTITION BY</code>	No	No	No	Permits <code>ALGORITHM=COPY</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code>
<code>ADD PARTITION</code>	No	Yes*	Yes*	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT NONE SHARED EXCLUSIVE}</code> is supported for <code>RANGE</code> and <code>LIST</code> partitions, <code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> for <code>HASH</code> and <code>KEY</code> partitions, and <code>ALGORITHM=COPY</code> , <code>LOCK={SHARED EXCLUSIVE}</code> for all partition types. Does not copy existing data for tables partitioned by <code>RANGE</code> or <code>LIST</code> . Concurrent queries are permitted with <code>ALGORITHM=COPY</code> for tables partitioned by <code>HASH</code> or <code>LIST</code> , as MySQL copies the data while holding a shared lock.
<code>DROP PARTITION</code>	No	Yes*	Yes*	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT NONE SHARED EXCLUSIVE}</code> is supported. Does not copy data for tables partitioned by <code>RANGE</code> or <code>LIST</code> . <code>DROP PARTITION</code> with <code>ALGORITHM=INPLACE</code> deletes data stored in the partition and drops the partition. However, <code>DROP PARTITION</code> with <code>ALGORITHM=COPY</code> or <code>old_alter_table=ON</code> rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible <code>PARTITION ... VALUES</code> definition. Data that cannot be moved to another partition is deleted.
<code>DISCARD PARTITION</code>	No	No	No	Only permits <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code>

Partitioning Clause	Instant	In Place	Permits DML	Notes
<code>IMPORT PARTITION</code>	No	No	No	Only permits <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code>
<code>TRUNCATE PARTITION</code>	No	Yes	Yes	Does not copy existing data. It merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.
<code>COALESCE PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>REORGANIZE PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>EXCHANGE PARTITION</code>	No	Yes	Yes	
<code>ANALYZE PARTITION</code>	No	Yes	Yes	
<code>CHECK PARTITION</code>	No	Yes	Yes	
<code>OPTIMIZE PARTITION</code>	No	No	No	<code>ALGORITHM</code> and <code>LOCK</code> clauses are ignored. Rebuilds the entire table. See Section 22.3.4, “Maintenance of Partitions” .
<code>REBUILD PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>REPAIR PARTITION</code>	No	Yes	Yes	
<code>REMOVE PARTITIONING</code>	No	No	No	Permits <code>ALGORITHM=COPY</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code>

Non-partitioning online `ALTER TABLE` operations on partitioned tables follow the same rules that apply to regular tables. However, `ALTER TABLE` performs online operations on each table partition, which causes increased demand on system resources due to operations being performed on multiple partitions.

For additional information about `ALTER TABLE` partitioning clauses, see [Partitioning Options](#), and [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#). For information about partitioning in general, see [Chapter 22, Partitioning](#).

15.12.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

- Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.
- Instant operations only modify metadata in the data dictionary. No metadata locks are taken on the table, and table data is unaffected, making operations instantaneous. Concurrent DML is unaffected.

- Online operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.
- Online operations read less data into the buffer pool than table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

The LOCK clause

By default, MySQL uses as little locking as possible during a DDL operation. The `LOCK` clause can be specified for in-place operations and some copy operations to enforce more restrictive locking, if required. If the `LOCK` clause specifies a less restrictive level of locking than is permitted for a particular DDL operation, the statement fails with an error. `LOCK` clauses are described below, in order of least to most restrictive:

- `LOCK=NONE`:

Permits concurrent queries and DML.

For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

- `LOCK=SHARED`:

Permits concurrent queries but blocks DML.

For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

- `LOCK=DEFAULT`:

Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the `LOCK` clause is the same as specifying `LOCK=DEFAULT`.

Use this clause when you know that the default locking level of the DDL statement will not cause availability problems for the table.

- `LOCK=EXCLUSIVE`:

Blocks concurrent queries and DML.

Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.

Online DDL and Metadata Locks

Online DDL operations can be viewed as having three phases:

- *Phase 1: Initialization*

In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified `ALGORITHM` and `LOCK` options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- *Phase 2: Execution*

In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.

- *Phase 3: Commit Table Definition*

In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.

The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

Session 1:

```
mysql> CREATE TABLE t1 (c1 INT) ENGINE=InnoDB;
mysql> START TRANSACTION;
mysql> SELECT * FROM t1;
```

The session 1 `SELECT` statement takes a shared metadata lock on table t1.

Session 2:

```
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

Session 3:

```
mysql> SELECT * FROM t1;
```

The `SELECT` statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the `ALTER TABLE` operation in session 2 to be granted.

You can use `SHOW FULL PROCESSLIST` to determine if transactions are waiting for a metadata lock.

```
mysql> SHOW FULL PROCESSLIST\G
...
***** 2. row *****
  Id: 5
  User: root
  Host: localhost
  db: test
Command: Query
  Time: 44
  State: Waiting for table metadata lock
  Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...
***** 4. row *****
```

```

Id: 7
User: root
Host: localhost
db: test
Command: Query
Time: 5
State: Waiting for table metadata lock
Info: SELECT * FROM t1
4 rows in set (0.00 sec)

```

Metadata lock information is also exposed through the Performance Schema `metadata_locks` table, which provides information about metadata lock dependencies between sessions, the metadata lock a session is waiting for, and the session that currently holds the metadata lock. For more information, see [Section 25.11.12.3, “The metadata_locks Table”](#).

Online DDL Performance

The performance of a DDL operation is largely determined by whether the operation is performed instantly, in place, and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using `ALGORITHM=INSTANT`, `ALGORITHM=INPLACE`, and `ALGORITHM=COPY`. A statement can also be run with `old_alter_table` enabled to force the use of `ALGORITHM=COPY`.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the “rows affected” value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but 0 rows affected shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and requires rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a small amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

Note

For a greater understanding of the MySQL processing associated with a DDL operation, examine Performance Schema and `INFORMATION_SCHEMA` tables

related to [InnoDB](#) before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Performance Schema stage events can be used to monitor [ALTER TABLE](#) progress. See [Section 15.15.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#).

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

15.12.3 Online DDL Space Requirements

Space requirements for in-place online DDL operations are outlined below. Space requirements do not apply to operations that are performed instantly.

- Space for temporary log files

A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of [innodb_sort_buffer_size](#) up to a maximum specified by [innodb_online_alter_log_max_size](#). If a temporary log file exceeds the size limit, the online DDL operation fails, and uncommitted concurrent DML operations are rolled back. A large [innodb_online_alter_log_max_size](#) setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of [innodb_online_alter_log_max_size](#), the online DDL operation fails with a [DB_ONLINE_LOG_TOO_BIG](#) error.

- Space for temporary sort files

Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory ([\\$TMPDIR](#) on Unix, [%TEMP%](#) on Windows, or the directory specified by [--tmpdir](#)) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold all secondary index columns plus the primary key columns of the clustered index. Temporary sort files are removed as soon as their contents are merged into the final table or index. Temporary sort files may require space equal to the amount of data in the table plus indexes. An online DDL operation that rebuilds the table reports an error if it uses all of the available disk space on the file system where the data directory resides.

If the MySQL temporary directory is not large enough to hold the sort files, set [tmpdir](#) to a different directory. Alternatively, define a separate temporary directory for online DDL operations using [innodb_tmpdir](#). This option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- Space for an intermediate table file

Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with [#sql-ib](#) prefix and only appear briefly during the online DDL operation.

The `innodb_tmpdir` option is not applicable to intermediate table files.

15.12.4 Simplifying DDL Statements with Online DDL

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done online, you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),  
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);  
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);  
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed online, that is, that still use the table-copy method.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

15.12.5 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.
- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- A timeout occurs while waiting for an [exclusive lock](#) on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see [Section 15.12.3, “Online DDL Space Requirements”](#).
- The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.

- Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a `primary key` index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively `rolled back`.

15.12.6 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied when creating an index on a `TEMPORARY TABLE`.
- The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Before an in-place online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.
- When running an in-place online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in `InnoDB` in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an `InnoDB` table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned `InnoDB` tables.
- Tables created before MySQL 5.6 that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALGORITHM=COPY` do not support `ALGORITHM=INPLACE`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:
 - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
 - Rollback of an online DDL operation can be expensive should the operation fail.
 - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the master before it is run on the slave. Also, DML that was processed concurrently on the master is only processed on the slave after the DDL operation on the slave is completed.

For additional information related to running online DDL operations on large tables, see [Section 15.12.2, “Online DDL Performance and Concurrency”](#).

15.13 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb_adaptive_hash_index` or `--skip-innodb_adaptive_hash_index` on the command line, or `innodb_adaptive_hash_index` or `skip-innodb_adaptive_hash_index` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 5.1.8.2, “Dynamic System Variables”](#)).
- For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.
- Certain options control the locations and layout of the InnoDB data files. [Section 15.6.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.
- For more information on specifying options and system variables, see [Section 4.2.4, “Specifying Program Options”](#).

Table 15.20 InnoDB Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dy
daemon_memcached_enable_binlog	Yes	Yes	Yes		Global	No
daemon_memcached_enable_lib_name	Yes	Yes	Yes		Global	No

InnoDB Command Options

- `--ignore-builtin-innodb`

Property	Value
Command-Line Format	<code>--ignore-builtin-innodb</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	ignore_builtin_innodb
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

In MySQL 5.1, this option caused the server to behave as if the built-in [InnoDB](#) were not present, which enabled the [InnoDB Plugin](#) to be used instead. In MySQL 8.0, [InnoDB](#) is the default storage engine and [InnoDB Plugin](#) is not used. This option was removed in MySQL 8.0.

- `--innodb[=value]`

Property	Value
Command-Line Format	<code>--innodb[=<i>value</i>]</code>
Deprecated	Yes
Type	Enumeration
Default Value	ON
Valid Values	OFF ON FORCE

Controls loading of the [InnoDB](#) storage engine, if the server was compiled with [InnoDB](#) support. This option has a tristate format, with possible values of [OFF](#), [ON](#), or [FORCE](#). See [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To disable [InnoDB](#), use [--innodb=OFF](#) or [--skip-innodb](#). In this case, because the default storage engine is [InnoDB](#), the server does not start unless you also use [--default-storage-engine](#) and [--default-tmp-storage-engine](#) to set the default to some other engine for both permanent and [TEMPORARY](#) tables.

The [InnoDB](#) storage engine can no longer be disabled, and the [--innodb=OFF](#) and [--skip-innodb](#) options are deprecated and have no effect. Their use results in a warning. These options will be removed in a future MySQL release.

- [--innodb-status-file](#)

Property	Value
Command-Line Format	--innodb-status-file
Type	Boolean
Default Value	OFF

The [--innodb-status-file](#) startup option controls whether [InnoDB](#) creates a file named [innodb_status.pid](#) in the data directory and writes [SHOW ENGINE INNODB STATUS](#) output to it every 15 seconds, approximately.

The [innodb_status.pid](#) file is not created by default. To create it, start [mysqld](#) with the [--innodb-status-file](#) option. [InnoDB](#) removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The [--innodb-status-file](#) option is intended for temporary use, as [SHOW ENGINE INNODB STATUS](#) output generation can affect performance, and the [innodb_status.pid](#) file can become quite large over time.

For related information, see [Section 15.16.2, “Enabling InnoDB Monitors”](#).

- [--skip-innodb](#)

Disable the [InnoDB](#) storage engine. See the description of [--innodb](#).

InnoDB System Variables

- [daemon_memcached_enable_binlog](#)

Property	Value
Command-Line Format	--daemon-memcached-enable-binlog=#
System Variable	daemon_memcached_enable_binlog
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	false

Enable this option on the [master server](#) to use the [InnoDB memcached](#) plugin ([daemon_memcached](#)) with the MySQL [binary log](#). This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option.

For more information, see [Section 15.19.7, “The InnoDB memcached Plugin and Replication”](#).

- [daemon_memcached_engine_lib_name](#)

Property	Value
Command-Line Format	<code>--daemon-memcached-engine-lib-name=library</code>
System Variable	daemon_memcached_engine_lib_name
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	innodb_engine.so

Specifies the shared library that implements the [InnoDB memcached](#) plugin.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon_memcached_engine_lib_path](#)

Property	Value
Command-Line Format	<code>--daemon-memcached-engine-lib-path=directory</code>
System Variable	daemon_memcached_engine_lib_path
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	NULL

The path of the directory containing the shared library that implements the [InnoDB memcached](#) plugin. The default value is [NULL](#), representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a [memcached](#) plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon_memcached_option](#)

Property	Value
Command-Line Format	<code>--daemon-memcached-option=options</code>
System Variable	daemon_memcached_option
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	

Used to pass space-separated memcached options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.

See [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#) for usage details. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

Property	Value
Command-Line Format	<code>--daemon-memcached-r-batch-size=#</code>
System Variable	<code>daemon_memcached_r_batch_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1

Specifies how many `memcached` read operations (`get` operations) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the `memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- `daemon_memcached_w_batch_size`

Property	Value
Command-Line Format	<code>--daemon-memcached-w-batch-size=#</code>
System Variable	<code>daemon_memcached_w_batch_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1

Specifies how many `memcached` write operations, such as `add`, `set`, and `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last $N-1$ uncommitted write operations could be lost if a crash occurs.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- `ignore_built_in_innodb`

Property	Value
Command-Line Format	<code>--ignore-builtin-innodb</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>ignore_built_in_innodb</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section. This variable was removed in MySQL 8.0.

- `innodb_adaptive_flushing`

Property	Value
Command-Line Format	<code>--innodb-adaptive-flushing=#</code>
System Variable	<code>innodb_adaptive_flushing</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Specifies whether to dynamically adjust the rate of flushing `dirty pages` in the `InnoDB buffer pool` based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

Property	Value
Command-Line Format	<code>--innodb-adaptive-flushing-lwm=#</code>
System Variable	<code>innodb_adaptive_flushing_lwm</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	70

Defines the low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_adaptive_hash_index`

Property	Value
Command-Line Format	<code>--innodb-adaptive-hash-index=#</code>
System Variable	<code>innodb_adaptive_hash_index</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether the InnoDB adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 15.4.3, “Adaptive Hash Index”](#) for details.

This variable is enabled by default. You can modify this parameter using the `SET GLOBAL` statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#). You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- `innodb_adaptive_hash_index_parts`

Property	Value
Command-Line Format	<code>--innodb-adaptive-hash-index-parts=#</code>
System Variable	<code>innodb_adaptive_hash_index_parts</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Numeric
Default Value	8

Property	Value
Minimum Value	1
Maximum Value	512

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

The adaptive hash index search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 15.4.3, “Adaptive Hash Index”](#).

- `innodb_adaptive_max_sleep_delay`

Property	Value
Command-Line Format	<code>--innodb-adaptive-max-sleep-delay=#</code>
System Variable	<code>innodb_adaptive_max_sleep_delay</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	150000
Minimum Value	0
Maximum Value	1000000

Permits InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_api_bk_commit_interval`

Property	Value
Command-Line Format	<code>--innodb-api-bk-commit-interval=#</code>
System Variable	<code>innodb_api_bk_commit_interval</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	1
Maximum Value	1073741824

How often to auto-commit idle connections that use the [InnoDB memcached](#) interface, in seconds. For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_disable_rowlock`

Property	Value
Command-Line Format	<code>--innodb-api-disable-rowlock=#</code>
System Variable	<code>innodb_api_disable_rowlock</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Use this option to disable row locks when [InnoDB memcached](#) performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that [memcached](#) requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is enabled, [memcached](#) requests a table lock instead of row locks.

`innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_enable_binlog`

Property	Value
Command-Line Format	<code>--innodb-api-enable-binlog=#</code>
System Variable	<code>innodb_api_enable_binlog</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Lets you use the [InnoDB memcached](#) plugin with the MySQL [binary log](#). For more information, see [Enabling the InnoDB memcached Binary Log](#).

- `innodb_api_enable_md1`

Property	Value
Command-Line Format	<code>--innodb-api-enable-md1=#</code>
System Variable	<code>innodb_api_enable_md1</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Locks the table used by the [InnoDB memcached](#) plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_trx_level`

Property	Value
Command-Line Format	<code>--innodb-api-trx-level=#</code>
System Variable	<code>innodb_api_trx_level</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

Controls the transaction [isolation level](#) on queries processed by the [memcached](#) interface. The constants corresponding to the familiar names are:

- 0 = `READ UNCOMMITTED`
- 1 = `READ COMMITTED`
- 2 = `REPEATABLE READ`
- 3 = `SERIALIZABLE`

For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_autoextend_increment`

Property	Value
Command-Line Format	<code>--innodb-autoextend-increment=#</code>
System Variable	<code>innodb_autoextend_increment</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	64
Minimum Value	1
Maximum Value	1000

The increment size (in megabytes) for extending the size of an auto-extending [InnoDB system tablespace](#) file when it becomes full. The default value is 64. For related information, see [System Tablespace Data File Configuration](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

The `innodb_autoextend_increment` setting does not affect [file-per-table](#) tablespace files or [general tablespace](#) files. These files are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

Property	Value
Command-Line Format	<code>--innodb-autoinc-lock-mode=#</code>
System Variable	<code>innodb_autoinc_lock_mode</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.3$)	2
Default Value ($\leq 8.0.2$)	1
Valid Values	0 1 2

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively.

The default setting is 2 (interleaved) as of MySQL 8.0, and 1 (consecutive) before that. The change to interleaved lock mode as the default setting reflects the change from statement-based to row-based replication as the default replication type, which occurred in MySQL 5.7. Statement-based replication requires the consecutive auto-increment lock mode to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements.

For the characteristics of each lock mode, see [InnoDB AUTO_INCREMENT Lock Modes](#).

- `innodb_background_drop_list_empty`

Property	Value
Command-Line Format	<code>--innodb-background-drop-list-empty=#</code>
System Variable	<code>innodb_background_drop_list_empty</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- `innodb_buffer_pool_chunk_size`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-chunk-size</code>
System Variable	<code>innodb_buffer_pool_chunk_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	1048576
Maximum Value	<code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code>

`innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically rounded to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized.

Important

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_debug`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-debug=#</code>
System Variable	<code>innodb_buffer_pool_debug</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enabling this option permits multiple buffer pool instances when the buffer pool is less than 1GB in size, ignoring the 1GB minimum buffer pool size constraint imposed on `innodb_buffer_pool_instances`. The `innodb_buffer_pool_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_buffer_pool_dump_at_shutdown`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-dump-at-shutdown=#</code>
System Variable	<code>innodb_buffer_pool_dump_at_shutdown</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether to record the pages cached in the [InnoDB buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`. The `innodb_buffer_pool_dump_pct` option defines the percentage of most recently used buffer pool pages to dump.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_dump_now`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-dump-now=#</code>
System Variable	<code>innodb_buffer_pool_dump_now</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Immediately records the pages cached in the [InnoDB buffer pool](#). Typically used in combination with [innodb_buffer_pool_load_now](#).

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb_buffer_pool_dump_pct](#)

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-dump-pct=#</code>
System Variable	innodb_buffer_pool_dump_pct
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25
Minimum Value	1
Maximum Value	100

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. The default value is 25. For example, if there are 4 buffer pools with 100 pages each, and [innodb_buffer_pool_dump_pct](#) is set to 25, the 25 most recently used pages from each buffer pool are dumped.

- [innodb_buffer_pool_filename](#)

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-filename=file</code>
System Variable	innodb_buffer_pool_filename
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	ib_buffer_pool

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by [innodb_buffer_pool_dump_at_shutdown](#) or [innodb_buffer_pool_dump_now](#). Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named [ib_buffer_pool](#) and is located in the [InnoDB](#) data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a [SET](#) statement:

```

SET innodb_buffer_pool_filename = 'data/ib_buffer_pool.dump';

```

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or **InnoDB** will return a startup error indicating that there is no such file or directory.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_in_core_file`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-in-core-file</code>
Introduced	8.0.14
System Variable	<code>innodb_buffer_pool_in_core_file</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

To reduce the size of core files, disable this variable to prevent **InnoDB** buffer pool pages from being written to core files.

If `innodb_buffer_pool_in_core_file` is disabled but an `madvise()` failure occurs or marking buffer pool pages as `MADV_DONTDUMP` is unsupported by the operating system, an error is written to the error log and the `core_file` variable is disabled to prevent core files from being written.

- `innodb_buffer_pool_instances`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-instances=#</code>
System Variable	<code>innodb_buffer_pool_instances</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value (Other)	8 (or 1 if <code>innodb_buffer_pool_size < 1GB</code>)
Default Value (Windows, 32-bit platforms)	(autosized)
Minimum Value	1
Maximum Value	64

The number of regions that the **InnoDB buffer pool** is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

This option only takes effect when setting `innodb_buffer_pool_size` to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size/128MB`, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

- `innodb_buffer_pool_load_abort`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-load-abort=#</code>
System Variable	<code>innodb_buffer_pool_load_abort</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Interrupts the process of restoring InnoDB buffer pool contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_load_at_startup`

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-load-at-startup=#</code>
System Variable	<code>innodb_buffer_pool_load_at_startup</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies that, on MySQL server startup, the [InnoDB buffer pool](#) is automatically **warmed up** by loading the same pages it held at an earlier time. Typically used in combination with [innodb_buffer_pool_dump_at_shutdown](#).

Both [innodb_buffer_pool_dump_at_shutdown](#) and [innodb_buffer_pool_load_at_startup](#) are enabled by default.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb_buffer_pool_load_now](#)

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-load-now=#</code>
System Variable	innodb_buffer_pool_load_now
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Immediately **warms up** the [InnoDB buffer pool](#) by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb_buffer_pool_size](#)

Property	Value
Command-Line Format	<code>--innodb-buffer-pool-size=#</code>
System Variable	innodb_buffer_pool_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	5242880
Maximum Value (64-bit platforms)	$2^{64}-1$
Maximum Value (32-bit platforms)	$2^{32}-1$

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture; the maximum is 4294967295 ($2^{32}-1$) on 32-bit systems and 18446744073709551615 ($2^{64}-1$) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb_buffer_pool_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the [innodb_buffer_pool_chunk_size](#) configuration option, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#). If you alter the buffer pool size to a value that is not equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#), buffer pool size is automatically adjusted to a value that is equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#).

[innodb_buffer_pool_size](#) can be set dynamically, which allows you to resize the buffer pool without restarting the server. The [InnoDB_buffer_pool_resize_status](#) status variable reports the status of online buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

If [innodb_dedicated_server](#) is enabled, the [innodb_buffer_pool_size](#) value is automatically configured if it is not explicitly defined. For more information, see [Section 15.6.13, “Enabling Automatic Configuration for a Dedicated MySQL Server”](#).

- [innodb_change_buffer_max_size](#)

Property	Value
Command-Line Format	--innodb-change-buffer-max-size=#
System Variable	innodb_change_buffer_max_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25
Minimum Value	0
Maximum Value	50

Maximum size for the [InnoDB change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering`

Property	Value
Command-Line Format	<code>--innodb-change-buffering=#</code>
System Variable	<code>innodb_change_buffering</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>all</code>
Valid Values	<code>none</code> <code>inserts</code> <code>deletes</code> <code>changes</code> <code>purges</code> <code>all</code>

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table. Values may also be specified numerically.

Table 15.21 Permitted Values for `innodb_change_buffering`

Value	Numeric Value	Description
<code>none</code>	0	Do not buffer any operations.
<code>inserts</code>	1	Buffer insert operations.
<code>deletes</code>	2	Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.
<code>changes</code>	3	Buffer inserts and delete-marking operations.
<code>purges</code>	4	Buffer the physical deletion operations that happen in the background.
<code>all</code>	5	The default. Buffer inserts, delete-marking operations, and purges.

For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering_debug`

Property	Value
Command-Line Format	<code>--innodb-change-buffering-debug=#</code>
System Variable	<code>innodb_change_buffering_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Maximum Value	2

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_checkpoint_disabled`

Property	Value
Command-Line Format	<code>--innodb-checkpoint-disabled=#</code>
Introduced	8.0.2
System Variable	<code>innodb_checkpoint_disabled</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This is a debug option that is only intended for expert debugging use. It disables checkpoints so that a deliberate server exit always initiates InnoDB recovery. It should only be enabled for a short interval, typically before running DML operations that write redo log entries that would require recovery following a server exit. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_checksum_algorithm`

Property	Value
Command-Line Format	<code>--innodb-checksum-algorithm=#</code>
System Variable	<code>innodb_checksum_algorithm</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>crc32</code>

Property	Value
Valid Values	innodb crc32 none strict_innodb strict_crc32 strict_none

Specifies how to generate and verify the [checksum](#) stored in the disk blocks of [InnoDB tablespaces](#). The default value for [innodb_checksum_algorithm](#) is [crc32](#).

Versions of [MySQL Enterprise Backup](#) up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. [MySQL Enterprise Backup](#) adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the [MySQL Enterprise Backup 3.8.1 Change History](#) for more information.

The value [innodb](#) is backward-compatible with earlier versions of MySQL. The value [crc32](#) uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the [innodb](#) checksum algorithm, which scans blocks 8 bits at a time. The value [none](#) writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the [crc32](#) algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

The following table shows the difference between the [none](#), [innodb](#), and [crc32](#) option values, and their strict counterparts. [none](#), [innodb](#), and [crc32](#) write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all [InnoDB](#) data files in an instance are created under an identical [innodb_checksum_algorithm](#) value.

Table 15.22 Permitted innodb_checksum_algorithm Values

Value	Generated checksum (when writing)	Permitted checksums (when reading)
none	A constant number.	Any of the checksums generated by none , innodb , or crc32 .
innodb	A checksum calculated in software, using the original algorithm from InnoDB .	Any of the checksums generated by none , innodb , or crc32 .
crc32	A checksum calculated using the crc32 algorithm, possibly done with a hardware assist.	Any of the checksums generated by none , innodb , or crc32 .

Value	Generated checksum (when writing)	Permitted checksums (when reading)
strict_none	A constant number	Any of the checksums generated by none , innodb , or crc32 . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB .	Any of the checksums generated by none , innodb , or crc32 . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_crc32	A checksum calculated using the crc32 algorithm, possibly done with a hardware assist.	Any of the checksums generated by none , innodb , or crc32 . InnoDB prints an error message if a valid but non-matching checksum is encountered.

- [innodb_cmp_per_index_enabled](#)

Property	Value
Command-Line Format	<code>--innodb-cmp-per-index-enabled=#</code>
System Variable	innodb_cmp_per_index_enabled
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF
Valid Values	OFF ON

Enables per-index compression-related statistics in the [INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX](#) table. Because these statistics can be expensive to gather, only enable this option on development, test, or slave instances during performance tuning related to [InnoDB compressed](#) tables.

For more information, see [Section 24.36.7, “The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables”](#), and [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#).

- [innodb_commit_concurrency](#)

Property	Value
Command-Line Format	<code>--innodb-commit-concurrency=#</code>
System Variable	innodb_commit_concurrency
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

Property	Value
Minimum Value	0
Maximum Value	1000

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of [innodb_commit_concurrency](#) cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- [innodb_compress_debug](#)

Property	Value
Command-Line Format	--innodb-compress-debug=#
System Variable	innodb_compress_debug
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	none
Valid Values	none zlib lz4 lz4hc

Compresses all tables using a specified compression algorithm without having to define a [COMPRESSION](#) attribute for each table. This option is only available if debugging support is compiled in using the [WITH_DEBUG CMake](#) option.

For related information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- [innodb_compression_failure_threshold_pct](#)

Property	Value
Command-Line Format	--innodb-compression-failure-threshold-pct=#
System Variable	innodb_compression_failure_threshold_pct
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	100

Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within [compressed](#) pages to avoid expensive [compression failures](#). When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by [innodb_compression_pad_pct_max](#). A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb_compression_level](#)

Property	Value
Command-Line Format	<code>--innodb-compression-level=#</code>
System Variable	innodb_compression_level
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	0
Maximum Value	9

Specifies the level of zlib compression to use for [InnoDB compressed](#) tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb_compression_pad_pct_max](#)

Property	Value
Command-Line Format	<code>--innodb-compression-pad-pct-max=#</code>
System Variable	innodb_compression_pad_pct_max
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	75

Specifies the maximum percentage that can be reserved as free space within each compressed [page](#), allowing room to reorganize the data and modification log within the page when a [compressed](#) table or index is updated and the data might be recompressed. Only applies when [innodb_compression_failure_threshold_pct](#) is set to a nonzero value, and the rate of [compression failures](#) passes the cutoff point.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- `innodb_concurrency_tickets`

Property	Value
Command-Line Format	<code>--innodb-concurrency-tickets=#</code>
System Variable	<code>innodb_concurrency_tickets</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	5000
Minimum Value	1
Maximum Value	4294967295

Determines the number of [threads](#) that can enter [InnoDB](#) concurrently. A thread is placed in a queue when it tries to enter [InnoDB](#) if the number of threads has already reached the concurrency limit. When a thread is permitted to enter [InnoDB](#), it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave [InnoDB](#) freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_data_file_path`

Property	Value
Command-Line Format	<code>--innodb-data-file-path=name</code>
System Variable	<code>innodb_data_file_path</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>ibdata1:12M:autoextend</code>

Defines the name, size, and attributes of [InnoDB system tablespace data files](#). If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

The full syntax for a data file specification includes the file name, file size, and `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 12MB.

A minimum file size is enforced for the *first* system tablespace data file to ensure that there is enough space for doublewrite buffer pages:

- For an `innodb_page_size` value of 16KB or less, the minimum file size is 3MB.
- For an `innodb_page_size` value of 32KB, the minimum file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum file size is 12MB.

The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#).

The `autoextend` and `max` attributes can be used only for the data file that is specified last in the `innodb_data_file_path` setting. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:12M:autoextend:max:500MB
```

If you specify the `autoextend` option, [InnoDB](#) extends the data file if it runs out of free space. The `autoextend` increment is 64MB by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

The full directory path for system tablespace data files is formed by concatenating the paths defined by `innodb_data_home_dir` and `innodb_data_file_path`.

For more information about configuring system tablespace data files, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

- `innodb_data_home_dir`

Property	Value
Command-Line Format	<code>--innodb-data-home-dir=dir_name</code>

Property	Value
System Variable	innodb_data_home_dir
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The common part of the directory path for [InnoDB system tablespace](#) data files. This setting does not affect the location of [file-per-table](#) tablespaces when [innodb_file_per_table](#) is enabled. The default value is the MySQL [data](#) directory. If you specify the value as an empty string, you can specify an absolute file paths for [innodb_data_file_path](#).

A trailing slash is required when specifying a value for [innodb_data_home_dir](#). For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

- [innodb_ddl_log_crash_reset_debug](#)

Property	Value
Command-Line Format	<code>--innodb-ddl-log-crash-reset-debug=#</code>
Introduced	8.0.3
System Variable	innodb_ddl_log_crash_reset_debug
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	False

Enable this debug option to reset DDL log crash injection counters to 1. This option is only available when debugging support is compiled in using the [WITH_DEBUG](#) CMake option.

- [innodb_deadlock_detect](#)

Property	Value
Command-Line Format	<code>--innodb-deadlock-detect</code>
System Variable	innodb_deadlock_detect
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

- `innodb_dedicated_server`

Property	Value
Command-Line Format	<code>--innodb-dedicated-server=#</code>
Introduced	8.0.3
System Variable	<code>innodb_dedicated_server</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When `innodb_dedicated_server` is enabled, InnoDB automatically configures the following options according to the amount of memory detected on the server:

- `innodb_buffer_pool_size`
- `innodb_log_file_size`
- `innodb_flush_method`

Only consider enabling this option if your MySQL instance runs on a dedicated server where the MySQL server is able to consume all available system resources. Enabling this option is not recommended if your MySQL instance shares system resources with other applications.

For more information, see [Section 15.6.13, “Enabling Automatic Configuration for a Dedicated MySQL Server”](#).

- `innodb_default_row_format`

Property	Value
Command-Line Format	<code>--innodb-default-row-format=#</code>
System Variable	<code>innodb_default_row_format</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	DYNAMIC
Valid Values	DYNAMIC COMPACT

Property	Value
	REDUNDANT

The `innodb_default_row_format` option defines the default row format for InnoDB tables and user-created temporary tables. The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the `system tablespace`, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

- `innodb_directories`

Property	Value
Command-Line Format	<code>--innodb-directories=#</code>
Introduced	8.0.4
System Variable	<code>innodb_directories</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

Defines directories to scan at startup for tablespace files. This option is used when moving or restoring tablespace files to a new location while the server is offline. It is also used to specify directories of tablespace files created using an absolute path or that reside outside of the data directory (see [Section 15.7.5, “Creating a Tablespace Outside of the Data Directory”](#)).

Directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are automatically appended to the `innodb_directories` argument value, regardless of whether the `innodb_directories` option is specified explicitly.

`innodb_directories` may be specified as an option in a startup command or in a MySQL option file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-directories="directory_path_1:directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_directories="directory_path_1;directory_path_2"
```

Wildcard expressions cannot be used to specify directories.

The `innodb_directories` scan also traverses the subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.

For more information, see [Section 15.7.7, “Moving Tablespace Files While the Server is Offline”](#).

- `innodb_disable_sort_file_cache`

Property	Value
Command-Line Format	<code>--innodb-disable-sort-file-cache=#</code>
System Variable	<code>innodb_disable_sort_file_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_doublewrite`

Property	Value
Command-Line Format	<code>--innodb-doublewrite</code>
System Variable	<code>innodb_doublewrite</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

When enabled (the default), InnoDB stores all data twice, first to the [doublewrite buffer](#), then to the actual [data files](#). This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

If system tablespace data files (`ibdata*` files) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see [Section 15.4.6, “Doublewrite Buffer”](#).

- `innodb_fast_shutdown`

Property	Value
Command-Line Format	<code>--innodb-fast-shutdown[=#]</code>
System Variable	<code>innodb_fast_shutdown</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Valid Values	0 1 2

The `InnoDB shutdown` mode. If the value is 0, `InnoDB` does a `slow shutdown`, a full `purge` and a change buffer merge before shutting down. If the value is 1 (the default), `InnoDB` skips these operations at shutdown, a process known as a `fast shutdown`. If the value is 2, `InnoDB` flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the `crash recovery` operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_fil_make_page_dirty_debug`

Property	Value
Command-Line Format	<code>--innodb-fil-make-page-dirty-debug=#</code>
System Variable	<code>innodb_fil_make_page_dirty_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Maximum Value	$2^{32}-1$

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_file_per_table`

Property	Value
Command-Line Format	<code>--innodb-file-per-table</code>
System Variable	<code>innodb_file_per_table</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

When `innodb_file_per_table` is enabled (the default), InnoDB stores the data and indexes for each newly created table in a separate `.ibd` file instead of the system tablespace. The storage for these tables is reclaimed when the tables are dropped or truncated. This setting enables InnoDB features such as table [compression](#). See [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#) for more information.

Enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation moves an InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` rebuilds the table (`ALGORITHM=COPY`). An exception to this rule is for tables placed in the system tablespace using the `TABLESPACE=innodb_system` option with `CREATE TABLE` or `ALTER TABLE`. These tables are unaffected by the `innodb_file_per_table` setting and can only be moved to file-per-table tablespaces using `ALTER TABLE ... TABLESPACE=innodb_file_per_table`.

When `innodb_file_per_table` is disabled, InnoDB stores the data for tables and indexes in the `ibdata` files that make up the [system tablespace](#). This setting reduces the performance overhead of file system operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an [instance](#), avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table` is disabled. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

`innodb_file_per_table` is enabled by default. Consider disabling it if backward compatibility with MySQL 5.5 or earlier is a concern. This will prevent `ALTER TABLE` from moving InnoDB tables from the system tablespace to individual `.ibd` files.

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`. You can also set this option in the MySQL [configuration file](#) (`my.cnf` or `my.ini`) but this requires shutting down and restarting the server.

Dynamically changing the value requires privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)) and immediately affects the operation of all connections.

The `innodb_file_per-table` setting does not affect the creation of temporary tables, which are created in the temporary tablespace by default.

- `innodb_fill_factor`

Property	Value
Command-Line Format	<code>--innodb-fill-factor=#</code>
System Variable	<code>innodb_fill_factor</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	10
Maximum Value	100

InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 15.8.2.3, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

Property	Value
System Variable	<code>innodb_flush_log_at_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	2700

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. The default setting for `innodb_flush_log_at_timeout` is once per second.

- `innodb_flush_log_at_trx_commit`

Property	Value
Command-Line Format	<code>--innodb-flush-log-at-trx-commit[=#]</code>
System Variable	<code>innodb_flush_log_at_trx_commit</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1 2

Controls the balance between strict [ACID](#) compliance for [commit](#) operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.
- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal [InnoDB](#) activities that cause logs to be flushed independently of the [innodb_flush_log_at_trx_commit](#) setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.
- Log flushing frequency is controlled by [innodb_flush_log_at_timeout](#), which allows you to set log flushing frequency to *N* seconds (where *N* is 1 ... 2700, with a default value of 1). However, any [mysqld](#) process crash can erase up to *N* seconds of transactions.
- DDL changes and other internal [InnoDB](#) activities flush the log independently of the [innodb_flush_log_at_trx_commit](#) setting.
- [InnoDB crash recovery](#) works regardless of the [innodb_flush_log_at_trx_commit](#) setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses [InnoDB](#) with transactions:

- If binary logging is enabled, set [sync_binlog=1](#).
- Always set [innodb_flush_log_at_trx_commit=1](#).

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell [mysqld](#) that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in

the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `innodb_flush_method`

Property	Value
Command-Line Format	<code>--innodb-flush-method=name</code>
System Variable	<code>innodb_flush_method</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value (Windows)	<code>unbuffered</code>
Default Value (Unix)	<code>fsync</code>
Valid Values (Windows)	<code>unbuffered</code> <code>normal</code>
Valid Values (Unix)	<code>fsync</code> <code>O_DSYNC</code> <code>littlesync</code> <code>nosync</code> <code>O_DIRECT</code> <code>O_DIRECT_NO_FSYNC</code>

Defines the method used to flush data to InnoDB data files and log files, which can affect I/O throughput.

On Unix-like systems, the default value is `fsync`. On Windows, the default value is `unbuffered`.

Note

In MySQL 8.0, `innodb_flush_method` options may be specified numerically.

The `innodb_flush_method` options for Unix-like systems include:

- `fsync` or 0: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- `O_DSYNC` or 1: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- `littlesync` or 2: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `nosync` or 3: This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- `O_DIRECT` or 4: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- `O_DIRECT_NO_FSYNC` or 5: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call afterward. This setting is suitable for some types of file systems but not others. For example, it is not suitable for XFS. If you are not sure whether the file system you use requires an `fsync()`, for example to preserve all file metadata, use `O_DIRECT` instead.

Warning

The `O_DIRECT_NO_FSYNC` setting is currently not recommended for use on Linux systems. It may cause the operating system to hang when data files change size.

The `innodb_flush_method` options for Windows systems include:

- `unbuffered` or 0: InnoDB uses simulated asynchronous I/O and non-buffered I/O.
- `normal` or 1: InnoDB uses simulated asynchronous I/O and buffered I/O.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `innodb_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

If `innodb_dedicated_server` is enabled, the `innodb_flush_method` value is automatically configured if it is not explicitly defined. For more information, see [Section 15.6.13, “Enabling Automatic Configuration for a Dedicated MySQL Server”](#).

- `innodb_flush_neighbors`

Property	Value
Command-Line Format	<code>--innodb-flush-neighbors</code>
System Variable	<code>innodb_flush_neighbors</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value (>= 8.0.3)	0
Default Value (<= 8.0.2)	1
Valid Values	0 1

Property	Value
	2

Specifies whether [flushing](#) a page from the [InnoDB buffer pool](#) also flushes other [dirty pages](#) in the same [extent](#).

- A setting of 0 turns [innodb_flush_neighbors](#) off and no other dirty pages are flushed from the buffer pool.
- A setting of 1 flushes contiguous dirty pages in the same extent from the buffer pool.
- A setting of 2 flushes dirty pages in the same extent from the buffer pool.

When the table data is stored on a traditional [HDD](#) storage device, flushing such [neighbor pages](#) in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on [SSD](#), seek time is not a significant factor and you can set this option to 0 to spread out write operations. For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- [innodb_flush_sync](#)

Property	Value
Command-Line Format	<code>--innodb-flush-sync=#</code>
System Variable	innodb_flush_sync
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

The [innodb_flush_sync](#) parameter, which is enabled by default, causes the [innodb_io_capacity](#) setting to be ignored for bursts of I/O activity that occur at [checkpoints](#). To adhere to the limit on InnoDB background I/O activity defined by the [innodb_io_capacity](#) setting, disable [innodb_flush_sync](#).

For related information, see [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#).

- [innodb_flushing_avg_loops](#)

Property	Value
Command-Line Format	<code>--innodb-flushing-avg-loops=#</code>
System Variable	innodb_flushing_avg_loops
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	1000

Number of iterations for which [InnoDB](#) keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- [innodb_force_load_corrupted](#)

Property	Value
Command-Line Format	<code>--innodb-force-load-corrupted</code>
System Variable	innodb_force_load_corrupted
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Permits [InnoDB](#) to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- [innodb_force_recovery](#)

Property	Value
Command-Line Format	<code>--innodb-force-recovery=#</code>
System Variable	innodb_force_recovery
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	6

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about [innodb_force_recovery](#), see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Warning

Only set this variable to a value greater than 0 in an emergency situation so that you can start [InnoDB](#) and dump your tables. As a safety measure, [InnoDB](#) prevents [INSERT](#), [UPDATE](#), or [DELETE](#) operations when [innodb_force_recovery](#) is greater than 0. An [innodb_force_recovery](#) setting of 4 or greater places [InnoDB](#) into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication stores the slave status logs in [InnoDB](#) tables.

- [innodb_fsync_threshold](#)

Property	Value
Command-Line Format	<code>--innodb-fsync-threshold=#</code>
Introduced	8.0.13
System Variable	innodb_fsync_threshold
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{*}64-1$

By default, when [InnoDB](#) creates a new data file, such as a new log file or tablespace file, it flushes the contents of the write buffer to disk only after the file is fully written, which can cause a large amount of disk write activity to occur at once. To force smaller, periodic flushes, use [innodb_fsync_threshold](#) to define a threshold size for the write buffer, in bytes. The contents of the write buffer are flushed to disk when the threshold size is reached. The default value of 0 forces the default behavior.

Specifying a write buffer threshold size to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a write buffer threshold size helps avoid such surges in disk write activity.

- [innodb_ft_aux_table](#)

Property	Value
Command-Line Format	<code>--innodb-ft-aux-table=#</code>
System Variable	innodb_ft_aux_table
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Specifies the qualified name of an [InnoDB](#) table containing a [FULLTEXT](#) index. This variable is intended for diagnostic purposes.

After you set this variable to a name in the format `db_name/table_name`, the [INFORMATION_SCHEMA](#) tables [INNODB_FT_INDEX_TABLE](#), [INNODB_FT_INDEX_CACHE](#), [INNODB_FT_CONFIG](#), [INNODB_FT_DELETED](#), and [INNODB_FT_BEING_DELETED](#) show information about the search index for the specified table.

For more information, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

- `innodb_ft_cache_size`

Property	Value
Command-Line Format	<code>--innodb-ft-cache-size=#</code>
System Variable	<code>innodb_ft_cache_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	8000000
Minimum Value	1600000
Maximum Value	80000000

The memory allocated, in bytes, for the [InnoDB FULLTEXT](#) search index cache, which holds a parsed document in memory while creating an [InnoDB FULLTEXT](#) index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached. `innodb_ft_cache_size` defines the cache size on a per table basis. To set a global limit for all tables, see `innodb_ft_total_cache_size`.

For more information, see [InnoDB Full-Text Index Cache](#).

- `innodb_ft_enable_diag_print`

Property	Value
Command-Line Format	<code>--innodb-ft-enable-diag-print=#</code>
System Variable	<code>innodb_ft_enable_diag_print</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
```

```
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- [innodb_ft_enable_stopword](#)

Property	Value
Command-Line Format	<code>--innodb-ft-enable-stopword=#</code>
System Variable	innodb_ft_enable_stopword
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies that a set of [stopwords](#) is associated with an [InnoDB FULLTEXT](#) index at the time the index is created. If the [innodb_ft_user_stopword_table](#) option is set, the stopwords are taken from that table. Else, if the [innodb_ft_server_stopword_table](#) option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- [innodb_ft_max_token_size](#)

Property	Value
Command-Line Format	<code>--innodb-ft-max-token-size=#</code>
System Variable	innodb_ft_max_token_size
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	84
Minimum Value	10
Maximum Value	84

Maximum character length of words that are stored in an [InnoDB FULLTEXT](#) index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_min_token_size`

Property	Value
Command-Line Format	<code>--innodb-ft-min-token-size=#</code>
System Variable	<code>innodb_ft_min_token_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	16

Minimum length of words that are stored in an `InnoDB FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_num_word_optimize`

Property	Value
Command-Line Format	<code>--innodb-ft-num-word-optimize=#</code>
System Variable	<code>innodb_ft_num_word_optimize</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2000

Number of words to process during each `OPTIMIZE TABLE` operation on an `InnoDB FULLTEXT` index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_result_cache_limit`

Property	Value
Command-Line Format	<code>--innodb-ft-result-cache-limit=#</code>
System Variable	<code>innodb_ft_result_cache_limit</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2000000000
Minimum Value	1000000
Maximum Value	$2^{32}-1$

The [InnoDB](#) full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final [InnoDB](#) full-text search query results are handled in memory. Use [innodb_ft_result_cache_limit](#) to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large [InnoDB](#) full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

The maximum value of [innodb_ft_result_cache_limit](#) for all platform types and bit sizes is $2^{32}-1$.

- [innodb_ft_server_stopword_table](#)

Property	Value
Command-Line Format	<code>--innodb-ft-server-stopword-table=db_name/table_name</code>
System Variable	innodb_ft_server_stopword_table
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list for all [InnoDB](#) tables. To configure your own stopwords list for a specific [InnoDB](#) table, use [innodb_ft_user_stopword_table](#).

Set [innodb_ft_server_stopword_table](#) to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopwords table must exist before you configure [innodb_ft_server_stopword_table](#). [innodb_ft_enable_stopword](#) must be enabled and [innodb_ft_server_stopword_table](#) option must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named `value`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- [innodb_ft_sort_pll_degree](#)

Property	Value
Command-Line Format	<code>--innodb-ft-sort-plt-degree=#</code>
System Variable	<code>innodb_ft_sort_plt_degree</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	32

Number of threads used in parallel to index and tokenize text in an [InnoDB FULLTEXT](#) index when building a [search index](#).

For related information, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [innodb_sort_buffer_size](#).

- `innodb_ft_total_cache_size`

Property	Value
Command-Line Format	<code>--innodb-ft-total-cache-size=#</code>
System Variable	<code>innodb_ft_total_cache_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	640000000
Minimum Value	32000000
Maximum Value	1600000000

The total memory allocated, in bytes, for the [InnoDB](#) full-text search index cache for all tables. Creating numerous tables, each with a [FULLTEXT](#) search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see [InnoDB Full-Text Index Cache](#).

- `innodb_ft_user_stopword_table`

Property	Value
Command-Line Format	<code>--innodb-ft-user-stopword-table=db_name/table_name</code>
System Variable	<code>innodb_ft_user_stopword_table</code>
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list on a specific table. To configure your own stopwords list for all [InnoDB](#) tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopwords table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named `value`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- `innodb_io_capacity`

Property	Value
Command-Line Format	<code>--innodb-io-capacity=#</code>
System Variable	<code>innodb_io_capacity</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	200
Minimum Value	100
Maximum Value (64-bit platforms)	$2^{**64}-1$
Maximum Value (32-bit platforms)	$2^{**32}-1$

The `innodb_io_capacity` parameter sets an upper limit on the number of I/O operations performed per second by [InnoDB](#) background tasks, such as [flushing](#) pages from the [buffer pool](#) and merging data from the [change buffer](#).

The `innodb_io_capacity` limit is a total limit for all buffer pool instances. When dirty pages are flushed, the limit is divided equally among buffer pool instances.

`innodb_io_capacity` should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly for caching to provide a significant benefit.

The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes.

In general, you can increase the value as a function of the number of drives used for [InnoDB I/O](#). For example, you can increase the value on systems that use multiple disks or solid-state disks (SSD).

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to [100](#), which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a very high value such as one million, in practice such large values have little if any benefit. Generally, a value of 20000 or higher is not recommended unless you have proven that lower values are insufficient for your workload.

Consider write workload when tuning [innodb_io_capacity](#). Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

You can set [innodb_io_capacity](#) to any number 100 or greater to a maximum defined by [innodb_io_capacity_max](#). [innodb_io_capacity](#) can be set in the MySQL option file ([my.cnf](#) or [my.ini](#)) or changed dynamically using a [SET GLOBAL](#) statement, which requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The [innodb_flush_sync](#) configuration option causes the [innodb_io_capacity](#) setting to be ignored during bursts of I/O activity that occur at checkpoints. [innodb_flush_sync](#) is enabled by default.

See [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more information. For general information about [InnoDB I/O](#) performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_io_capacity_max](#)

Property	Value
Command-Line Format	<code>--innodb-io-capacity-max=#</code>
System Variable	innodb_io_capacity_max
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	see description
Minimum Value	100
Maximum Value (Windows, 64-bit platforms)	$2^{32}-1$
Maximum Value (Unix, 64-bit platforms)	$2^{64}-1$
Maximum Value (32-bit platforms)	$2^{32}-1$

If flushing activity falls behind, [InnoDB](#) can flush more aggressively than the limit imposed by [innodb_io_capacity](#). [innodb_io_capacity_max](#) defines an upper limit the number of I/O operations performed per second by [InnoDB](#) background tasks in such situations.

The [innodb_io_capacity_max](#) setting is a total limit for all buffer pool instances.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`, with a minimum value of 2000.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use a solid-state disk (SSD) or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSD or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend beyond the `innodb_io_capacity` limit, if necessary.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_limit_optimistic_insert_debug`

Property	Value
Command-Line Format	<code>--innodb-limit-optimistic-insert-debug=#</code>
System Variable	<code>innodb_limit_optimistic_insert_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{32}-1$

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_lock_wait_timeout`

Property	Value
Command-Line Format	<code>--innodb-lock-wait-timeout=#</code>
System Variable	<code>innodb_lock_wait_timeout</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	50
Minimum Value	1
Maximum Value	1073741824

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 15.20.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#) when `innodb_deadlock_detect` is enabled (the default) because [InnoDB](#) detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, [InnoDB](#) relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs. See [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_log_buffer_size`

Property	Value
Command-Line Format	<code>--innodb-log-buffer-size=#</code>
System Variable ($\geq 8.0.11$)	<code>innodb_log_buffer_size</code>
System Variable ($\leq 8.0.4$)	<code>innodb_log_buffer_size</code>
Scope ($\geq 8.0.11$)	Global
Scope ($\leq 8.0.4$)	Global
Dynamic ($\geq 8.0.11$)	Yes
Dynamic ($\leq 8.0.4$)	No
SET_VAR Hint Applies ($\geq 8.0.11$)	No
SET_VAR Hint Applies ($\leq 8.0.4$)	No

Property	Value
Type	Integer
Default Value	16777216
Minimum Value	1048576
Maximum Value	4294967295

The size in bytes of the buffer that InnoDB uses to write to the [log files](#) on disk. The default is 16MB. A large [log buffer](#) enables large [transactions](#) to run without the need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see [InnoDB Memory Configuration](#), and [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_log_checkpoint_fuzzy_now](#)

Property	Value
Command-Line Format	<code>--innodb-log-checkpoint-fuzzy-now</code>
Introduced	8.0.13
System Variable	innodb_log_checkpoint_fuzzy_now
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enable this debug option to force InnoDB to write a fuzzy checkpoint. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- [innodb_log_checkpoint_now](#)

Property	Value
Command-Line Format	<code>--innodb-log-checkpoint-now</code>
System Variable	innodb_log_checkpoint_now
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enable this debug option to force InnoDB to write a checkpoint. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- [innodb_log_checksums](#)

Property	Value
Command-Line Format	<code>--innodb-log-checksums=#</code>

Property	Value
System Variable	innodb_log_checksums
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Enables or disables checksums for redo log pages.

[innodb_log_checksums=ON](#) enables the [CRC-32C](#) checksum algorithm for redo log pages. When [innodb_log_checksums](#) is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- [innodb_log_compressed_pages](#)

Property	Value
Command-Line Format	--innodb-log-compressed-pages=#
System Variable	innodb_log_compressed_pages
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether images of [re-compressed pages](#) are written to the [redo log](#). Re-compression may occur when changes are made to compressed data.

[innodb_log_compressed_pages](#) is enabled by default to prevent corruption that could occur if a different version of the [zlib](#) compression algorithm is used during recovery. If you are certain that the [zlib](#) version will not change, you can disable [innodb_log_compressed_pages](#) to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling [innodb_log_compressed_pages](#), compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the [Log sequence number](#) (LSN) in the [LOG](#) section of [SHOW ENGINE INNODB STATUS](#) output, or monitoring [Innodb_os_log_written](#) status for the number of bytes written to the redo log files.

For related information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb_log_file_size](#)

Property	Value
Command-Line Format	--innodb-log-file-size=#
System Variable	innodb_log_file_size
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	50331648
Minimum Value	4194304
Maximum Value	512GB / innodb_log_files_in_group

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration.

The minimum `innodb_log_file_size` is 4MB.

For related information, see [InnoDB Log File Configuration](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

If `innodb_dedicated_server` is enabled, the `innodb_log_file_size` value is automatically configured if it is not explicitly defined. For more information, see [Section 15.6.13, “Enabling Automatic Configuration for a Dedicated MySQL Server”](#).

- `innodb_log_files_in_group`

Property	Value
Command-Line Format	<code>--innodb-log-files-in-group=#</code>
System Variable	<code>innodb_log_files_in_group</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	2
Maximum Value	100

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) can be up to 512GB.

For related information, see [InnoDB Log File Configuration](#).

- `innodb_log_group_home_dir`

Property	Value
Command-Line Format	<code>--innodb-log-group-home-dir=dir_name</code>
System Variable	<code>innodb_log_group_home_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory path to the [InnoDB redo log](#) files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any [InnoDB](#) log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the `innodb_log_file_size` system variable.

For related information, see [InnoDB Log File Configuration](#).

- `innodb_log_spin_cpu_abs_lwm`

Property	Value
Command-Line Format	<code>--innodb-log-spin-cpu-abs-lwm=#</code>
Introduced	8.0.11
System Variable	<code>innodb_log_spin_cpu_abs_lwm</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	80
Minimum Value	0
Maximum Value	4294967295

Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, The default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.

For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_log_spin_cpu_pct_hwm`

Property	Value
Command-Line Format	<code>--innodb-log-spin-cpu-pct-hwm=#</code>
Introduced	8.0.11
System Variable	<code>innodb_log_spin_cpu_pct_hwm</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	100

Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

The `innodb_log_spin_cpu_pct_hwm` configuration option respects processor affinity. For example, if a server has 48 cores but the `mysqld` process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_log_wait_for_flush_spin_hwm`

Property	Value
Command-Line Format	<code>--innodb-log-wait-for-flush-spin-hwm=#</code>
Introduced	8.0.11
System Variable	<code>innodb_log_wait_for_flush_spin_hwm</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	400
Minimum Value	0
Maximum Value (64-bit platforms)	$2^{64}-1$
Maximum Value (32-bit platforms)	$2^{32}-1$

Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.

For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_log_write_ahead_size`

Property	Value
Command-Line Format	<code>--innodb-log-write-ahead-size=#</code>
System Variable	<code>innodb_log_write_ahead_size</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	512 (log file block size)
Maximum Value	Equal to innodb_page_size

Defines the write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. The default setting is 8192 bytes. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size (2^n). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_lru_scan_depth`

Property	Value
Command-Line Format	<code>--innodb-lru-scan-depth=#</code>
System Variable	<code>innodb_lru_scan_depth</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	100
Maximum Value (64-bit platforms)	$2^{64}-1$
Maximum Value (32-bit platforms)	$2^{32}-1$

A parameter that influences the algorithms and heuristics for the `flush` operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth` * `innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct`

Property	Value
Command-Line Format	<code>--innodb-max-dirty-pages-pct=#</code>
System Variable	<code>innodb_max_dirty_pages_pct</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Numeric
Default Value (>= 8.0.3)	90
Default Value (<= 8.0.2)	75
Minimum Value	0
Maximum Value	99.99

InnoDB tries to [flush](#) data from the [buffer pool](#) so that the percentage of [dirty pages](#) does not exceed this value.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct_lwm`

Property	Value
Command-Line Format	<code>--innodb-max-dirty-pages-pct-lwm=#</code>
System Variable	<code>innodb_max_dirty_pages_pct_lwm</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Numeric
Default Value (>= 8.0.3)	10
Default Value (<= 8.0.2)	0
Minimum Value	0
Maximum Value	99.99

Defines a low water mark representing the percentage of [dirty pages](#) at which preflushing is enabled to control the dirty page ratio. A value of 0 disables the pre-flushing behavior entirely. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- [innodb_max_purge_lag](#)

Property	Value
Command-Line Format	<code>--innodb-max-purge-lag=#</code>
System Variable	innodb_max_purge_lag
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Defines the maximum length of the purge queue. The default value of 0 indicates no limit (no delays).

Use this option to impose a delay for [INSERT](#), [UPDATE](#), and [DELETE](#) operations when [purge](#) operations are lagging (see [Section 15.3, “InnoDB Multi-Versioning”](#)).

The [InnoDB](#) transaction system maintains a list of transactions that have index records delete-marked by [UPDATE](#) or [DELETE](#) operations. The length of the list represents the [purge_lag](#) value. When [purge_lag](#) exceeds [innodb_max_purge_lag](#), [INSERT](#), [UPDATE](#), and [DELETE](#) operations are delayed.

To prevent excessive delays in extreme situations where [purge_lag](#) becomes huge, you can limit the delay by setting the [innodb_max_purge_lag_delay](#) configuration option. The delay is computed at the beginning of a purge batch.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged [InnoDB](#) table rows.

The lag value is displayed as the history list length in the [TRANSACTIONS](#) section of [InnoDB Monitor output](#). The lag value is 20 in this example output:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_max_purge_lag_delay](#)

Property	Value
Command-Line Format	<code>--innodb-max-purge-lag-delay=#</code>
System Variable	innodb_max_purge_lag_delay

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Specifies the maximum delay in microseconds for the delay imposed by the `innodb_max_purge_lag` configuration option. A nonzero value represents an upper limit on the delay period computed from the formula based on the value of `innodb_max_purge_lag`. The default of zero means that there is no upper limit imposed on the delay interval.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_undo_log_size`

Property	Value
Command-Line Format	<code>--innodb-max-undo-log-size=#</code>
System Variable	<code>innodb_max_undo_log_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	10485760
Maximum Value	$2^{64}-1$

Defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1073741824 bytes (1024 MiB).

For more information, see [Section 15.7.9, “Truncating Undo Tablespaces”](#).

- `innodb_merge_threshold_set_all_debug`

Property	Value
Command-Line Format	<code>--innodb-merge-threshold-set-all-debug=#</code>
System Variable	<code>innodb_merge_threshold_set_all_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	50

Property	Value
Minimum Value	1
Maximum Value	50

Defines a page-full percentage value for index pages that overrides the current `MERGE_THRESHOLD` setting for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option. For related information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

Property	Value
Command-Line Format	<code>--innodb-monitor-disable=[counter module pattern all]</code>
System Variable	<code>innodb_monitor_disable</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Disables [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.6.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_enable`

Property	Value
Command-Line Format	<code>--innodb-monitor-enable=[counter module pattern all]</code>
System Variable	<code>innodb_monitor_enable</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Enables [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.6.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset`

Property	Value
Command-Line Format	<code>--innodb-monitor-reset=[counter module pattern all]</code>
System Variable	<code>innodb_monitor_reset</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Resets the count value for [InnoDB metrics counters](#) to zero. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.6.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset_all`

Property	Value
Command-Line Format	<code>--innodb-monitor-reset-all=[counter module pattern all]</code>
System Variable	<code>innodb_monitor_reset_all</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Resets all values (minimum, maximum, and so on) for [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

- `innodb_numa_interleave`

Property	Value
Command-Line Format	<code>--innodb-numa-interleave=#</code>
System Variable	<code>innodb_numa_interleave</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enables the NUMA interleave memory policy for allocation of the [InnoDB buffer pool](#). When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB buffer pool](#) is allocated, the NUMA memory policy is set back to

`MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

CMake sets the default `WITH_NUMA` value based on whether the current platform has NUMA support. For more information, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- `innodb_old_blocks_pct`

Property	Value
Command-Line Format	<code>--innodb-old-blocks-pct=#</code>
System Variable	<code>innodb_old_blocks_pct</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	37
Minimum Value	5
Maximum Value	95

Specifies the approximate percentage of the InnoDB buffer pool used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`.

For more information, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the LRU algorithm, and eviction policies, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- `innodb_old_blocks_time`

Property	Value
Command-Line Format	<code>--innodb-old-blocks-time=#</code>
System Variable	<code>innodb_old_blocks_time</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	$2^{*}32-1$

Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at

least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This configuration option is often used in combination with `innodb_old_blocks_pct`. For more information, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the LRU algorithm, and eviction policies, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- `innodb_online_alter_log_max_size`

Property	Value
Command-Line Format	<code>--innodb-online-alter-log-max-size=#</code>
System Variable	<code>innodb_online_alter_log_max_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	65536
Maximum Value	$2^{*}64-1$

Specifies an upper limit in bytes on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

Property	Value
Command-Line Format	<code>--innodb-open-files=#</code>
System Variable	<code>innodb_open_files</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	10
Maximum Value	4294967295

This configuration option is only relevant if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of [.ibd files](#) that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if [innodb_file_per_table](#) is not enabled, and the higher of 300 and [table_open_cache](#) otherwise.

The file descriptors used for [.ibd files](#) are for [InnoDB tables](#) only. They are independent of those specified by the [--open-files-limit](#) server option, and do not affect the operation of the table cache. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_optimize_fulltext_only](#)

Property	Value
Command-Line Format	--innodb-optimize-fulltext-only=#
System Variable	innodb_optimize_fulltext_only
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Changes the way [OPTIMIZE TABLE](#) operates on [InnoDB tables](#). Intended to be enabled temporarily, during maintenance operations for [InnoDB tables](#) with [FULLTEXT](#) indexes.

By default, [OPTIMIZE TABLE](#) reorganizes data in the [clustered index](#) of the table. When this option is enabled, [OPTIMIZE TABLE](#) skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for [InnoDB FULLTEXT](#) indexes. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

- [innodb_page_cleaners](#)

Property	Value
Command-Line Format	--innodb-page-cleaners=#
System Variable	innodb_page_cleaners
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	64

The number of page cleaner threads that flush dirty pages from buffer pool instances. Page cleaner threads perform flush list and LRU flushing. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The [innodb_page_cleaners](#) default value is 4. If the number of page cleaner threads exceeds the number of buffer pool instances, [innodb_page_cleaners](#) is automatically set to the same value as [innodb_buffer_pool_instances](#).

If your workload is write-IO bound when flushing dirty pages from buffer pool instances to data files, and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multithreaded page cleaner support extends to shutdown and recovery phases.

The `setpriority()` system call is used on Linux platforms where it is supported, and where the `mysqld` execution user is authorized to give `page_cleaner` threads priority over other MySQL and InnoDB threads to help page flushing keep pace with the current workload. `setpriority()` support is indicated by this InnoDB startup message:

```
[Note] InnoDB: If the mysqld execution user is authorized, page cleaner
thread priority can be changed. See the man page of setpriority().
```

For systems where server startup and shutdown is not managed by `systemd`, `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For example, if `mysqld` is run under the `mysql` user, you can authorize the `mysql` user by adding these lines to `/etc/security/limits.conf`:

```
mysql          hard    nice    -20
mysql          soft    nice    -20
```

For `systemd` managed systems, the same can be achieved by specifying `LimitNICE=-20` in a localized `systemd` configuration file. For example, create a file named `override.conf` in `/etc/systemd/system/mysql.service.d/override.conf` and add this entry:

```
[Service]
LimitNICE=-20
```

After creating or changing `override.conf`, reload the `systemd` configuration, then tell `systemd` to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

For more information about using a localized `systemd` configuration file, see [Configuring systemd for MySQL](#).

After authorizing the `mysqld` execution user, use the `cat` command to verify the configured `Nice` limits for the `mysqld` process:

```
shell> cat /proc/mysqld_pid/limits | grep nice
Max nice priority          18446744073709551596 18446744073709551596
```

- `innodb_page_size`

Property	Value
Command-Line Format	<code>--innodb-page-size=#k</code>
System Variable	<code>innodb_page_size</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	16384
Valid Values	4096 8192 16384 32768 65536

Specifies the [page size](#) for [InnoDB tablespaces](#). Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

[innodb_page_size](#) can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See [Section 15.6.1, “InnoDB Startup Configuration”](#).

For both 32KB and 64KB page sizes, the maximum row length is approximately 16000 bytes. [ROW_FORMAT=COMPRESSED](#) is not supported when [innodb_page_size](#) is set to 32KB or 64KB. For [innodb_page_size=32KB](#), extent size is 2MB. For [innodb_page_size=64KB](#), extent size is 4MB. [innodb_log_buffer_size](#) should be set to at least 16M (the default) when using 32KB or 64KB page sizes.

The default 16KB page size or larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file ([ibdata1](#)) differs depending on the [innodb_page_size](#) value. See the [innodb_data_file_path](#) option description for more information.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_parallel_read_threads](#)

Property	Value
Command-Line Format	<code>--innodb-parallel-read-threads=#</code>
Introduced	8.0.14
System Variable	innodb_parallel_read_threads
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	256

Defines the number of threads that can be used for parallel index reads. Parallel index reads improve performance of non-locking `SELECT COUNT(*)` queries and `CHECK TABLE` operations. The `innodb_parallel_read_threads` session variable must be set to a value greater than 1 for or parallel index reads to occur. The actual number of threads used to perform a parallel index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller.

- `innodb_print_all_deadlocks`

Property	Value
Command-Line Format	<code>--innodb-print-all-deadlocks=#</code>
System Variable	<code>innodb_print_all_deadlocks</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When this option is enabled, information about all [deadlocks](#) in [InnoDB](#) user transactions is recorded in the [mysqld error log](#). Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional [InnoDB](#) deadlock is not necessarily an issue, because [InnoDB](#) detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

- `innodb_print_ddl_logs`

Property	Value
Command-Line Format	<code>--innodb-print-ddl-logs=#</code>
Introduced	8.0.3
System Variable	<code>innodb_print_ddl_logs</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	OFF

Enabling this option causes MySQL to write DDL logs to `stderr`. For more information, see [Viewing DDL Logs](#).

- `innodb_purge_batch_size`

Property	Value
Command-Line Format	<code>--innodb-purge-batch-size=#</code>
System Variable	<code>innodb_purge_batch_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	5000

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread. The `innodb_purge_batch_size` option also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The `innodb_purge_batch_size` option is intended for advanced performance tuning in combination with the `innodb_purge_threads` setting. Most MySQL users need not change `innodb_purge_batch_size` from its default value.

For related information, see [Section 15.6.10, “Configuring InnoDB Purge Scheduling”](#).

- `innodb_purge_threads`

Property	Value
Command-Line Format	<code>--innodb-purge-threads=#</code>
System Variable	<code>innodb_purge_threads</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	32

The number of background threads devoted to the [InnoDB purge](#) operation. A minimum value of 1 signifies that the purge operation is always performed by a background thread, never as part of the [master thread](#). Running the purge operation in one or more background threads helps reduce internal

contention within [InnoDB](#), improving scalability. Increasing the value to greater than 1 creates that many separate purge threads, which can improve efficiency on systems where [DML](#) operations are performed on multiple tables. The maximum is 32.

For related information, see [Section 15.6.10, “Configuring InnoDB Purge Scheduling”](#).

- `innodb_purge_rseg_truncate_frequency`

Property	Value
Command-Line Format	<code>--innodb-purge-rseg-truncate-frequency=#</code>
System Variable	<code>innodb_purge_rseg_truncate_frequency</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	128
Minimum Value	1
Maximum Value	128

Defines the frequency with which the purge system frees rollback segments in terms of the number of times that purge is invoked. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. The default value is 128. Reducing this value increases the frequency with which the purge thread frees rollback segments.

`innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see [Section 15.7.9, “Truncating Undo Tablespaces”](#).

- `innodb_random_read_ahead`

Property	Value
Command-Line Format	<code>--innodb-random-read-ahead=#</code>
System Variable	<code>innodb_random_read_ahead</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enables the random [read-ahead](#) technique for optimizing [InnoDB](#) I/O.

For details about performance considerations for different types of read-ahead requests, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

Property	Value
Command-Line Format	<code>--innodb-read-ahead-threshold=#</code>
System Variable	<code>innodb_read_ahead_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	56
Minimum Value	0
Maximum Value	64

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_read_ahead_threshold` setting. `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the [BUFFER POOL AND MEMORY](#) section of the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

Property	Value
Command-Line Format	<code>--innodb-read-io-threads=#</code>
System Variable	<code>innodb_read_io_threads</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	64

The number of I/O threads for read operations in [InnoDB](#). Its counterpart for write threads is [innodb_write_io_threads](#). For more information, see [Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for [innodb_read_io_threads](#), [innodb_write_io_threads](#), and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- [innodb_read_only](#)

Property	Value
Command-Line Format	<code>--innodb-read-only=#</code>
System Variable	innodb_read_only
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Starts [InnoDB](#) in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see [Section 15.6.2, “Configuring InnoDB for Read-Only Operation”](#).

Previously, enabling the [innodb_read_only](#) system variable prevented creating and dropping tables only for the [InnoDB](#) storage engine. As of MySQL 8.0, enabling [innodb_read_only](#) prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the `mysql` system database, but those tables use the [InnoDB](#) storage engine and cannot be modified when [innodb_read_only](#) is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:

- If the [innodb_read_only](#) system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use [InnoDB](#). For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.
- `ALTER TABLE tbl_name ENGINE=engine_name` fails because it updates the storage engine designation, which is stored in the data dictionary.

In addition, other tables in the `mysql` system database use the [InnoDB](#) storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. Examples:

- Account-management statements such as `CREATE USER` and `GRANT` fail because the grant tables use [InnoDB](#).
- The `INSTALL PLUGIN` and `UNINSTALL PLUGIN` plugin-management statements fail because the `plugin` table uses [InnoDB](#).

- The `CREATE FUNCTION` and `DROP FUNCTION` UDF-management statements fail because the `func` table uses InnoDB.
- `innodb_redo_log_encrypt`

Property	Value
Command-Line Format	<code>--innodb-redo-log-encrypt=#</code>
Introduced	8.0.1
System Variable	<code>innodb_redo_log_encrypt</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls encryption of redo log data for tables encrypted using the [InnoDB tablespace encryption feature](#). Encryption of redo log data is disabled by default. For more information, see [Redo Log Data Encryption](#).

- `innodb_replication_delay`

Property	Value
Command-Line Format	<code>--innodb-replication-delay=#</code>
System Variable	<code>innodb_replication_delay</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

The replication thread delay in milliseconds on a slave server if `innodb_thread_concurrency` is reached.

- `innodb_rollback_on_timeout`

Property	Value
Command-Line Format	<code>--innodb-rollback-on-timeout</code>
System Variable	<code>innodb_rollback_on_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	OFF

InnoDB **rolls back** only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction.

Note

If the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

For more information, see [Section 15.20.4, “InnoDB Error Handling”](#).

- `innodb_rollback_segments`

Property	Value
Command-Line Format	<code>--innodb-rollback-segments=#</code>
System Variable	<code>innodb_rollback_segments</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	128
Minimum Value	1
Maximum Value	128

`innodb_rollback_segments` defines the number of **rollback segments** allocated to the global temporary tablespace and each undo tablespace. Each rollback segment can support a maximum of 1023 data-modifying transactions.

For more information about rollback segments, see [Section 15.3, “InnoDB Multi-Versioning”](#). For information about undo tablespaces, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

- `innodb_scan_directories`

Property	Value
Command-Line Format	<code>--innodb-scan-directories=#</code>
Introduced	8.0.2
System Variable	<code>innodb_scan_directories</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

If, during recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces is referred to as tablespace discovery. Tablespace discovery depends on tablespace map files that map tablespace IDs in the redo logs to tablespace files. If tablespace map files are lost or corrupted, the `innodb_scan_directories` startup option can be used to specify tablespace file directories. This option causes InnoDB to read the first page of each tablespace file in the specified directories and recreate tablespace map files so that the recovery process can apply redo logs to affected tablespaces.

`innodb_scan_directories` may be specified as an option in a startup command or in a MySQL option file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-scan-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_scan_directories="directory_path_1;directory_path_2"
```

For more information, see [Lost or Corrupted Tablespace Map Files](#).

- `innodb_saved_page_number_debug`

Property	Value
Command-Line Format	<code>--innodb-saved-page-number-debug=#</code>
System Variable	<code>innodb_saved_page_number_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Maximum Value	$2^{23}-1$

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_sort_buffer_size`

Property	Value
Command-Line Format	<code>--innodb-sort-buffer-size=#</code>
System Variable	<code>innodb_sort_buffer_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	1048576
Minimum Value	65536
Maximum Value	67108864

Specifies the size of sort buffers used to sort data during creation of an [InnoDB](#) index. The specified size defines the amount of data that is read into memory for internal sorting and then written out to disk. This process is referred to as a “run”. During the merge phase, pairs of buffers of the specified size are read in and merged. The larger the setting, the fewer runs and merges there are.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended to record concurrent DML during [online DDL](#) operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), which remains the default.

During an [ALTER TABLE](#) or [CREATE TABLE](#) statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this one can be used to estimate memory consumption:

```
(6 /*FTS_NUM_AUX_INDEX*/ * (3*@@global.innodb_sort_buffer_size)
+ 2 * number_of_partitions * number_of_secondary_indexes_created
* (3*@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)
* 8 /*64-bit sizeof *buf->tuples*/)
```

`@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)` indicates the maximum tuples held. `2 * (3*@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*)` indicates auxiliary pointers allocated.

Note

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

```
(6 /*FTS_NUM_AUX_INDEX*/ * @@global.innodb_ft_sort_pll_degree)
```

- `innodb_spin_wait_delay`

Property	Value
Command-Line Format	<code>--innodb-spin-wait-delay=#</code>
System Variable	<code>innodb_spin_wait_delay</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	0
Maximum Value (64-bit platforms, <= 8.0.13)	$2^{64}-1$
Maximum Value (32-bit platforms, <= 8.0.13)	$2^{32}-1$
Maximum Value (>= 8.0.14)	1000

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see [Section 15.6.9, “Configuring Spin Lock Polling”](#).

- `innodb_stats_auto_recalc`

Property	Value
Command-Line Format	<code>--innodb-stats-auto-recalc=#</code>
System Variable	<code>innodb_stats_auto_recalc</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Causes InnoDB to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` configuration option.

For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_include_delete_marked`

Property	Value
Command-Line Format	<code>--innodb-stats-include-delete-marked=#</code>
Introduced	8.0.1
System Variable	<code>innodb_stats_include_delete_marked</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

By default, [InnoDB](#) reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, [InnoDB](#) excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than [READ UNCOMMITTED](#). To avoid this scenario, [innodb_stats_include_delete_marked](#) can be enabled to ensure that [InnoDB](#) includes delete-marked records when calculating persistent optimizer statistics.

When [innodb_stats_include_delete_marked](#) is enabled, [ANALYZE TABLE](#) considers delete-marked records when recalculating statistics.

[innodb_stats_include_delete_marked](#) is a global setting that affects all [InnoDB](#) tables. It is only applicable to persistent optimizer statistics.

For related information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb_stats_method](#)

Property	Value
Command-Line Format	<code>--innodb-stats-method=name</code>
System Variable	innodb_stats_method
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	nulls_equal
Valid Values	nulls_equal nulls_unequal nulls_ignored

How the server treats [NULL](#) values when collecting [statistics](#) about the distribution of index values for [InnoDB](#) tables. Permitted values are [nulls_equal](#), [nulls_unequal](#), and [nulls_ignored](#). For [nulls_equal](#), all [NULL](#) index values are considered equal and form a single value group with a size equal to the number of [NULL](#) values. For [nulls_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls_ignored](#), [NULL](#) values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

- [innodb_stats_on_metadata](#)

Property	Value
Command-Line Format	<code>--innodb-stats-on-metadata</code>
System Variable	innodb_stats_on_metadata
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Boolean
Default Value	OFF

This option only applies when optimizer [statistics](#) are configured to be non-persistent. Optimizer statistics are not persisted to disk when `innodb_stats_persistent` is disabled or when individual tables are created or altered with `STATS_PERSISTENT=0`. For more information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

When `innodb_stats_on_metadata` is enabled, InnoDB updates non-persistent [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)) and immediately affects the operation of all connections.

- `innodb_stats_persistent`

Property	Value
Command-Line Format	<code>--innodb-stats-persistent=setting</code>
System Variable	<code>innodb_stats_persistent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON
Valid Values	OFF ON 0 1

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

Property	Value
Command-Line Format	<code>--innodb-stats-persistent-sample-pages=#</code>
System Variable	<code>innodb_stats_persistent_sample_pages</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	20

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of `ANALYZE TABLE` for an InnoDB table. For more information, see [Section 15.6.11.1](#), “Configuring Persistent Optimizer Statistics Parameters”.

Note

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 15.6.11.3](#), “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

`innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.

- `innodb_stats_transient_sample_pages`

Property	Value
Command-Line Format	<code>--innodb-stats-transient-sample-pages=#</code>
System Variable	<code>innodb_stats_transient_sample_pages</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see [Section 15.6.11.2](#), “Configuring Non-Persistent Optimizer Statistics Parameters”.

**Note**

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages`. For more information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

- `innodb_status_output`

Property	Value
Command-Line Format	<code>--innodb-status-output</code>
System Variable	<code>innodb_status_output</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enables or disables periodic output for the standard `InnoDB` Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the `InnoDB` Lock Monitor. For more information, see [Section 15.16.2, “Enabling InnoDB Monitors”](#).

- `innodb_status_output_locks`

Property	Value
Command-Line Format	<code>--innodb-status-output-lock</code>
System Variable	<code>innodb_status_output_locks</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enables or disables the `InnoDB` Lock Monitor. When enabled, the `InnoDB` Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the `InnoDB` Lock Monitor is printed as part of the standard `InnoDB` Monitor output. The standard `InnoDB` Monitor must therefore be enabled for the `InnoDB` Lock Monitor to print data to the MySQL error log periodically. For more information, see [Section 15.16.2, “Enabling InnoDB Monitors”](#).

- `innodb_strict_mode`

Property	Value
Command-Line Format	<code>--innodb-strict-mode=#</code>
System Variable	<code>innodb_strict_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings for certain conditions.

Strict mode helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is enabled, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is disabled, InnoDB ignores conflicting clauses and creates the table or index with only a warning in the message log. The resulting table might have different characteristics than intended, such as lack of compression support when attempting to create a compressed table. When `innodb_strict_mode` is enabled, such problems generate an immediate error and the table or index is not created.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL [configuration file](#). You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to [general tablespaces](#). Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.19, “CREATE TABLESPACE Syntax”](#).

- `innodb_sync_array_size`

Property	Value
Command-Line Format	<code>--innodb-sync-array-size=#</code>
System Variable	<code>innodb_sync_array_size</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	1024

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- [innodb_sync_spin_loops](#)

Property	Value
Command-Line Format	<code>--innodb-sync-spin-loops=#</code>
System Variable	innodb_sync_spin_loops
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	4294967295

The number of times a thread waits for an [InnoDB](#) mutex to be freed before the thread is suspended.

- [innodb_sync_debug](#)

Property	Value
Command-Line Format	<code>--innodb-sync-debug=#</code>
System Variable	innodb_sync_debug
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enables sync debug checking for the [InnoDB](#) storage engine. This option is only available if debugging support is compiled in using the [WITH_DEBUG CMake](#) option.

- [innodb_table_locks](#)

Property	Value
Command-Line Format	<code>--innodb-table-locks</code>
System Variable	<code>innodb_table_locks</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	TRUE

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

In MySQL 8.0, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

For related information, see [Section 15.5, “InnoDB Locking and Transaction Model”](#).

- `innodb_temp_data_file_path`

Property	Value
Command-Line Format	<code>--innodb-temp-data-file-path=file</code>
System Variable	<code>innodb_temp_data_file_path</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>ibtmp1:12M:autoextend</code>

Defines the relative path, name, size, and attributes of [InnoDB temporary tablespace data files](#). If you do not specify a value for `innodb_temp_data_file_path`, the default behavior is to create a single, auto-extending data file named `ibtmp1` in the MySQL data directory. The initial file size is slightly larger than 12MB.

The full syntax for a temporary tablespace data file specification includes the file name, file size, and `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The temporary tablespace data file cannot have the same name as another [InnoDB data file](#). Any inability or error creating a temporary tablespace data file is treated as fatal and server startup is refused. The temporary tablespace has a dynamically generated space ID, which can change on each server restart.

File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. Use of raw disk partitions for temporary tablespace data files is not supported.

The `autoextend` and `max` attributes can be used only for the data file that is specified last in the `innodb_temp_data_file_path` setting. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:50M:ibtmp2:12M:autoextend:max:500MB
```

If you specify the `autoextend` option, InnoDB extends the data file if it runs out of free space. The `autoextend` increment is 64MB by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

The full directory path for temporary tablespace data files is formed by concatenating the paths defined by `innodb_data_home_dir` and `innodb_temp_data_file_path`.

The temporary tablespace is shared by all InnoDB temporary tables.

Before running InnoDB in read-only mode, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

```
--innodb_temp_data_file_path=../../tmp/ibtmp1:12M:autoextend
```

Metadata about active InnoDB temporary tables is located in `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO`.

For related information, see [Section 15.4.11, “Temporary Tablespace”](#).

- `innodb_temp_tablespaces_dir`

Property	Value
Command-Line Format	<code>--innodb-temp-tablespaces-dir=dir_name</code>
Introduced	8.0.13
System Variable	<code>innodb_temp_tablespaces_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	<code>#innodb_temp</code>

Defines the location where InnoDB creates a pool of session temporary tablespaces at startup. The default location is the `#innodb_temp` directory in the data directory. A fully qualified path or path relative to the data directory is permitted.

Session temporary tablespaces store user-created temporary tables and internal temporary tables created by the optimizer when InnoDB is configured as the on-disk storage engine for internal temporary tables. The `internal_tmp_disk_storage_engine` variable defines the storage engine for on-disk internal temporary tables and is set to InnoDB by default.

- `innodb_thread_concurrency`

Property	Value
Command-Line Format	<code>--innodb-thread-concurrency=#</code>
System Variable	<code>innodb_thread_concurrency</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128` and then lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the virtual CPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the virtual CPUs but also allow other applications to use some or all of the virtual CPUs.

**Note**

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.
- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of virtual CPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_thread_sleep_delay`

Property	Value
Command-Line Format	<code>--innodb-thread-sleep-delay=#</code>
System Variable	<code>innodb_thread_sleep_delay</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	1000000

How long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_tmpdir`

Property	Value
Command-Line Format	<code>--innodb-tmpdir=path</code>
System Variable	<code>innodb_tmpdir</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Directory name
Default Value	NULL

Used to define an alternate directory for temporary sort files created during online [ALTER TABLE](#) operations that rebuild the table.

Online [ALTER TABLE](#) operations that rebuild the table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration option). If a directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a [SET](#) statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online [ALTER TABLE](#) operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online [ALTER TABLE](#) operations.

The [FILE](#) privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online [ALTER TABLE](#) operations that rebuild the table.

In replication environments, only consider replicating the `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating the `innodb_tmpdir` setting could result in a replication failure when running online [ALTER TABLE](#) operations that rebuild the table. If server operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For more information, see [Section 15.12.3, “Online DDL Space Requirements”](#). For information about online [ALTER TABLE](#) operations, see [Section 15.12, “InnoDB and Online DDL”](#).

- `innodb_trx_purge_view_update_only_debug`

Property	Value
Command-Line Format	<code>--innodb-trx-purge-view-update-only-debug=#</code>
System Variable	<code>innodb_trx_purge_view_update_only_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

Property	Value
Command-Line Format	<code>--innodb-trx-rseg-n-slots-debug=#</code>
System Variable	<code>innodb_trx_rseg_n_slots_debug</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Maximum Value	1024

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_undo_directory`

Property	Value
Command-Line Format	<code>--innodb-undo-directory=dir_name</code>
System Variable	<code>innodb_undo_directory</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path where InnoDB creates undo tablespaces. Typically used to place undo logs on a different storage device. Used in conjunction with `innodb_rollback_segments` and `innodb_undo_tablespaces`.

There is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.

For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

- `innodb_undo_log_encrypt`

Property	Value
Command-Line Format	<code>--innodb-undo-log-encrypt=#</code>
Introduced	8.0.1
System Variable	<code>innodb_undo_log_encrypt</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls encryption of undo log data for tables encrypted using the [InnoDB tablespace encryption feature](#). Only applies to undo logs that reside in separate [undo tablespaces](#). See [Section 15.7.8, “Configuring Undo Tablespaces”](#). Encryption is not supported for undo log data that resides in the system tablespace. For more information, see [Undo Log Data Encryption](#).

- [innodb_undo_log_truncate](#)

Property	Value
Command-Line Format	<code>--innodb-undo-log-truncate=#</code>
System Variable	innodb_undo_log_truncate
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value (>= 8.0.2)	ON
Default Value (<= 8.0.1)	OFF

When enabled, undo tablespaces that exceed the threshold value defined by [innodb_max_undo_log_size](#) are marked for truncation. Only undo tablespaces can be truncated. Truncating undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces.

The [innodb_purge_rseg_truncate_frequency](#) configuration option can be used to expedite truncation of undo tablespaces.

For more information, see [Section 15.7.9, “Truncating Undo Tablespaces”](#).

- [innodb_undo_logs](#)

Property	Value
Command-Line Format	<code>--innodb-undo-logs=#</code>
Deprecated	Yes (removed in 8.0.2)
System Variable	innodb_undo_logs
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	128
Minimum Value	1
Maximum Value	128

Note

[innodb_undo_logs](#) was removed in MySQL 8.0.2.

The [innodb_undo_logs](#) option is an alias for [innodb_rollback_segments](#). For more information, see the description of [innodb_rollback_segments](#).

- `innodb_undo_tablespaces`

Property	Value
Command-Line Format	<code>--innodb-undo-tablespaces=#</code>
Deprecated	8.0.4
System Variable	<code>innodb_undo_tablespaces</code>
Scope	Global
Dynamic ($\geq 8.0.2$)	Yes
Dynamic ($\leq 8.0.1$)	No
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.2$)	2
Default Value ($\leq 8.0.1$)	0
Minimum Value ($\geq 8.0.3$)	2
Minimum Value ($\leq 8.0.2$)	0
Maximum Value ($\geq 8.0.2$)	127
Maximum Value ($\leq 8.0.1$)	95

The number of `undo tablespaces` used by InnoDB. The default and minimum value is 2.

Note

`innodb_undo_tablespaces` is deprecated and will be removed in a future release.

Undo logs can become large during long-running transactions. Using multiple undo tablespaces reduces the size of any one undo tablespace.

In previous releases, `innodb_undo_tablespaces` could be set to 0 to use the system tablespace for rollback segments. A value greater than 0 meant that rollback segments in the system tablespace were no longer assigned to transactions. As of MySQL 8.0, a setting of 0 is no longer permitted and rollback segments are only created in undo tablespaces.

Undo tablespace files are created in the location defined by `innodb_undo_directory`. File names are in the form of `undo_NNN`, where `NNN` is the undo space number.

The initial size of an undo tablespace file depends on the `innodb_page_size` value. For the default 16KB InnoDB page size, the initial undo tablespace file size is 10MiB. For 4KB, 8KB, 32KB, and 64KB page sizes, the initial undo tablespace files sizes are 7MiB, 8MiB, 20MiB, and 40MiB, respectively.

`innodb_undo_tablespaces` may be configured at startup or while the server is running. Increasing the `innodb_undo_tablespaces` setting creates the specified number of undo tablespaces and adds them to the list of active undo tablespaces. Decreasing the `innodb_undo_tablespaces` setting removes undo tablespaces from the list of active undo tablespaces. However, these undo tablespaces remain active until they are no longer used by existing transactions. Undo tablespaces are made inactive rather than deleted so that the number of active undo tablespaces can be increased again easily.

For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

- `innodb_use_native_aio`

Property	Value
Command-Line Format	<code>--innodb-use-native-aio=#</code>
System Variable	<code>innodb_use_native_aio</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

The [asynchronous I/O](#) capability that [InnoDB](#) has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output.

Running with a large number of [InnoDB](#) I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents [InnoDB](#) from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if [InnoDB](#) detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

For more information, see [Section 15.6.7, “Using Asynchronous I/O on Linux”](#).

- `innodb_version`

The [InnoDB](#) version number. In MySQL 8.0, separate version numbering for [InnoDB](#) does not apply and this value is the same the `version` number of the server.

- `innodb_write_io_threads`

Property	Value
Command-Line Format	<code>--innodb-write-io-threads=#</code>
System Variable	<code>innodb_write_io_threads</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4

Property	Value
Minimum Value	1
Maximum Value	64

The number of I/O threads for write operations in [InnoDB](#). The default value is 4. Its counterpart for read threads is [innodb_read_io_threads](#). For more information, see [Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for [innodb_read_io_threads](#), [innodb_write_io_threads](#), and the Linux [aio-max-nr](#) setting can exceed system limits. Ideally, increase the [aio-max-nr](#) setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

Also take into consideration the value of [sync_binlog](#), which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.14 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for [InnoDB INFORMATION_SCHEMA](#) tables.

[InnoDB INFORMATION_SCHEMA](#) tables provide metadata, status information, and statistics about various aspects of the [InnoDB](#) storage engine. You can view a list of [InnoDB INFORMATION_SCHEMA](#) tables by issuing a [SHOW TABLES](#) statement on the [INFORMATION_SCHEMA](#) database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 24.36, “INFORMATION_SCHEMA InnoDB Tables”](#). For general information regarding the [MySQL INFORMATION_SCHEMA](#) database, see [Chapter 24, INFORMATION_SCHEMA Tables](#).

15.14.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of [InnoDB INFORMATION_SCHEMA](#) tables about compression that can provide insight into how well compression is working overall:

- [INNODB_CMP](#) and [INNODB_CMP_RESET](#) provide information about the number of compression operations and the amount of time spent performing compression.
- [INNODB_CMPMEM](#) and [INNODB_CMP_RESET](#) provide information about the way memory is allocated for compression.

15.14.1.1 INNODB_CMP and INNODB_CMP_RESET

The [INNODB_CMP](#) and [INNODB_CMP_RESET](#) tables provide status information about operations related to compressed tables, which are described in [Section 15.9, “InnoDB Table and Page Compression”](#). The [PAGE_SIZE](#) column reports the compressed [page size](#).

These two tables have identical contents, but reading from [INNODB_CMP_RESET](#) resets the statistics on compression and uncompression operations. For example, if you archive the output of

[INNODB_CMP_RESET](#) every 60 minutes, you see the statistics for each hourly period. If you monitor the output of [INNODB_CMP](#) (making sure never to read [INNODB_CMP_RESET](#)), you see the cumulative statistics since InnoDB was started.

For the table definition, see [Section 24.36.5, “The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables”](#).

15.14.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The [INNODB_CMPMEM](#) and [INNODB_CMPMEM_RESET](#) tables provide status information about compressed pages that reside in the buffer pool. Please consult [Section 15.9, “InnoDB Table and Page Compression”](#) for further information on compressed tables and the use of the buffer pool. The [INNODB_CMP](#) and [INNODB_CMP_RESET](#) tables should provide more useful statistics on compression.

Internal Details

InnoDB uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The [INNODB_CMPMEM](#) and [INNODB_CMPMEM_RESET](#) tables have identical contents, but reading from [INNODB_CMPMEM_RESET](#) resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of [INNODB_CMPMEM_RESET](#), it would show the hourly statistics. If you never read [INNODB_CMPMEM_RESET](#) and monitored the output of [INNODB_CMPMEM](#) instead, it would show the cumulative statistics since InnoDB was started.

For the table definition, see [Section 24.36.6, “The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables”](#).

15.14.1.3 Using the Compression Information Schema Tables

Example 15.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 15.9, “InnoDB Table and Page Compression”](#), [INNODB_CMP](#), [INNODB_CMP_PER_INDEX](#), and [INNODB_CMPMEM](#)).

The following table shows the contents of [INFORMATION_SCHEMA.INNODB_CMP](#) under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns [COMPRESS_TIME](#) and [UNCOMPRESS_TIME](#) are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to [INNODB_CMPMEM](#), there are 6169 compressed 8KB pages in the [buffer pool](#). The only other allocated block size is 64 bytes. The smallest [PAGE_SIZE](#) in [INNODB_CMPMEM](#) is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see

that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light workload. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

page size	pages used	pages free	relocation ops	relocation time
64	5910	0	2436	0
128	0	1	0	0
256	0	0	0	0
512	0	1	0	0
1024	0	0	0	0
2048	0	1	0	0
4096	0	1	0	0
8192	6169	0	5	0
16384	0	0	0	0

15.14.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA.INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [InnoDB INFORMATION_SCHEMA Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

One `INFORMATION_SCHEMA` table and two Performance Schema tables enable you to monitor InnoDB transactions and diagnose potential locking problems:

- `INNODB_TRX`: This `INFORMATION_SCHEMA` table provides information about every transaction currently executing inside InnoDB, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- `data_locks`: This Performance Schema table contains a row for each held lock and each lock request that is blocked waiting for a held lock to be released:
 - There is one row for each held lock, whatever the state of the transaction that holds the lock (`INNODB_TRX.TRX_STATE` is `RUNNING`, `LOCK WAIT`, `ROLLING BACK` or `COMMITTING`).
 - Each transaction in InnoDB that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE` is `LOCK WAIT`) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock request always has a mode that is incompatible with the mode of the held lock that blocks the request (read vs. write, shared vs. exclusive).

The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `data_locks` contains one row that describes each lock the transaction has requested, and for which it is waiting.

- `data_lock_waits`: This Performance Schema table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTING_ENGINE_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_ENGINE_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `data_lock_waits` have the same value for `REQUESTING_ENGINE_LOCK_ID` and different values for `BLOCKING_ENGINE_LOCK_ID`.

For more information about the preceding tables, see [Section 24.36.29, “The INFORMATION_SCHEMA INNODB_TRX Table”](#), [Section 25.11.12.1, “The data_locks Table”](#), and [Section 25.11.12.2, “The data_lock_waits Table”](#).

15.14.2.1 Using InnoDB Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [Using InnoDB Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about InnoDB transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 15.14.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”](#).)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```

SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM
  performance_schema.data_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_engine_transaction_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_engine_transaction_id;

```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```

SELECT
  waiting_trx_id,
  waiting_pid,
  waiting_query,
  blocking_trx_id,
  blocking_pid,
  blocking_query
FROM sys.innodb_lock_waits;

```

If a NULL value is reported for the blocking query, see [Identifying a Blocking Query After the Issuing Session Becomes Idle](#).

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id [A4](#), thread [6](#)) and Session C (trx id [A5](#), thread [7](#)) are both waiting for Session A (trx id [A3](#), thread [5](#)).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the `INFORMATION_SCHEMA INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables.

The following table shows some sample contents of the `INNODB_TRX` table.

trx id	trx state	trx started
A3	RUNNING	2008-01-15 16:44:54
A4	LOCK WAIT	2008-01-15 16:45:09
A5	LOCK WAIT	2008-01-15 16:45:14

The following table shows some sample contents of the `data_locks` table.

lock id	lock trx id	lock mode	lock type
A3:1:3:2	A3	X	RECORD
A4:1:3:2	A4	X	RECORD

lock id	lock trx id	lock mode	lock type
A5:1:3:2	A5	X	RECORD

The following table shows some sample contents of the `data_lock_waits` table.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A4	A4:1:3:2

Identifying a Blocking Query After the Issuing Session Becomes Idle

When identifying blocking transactions, a NULL value is reported for the blocking query if the session that issued the query has become idle. In this case, use the following steps to determine the blocking query:

1. Identify the processlist ID of the blocking transaction. In the `sys.innodb_lock_waits` table, the processlist ID of the blocking transaction is the `blocking_pid` value.
2. Using the `blocking_pid`, query the MySQL Performance Schema `threads` table to determine the `THREAD_ID` of the blocking transaction. For example, if the `blocking_pid` is 6, issue this query:

```
SELECT THREAD_ID FROM performance_schema.threads WHERE PROCESSLIST_ID = 6;
```

3. Using the `THREAD_ID`, query the Performance Schema `events_statements_current` table to determine the last query executed by the thread. For example, if the `THREAD_ID` is 28, issue this query:

```
SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_current
WHERE THREAD_ID = 28\G
```

4. If the last query executed by the thread is not enough information to determine why a lock is held, you can query the Performance Schema `events_statements_history` table to view the last 10 statements executed by the thread.

```
SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_history
WHERE THREAD_ID = 28 ORDER BY EVENT_ID;
```

Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `data_locks` and `data_lock_waits` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.

- Transaction [77D](#) (executing an [INSERT](#)) is waiting for transaction [77B](#) to commit.
- Transaction [77B](#) (executing an [INSERT](#)) is waiting for transaction [77A](#) to commit.
- Transaction [77A](#) is running, currently executing [SELECT](#).
- Transaction [E56](#) (executing an [INSERT](#)) is waiting for transaction [E55](#) to commit.
- Transaction [E55](#) (executing an [INSERT](#)) is waiting for transaction [19C](#) to commit.
- Transaction [19C](#) is running, currently executing an [INSERT](#).

**Note**

There may be inconsistencies between queries shown in the [INFORMATION_SCHEMA PROCESSLIST](#) and [INNODB_TRX](#) tables. For an explanation, see [Section 15.14.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of the [PROCESSLIST](#) table for a system running a heavy [workload](#).

ID	USER	HOST	DB	COMMAND	TIME	STATE
384	root	localhost	test	Query	10	update
257	root	localhost	test	Query	3	update
130	root	localhost	test	Query	0	update
61	root	localhost	test	Query	1	update
8	root	localhost	test	Query	1	update
4	root	localhost	test	Query	0	prepar
2	root	localhost	test	Sleep	566	

The following table shows the contents of the [INNODB_TRX](#) table for a system running a heavy [workload](#).

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight
77F	LOCK WAIT	2008-01-15 13:10:16	77F	2008-01-15 13:10:16	1
77E	LOCK WAIT	2008-01-15 13:10:16	77E	2008-01-15 13:10:16	1
77D	LOCK WAIT	2008-01-15 13:10:16	77D	2008-01-15 13:10:16	1
77B	LOCK WAIT	2008-01-15 13:10:16	77B:733:12:1	2008-01-15 13:10:16	4
77A	RUNNING	2008-01-15 13:10:16	NULL	NULL	4

15.14.2.2 InnoDB Lock and Lock-Wait Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede

the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [InnoDB Lock and Lock-Wait Information](#) in [MySQL 5.7 Reference Manual](#).

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA INNODB_TRX` table indicates transaction state values.)

The Performance Schema `data_locks` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The Performance Schema `data_lock_waits` table shows which locks already held by a transaction are blocking locks requested by other transactions.

15.14.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [Persistence and Consistency of InnoDB Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

The data exposed by the transaction and locking tables (`INFORMATION_SCHEMA INNODB_TRX` table, Performance Schema `data_locks` and `data_lock_waits` tables) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly:

- Data might not be consistent between the `INNODB_TRX`, `data_locks`, and `data_lock_waits` tables.

The `data_locks` and `data_lock_waits` tables expose live data from the InnoDB storage engine, to provide lock information about the transactions in the `INNODB_TRX` table. Data retrieved from the lock tables exists when the `SELECT` is executed, but might be gone or changed by the time the query result is consumed by the client.

Joining `data_locks` with `data_lock_waits` can show rows in `data_lock_waits` that identify a parent row in `data_locks` that no longer exists or does not exist yet.

- Data in the transaction and locking tables might not be consistent with data in the `INFORMATION_SCHEMA PROCESSLIST` table or Performance Schema `threads` table.

For example, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. Even if you issue a single `SELECT` (joining `INNODB_TRX`

and `PROCESSLIST`, for example), the content of those tables is generally not consistent. It is possible for `INNODB_TRX` to reference rows that are not present in `PROCESSLIST` or for the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` to differ from the one in `PROCESSLIST.INFO`.

15.14.3 InnoDB INFORMATION_SCHEMA Schema Object Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` tables. This information comes from the data dictionary. Traditionally, you would get this type of information using the techniques from [Section 15.16, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB `INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

InnoDB `INFORMATION_SCHEMA` schema object tables include the tables listed below.

```
INNODB_DATAFILES
INNODB_TABLESTATS
INNODB_FOREIGN
INNODB_COLUMNS
INNODB_INDEXES
INNODB_FIELDS
INNODB_TABLESPACES
INNODB_TABLESPACES_BRIEF
INNODB_FOREIGN_COLS
INNODB_TABLES
```

The table names are indicative of the type of data provided:

- `INNODB_TABLES` provides metadata about InnoDB tables.
- `INNODB_COLUMNS` provides metadata about InnoDB table columns.
- `INNODB_INDEXES` provides metadata about InnoDB indexes.
- `INNODB_FIELDS` provides metadata about the key columns (fields) of InnoDB indexes.
- `INNODB_TABLESTATS` provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures.
- `INNODB_DATAFILES` provides data file path information for InnoDB file-per-table and general tablespaces.
- `INNODB_TABLESPACES` provides metadata about InnoDB file-per-table and general tablespaces.
- `INNODB_TABLESPACES_BRIEF` provides a subset of metadata about InnoDB tablespaces.
- `INNODB_FOREIGN` provides metadata about foreign keys defined on InnoDB tables.
- `INNODB_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on InnoDB tables.

InnoDB `INFORMATION_SCHEMA` schema object tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the [InnoDB INFORMATION_SCHEMA](#) documentation for information about the columns of each table.

Example 15.2 InnoDB INFORMATION_SCHEMA Schema Object Tables

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the `InnoDB INFORMATION_SCHEMA` schema object tables.

1. Create a test database and table `t1`:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
    col1 INT,
    col2 CHAR(10),
    col3 VARCHAR(10))
    ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table `t1`, query `INNODB_TABLES` to locate the metadata for `test/t1`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
        FLAG: 1
      N_COLS: 6
      SPACE: 57
    ROW_FORMAT: Compact
  ZIP_PAGE_SIZE: 0
  INSTANT_COLS: 0
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format. `INSTANT_COLS` shows number of columns in the table prior to adding the first instant column using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT`.

3. Using the `TABLE_ID` information from `INNODB_TABLES`, query the `INNODB_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
      TABLE_ID: 71
        NAME: col1
        POS: 0
        MTYPE: 6
      PRTYPE: 1027
        LEN: 4
    HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL
***** 2. row *****
      TABLE_ID: 71
        NAME: col2
        POS: 1
        MTYPE: 2
      PRTYPE: 524542
        LEN: 10
    HAS_DEFAULT: 0
```

```

DEFAULT_VALUE: NULL
***** 3. row *****
TABLE_ID: 71
NAME: col3
POS: 2
MTYPE: 1
PRTYPE: 524303
LEN: 10
HAS_DEFAULT: 0
DEFAULT_VALUE: NULL

```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`). The `HAS_DEFAULT` and `DEFAULT_VALUE` columns only apply to columns added instantly using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT`.

- Using the `TABLE_ID` information from `INNODB_TABLES` once again, query `INNODB_INDEXES` for information about the indexes associated with table `t1`.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
INDEX_ID: 111
NAME: GEN_CLUST_INDEX
TABLE_ID: 71
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 57
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 112
NAME: i1
TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 50

```

`INNODB_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by InnoDB if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_INDEXES`, query `INNODB_FIELDS` for information about the fields of index `i1`.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FIELDS where INDEX_ID = 112 \G
***** 1. row *****

```

```
INDEX_ID: 112
NAME: col1
POS: 0
```

`INNODB_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (i1) had been defined on multiple fields, `INNODB_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_TABLES`, query `INNODB_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
      SPACE: 57
      NAME: test/t1
      FLAG: 16417
      ROW_FORMAT: Dynamic
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
      FS_BLOCK_SIZE: 4096
      FILE_SIZE: 114688
      ALLOCATED_SIZE: 98304
      SERVER_VERSION: 8.0.4
      SPACE_VERSION: 1
      ENCRYPTION: N
```

In addition to the `SPACE` ID of the tablespace and the `NAME` of the associated table, `INNODB_TABLESPACES` provides tablespace `FLAG` data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace `ROW_FORMAT`, `PAGE_SIZE`, and several other tablespace metadata items.

- Using the `SPACE` information from `INNODB_TABLES` once again, query `INNODB_DATAFILES` for the location of the tablespace data file.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
      SPACE: 57
      PATH: ./test/t1.ibd
```

The datafile is located in the `test` directory under MySQL's `data` directory. If a `file-per-table` tablespace were created in a location outside the MySQL data directory using the `DATA DIRECTORY` clause of the `CREATE TABLE` statement, the tablespace `PATH` would be a fully qualified directory path.

- As a final step, insert a row into table `t1` (`TABLE_ID = 71`) and view the data in the `INNODB_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures.

```
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
      NAME: test/t1
      STATS_INITIALIZED: Initialized
      NUM_ROWS: 1
      CLUST_INDEX_SIZE: 1
      OTHER_INDEX_SIZE: 0
```

```

MODIFIED_COUNTER: 1
  AUTOINC: 0
  REF_COUNT: 1

```

The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

Example 15.3 Foreign Key INFORMATION_SCHEMA Schema Object Tables

The `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables.

1. Create the test database with parent and child tables:

```

mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
  PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
  INDEX par_ind (parent_id),
  CONSTRAINT fk1
  FOREIGN KEY (parent_id) REFERENCES parent(id)
  ON DELETE CASCADE) ENGINE=INNODB;

```

2. After the parent and child tables are created, query `INNODB_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN \G
***** 1. row *****
      ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
  N_COLS: 1
    TYPE: 1

```

Metadata includes the foreign key ID (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key ID, query `INNODB_FOREIGN_COLS` to view data about the columns of the foreign key.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1

```

```
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

Example 15.4 Joining InnoDB INFORMATION_SCHEMA Schema Object Tables

This example demonstrates joining three `InnoDB INFORMATION_SCHEMA` schema object tables (`INNODB_TABLES`, `INNODB_TABLESPACES`, and `INNODB_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_TABLES: a`
- `INFORMATION_SCHEMA.INNODB_TABLESPACES: b`
- `INFORMATION_SCHEMA.INNODB_TABLESTATS: c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.ROW_FORMAT,
      @page_size :=
        IF(a.ROW_FORMAT='Compressed',
          b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
      AS page_size,
      ROUND((@page_size * c.CLUST_INDEX_SIZE)
        /(1024*1024)) AS pk_mb,
      ROUND((@page_size * c.OTHER_INDEX_SIZE)
        /(1024*1024)) AS secidx_mb
      FROM INFORMATION_SCHEMA.INNODB_TABLES a
      INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESPACES b on a.NAME = b.NAME
      INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESTATS c on b.NAME = c.NAME
      WHERE a.NAME LIKE 'employees/%'
      ORDER BY a.NAME DESC;
```

NAME	ROW_FORMAT	page_size	pk_mb	secidx_mb
employees/titles	Dynamic	16384	20	11
employees/salaries	Dynamic	16384	93	34
employees/employees	Dynamic	16384	15	0
employees/dept_manager	Dynamic	16384	0	0
employees/dept_emp	Dynamic	16384	12	10
employees/departments	Dynamic	16384	0	0

15.14.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for `FULLTEXT` indexes:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_FT%) |
+-----+
| INNODB_FT_CONFIG                           |
| INNODB_FT_BEING_DELETED                   |
```

INNODB_FT_DELETED	
INNODB_FT_DEFAULT_STOPWORD	
INNODB_FT_INDEX_TABLE	
INNODB_FT_INDEX_CACHE	

Table Overview

- **INNODB_FT_CONFIG**: Provides metadata about the **FULLTEXT** index and associated processing for an InnoDB table.
- **INNODB_FT_BEING_DELETED**: Provides a snapshot of the **INNODB_FT_DELETED** table; it is used only during an **OPTIMIZE TABLE** maintenance operation. When **OPTIMIZE TABLE** is run, the **INNODB_FT_BEING_DELETED** table is emptied, and **DOC_ID** values are removed from the **INNODB_FT_DELETED** table. Because the contents of **INNODB_FT_BEING_DELETED** typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running **OPTIMIZE TABLE** on tables with **FULLTEXT** indexes, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- **INNODB_FT_DELETED**: Stores rows that are deleted from the **FULLTEXT** index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB **FULLTEXT** index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an **OPTIMIZE TABLE** statement for the InnoDB table.
- **INNODB_FT_DEFAULT_STOPWORD**: Holds a list of **stopwords** that are used by default when creating a **FULLTEXT** index on InnoDB tables.

For information about the **INNODB_FT_DEFAULT_STOPWORD** table, see [Section 12.9.4, “Full-Text Stopwords”](#).

- **INNODB_FT_INDEX_TABLE**: Provides information about the inverted index used to process text searches against the **FULLTEXT** index of an InnoDB table.
- **INNODB_FT_INDEX_CACHE**: Provides token information about newly inserted rows in a **FULLTEXT** index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when **OPTIMIZE TABLE** is run, when the server is shut down, or when the cache size exceeds a limit defined by the **innodb_ft_cache_size** or **innodb_ft_total_cache_size** system variable.

Note

With the exception of the **INNODB_FT_DEFAULT_STOPWORD** table, these tables are empty initially. Before querying any of them, set the value of the **innodb_ft_aux_table** system variable to the name (including the database name) of the table that contains the **FULLTEXT** index; for example **test/articles**.

Example 15.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables

This example uses a table with a **FULLTEXT** index to demonstrate the data contained in the **FULLTEXT** index **INFORMATION_SCHEMA** tables.

1. Create a table with a **FULLTEXT** index and insert some data:

```
mysql> CREATE TABLE articles (
      id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
      title VARCHAR(200),
```

```

        body TEXT,
        FULLTEXT (title,body)
    ) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
    ('MySQL Tutorial','DBMS stands for DataBase ...'),
    ('How To Use MySQL Well','After you went through a ...'),
    ('Optimizing MySQL','In this tutorial we will show ...'),
    ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    ('MySQL vs. YourSQL','In the following database comparison ...'),
    ('MySQL Security','When configured properly, MySQL ...');

```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the `InnoDB FULLTEXT INFORMATION_SCHEMA` tables are empty, with the exception of `INNODB_FT_DEFAULT_STOPWORD`.

```
mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shut down or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

4. Enable the `innodb_optimize_fulltext_only` system variable and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on `InnoDB` tables, and is intended to be enabled temporarily, during maintenance operations on `InnoDB` tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
```

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20

database	2	6	2	2	31
----------	---	---	---	---	----

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      2 |
|      3 |
|      4 |
+-----+
```

8. Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK       |
+-----+-----+-----+-----+
```

The `INNODB_FT_DELETED` table should now be empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:
 - `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.
 - `synced_doc_id`: The next `DOC_ID` to be issued.
 - `stopword_table_name`: The `database/table` name for a user-defined stopwords table. The `VALUE` column is empty if there is no user-defined stopwords table.
 - `use_stopword`: Indicates whether a stopwords table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
```

KEY	VALUE
optimize_checkpoint_limit	180
synced_doc_id	8
stopword_table_name	
use_stopword	1

10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

15.14.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool.

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
```

Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%)
INNODB_BUFFER_PAGE_LRU
INNODB_BUFFER_PAGE
INNODB_BUFFER_POOL_STATS

Table Overview

- `INNODB_BUFFER_PAGE`: Holds information about each page in the `InnoDB` buffer pool.
- `INNODB_BUFFER_PAGE_LRU`: Holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.
- `INNODB_BUFFER_POOL_STATS`: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using `InnoDB` buffer pool server status variables.

Warning

Querying the `INNODB_BUFFER_PAGE` or `INNODB_BUFFER_PAGE_LRU` table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

Example 15.6 Querying System Data in the `INNODB_BUFFER_PAGE` Table

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash `/` or period `.` in the table name, which indicates a user-defined table.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
      WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

```

| COUNT(*) |
+-----+
|      1516 |
+-----+

```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```

mysql> SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
   ) AS system_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ROUND((system_pages/total_pages) * 100)
  ) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
+-----+-----+-----+
|          295 |          8192 |                      4 |
+-----+-----+-----+

```

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```

mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| PAGE_TYPE |
+-----+
| SYSTEM    |
| IBUF_BITMAP |
| UNKNOWN   |
| FILE_SPACE_HEADER |
| INODE     |
| UNDO_LOG  |
| ALLOCATED  |
+-----+

```

Example 15.7 Querying User Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL` and `NOT LIKE '%INNODB_TABLES%'`.

```

mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_TABLES%';
+-----+
| COUNT(*) |
+-----+
|      7897 |
+-----+

```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```

mysql> SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
  ) AS user_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ROUND((user_pages/total_pages) * 100)
  ) AS user_page_percentage;

```

```

) AS user_pages,
(
SELECT COUNT(*)
FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;

```

user_pages	total_pages	user_page_percentage
7897	8192	96

This query identifies user-defined tables with pages in the buffer pool:

```

mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE 'mysql`.`innodb_%';

```

TABLE_NAME
`employees`.`salaries`
`employees`.`employees`

Example 15.8 Querying Index Data in the INNODB_BUFFER_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```

mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`';

```

INDEX_NAME	Pages	Total Data (MB)
emp_no	1609	25

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```

mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = '`employees`.`salaries`'
GROUP BY INDEX_NAME;

```

INDEX_NAME	Pages	Total Data (MB)
emp_no	1608	25
PRIMARY	6086	95

Example 15.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes

full. The definition for this page is the same as for [INNODB_BUFFER_PAGE](#), except this table has an [LRU_POSITION](#) column instead of a [BLOCK_ID](#) column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
        WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
+-----+
| COUNT(LRU_POSITION) |
+-----+
|                548 |
+-----+
```

Example 15.10 Querying the INNODB_BUFFER_POOL_STATS Table

The [INNODB_BUFFER_POOL_STATS](#) table provides information similar to `SHOW ENGINE INNODB STATUS` and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
      POOL_ID: 0
     POOL_SIZE: 8192
    FREE_BUFFERS: 1
   DATABASE_PAGES: 8173
  OLD_DATABASE_PAGES: 3014
 MODIFIED_DATABASE_PAGES: 0
  PENDING_DECOMPRESS: 0
    PENDING_READS: 0
   PENDING_FLUSH_LRU: 0
  PENDING_FLUSH_LIST: 0
    PAGES_MADE_YOUNG: 15907
  PAGES_NOT_MADE_YOUNG: 3803101
  PAGES_MADE_YOUNG_RATE: 0
 PAGES_MADE_NOT_YOUNG_RATE: 0
    NUMBER_PAGES_READ: 3270
  NUMBER_PAGES_CREATED: 13176
  NUMBER_PAGES_WRITTEN: 15109
    PAGES_READ_RATE: 0
    PAGES_CREATE_RATE: 0
    PAGES_WRITTEN_RATE: 0
    NUMBER_PAGES_GET: 33069332
      HIT_RATE: 0
 YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
    NUMBER_PAGES_READ_AHEAD: 2713
  NUMBER_READ_AHEAD_EVICTED: 0
    READ_AHEAD_RATE: 0
  READ_AHEAD_EVICTED_RATE: 0
      LRU_IO_TOTAL: 0
      LRU_IO_CURRENT: 0
    UNCOMPRESS_TOTAL: 0
    UNCOMPRESS_CURRENT: 0
```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 15.16.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```
mysql> SHOW ENGINE INNODB STATUS \G
...
```

BUFFER POOL AND MEMORY

```

-----
Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size      8192
Free buffers          1
Database pages        8173
Old database pages    3014
Modified db pages     0
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 youngs/s, 0.00 non-youngs/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 5.1.9, “Server Status Variables”](#).

```
mysql> SHOW STATUS LIKE 'Innodb_buffer%';
```

Variable_name	Value
Innodb_buffer_pool_dump_status	not started
Innodb_buffer_pool_load_status	not started
Innodb_buffer_pool_resize_status	not started
Innodb_buffer_pool_pages_data	8173
Innodb_buffer_pool_bytes_data	133906432
Innodb_buffer_pool_pages_dirty	0
Innodb_buffer_pool_bytes_dirty	0
Innodb_buffer_pool_pages_flushed	15109
Innodb_buffer_pool_pages_free	1
Innodb_buffer_pool_pages_misc	18
Innodb_buffer_pool_pages_total	8192
Innodb_buffer_pool_read_ahead_rnd	0
Innodb_buffer_pool_read_ahead	2713
Innodb_buffer_pool_read_ahead_evicted	0
Innodb_buffer_pool_read_requests	33069332
Innodb_buffer_pool_reads	558
Innodb_buffer_pool_wait_free	0
Innodb_buffer_pool_write_requests	11985961

15.14.6 InnoDB INFORMATION_SCHEMA Metrics Table

The `INNODB_METRICS` table provides information about InnoDB performance and resource-related counters:

The columns of the `INNODB_METRICS` table are shown in the following example. For a description of each column, see [Section 24.36.22, “The INFORMATION_SCHEMA INNODB_METRICS Table”](#).

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 46273
    MAX_COUNT: 46273
    MIN_COUNT: NULL
    AVG_COUNT: 492.2659574468085

```

```

COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-11-28 16:07:53
TIME_DISABLED: NULL
TIME_ELAPSED: 94
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following configuration options:

- `innodb_monitor_enable`: Enables one or more counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables one or more counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets the count value for one or more counters to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all values for one or more counters. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

You can also enable counters and counter modules at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of your `my.cnf` configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in your configuration file, you must specify the `innodb_monitor_enable` configuration option followed by counter and module names separated by a comma, as shown in the example above. Only the `innodb_monitor_enable` option can be used in your configuration file. The disable and reset configuration options are only supported on the command line.

Note

Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.

Counters

The counters represented in the `INNODB_METRICS` table are subject to change, so for the most up-to-date list, query a running MySQL server. The list below shows counters that are available as of MySQL 8.0.

Counters that are enabled by default correspond to those used by `SHOW ENGINE INNODB STATUS`. Counters used by `SHOW ENGINE INNODB STATUS` are always “on” at a system level but you can disable these counters for the `INNODB_METRICS` table, as required. Also, counter status is not persistent. Unless specified otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by additions or changes to the `INNODB_METRICS` table, it is recommended that you review releases notes and query the `INNODB_METRICS` table for the new release prior to upgrading.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

Counter Modules

The module names correspond to, but are not identical to, the values from the [SUBSYSTEM](#) column of the [INNODB_METRICS](#) table. Rather enabling, disabling, or resetting counters individually, you can use module names to quickly enable, disable, or reset all counters for a particular subsystem. For example, use [module_dml](#) to enable all counters associated with the [dml](#) subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
        WHERE subsystem = 'dml';
+-----+-----+-----+
| name          | subsystem | status |
+-----+-----+-----+
```

dml_reads	dml	enabled
dml_inserts	dml	enabled
dml_deletes	dml	enabled
dml_updates	dml	enabled

Here are the values you can use for `module_name` with the `innodb_monitor_enable` and related configuration options, along with the corresponding `SUBSYSTEM` names:

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)

Example 15.11 Working with INNODB_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple `InnoDB` table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME          | COMMENT                                |
+-----+-----+
| dml_inserts   | Number of rows inserted              |
+-----+-----+
```

- Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since this time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: 0
    MIN_COUNT: NULL
    AVG_COUNT: 0
    COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
  TIME_ENABLED: 2014-12-04 14:18:28
  TIME_DISABLED: NULL
  TIME_ELAPSED: 28
    TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
```

- Insert three rows of data into the table.

```
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

- Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.046153846153846156
```

```

COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 65
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

6. Reset the `dml_inserts` counter, and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `%_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```

mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.03529411764705882
    COUNT_RESET: 0
    MAX_COUNT_RESET: 0
    MIN_COUNT_RESET: NULL
    AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 85
    TIME_RESET: 2014-12-04 14:19:44
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```

mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.030612244897959183
    COUNT_RESET: 0
    MAX_COUNT_RESET: 0
    MIN_COUNT_RESET: NULL
    AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: 2014-12-04 14:20:06
    TIME_ELAPSED: 98
    TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter

```

COMMENT: Number of rows inserted

**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

- After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: NULL
    MIN_COUNT: NULL
    AVG_COUNT: NULL
    COUNT_RESET: 0
    MAX_COUNT_RESET: NULL
    MIN_COUNT_RESET: NULL
    AVG_COUNT_RESET: NULL
    TIME_ENABLED: NULL
    TIME_DISABLED: NULL
    TIME_ELAPSED: NULL
    TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
```

15.14.7 InnoDB INFORMATION_SCHEMA Temporary Table Info Table

`INNODB_TEMP_TABLE_INFO` provides information about user-created InnoDB temporary tables that are active in the InnoDB instance. It does not provide information about internal InnoDB temporary tables used by the optimizer.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO                       |
+-----+
```

For the table definition, see [Section 24.36.28, “The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table”](#).

Example 15.12 INNODB_TEMP_TABLE_INFO

This example demonstrates characteristics of the `INNODB_TEMP_TABLE_INFO` table.

- Create a simple InnoDB temporary table:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

2. Query `INNODB_TEMP_TABLE_INFO` to view the temporary table metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
      N_COLS: 4
      SPACE: 182
```

The `TABLE_ID` is a unique identifier for the temporary table. The `NAME` column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (`N_COLS`) is 4 rather than 1 because InnoDB always creates three hidden table columns (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`).

3. Restart MySQL and query `INNODB_TEMP_TABLE_INFO`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
```

An empty set is returned because `INNODB_TEMP_TABLE_INFO` and its data are not persisted to disk when the server is shut down.

4. Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

5. Query `INNODB_TEMP_TABLE_INFO` to view the temporary table metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 196
        NAME: #sql7b0e_1_0
      N_COLS: 4
      SPACE: 184
```

The `SPACE` ID may be different because it is dynamically generated when the server is started.

15.14.8 Retrieving InnoDB Tablespace Metadata from INFORMATION_SCHEMA.FILES

The `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including [file-per-table tablespaces](#), [general tablespaces](#), the [system tablespace](#), [temporary table tablespaces](#), and [undo tablespaces](#) (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the `INFORMATION_SCHEMA.FILES` table, see [Section 24.10, “The INFORMATION_SCHEMA FILES Table”](#).

Note

The `INNODB_TABLESPACES` and `INNODB_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to InnoDB tablespaces.

`INFORMATION_SCHEMA.FILES` fields that are not relevant to InnoDB always return NULL, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
        TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
        FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
      FILE_ID: 0
      FILE_NAME: ./ibdata1
      FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
      FREE_EXTENTS: 0
      TOTAL_EXTENTS: 12
      EXTENT_SIZE: 1048576
      INITIAL_SIZE: 12582912
      MAXIMUM_SIZE: NULL
      AUTOEXTEND_SIZE: 67108864
      DATA_FREE: 4194304
      ENGINE: NORMAL
```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
        WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
| 2 | ./mysql/plugin.ibd |
| 3 | ./mysql/servers.ibd |
| 4 | ./mysql/help_topic.ibd |
| 5 | ./mysql/help_category.ibd |
| 6 | ./mysql/help_relation.ibd |
| 7 | ./mysql/help_keyword.ibd |
| 8 | ./mysql/time_zone_name.ibd |
| 9 | ./mysql/time_zone.ibd |
| 10 | ./mysql/time_zone_transition.ibd |
| 11 | ./mysql/time_zone_transition_type.ibd |
| 12 | ./mysql/time_zone_leap_second.ibd |
| 13 | ./mysql/innodb_table_stats.ibd |
| 14 | ./mysql/innodb_index_stats.ibd |
| 15 | ./mysql/slave_relay_log_info.ibd |
| 16 | ./mysql/slave_master_info.ibd |
| 17 | ./mysql/slave_worker_info.ibd |
| 18 | ./mysql/gtid_executed.ibd |
| 19 | ./mysql/server_cost.ibd |
| 20 | ./mysql/engine_cost.ibd |
| 21 | ./sys/sys_config.ibd |
| 23 | ./test/t1.ibd |
| 26 | /home/user/test/test/t2.ibd |
+-----+-----+
```

This query retrieves the `FILE_ID` and `FILE_NAME` for the InnoDB global temporary tablespace. Global temporary tablespace file names are prefixed by `ibtmp`.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
        WHERE FILE_NAME LIKE '%ibtmp%';
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
| 22 | ./ibtmp1 |
+-----+-----+
```

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
        WHERE FILE_NAME LIKE '%undo%';
```

15.15 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 25, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 25.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain `'innodb'`.

```
mysql> SELECT *
        FROM performance_schema.setup_instruments
        WHERE NAME LIKE '%innodb%';
```

...
+-----+-----+-----+
155 rows in set (0.00 sec)

```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex_instances](#) table
- The [rwlock_instances](#) table
- The [cond_instances](#) table
- The [file_instances](#) table

Note

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the [SHOW ENGINE INNODB MUTEX](#) command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```

mysql> SELECT *
      FROM performance_schema.file_instances
      WHERE EVENT_NAME LIKE '%innodb%'\G
***** 1. row *****
FILE_NAME: /path/to/mysql-8.0/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /path/to/mysql-8.0/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /path/to/mysql-8.0/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 4. row *****
FILE_NAME: /path/to/mysql-8.0/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
...

```

- You should be familiar with [performance_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
 - The [Wait Event](#) tables, which store wait events.
 - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
 - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 15.15.1, “Monitoring ALTER TABLE Progress for](#)

[InnoDB Tables Using Performance Schema](#)", and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in InnoDB-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

15.15.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

You can monitor `ALTER TABLE` progress for InnoDB tables using [Performance Schema](#).

There are seven stage events that represent different phases of `ALTER TABLE`. Each stage event reports a running total of `WORK_COMPLETED` and `WORK_ESTIMATED` for the overall `ALTER TABLE` operation as it progresses through its different phases. `WORK_ESTIMATED` is calculated using a formula that takes into account all of the work that `ALTER TABLE` performs, and may be revised during `ALTER TABLE` processing. `WORK_COMPLETED` and `WORK_ESTIMATED` values are an abstract representation of all of the work performed by `ALTER TABLE`.

In order of occurrence, `ALTER TABLE` stage events include:

- `stage/innodb/alter table (read PK and internal sort)`: This stage is active when `ALTER TABLE` is in the reading-primary-key phase. It starts with `WORK_COMPLETED=0` and `WORK_ESTIMATED` set to the estimated number of pages in the primary key. When the stage is completed, `WORK_ESTIMATED` is updated to the actual number of pages in the primary key.
- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 25.11.5, "Performance Schema Stage Event Tables"](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE performance_schema.setup_instruments
      SET ENABLED = 'YES'
      WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7  Changed: 7  Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers
      SET ENABLED = 'YES'
      WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
      FROM performance_schema.events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 280 | 1245 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
      FROM performance_schema.events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 886 | 1213 |
| stage/innodb/alter table (flush) | 1213 | 1213 |
| stage/innodb/alter table (log apply table) | 1597 | 1597 |
| stage/innodb/alter table (end) | 1597 | 1597 |
| stage/innodb/alter table (log apply table) | 1981 | 1981 |
+-----+-----+-----+
5 rows in set (0.00 sec)
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

15.15.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For [InnoDB](#) mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable [InnoDB](#) mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available [InnoDB](#) mutex wait instruments, query the Performance Schema `setup_instruments` table. All [InnoDB](#) mutex wait instruments are disabled by default.

```
mysql> SELECT *
      FROM performance_schema.setup_instruments
      WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_persisted_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_free_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_free_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_hash_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/fil_system_mutex	NO	NO
wait/synch/mutex/innodb/flush_list_mutex	NO	NO
wait/synch/mutex/innodb/fts_bg_threads_mutex	NO	NO
wait/synch/mutex/innodb/fts_delete_mutex	NO	NO
wait/synch/mutex/innodb/fts_optimize_mutex	NO	NO
wait/synch/mutex/innodb/fts_doc_id_mutex	NO	NO
wait/synch/mutex/innodb/log_flush_order_mutex	NO	NO
wait/synch/mutex/innodb/hash_table_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_bitmap_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_write_mutex	NO	NO
wait/synch/mutex/innodb/mutex_list_mutex	NO	NO
wait/synch/mutex/innodb/page_zip_stat_per_index_mutex	NO	NO
wait/synch/mutex/innodb/purge_sys_pq_mutex	NO	NO
wait/synch/mutex/innodb/recv_sys_mutex	NO	NO
wait/synch/mutex/innodb/recv_writer_mutex	NO	NO
wait/synch/mutex/innodb/redo_rseg_mutex	NO	NO
wait/synch/mutex/innodb/noredoreg_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_list_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_mutex	NO	NO
wait/synch/mutex/innodb/srv_dict_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	NO	NO
wait/synch/mutex/innodb/srv_misc_tmpfile_mutex	NO	NO

wait/synch/mutex/innodb/srv_monitor_file_mutex	NO	NO
wait/synch/mutex/innodb/buf_dblwr_mutex	NO	NO
wait/synch/mutex/innodb/trx_undo_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_manager_mutex	NO	NO
wait/synch/mutex/innodb/srv_sys_mutex	NO	NO
wait/synch/mutex/innodb/lock_mutex	NO	NO
wait/synch/mutex/innodb/lock_wait_mutex	NO	NO
wait/synch/mutex/innodb/trx_mutex	NO	NO
wait/synch/mutex/innodb/srv_threads_mutex	NO	NO
wait/synch/mutex/innodb/rtr_active_mutex	NO	NO
wait/synch/mutex/innodb/rtr_match_mutex	NO	NO
wait/synch/mutex/innodb/rtr_path_mutex	NO	NO
wait/synch/mutex/innodb/rtr_ssn_mutex	NO	NO
wait/synch/mutex/innodb/trx_sys_mutex	NO	NO
wait/synch/mutex/innodb/zip_pad_mutex	NO	NO
wait/synch/mutex/innodb/master_key_id_mutex	NO	NO

- Some [InnoDB](#) mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all [InnoDB](#) mutex instances are instrumented and enabled, add the following [performance-schema-instrument](#) rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all [InnoDB](#) mutexes, you can disable specific instruments by adding additional [performance-schema-instrument](#) rules to your MySQL configuration file. For example, to disable [InnoDB](#) mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

Note

Rules with a longer prefix such as [wait/synch/mutex/innodb/fts%](#) take precedence over rules with shorter prefixes such as [wait/synch/mutex/innodb/%](#).

After adding the [performance-schema-instrument](#) rules to your configuration file, restart the server. All the [InnoDB](#) mutexes except for those related to full text search are enabled. To verify, query the [setup_instruments](#) table. The [ENABLED](#) and [TIMED](#) columns should be set to [YES](#) for the instruments that you enabled.

```
mysql> SELECT *
      FROM performance_schema.setup_instruments
      WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	YES	YES
wait/synch/mutex/innodb/innobase_share_mutex	YES	YES
wait/synch/mutex/innodb/autoinc_mutex	YES	YES
...		
wait/synch/mutex/innodb/master_key_id_mutex	YES	YES

49 rows in set (0.00 sec)

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
      SET enabled = 'YES'
      WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | YES     |
| events_statements_history_long      | NO      |
| events_transactions_current         | YES     |
| events_transactions_history         | YES     |
| events_transactions_history_long    | NO      |
| events_waits_current                | YES     |
| events_waits_history                | YES     |
| events_waits_history_long           | YES     |
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| statements_digest                   | YES     |
+-----+-----+
15 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
      --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
FROM performance_schema.events_waits_summary_global_by_event_name
WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
ORDER BY COUNT_STAR DESC;
```

EVENT_NAME	COUNT_STAR	SUM_TIMER_WAIT_MS
wait/synch/mutex/innodb/trx_mutex	201111	23.4719
wait/synch/mutex/innodb/file_system_mutex	62244	9.6426
wait/synch/mutex/innodb/redo_rseg_mutex	48238	3.1135
wait/synch/mutex/innodb/log_sys_mutex	46113	2.0434
wait/synch/mutex/innodb/trx_sys_mutex	35134	1068.1588
wait/synch/mutex/innodb/lock_mutex	34872	1039.2589
wait/synch/mutex/innodb/log_sys_write_mutex	17805	1526.0490
wait/synch/mutex/innodb/dict_sys_mutex	14912	1606.7348
wait/synch/mutex/innodb/trx_undo_mutex	10634	1.1424
wait/synch/mutex/innodb/rw_lock_list_mutex	8538	0.1960
wait/synch/mutex/innodb/buf_pool_free_list_mutex	5961	0.6473
wait/synch/mutex/innodb/trx_pool_mutex	4885	8821.7496
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	4364	0.2077
wait/synch/mutex/innodb/innobase_share_mutex	3212	0.2650
wait/synch/mutex/innodb/flush_list_mutex	3178	0.2349
wait/synch/mutex/innodb/trx_pool_manager_mutex	2495	0.1310
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	1318	0.2161
wait/synch/mutex/innodb/log_flush_order_mutex	1250	0.0893
wait/synch/mutex/innodb/buf_dblwr_mutex	951	0.0918
wait/synch/mutex/innodb/recalc_pool_mutex	670	0.0942
wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	345	0.0414
wait/synch/mutex/innodb/lock_wait_mutex	303	0.1565
wait/synch/mutex/innodb/autoinc_mutex	196	0.0213
wait/synch/mutex/innodb/autoinc_persisted_mutex	196	0.0175
wait/synch/mutex/innodb/purge_sys_pq_mutex	117	0.0308
wait/synch/mutex/innodb/srv_sys_mutex	94	0.0077
wait/synch/mutex/innodb/ibuf_mutex	22	0.0086
wait/synch/mutex/innodb/recv_sys_mutex	12	0.0008
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	4	0.0009
wait/synch/mutex/innodb/recv_writer_mutex	1	0.0005

Note

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

15.16 InnoDB Monitors

[InnoDB](#) monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning.

15.16.1 InnoDB Monitor Types

There are two types of [InnoDB](#) monitor:

- The standard [InnoDB](#) Monitor displays the following types of information:
 - Work done by the main background thread
 - Semaphore waits
 - Data about the most recent foreign key and deadlock errors
 - Lock waits for transactions
 - Table and record locks held by active transactions
 - Pending I/O operations and related statistics
 - Insert buffer and adaptive hash index statistics
 - Redo log data
 - Buffer pool statistics
 - Row operation data
- The [InnoDB](#) Lock Monitor prints additional lock information as part of the standard [InnoDB](#) Monitor output.

15.16.2 Enabling InnoDB Monitors

When [InnoDB](#) monitors are enabled for periodic output, [InnoDB](#) writes the output to [mysqld](#) server standard error output ([stderr](#)) every 15 seconds, approximately.

[InnoDB](#) sends the monitor output to [stderr](#) rather than to [stdout](#) or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, [stderr](#) is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command prompt in a console window with the `--console` option. For more information, see [Error Logging on Windows](#).

On Unix and Unix-like systems, [stderr](#) is typically directed to the terminal unless configured otherwise. For more information, see [Error Logging on Unix and Unix-Like Systems](#).

[InnoDB](#) monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later.

**Note**

To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see [Section 15.20, “InnoDB Troubleshooting”](#).

InnoDB monitor output begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard InnoDB Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The `innodb_status_output` and `innodb_status_output_locks` system variables are used to enable the standard InnoDB Monitor and InnoDB Lock Monitor.

The `PROCESS` privilege is required to enable or disable InnoDB Monitors.

Enabling the Standard InnoDB Monitor

Enable the standard InnoDB Monitor by setting the `innodb_status_output` system variable to `ON`.

```
SET GLOBAL innodb_status_output=ON;
```

To disable the standard InnoDB Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

Enabling the InnoDB Lock Monitor

InnoDB Lock Monitor data is printed with the InnoDB Standard Monitor output. Both the InnoDB Standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically.

To enable the InnoDB Lock Monitor, set the `innodb_status_output_locks` system variable to `ON`. Both the InnoDB standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically:

```
SET GLOBAL innodb_status_output=ON;
SET GLOBAL innodb_status_output_locks=ON;
```

To disable the InnoDB Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to `OFF` to also disable the InnoDB Standard Monitor.

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

**Note**

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which

fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.

Directing Standard InnoDB Monitor Output to a Status File

Standard InnoDB Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, InnoDB creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately.

InnoDB removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

15.16.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
  Status:
=====
2018-04-12 15:14:08 0x7f971c063700 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT
=====

```

Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

- [Status](#)

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB](#) Monitor output was printed.

- [BACKGROUND THREAD](#)

The [srv_master_thread](#) lines shows work done by the main background thread.

- [SEMAPHORES](#)

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the [innodb_thread_concurrency](#) system variable smaller than the default value might help in such situations. The [Spin rounds per wait](#) line shows the number of spinlock rounds per OS wait for a mutex.

Mutex metrics are reported by [SHOW ENGINE INNODB MUTEX](#).

- [LATEST FOREIGN KEY ERROR](#)

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- [LATEST DETECTED DEADLOCK](#)

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction [InnoDB](#) decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 15.5.1, “InnoDB Locking”](#).

- [TRANSACTIONS](#)

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- [FILE I/O](#)

This section provides information about threads that [InnoDB](#) uses to perform various types of I/O. The first few of these are dedicated to general [InnoDB](#) processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the [innodb_read_io_threads](#) and [innodb_write_io_threads](#) parameters. See [Section 15.13, “InnoDB Startup Options and System Variables”](#).

- [INSERT BUFFER AND ADAPTIVE HASH INDEX](#)

This section shows the status of the [InnoDB](#) insert buffer (also referred to as the [change buffer](#)) and the adaptive hash index.

For related information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.4.3, “Adaptive Hash Index”](#).

- [LOG](#)

This section displays information about the [InnoDB](#) log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which [InnoDB](#) last took a checkpoint. (See [Section 15.11.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

- [BUFFER POOL AND MEMORY](#)

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#). For additional information about the operation of the buffer pool, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- [ROW OPERATIONS](#)

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

15.17 InnoDB Backup and Recovery

This section covers topics related to [InnoDB](#) backup and recovery.

- For information about backup techniques applicable to [InnoDB](#), see [Section 15.17.1, “InnoDB Backup”](#).
- For information about point-in-time recovery, recovery from disk failure or corruption, and how [InnoDB](#) performs crash recovery, see [Section 15.17.2, “InnoDB Recovery”](#).

15.17.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: [hot backup](#) with *MySQL Enterprise Backup*; [cold backup](#) by copying files while the MySQL server is shut down; [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects. Hot and cold backups are [physical backups](#) that copy actual data files, which can be used directly by the `mysql` server for faster restore.

Using *MySQL Enterprise Backup* is the recommended method for backing up [InnoDB](#) data.

Note

[InnoDB](#) does not support databases that are restored using third-party backup tools.

Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including [InnoDB](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying [InnoDB](#) tables, reads and writes to [InnoDB](#) tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).

Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by [InnoDB](#) to manage its tables. Use the following procedure:

1. Perform a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all [InnoDB](#) data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all [InnoDB](#) log files (`ib_logfile` files) to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.

Logical Backups Using `mysqldump`

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See [Section 15.18, “InnoDB and MySQL Replication”](#).

15.17.2 InnoDB Recovery

This section describes [InnoDB](#) recovery. Topics include:

- [Point-in-Time Recovery](#)
- [Recovery from Data Corruption or Disk Failure](#)
- [InnoDB Crash Recovery](#)
- [Tablespace Discovery During Crash Recovery](#)
- [Lost or Corrupted Tablespace Map Files](#)

Point-in-Time Recovery

To recover an [InnoDB](#) database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using [mysqlbinlog](#) and [mysql](#) to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the [CHECK TABLE](#) statement to check whether a table is corrupt, although [CHECK TABLE](#) naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of [InnoDB](#) consistency problems, see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in recovery mode, which permits you to dump the data.

InnoDB Crash Recovery

To recover from a MySQL server crash, the only requirement is to restart the MySQL server. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, [mysqld](#) displays output similar to this:

```
InnoDB: The log sequence number 664050266 in the system tablespace does not match
the log sequence number 685111586 in the ib_logfiles!
InnoDB: Database was not shutdown normally!

InnoDB: Waiting for purge to start
InnoDB: Starting in background the rollback of uncommitted transactions
InnoDB: Rolling back trx with id 3596, 561887 rows to undo
...
./mysqld: ready for connections....

```

InnoDB crash recovery consists of several steps:

- **Tablespace discovery**

Tablespace discovery is the process that InnoDB uses to identify tablespaces that require redo log application. See [Tablespace Discovery During Crash Recovery](#).

- **Redo log application**

Redo log application is performed during initialization, before accepting any connections. If all changes are flushed from the [buffer pool](#) to the [tablespaces](#) (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, redo log application is skipped. InnoDB also skips redo log application if redo log files are missing at startup.

- The current maximum auto-increment counter value is written to the redo log each time the value changes, which makes it crash-safe. During recovery, InnoDB scans the redo log to collect counter value changes and applies the changes to the in-memory table object.

For more information about how InnoDB handles auto-increment values, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#), and [InnoDB AUTO_INCREMENT Counter Initialization](#).

- When encountering index tree corruption, InnoDB writes a corruption flag to the redo log, which makes the corruption flag crash-safe. InnoDB also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, InnoDB reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.
- Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with `innodb_fast_shutdown` set to 0 or 1.
- **Roll back** of incomplete [transactions](#)

Incomplete transactions are any transactions that were active at the time of crash or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

- [Change buffer](#) merge

Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- [Purge](#)

Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, [InnoDB](#) attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, [InnoDB](#) rolls back transactions that were not committed or in [XA PREPARE](#) state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted [InnoDB](#) data, MySQL might refuse to start. In this case, see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

For information about the binary log and [InnoDB](#) crash recovery, see [Section 5.4.4, “The Binary Log”](#).

Tablespace Discovery During Crash Recovery

If, during recovery, [InnoDB](#) encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces during recovery is referred to as *tablespace discovery*.

Tablespace discovery is performed using tablespace map files that map tablespace IDs to tablespace file names. Tablespace map files are stored in the [innodb_data_home_dir](#) directory. If [innodb_data_home_dir](#) is not configured, the default location is the MySQL data directory ([datadir](#)).

There are two tablespace map files ([tablespaces.open.1](#) and [tablespaces.open.2](#)) that are written to in circular fashion. Tablespace map files are only used during recovery. The files are ignored during normal startup.

In case of lost or corrupted tablespace map files, see [Lost or Corrupted Tablespace Map Files](#).

Lost or Corrupted Tablespace Map Files

If tablespace map files are lost or corrupted, the [innodb_scan_directories](#) option can be used to specify tablespace file directories at startup. This option causes [InnoDB](#) to read the first page of each tablespace file in the specified directories and recreate tablespace map files so that the recovery process can apply redo logs.

This option can also be used to specify the directory path of a missing tablespace file. For example, if recovery reports an error due to a missing tablespace file, you can configure [innodb_scan_directories](#) to search for the tablespace file in a specific directory.

[innodb_scan_directories](#) may be specified as an option in a startup command or in a MySQL option file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as

a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-scan-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_scan_directories="directory_path_1;directory_path_2"
```

When `innodb_scan_directories` is specified at startup, the InnoDB startup process prints messages similar to the following, reporting the directories that were scanned and the number of tablespace files found:

```
InnoDB: Directories to scan 'directory_path_1;directory_path_2'
InnoDB: Scanning 'directory_path_1'
InnoDB: Scanning 'directory_path_2'
InnoDB: Found 10 '.ibd' file(s)
```

15.18 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave. For more information see, [Section 17.3.4, “Using Replication with Different Master and Slave Storage Engines”](#).

For information about setting up a new slave for a master, see [Section 17.1.2.6, “Setting Up Replication Slaves”](#), and [Section 17.1.2.5, “Choosing a Method for Data Snapshots”](#). To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Replication and CASCADE. Cascading actions for InnoDB tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```

master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0

```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```

master> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the master:

```

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 2 | 2 |
+-----+

```

```
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+-----+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the [InnoDB](#) storage engine, which means that none of the changes are logged.

15.19 InnoDB memcached Plugin

The [InnoDB memcached](#) plugin (`daemon_memcached`) provides an integrated [memcached](#) daemon that automatically stores and retrieves data from [InnoDB](#) tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same [InnoDB](#) tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the [memcached](#) API to speed up database operations, letting [InnoDB](#) handle memory caching using its [buffer pool](#) mechanism. Data modified through [memcached](#) operations such as `add`, `set`, and `incr` are stored to disk, in [InnoDB](#) tables. The combination of [memcached](#) simplicity and [InnoDB](#) reliability and consistency provides users with the best of both worlds, as explained in [Section 15.19.1, “Benefits of the InnoDB memcached Plugin”](#). For an architectural overview, see [Section 15.19.2, “InnoDB memcached Architecture”](#).

15.19.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the `daemon_memcached` plugin. The combination of [InnoDB](#) tables and [memcached](#) offers advantages over using either by themselves.

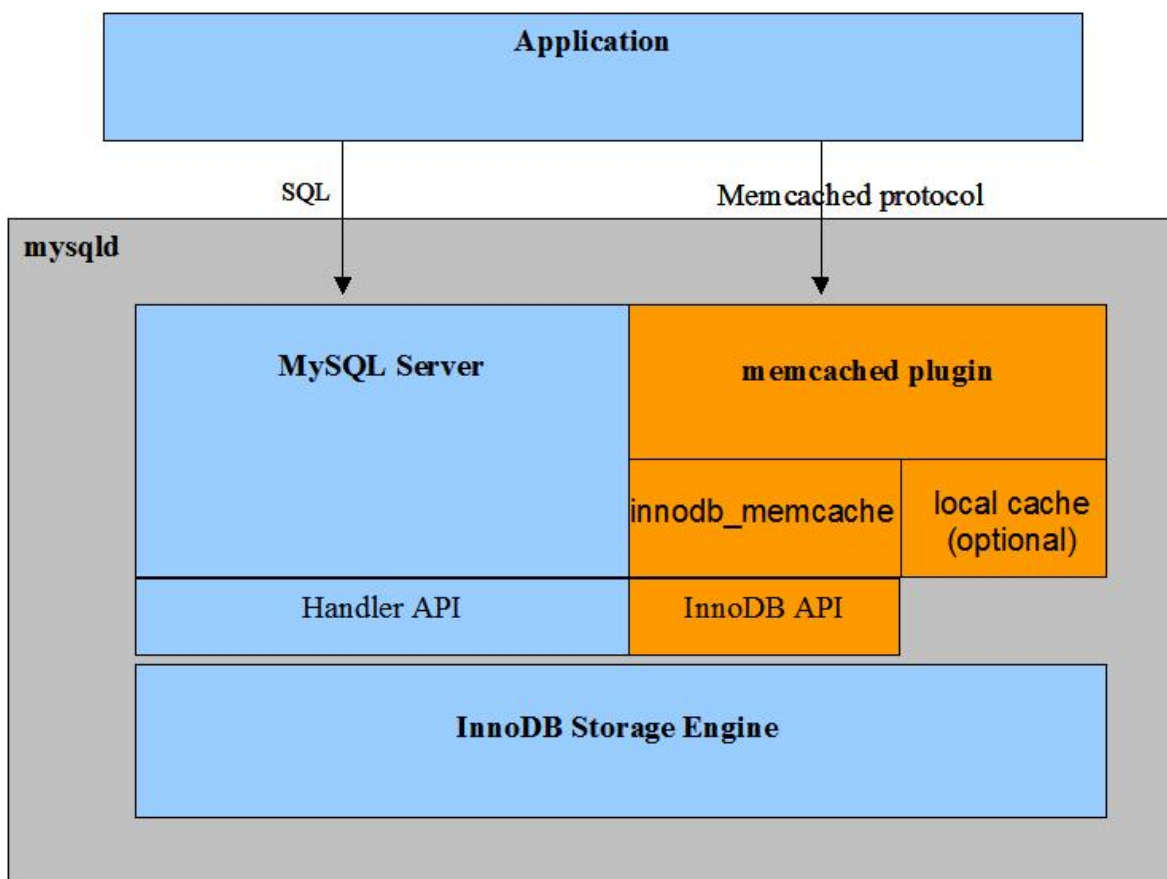

- Direct access to the [InnoDB](#) storage engine avoids the parsing and planning overhead of SQL.
- Running [memcached](#) in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the [memcached](#) protocol is transparently written to an [InnoDB](#) table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the [memcached](#) protocol is transparently queried from an [InnoDB](#) table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the [InnoDB](#) buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using [InnoDB](#) configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.

- InnoDB can handle composing and decomposing multiple column values into a single memcached item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value 2 | 4 | 6 | 8 in the memcached cache, and have InnoDB split the value based on a separator character, then store the result in four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying InnoDB table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
- You can ensure high availability by using the daemon_memcached plugin on a master server in combination with MySQL replication.
- The integration of memcached with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more add, incr, and similar write operations in your application without concern that data could be lost. You can stop and start the memcached server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of InnoDB crash recovery, replication, and backup capabilities.
- The way InnoDB does fast primary key lookups is a natural fit for memcached single-item queries. The direct, low-level database access path used by the daemon_memcached plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of memcached, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.
- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as AVG () and MAX () on memcached data. All of these operations are expensive or complicated using memcached by itself.
- You do not need to manually load data into memcached at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the InnoDB buffer pool.
- Because memcached consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.
- Because data consistency is enforced by mechanisms used for regular InnoDB tables, you do not have to worry about stale memcached data or fallback logic to query the database in the case of a missing key.

15.19.2 InnoDB memcached Architecture

The InnoDB memcached plugin implements memcached as a MySQL plugin daemon that accesses the InnoDB storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the daemon_memcached plugin, compared with SQL.

Figure 15.1 MySQL Server with Integrated `memcached` Server

Features of the `daemon_memcached` plugin:

- `memcached` as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.
- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.
- Standard `memcached` protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.
- Multi-column support. You can map multiple columns into the “value” part of the key/value store, with column values delimited by a user-specified separator character.
- By default, the `memcached` protocol is used to read and write data directly to `InnoDB`, letting MySQL manage in-memory caching using the `InnoDB` buffer pool. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for `memcached get` requests.
- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` engine (memory caching), or use a combination of the “`memcached` engine” (memory caching) and the `InnoDB memcached` engine (`InnoDB` as back-end persistent storage).
- Control over how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and

`daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.

- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.
- The `innodb_api_trx_level` configuration option controls the transaction `isolation level` on queries processed by `memcached`. Although `memcached` has no concept of `transactions`, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.
- The `innodb_api_enable_md1` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by `DDL` through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in `InnoDB` storage until `memcached` or some other user stops using it. “MDL” stands for “metadata locking”.

Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in [Using MySQL with memcached](#). This section describes how features of the integrated `InnoDB memcached` plugin differ from traditional `memcached`.

- **Installation:** The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a `demo_test` table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

For comparison with traditional `memcached`, see [Installing memcached](#).

- **Deployment:** With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and in-memory lookups are served from the `InnoDB buffer pool`, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see [memcached Deployment](#).

- **Expiry:** By default (that is, using the `innodb_only` caching policy), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache-only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional `memcached`, see [Data Expiry](#).

- **Namespaces:** `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format

`@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The `@@` notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a session, perform a `get` request using the `@@` notation with a `table_id`, but without the key portion. For example:

```
get @@table_id
```

Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcache.containers.name` column.

For comparison with traditional `memcached`, see [Using Namespaces](#).

- Hashing and distribution: The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replication slave servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional `memcached`, see [memcached Hashing/Distribution Types](#).

- Memory usage: By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with InnoDB tables, and the InnoDB buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache-only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar [statistics](#) system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool` script to install a full `memcached` distribution.

For comparison with traditional `memcached`, see [Memory Allocation within memcached](#).

- Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional `memcached`, see [memcached Thread Support](#).

- Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL [error log](#).

For comparison with traditional `memcached`, see [memcached Logs](#).

- `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Basic memcached Operations](#).

- Using [memcached](#) as a MySQL front end: This is the primary purpose of the [InnoDB memcached](#) plugin. An integrated [memcached](#) daemon improves application performance, and having [InnoDB](#) handle data transfers between memory and disk simplifies application logic.

For comparison with traditional [memcached](#), see [Using memcached as a MySQL Caching Layer](#).

- Utilities: The MySQL server includes the [libmemcached](#) library but not additional command-line utilities. To use commands such as [memcp](#), [memcat](#), and [memcapable](#) commands, install a full [memcached](#) distribution. When [memrm](#) and [memflush](#) remove items from the cache, the items are also removed from the underlying [InnoDB](#) table.

For comparison with traditional [memcached](#), see [libmemcached Command-Line Utilities](#).

- Programming interfaces: You can access the MySQL server through the [daemon_memcached](#) plugin using all supported languages: [C and C++](#), [Java](#), [Perl](#), [Python](#), [PHP](#), and [Ruby](#). Specify the server hostname and port as with a traditional [memcached](#) server. By default, the [daemon_memcached](#) plugin listens on port [11211](#). You can use both the [text and binary protocols](#). You can customize the [behavior](#) of [memcached](#) functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional [memcached](#), see [Developing a memcached Application](#).

- Frequently asked questions: MySQL has an extensive FAQ for traditional [memcached](#). The FAQ is mostly applicable, except that using [InnoDB](#) tables as a storage medium for [memcached](#) data means that you can use [memcached](#) for more write-intensive applications than before, rather than as a read-only cache.

See [memcached FAQ](#).

15.19.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the [daemon_memcached](#) plugin on a MySQL server. Because the [memcached](#) daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

Note

Before setting up the [daemon_memcached](#) plugin, consult [Section 15.19.5, “Security Considerations for the InnoDB memcached Plugin”](#) to understand the security procedures required to prevent unauthorized access.

Prerequisites

- The [daemon_memcached](#) plugin is only supported on Linux, Solaris, and OS X platforms. Other operating systems are not supported.
- When building MySQL from source, you must build with `-DWITH_INNODB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the [daemon_memcached](#) plugin:
 - [libmemcached.so](#): the [memcached](#) daemon plugin to MySQL.
 - [innodb_engine.so](#): an [InnoDB](#) API plugin to [memcached](#).
- [libevent](#) must be installed.
 - If you did not build MySQL from source, the [libevent](#) library is not included in your installation. Use the installation method for your operating system to install [libevent](#) 1.4.12 or later. For example,

depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:

```
sudo apt-get install libevent-dev
```

- If you installed MySQL from a source code release, `libevent` 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

```
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

```
mysql> USE innodb_memcache;
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies             |
| config_options             |
| containers                  |
+-----+

mysql> USE test;
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| demo_test      |
+-----+
```

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
    key_columns: c1
  value_columns: c2
         flags: c3
    cas_column: c4
```

```

    expire_time_column: c5
    unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2          | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8  | 0  | 0  |
+-----+-----+-----+-----+-----+

```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```

telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END

```

2. Insert data using a `set` command.

```

set BB 10 0 16
GOODBYE, GOODBYE
STORED

```

where:

- `set` is the command to store a value
 - `BB` is the key
 - `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
 - `0` is the expiration time (TTL); specify `0` if unused
 - `16` is the length of the supplied value block in bytes
 - `GOODBYE, GOODBYE` is the value that is stored
3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
```

c1	c2	c3	c4	c5
AA	HELLO, HELLO	8	0	0
BB	GOODBYE, GOODBYE	10	1	0

- Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
quit
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the `InnoDB memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key/value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

Creating a New Table and Column Mapping

This example shows how to setup your own `InnoDB` table with the `daemon_memcached` plugin.

- Create an `InnoDB` table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

Note

There is no special requirement with respect to column names as long as a valid mapping is added to the `innodb_memcache.containers` table.

```
mysql> CREATE TABLE city (
  city_id VARCHAR(32),
  name VARCHAR(1024),
  state VARCHAR(1024),
  country VARCHAR(1024),
  flags INT,
  cas BIGINT UNSIGNED,
  expiry INT,
  primary key(city_id)
) ENGINE=InnoDB;
```

- Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the `InnoDB` table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

```
mysql> DESCRIBE innodb_memcache.containers;
```

Field	Type	Null	Key	Default	Extra
name	varchar(50)	NO	PRI	NULL	
db_schema	varchar(250)	NO		NULL	
db_table	varchar(250)	NO		NULL	
key_columns	varchar(250)	NO		NULL	
value_columns	varchar(250)	YES		NULL	
flags	varchar(250)	NO		0	
cas_column	varchar(250)	YES		NULL	
expire_time_column	varchar(250)	YES		NULL	
unique_idx_name_on_key	varchar(250)	NO		NULL	

The `innodb_memcache.containers` table entry for the `city` table is defined as:

```
mysql> INSERT INTO `innodb_memcache`.`containers` (
  `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
  `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)
VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
  'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.
 - Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a “|” delimiter.
 - The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify 0 for these columns if they are unused.
3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcache` plugin to apply the changes.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+-----+-----+-----+-----+-----+-----+-----+
| city_id | name      | state      | country | flags | cas | expiry |
+-----+-----+-----+-----+-----+-----+-----+
| B       | BANGALORE | BANGALORE | IN      | 0     | 3   | 0       |
+-----+-----+-----+-----+-----+-----+-----+
```

6. Using MySQL, insert additional data into the `test.city` table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

Note

It is recommended that you specify a value of 0 for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

- Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the InnoDB `memcached` plugin. The default setting is `innodb_engine.so`.
- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the InnoDB `memcached` plugin. The default is NULL, representing the plugin directory.
- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a `commit` occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the InnoDB table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.
- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

15.19.4 InnoDB memcached Multiple get and Range Query Support

The `daemon_memcached` plugin supports multiple get operations (fetching multiple key/value pairs in a single `memcached` query) and range queries.

Multiple get Operations

The ability to fetch multiple key/value pairs in a single `memcached` query improves read performance by reducing communication traffic between the client and server. For `InnoDB`, it means fewer transactions and open-table operations.

The following example demonstrates multiple-get support. The example uses the `test.city` table described in [Creating a New Table and Column Mapping](#).

```
mysql> USE test;
mysql> SELECT * FROM test.city;
```

city_id	name	state	country	flags	cas	expiry
B	BANGALORE	BANGALORE	IN	0	1	0
C	CHENNAI	TAMIL NADU	IN	0	0	0
D	DELHI	DELHI	IN	0	0	0
H	HYDERABAD	TELANGANA	IN	0	0	0
M	MUMBAI	MAHARASHTRA	IN	0	0	0

Run a `get` command to retrieve all values from the `city` table. The results are returned in a key/value pair sequence.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
get B C D H M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
```

```
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

When retrieving multiple values in a single `get` command, you can switch tables (using `@@containers.name` notation) to retrieve the value for the first key, but you cannot switch tables for subsequent keys. For example, the table switch in this example is valid:

```
get @aaa.AA BB
VALUE @aaa.AA 8 12
HELLO, HELLO
VALUE BB 10 16
GOODBYE, GOODBYE
END
```

Attempting to switch tables again in the same `get` command to retrieve a key value from a different table is not supported.

Range Queries

For range queries, the `daemon_memcached` plugin supports the following comparison operators: `<`, `>`, `<=`, `>=`. An operator must be preceded by an `@` symbol. When a range query finds multiple matching key/value pairs, results are returned in a key/value pair sequence.

The following examples demonstrate range query support. The examples use the `test.city` table described in [Creating a New Table and Column Mapping](#).

```
mysql> SELECT * FROM test.city;
```

city_id	name	state	country	flags	cas	expiry
B	BANGALORE	BANGALORE	IN	0	1	0
C	CHENNAI	TAMIL NADU	IN	0	0	0
D	DELHI	DELHI	IN	0	0	0
H	HYDERABAD	TELANGANA	IN	0	0	0
M	MUMBAI	MAHARASHTRA	IN	0	0	0

Open a telnet session:

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
```

To get all values greater than B, enter `get @>B`:

```
get @>B
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

To get all values less than **M**, enter `get @<M`:

```
get @<M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

To get all values less than and including **M**, enter `get @<=M`:

```
get @<=M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
```

To get values greater than **B** but less than **M**, enter `get @>B@<M`:

```
get @>B@<M
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

A maximum of two comparison operators can be parsed, one being either a 'less than' (`@<`) or 'less than or equal to' (`@<=`) operator, and the other being either a 'greater than' (`@>`) or 'greater than or equal to' (`@>=`) operator. Any additional operators are assumed to be part of the key. For example, if you issue a `get` command with three operators, the third operator (`@>C`) is treated as part of the key, and the `get` command searches for values smaller than **M** and greater than **B@>C**.

```
get @<M@>B@>C
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
```

15.19.5 Security Considerations for the InnoDB memcached Plugin

Caution

Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

Password-Protecting memcached Using SASL

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enable SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.

`memcached` clients are only able to access InnoDB tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to InnoDB tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

```
sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
```

2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides *simple cleartext password support*, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.

In summary, add following three `cmake` options:

```
cmake ... -DWITH_INNOODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
```

3. Install the `daemon_memcached` plugin, as described in [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).
4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)
 - a. In a file, create a user named `testname` and define the password as `testpasswd`:

```
echo "testname:testpasswd::::::::" >/home/jy/memcached-sasl-db
```

- b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform `memcached` of the user name and password file:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

- c. Inform `memcached` that a cleartext password is used:

```
echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

```
mysqld ... --daemon_memcached_option="-S"
```

6. To test the setup, use an SASL-enabled client such as [SASL-enabled libmemcached](#).

```
memcp --servers=localhost:11211 --binary --username=testname
--password=password myfile.txt

memcat --servers=localhost:11211 --binary --username=testname
--password=password myfile.txt
```

If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with `memcached`, but the method described above is the most straightforward.

15.19.6 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the `InnoDB memcached` plugin involves some degree of rewriting or adapting existing code that uses MySQL or the `memcached` API.

- With the `daemon_memcached` plugin, instead of many traditional `memcached` servers running on low-powered machines, you have the same number of `memcached` servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the `memcached` API, but adaptation is likely required due to the different server configuration.
- The data stored through the `daemon_memcached` plugin goes into `VARCHAR`, `TEXT`, or `BLOB` columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the `CAST()` function in queries.
- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by `memcached` code likely have only a few or even a single column holding data values.

- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both [queries](#) (read) and [DML](#) (write) operations can be substantially faster when performed through the [InnoDB memcached](#) interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a website.

The following sections explore these points in more detail.

15.19.6.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of [memcached](#) applications when adapting an existing MySQL schema or application to use the [daemon_memcached](#) plugin:

- [memcached](#) keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to [add\(\)](#), [set\(\)](#), [get\(\)](#), and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.
- If there is a short numeric [primary key](#) column in an [InnoDB](#) table, use it as the unique lookup key for [memcached](#) by converting the integer to a string value. If the [memcached](#) server is used for multiple applications, or with more than one [InnoDB](#) table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

Note

The [daemon_memcached](#) plugin supports inserts and reads on mapped [InnoDB](#) tables that have an [INTEGER](#) defined as the primary key.

- You cannot use a partitioned table for data queried or stored using [memcached](#).
- The [memcached](#) protocol passes numeric values around as strings. To store numeric values in the underlying [InnoDB](#) table, to implement counters that can be used in SQL functions such as [SUM\(\)](#) or [AVG\(\)](#), for example:
 - Use [VARCHAR](#) columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
 - In any query that performs arithmetic using column values, use the [CAST\(\)](#) function to convert the values from string to integer, or to some other numeric type. For example:

```
# Alphabetic entries are returned as zero.

SELECT CAST(c2 as unsigned integer) FROM demo_test;

# Since there could be numeric values of 0, can't disqualify them.
# Test the string values to find the ones that are integers, and average only those.

SELECT AVG(cast(c2 as unsigned integer)) FROM demo_test
  WHERE c2 BETWEEN '0' and '9999999999';

# Views let you hide the complexity of queries. The results are already converted;
# no need to repeat conversion functions and WHERE clauses each time.

CREATE VIEW numbers AS SELECT c1 KEY, CAST(c2 AS UNSIGNED INTEGER) val
  FROM demo_test WHERE c2 BETWEEN '0' and '9999999999';
SELECT SUM(val) FROM numbers;
```

**Note**

Any alphabetic values in the result set are converted into 0 by the call to `CAST()`. When using functions such as `AVG()`, which depend on the number of rows in the result set, include `WHERE` clauses to filter out non-numeric values.

- If the `InnoDB` column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.
- To use an existing table with the `daemon_memcached` plugin, define an entry for it in the `innodb_memcache.containers` table. To make that table the default for all `memcached` requests, specify a value of `default` in the `name` column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choice, then issue a `memcached` request in the form of `get @@name` or `set @@name` within the application to specify the table to be used for subsequent `memcached` requests.

For an example of using a table other than the predefined `test.demo_test` table, see [Example 15.13, “Using Your Own Table with an InnoDB memcached Application”](#). For the required table layout, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

- To use multiple `InnoDB` table column values with `memcached` key/value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the `InnoDB` table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

Example 15.13 Using Your Own Table with an InnoDB memcached Application

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#). It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data ('R' for right and 'L' for left).

```
mysql> USE test;

mysql> CREATE TABLE `multicol` (
  `country` varchar(128) NOT NULL DEFAULT '',
  `population` varchar(10) DEFAULT NULL,
  `area_sq_km` varchar(9) DEFAULT NULL,
  `drive_side` varchar(1) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` bigint(20) unsigned DEFAULT NULL,
  `c5` int(11) DEFAULT NULL,
  PRIMARY KEY (`country`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```
mysql> INSERT INTO innodb_memcache.containers
      (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
      expire_time_column,unique_idx_name_on_key)
      VALUES
      ('bbb','test','multicol','country','population,area_sq_km,drive_side',
      'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of `'bbb'`, which is the table identifier.

Note

If a single InnoDB table is used for all memcached applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.
 - The `db_table` column is set to `multicol`, which is the name of the InnoDB table.
 - `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.
 - Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.
 - Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.
 - The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.
3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the `daemon_memcached` plugin.

```
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)
```

```

country_data = [
    ("Canada", "34820000", "9984670", "R"),
    ("USA", "314242000", "9826675", "R"),
    ("Ireland", "6399152", "84421", "L"),
    ("UK", "62262000", "243610", "L"),
    ("Mexico", "113910608", "1972550", "R"),

    ("India", "1210193422", "3287263", "L"),
    ("China", "1347350000", "9640821", "R"),
]

def switch_table(memc, table):
    key = "@@" + table
    print "Switching default table to '" + table + "' by issuing GET for '" + key + "'."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population, area, drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key, value):
            print "Added new key, value pair."
        else:
            print "Updating value for existing key."
            memc.set(key, value)

def query_country_data(memc):
    banner("Retrieving data for all keys (country names)")
    for item in country_data:
        key = item[0]
        result = memc.get(key)
        print "Here is the result retrieved from the database for key " + key + ":"
        print result
        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value      : " + m_area
        print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':
    memc = connect_to_memcached()
    switch_table(memc, "bbb")
    insert_country_data(memc)
    query_country_data(memc)

    sys.exit(0)

```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the [memcached](#) interface. The only required information is the port number on the local system where the [memcached](#) daemon listens.

- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

4. Run the sample Python application.

```
shell> python multicol.py
```

If successful, the sample application returns this output:

```
Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

Unpacked area value      : 3287263
Unpacked drive side value: L
Here is the result retrieved from the database for key China:
1347350000|9640821|R
Unpacked population value: 1347350000
Unpacked area value      : 9640821
Unpacked drive side value: R

```

5. Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```

mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
    db_table: demo_test
  key_columns: c1
value_columns: c2
      flags: c3
   cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY

```

```
***** 2. row *****
      name: bbb
      db_schema: test
      db_table: multicol
      key_columns: country
      value_columns: population,area_sq_km,drive_side
      flags: c3
      cas_column: c4
      expire_time_column: c5
      unique_idx_name_on_key: PRIMARY
```

6. Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL [queries](#), which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate [MySQL Connector or API](#)).

```
mysql> SELECT * FROM test.multicol;
```

country	population	area_sq_km	drive_side	c3	c4	c5
Canada	34820000	9984670	R	0	11	0
China	1347350000	9640821	R	0	20	0
Denmark	5543453	43094	R	0	16	0
India	1210193422	3287263	L	0	19	0
Ireland	6399152	84421	L	0	13	0
Mexico	113910608	1972550	R	0	15	0
Norway	5002942	385252	R	0	17	0
UAE	8264070	83600	R	0	18	0
UK	62262000	243610	L	0	14	0
USA	314242000	9826675	R	0	12	0

Note

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

7. Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
```

avg(population)
261304724.7142857

```
mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
```

sum(area_sq_km)
10153885

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach *does not work* for operators such as `<` or `>`, for example, when comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple `SELECT *` queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the `multicol` table, and with population and area figures treated as numbers:

```
mysql> CREATE VIEW populous_countries AS
      SELECT
        country,
        cast(population as unsigned integer) population,
        cast(area_sq_km as unsigned integer) area_sq_km,
        drive_side FROM multicol
      ORDER BY CAST(population as unsigned integer) DESC
      LIMIT 3;
```

```
mysql> SELECT * FROM populous_countries;
```

country	population	area_sq_km	drive_side
China	1347350000	9640821	R
India	1210193422	3287263	L
USA	314242000	9826675	R

```
mysql> DESC populous_countries;
```

Field	Type	Null	Key	Default	Extra
country	varchar(128)	NO			
population	bigint(10) unsigned	YES		NULL	
area_sq_km	int(9) unsigned	YES		NULL	
drive_side	varchar(1)	YES		NULL	

15.19.6.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the **primary key** of the InnoDB table, and to create a unique **secondary index** on the column that contains the memcached key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.
- If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the `@@table_id.key` notation to store and retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable **compression** for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You

might create additional [secondary indexes](#) on tables that are frequently used to generate reports using SQL.

- Preferably, configure a stable set of table definitions for use with the `daemon_memcached` plugin, and leave the tables in place permanently. Changes to the `innodb_memcache.containers` table take effect the next time the `innodb_memcache.containers` table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by `containers.name`) is requested using @@ notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.
- When you use the default `innodb_only` caching policy, calls to `add()`, `set()`, `incr()`, and so on can succeed but still trigger debugging messages such as `while expecting 'STORED', got unexpected response 'NOT_STORED'`. Debug messages occur because new and updated values are sent directly to the InnoDB table without being saved in the memory cache, due to the `innodb_only` caching policy.

15.19.6.3 Tuning InnoDB memcached Plugin Performance

Because using InnoDB in combination with `memcached` involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using `memcached` by itself. When using the InnoDB `memcached` plugin, focus tuning goals for `memcached` operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and DML operations (inserts, updates, and deletes) that use the `memcached` interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the `memcached` interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

Adapting SQL Queries

The types of queries that are most suited to simple `GET` requests are those with a single clause or a set of `AND` conditions in the `WHERE` clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
get key_value

SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
get key_value

SQL:
SELECT 'key exists!' FROM tbl
  WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
```

```
get key_value
```

Using System Memory

For best performance, deploy the `daemon_memcached` plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the InnoDB buffer pool, through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of `innodb_buffer_pool_instances` for maximum throughput when most operations involve data that is already cached in memory.

Reducing Redundant I/O

InnoDB has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the `innodb_doublewrite` to 0 and `innodb_flush_log_at_trx_commit` to 2. Measure performance with different `innodb_flush_method` settings.

For other ways to reduce or tune I/O for table operations, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent `commit` operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to `memcached` immediately (that is, until *N* more `get` operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last *N* updates in a crash is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way InnoDB organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and `add` them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key/value pairs to use in your own benchmarks. See [libmemcached Command-Line Utilities](#) for details.

15.19.6.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is `committed`. If data is critical, it should be committed immediately so that it is safe in case of a crash or outage. If data is less critical, such as counters that are reset after a crash or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction `isolation level`. Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater `locking` overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

Allowing or Disallowing DDL

By default, you can perform `DDL` operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_ddl` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL,

because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache-only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache-only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```
mysql> SELECT * FROM innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+
| policy_name | get_policy | set_policy | delete_policy | flush_policy |
+-----+-----+-----+-----+-----+
| cache_policy | innodb_only | innodb_only | innodb_only | innodb_only |
+-----+-----+-----+-----+-----+

mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
      WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

15.19.6.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up **DML** operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

15.19.6.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying `InnoDB` table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than `1`, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
```

```
mysql> SELECT * FROM demo_test;
```

cx	cy	c1	cz	c2	ca	CB	c3	cu	c4	C5
NULL	NULL	a11	NULL	123456789	NULL	NULL	10	NULL	3	NULL

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than `1`, changes made to the table using SQL are not immediately visible to `memcached` operations.
- The `InnoDB` table is either `IS` (intention shared) or `IX` (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of `1`, the table is most likely locked between each operation, preventing `DDL` statements on the table.

15.19.7 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL `binary log`, updates made on a `master server` through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on `slave servers`. The primary advantage of this configuration is increased write throughput on the master. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

Enabling the InnoDB memcached Binary Log

1. To use the `daemon_memcached` plugin with the MySQL `binary log`, enable the `innodb_api_enable_binlog` configuration option on the `master server`. This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option. You can add these options to the MySQL configuration file, or on the `mysqld` command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

2. Configure the master and slave server, as described in [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#).
3. Use `mysqldump` to create a master data snapshot, and sync the snapshot to the slave server.

```
master shell> mysqldump --all-databases --lock-all-tables > dbdump.db
slave shell> mysql < dbdump.db
```

4. On the master server, issue `SHOW MASTER STATUS` to obtain the master binary log coordinates.

```
mysql> SHOW MASTER STATUS;
```

5. On the slave server, use a `CHANGE MASTER TO` statement to set up a slave server using the master binary log coordinates.

```
mysql> CHANGE MASTER TO
      MASTER_HOST='localhost',
      MASTER_USER='root',
      MASTER_PASSWORD='',
      MASTER_PORT = 13000,
      MASTER_LOG_FILE='0.000001',
      MASTER_LOG_POS=114;
```

6. Start the slave.

```
mysql> START SLAVE;
```

If the error log prints output similar to the following, the slave is ready for replication.

```
2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
master 'root@localhost:13000', replication started in log '0.000001'
at position 114
```

Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the `InnoDB memcached` replication configuration using the `memcached` and `telnet` to insert, update, and delete data. A MySQL client is used to verify results on the master and slave servers.

The example uses the `demo_test` table, which was created by the `innodb_memcached_config.sql` configuration script during the initial setup of the `daemon_memcached` plugin. The `demo_test` table contains a single example record.

1. Use the `set` command to insert a record with a key of `test1`, a flag value of `10`, an expiration value of `0`, a cas value of `1`, and a value of `t1`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 1
t1
STORED
```

2. On the master server, check that the record was inserted into the `demo_test` table. Assuming the `demo_test` table was not previously modified, there should be two records. The example record with a key of `AA`, and the record you just inserted, with a key of `test1`. The `c1` column maps to the key, the `c2` column to the value, the `c3` column to the flag value, the `c4` column to the cas value, and the `c5` column to the expiration time. The expiration time was set to 0, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

3. Check to verify that the same record was replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

The update is replicated to the slave server (notice that the `cas` value is also updated).

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | new          | 10    | 2     | 0     |
+-----+-----+-----+-----+-----+
```

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
STORED
```

```
delete test1
DELETED
```

When the `delete` operation is replicated to the slave, the `test1` record on the slave is also deleted.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+
```

- Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

- Telnet to the master server and enter two new records.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

- Confirm that the two records were replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| test2 | again | 10 | 4 | 0 |
| test3 | again1 | 10 | 5 | 0 |
+-----+-----+-----+-----+
```

- Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

- Check to ensure that the `flush_all` operation was replicated on the slave server.

```
mysql> SELECT * FROM test.demo_test;
```

```
Empty set (0.00 sec)
```

InnoDB memcached Binary Log Notes

Binary Log Format:

- Most `memcached` operations are mapped to `DML` statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.
- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command in MySQL 5.7 and earlier. Since `DDL` commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement. In MySQL 8.0 and later, `flush_all` is mapped to `DELETE` but is still replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of `transactions` has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying `InnoDB` table is replicated after successful completion.
- The default value of `daemon_memcached_w_batch_size` is `1`, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the master and slave servers. The replicated records are always available immediately on the slave server. If you set `daemon_memcached_w_batch_size` to a value greater than `1`, records inserted or updated through `memcached` are not immediately visible on the master server; to view the records on the master server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`.

15.19.8 InnoDB memcached Plugin Internals

InnoDB API for the InnoDB memcached Plugin

The `InnoDB memcached` engine accesses `InnoDB` through `InnoDB` APIs, most of which are directly adopted from embedded `InnoDB`. `InnoDB` API functions are passed to the `InnoDB memcached` engine as callback functions. `InnoDB` API functions access the `InnoDB` tables directly, and are mostly `DML` operations with the exception of `TRUNCATE TABLE`.

`memcached` commands are implemented through the `InnoDB memcached` API. The following table outlines how `memcached` commands are mapped to `DML` or `DDL` operations.

Table 15.23 memcached Commands and Associated DML or DDL Operations

memcached Command	DML or DDL Operations
<code>get</code>	a read/fetch command
<code>set</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code> (depending on whether or not a key exists)
<code>add</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code>
<code>replace</code>	a search followed by an <code>UPDATE</code>
<code>append</code>	a search followed by an <code>UPDATE</code> (appends data to the result before <code>UPDATE</code>)

memcached Command	DML or DDL Operations
<code>prepend</code>	a search followed by an <code>UPDATE</code> (prepends data to the result before <code>UPDATE</code>)
<code>incr</code>	a search followed by an <code>UPDATE</code>
<code>decr</code>	a search followed by an <code>UPDATE</code>
<code>delete</code>	a search followed by a <code>DELETE</code>
<code>flush_all</code>	<code>TRUNCATE TABLE</code> (DDL)

InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the `daemon_memcached` plugin. The `cache_policies` table, `config_options` table, and `containers` table are created by the `innodb_memcached_config.sql` configuration script in the `innodb_memcache` database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies             |
| config_options             |
| containers                  |
+-----+
```

cache_policies Table

The `cache_policies` table defines a cache policy for the InnoDB memcached installation. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations, within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use InnoDB as the data store.
- `cache-only`: Use the memcached engine as the data store.
- `caching`: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- `disable`: Disable caching.

Table 15.24 `cache_policies` Columns

Column	Description
<code>policy_name</code>	Name of the cache policy. The default cache policy name is <code>cache_policy</code> .
<code>get_policy</code>	The cache policy for get operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>set_policy</code>	The cache policy for set operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>delete_policy</code>	The cache policy for delete operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

Column	Description
<code>flush_policy</code>	The cache policy for flush operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

config_options Table

The `config_options` table stores `memcached`-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

Table 15.25 config_options Columns

Column	Description
<code>Name</code>	<p>Name of the <code>memcached</code>-related configuration option. The following configuration options are supported by the <code>config_options</code> table:</p> <ul style="list-style-type: none"> <code>separator</code>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a <code> </code> character. For example, if you define <code>col1</code>, <code>col2</code> as value columns, and you define <code> </code> as the separator, you can issue the following <code>memcached</code> command to insert values into <code>col1</code> and <code>col2</code>, respectively: <pre>set keyx 10 0 19 valuecolx valuecoly</pre> <p><code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</p> <code>table_map_delimiter</code>: The character separating the schema name and the table name when you use the <code>@@</code> notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.
<code>Value</code>	The value assigned to the <code>memcached</code> -related configuration option.

containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own `InnoDB` table, you must create an entry in the `containers` table.

Table 15.26 containers Columns

Column	Description
<code>name</code>	The name given to the container. If an <code>InnoDB</code> table is not requested by name using <code>@@</code> notation, the <code>daemon_memcached</code> plugin uses the <code>InnoDB</code> table with a <code>containers.name</code> value of <code>default</code> . If there is no such entry, the first entry in the <code>containers</code> table, ordered alphabetically by <code>name</code> (ascending), determines the default <code>InnoDB</code> table.

Column	Description
<code>db_schema</code>	The name of the database where the <code>InnoDB</code> table resides. This is a required value.
<code>db_table</code>	The name of the <code>InnoDB</code> table that stores <code>memcached</code> values. This is a required value.
<code>key_columns</code>	The column in the <code>InnoDB</code> table that contains lookup key values for <code>memcached</code> operations. This is a required value.
<code>value_columns</code>	The <code>InnoDB</code> table columns (one or more) that store <code>memcached</code> data. Multiple columns can be specified using the separator character specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character (“ ”). To specify multiple columns, separate them with the defined separator character. For example: <code>col1 col2 col3</code> . This is a required value.
<code>flags</code>	The <code>InnoDB</code> table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for <code>memcached</code> . A flag value can be used as a column specifier for some operations (such as <code>incr</code> , <code>prepend</code>) if a <code>memcached</code> value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a <code>value_columns</code> to three <code>InnoDB</code> table columns, and only want the increment operation performed on one columns, use the <code>flags</code> column to specify the column. If you do not use the <code>flags</code> column, set a value of 0 to indicate that it is unused.
<code>cas_column</code>	The <code>InnoDB</code> table column that stores compare-and-swap (cas) values. The <code>cas_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the <code>InnoDB memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the <code>InnoDB buffer pool</code> , this column is rarely needed. If you do not use this column, set a value of 0 to indicate that it is unused.
<code>expire_time_column</code>	The <code>InnoDB</code> table column that stores expiration values. The <code>expire_time_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the <code>InnoDB memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the <code>InnoDB buffer pool</code> , this column is rarely needed. If you do not use this column, set a value of 0 to indicate that the column is unused. The maximum expire time is defined as <code>INT_MAX32</code> or 2147483647 seconds (approximately 68 years).
<code>unique_idx_name_on_key</code>	The name of the index on the key column. It must be a unique index. It can be the <code>primary key</code> or a <code>secondary index</code> . Preferably, use the primary key of the <code>InnoDB</code> table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a <code>covering index</code> for <code>memcached</code> lookups; <code>InnoDB</code> returns an error if you try to define a composite secondary index over both the key and value columns.

containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify 0 for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.

- **key_columns**: The maximum limit for a **memcached** key is 250 characters, which is enforced by **memcached**. The mapped key must be a non-Null **CHAR** or **VARCHAR** type.
- **value_columns**: Must be mapped to a **CHAR**, **VARCHAR**, or **BLOB** column. There is no length restriction and the value can be NULL.
- **cas_column**: The **cas** value is a 64 bit integer. It must be mapped to a **BIGINT** of at least 8 bytes. If you do not use this column, set a value of 0 to indicate that it is unused.
- **expiration_time_column**: Must mapped to an **INTEGER** of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60*60*24*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of 0 to indicate that it is unused.
- **flags**: Must be mapped to an **INTEGER** of at least 32-bits and can be NULL. If you do not use this column, set a value of 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin is not loaded.

Multiple Value Column Mapping

- During plugin initialization, when **InnoDB memcached** is configured with information defined in the **containers** table, each mapped column defined in **containers.value_columns** is verified against the mapped **InnoDB** table. If multiple **InnoDB** table columns are mapped, there is a check to ensure that each column exists and is the right type.
- At run-time, for **memcached** insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.
- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations fail.
- If a table has more columns than mapped values, the extra columns do not affect results.

The demo_test Example Table

The **innodb_memcached_config.sql** configuration script creates a **demo_test** table in the **test** database, which can be used to verify **InnoDB memcached** plugin installation immediately after setup.

The **innodb_memcached_config.sql** configuration script also creates an entry for the **demo_test** table in the **innodb_memcache.containers** table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
    key_columns: c1
  value_columns: c2
         flags: c3
      cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY
mysql> SELECT * FROM test.demo_test;
```

c1	c2	c3	c4	c5
AA	HELLO, HELLO	8	0	0

15.19.9 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the [InnoDB memcached](#) plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

```
failed to set rlimit for open files. Try running as root or requesting
smaller maxconns value.
```

The error message is from the [memcached](#) daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and OS X:

```
# Linux
shell> ulimit -n
1024
shell> ulimit -n 4096
shell> ulimit -n
4096

# OS X
shell> ulimit -n
256
shell> ulimit -n 4096
shell> ulimit -n
4096
```

The other solution is to reduce the number of concurrent connections permitted for the [memcached](#) daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

```
[mysqld]
...
loose-daemon_memcached_option='-c 64'
```

- To troubleshoot problems where the [memcached](#) daemon is unable to store or retrieve [InnoDB](#) table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to [memcached](#) operations.

```
[mysqld]
...
loose-daemon_memcached_option='-vvv'
```

- If columns specified to hold [memcached](#) values are the wrong data type, such as a numeric type instead of a string type, attempts to store key/value pairs fail with no specific error code or message.
- If the `daemon_memcached` plugin causes MySQL server startup issues, you can temporarily disable the `daemon_memcached` plugin while troubleshooting by adding this line under the `[mysqld]` group in the MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the `INSTALL PLUGIN` statement before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables, the server might crash and fail to start. The server could also fail to start if you incorrectly configure an entry in the `innodb_memcache.containers` table.

To uninstall the `memcached` plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine with the `daemon_memcached` plugin enabled in each instance, use the `daemon_memcached_option` configuration parameter to specify a unique `memcached` port for each `daemon_memcached` plugin.
- If an SQL statement cannot find the `InnoDB` table or finds no data in the table, but `memcached` API calls retrieve the expected data, you may be missing an entry for the `InnoDB` table in the `innodb_memcache.containers` table, or you may have not switched to the correct `InnoDB` table by issuing a `get` or `set` request using `@@table_id` notation. This problem could also occur if you change an existing entry in the `innodb_memcache.containers` table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as `col1|col2|col3` may still work, even if the daemon is using the `test.demo_test` table which stores values in a single column.
- When defining your own `InnoDB` table for use with the `daemon_memcached` plugin, and columns in the table are defined as `NOT NULL`, ensure that values are supplied for the `NOT NULL` columns when inserting a record for the table into the `innodb_memcache.containers` table. If the `INSERT` statement for the `innodb_memcache.containers` record contains fewer delimited values than there are mapped columns, unfilled columns are set to `NULL`. Attempting to insert a `NULL` value into a `NOT NULL` column causes the `INSERT` to fail, which may only become evident after you reinitialize the `daemon_memcached` plugin to apply changes to the `innodb_memcache.containers` table.
- If `cas_column` and `expire_time_column` fields of the `innodb_memcached.containers` table are set to `NULL`, the following error is returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcache' has an invalid NULL value.
```

The `memcached` plugin rejects usage of `NULL` in the `cas_column` and `expire_time_column` columns. Set the value of these columns to `0` when the columns are unused.

- As the length of the `memcached` key and values increase, you might encounter size and length limits.
 - When the key exceeds 250 bytes, `memcached` operations return an error. This is currently a fixed limit within `memcached`.
 - `InnoDB` table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the `innodb_page_size` value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See [Section 15.8.1.7, “Limits on InnoDB Tables”](#) for details.
 - The maximum size for the key-value combination is 1 MB.
- If you share configuration files across MySQL servers of different versions, using the latest configuration options for the `daemon_memcached` plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the `loose` prefix with option names. For example, use `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.

- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.
- `memcached` connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a `memcached` connection does not have access to the server code.

15.20 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 5.4.2, “The Error Log”](#)). [Section B.3, “Server Error Codes and Messages”](#) provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.
- If the failure is related to a [deadlock](#), run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).
- If the issue is related to the `InnoDB` data dictionary, see [Section 15.20.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the `InnoDB` Monitors to obtain information about a problem (see [Section 15.16, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of `InnoDB`. If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the [InnoDB Information Schema system tables](#) to examine contents of the `InnoDB` internal data dictionary.

`InnoDB` temporarily enables standard `InnoDB` Monitor output under the following conditions:

- A long semaphore wait
- `InnoDB` cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

15.20.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for `InnoDB` I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

Initialization Problems

If something goes wrong when `InnoDB` attempts to initialize its tablespace or its log files, delete all files created by `InnoDB`: all `ibdata` files and all `ib_logfile` files. If you already created some `InnoDB` tables, also delete any `.ibd` files from the MySQL database directories. Then try the `InnoDB` database

creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

Runtime Problems

If [InnoDB](#) prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure [mysqld](#) has access rights to create files in those directories.
- Make sure [mysqld](#) can read the proper [my.cnf](#) or [my.ini](#) option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the [innodb_data_home_dir](#) and [innodb_data_file_path](#) values. In particular, any [MAX](#) value in the [innodb_data_file_path](#) option is a hard limit, and exceeding that limit causes a fatal error.

15.20.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with [SELECT ... INTO outfile](#). Usually, most of the data obtained in this way is intact. Serious corruption might cause [SELECT * FROM tbl_name](#) statements or [InnoDB](#) background operations to crash or assert, or even cause [InnoDB](#) roll-forward recovery to crash. In such cases, you can use the [innodb_force_recovery](#) option to force the [InnoDB](#) storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the [\[mysqld\]](#) section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

Warning

Only set [innodb_force_recovery](#) to a value greater than 0 in an emergency situation, so that you can start [InnoDB](#) and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an [innodb_force_recovery](#) setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing [InnoDB](#) recovery, you should always start with [innodb_force_recovery=1](#) and only increase the value incrementally, as necessary.

[innodb_force_recovery](#) is 0 by default (normal startup without forced recovery). The permissible nonzero values for [innodb_force_recovery](#) are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an [innodb_force_recovery](#) value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because

database pages are left in an obsolete state, which in turn may introduce more corruption into [B-trees](#) and other database structures.

As a safety measure, [InnoDB](#) prevents [INSERT](#), [UPDATE](#), or [DELETE](#) operations when [innodb_force_recovery](#) is greater than 0. An [innodb_force_recovery](#) setting of 4 or greater places [InnoDB](#) in read-only mode.

- 1 ([SRV_FORCE_IGNORE_CORRUPT](#))

Lets the server run even if it detects a corrupt [page](#). Tries to make [SELECT * FROM tbl_name](#) jump over corrupt index records and pages, which helps in dumping tables.

- 2 ([SRV_FORCE_NO_BACKGROUND](#))

Prevents the [master thread](#) and any [purge threads](#) from running. If a crash would occur during the [purge](#) operation, this recovery value prevents it.

- 3 ([SRV_FORCE_NO_TRX_UNDO](#))

Does not run transaction [rollbacks](#) after [crash recovery](#).

- 4 ([SRV_FORCE_NO_IBUF_MERGE](#))

Prevents [insert buffer](#) merge operations. If they would cause a crash, does not do them. Does not calculate table [statistics](#). This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. Sets [InnoDB](#) to read-only.

- 5 ([SRV_FORCE_NO_UNDO_LOG_SCAN](#))

Does not look at [undo logs](#) when starting the database: [InnoDB](#) treats even incomplete transactions as committed. This value can permanently corrupt data files. Sets [InnoDB](#) to read-only.

- 6 ([SRV_FORCE_NO_LOG_REDO](#))

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into [B-trees](#) and other database structures. Sets [InnoDB](#) to read-only.

You can [SELECT](#) from tables to dump them. With an [innodb_force_recovery](#) value of 3 or less you can [DROP](#) or [CREATE](#) tables. [DROP TABLE](#) is also supported with an [innodb_force_recovery](#) value greater than 3. [DROP TABLE](#) is not permitted with an [innodb_force_recovery](#) value greater than 4.

If you know that a given table is causing a crash on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or [ALTER TABLE](#), you can kill the [mysqld](#) process and set [innodb_force_recovery](#) to 3 to bring the database up without the rollback, and then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb_force_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT * FROM t](#) queries.

15.20.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored in the InnoDB [data dictionary](#). If you move data files around, dictionary data can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

Cannot Open Datafile

With `innodb_file_per_table` enabled (the default), the following messages may appear at startup if a [file-per-table](#) tablespace file (`.ibd` file) is missing:

```
[ERROR] InnoDB: Operating system error number 2 in a file operation.
[ERROR] InnoDB: The error means the system cannot find the path specified.
[ERROR] InnoDB: Cannot open datafile for read-only: './test/t1.ibd' OS error: 71
[Warning] InnoDB: Ignoring tablespace `test/t1` because it could not be opened.
```

To address these messages, issue `DROP TABLE` statement to remove data about the missing table from the data dictionary.

Restoring Orphan File-Per-Table ibd Files

This procedure describes how to restore orphan [file-per-table](#) `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for [general tablespace](#) `.ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See [Section 15.8.1.3, “Moving or Copying InnoDB Tables”](#) for information about creating clean backups.

Tablespace copying limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#) are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
    actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    first_name VARCHAR(45) NOT NULL,
    last_name VARCHAR(45) NOT NULL,
    last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (actor_id),
    KEY idx_actor_last_name (last_name)
)ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan `.ibd` file from your backup directory to the new database directory.

```
shell> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

4. Ensure that the `.ibd` file has the necessary file permissions.
5. Import the orphan `.ibd` file. A warning is issued indicating that InnoDB will attempt to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
| count(*) |
+-----+
|      200 |
+-----+
```

15.20.4 InnoDB Error Handling

The following items describe how InnoDB performs error handling. InnoDB sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a `tablespace`, a MySQL `Table is full` error occurs and InnoDB rolls back the SQL statement.
- A transaction `deadlock` causes InnoDB to `roll back` the entire `transaction`. Retry the whole transaction when this happens.

A lock wait timeout causes InnoDB to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

Chapter 16 Alternative Storage Engines

Table of Contents

16.1 Setting the Storage Engine	2851

16.11 Overview of MySQL Storage Engine Architecture	2883
16.11.1 Pluggable Storage Engine Architecture	2883
16.11.2 The Common Database Server Layer	2884

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 8.0 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
```

```
***** 2. row *****
Engine: InnoDB
Support: DEFAULT
Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
Savepoints: YES
***** 3. row *****
Engine: MRG_MYISAM
Support: YES
Comment: Collection of identical MyISAM tables
Transactions: NO
XA: NO
Savepoints: NO
***** 4. row *****
Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
XA: NO
Savepoints: NO
***** 5. row *****
Engine: MyISAM
Support: YES
Comment: MyISAM storage engine
Transactions: NO
XA: NO
Savepoints: NO
...
```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 15, The InnoDB Storage Engine](#) and [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#). For advanced users, it also contains a description of the pluggable storage engine architecture (see [Section 16.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about features offered in commercial MySQL Server binaries, see [MySQL Editions](#), on the MySQL website. The storage engines available might depend on which edition of MySQL you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 8.0 FAQ: Storage Engines”](#).

MySQL 8.0 Supported Storage Engines

- **InnoDB**: The default storage engine in MySQL 8.0. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 15, The InnoDB Storage Engine](#).
- **MyISAM**: These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- **Memory**: Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.

- **CSV:** Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in **InnoDB** tables during normal operation, and only use CSV tables during the import or export stage.
- **Archive:** These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- **Blackhole:** The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to slave servers, but the master server does not keep its own copy of the data.
- **Merge:** Enables a MySQL DBA or developer to logically group a series of identical **MyISAM** tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Federated:** Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **Example:** This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly **InnoDB** tables, with one **CSV** table for exporting data to a spreadsheet and a few **MEMORY** tables for temporary workspaces.

Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL, with clarifying notes following the table.

Table 16.1 Storage Engines Feature Summary

Feature	MyISAM	Memory	InnoDB	Archive	NDB
B-tree indexes	Yes	Yes	Yes	No	No
Backup/point-in-time recovery (note 1)	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Clustered indexes	No	No	Yes	No	No
Compressed data	Yes (note 2)	No	Yes	Yes	No
Data caches	No	N/A	Yes	No	Yes

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Encrypted data (note 3)	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	Yes (note 4)
Full-text search indexes	Yes	No	Yes (note 5)	No	No
Geospatial data type support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	Yes (note 6)	No	No
Hash indexes	No	Yes	No (note 7)	No	Yes
Index caches	Yes	N/A	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC	No	No	Yes	No	No
Replication support (note 1)	Yes	Limited (note 8)	Yes	Yes	Yes
Storage limits	256TB	RAM	64TB	None	384EB
T-tree indexes	No	No	No	No	Yes
Transactions	Yes	No	Yes	No	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

Notes:

1. Implemented in the server, rather than in the storage engine.
2. Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.
3. Implemented in the server via encryption functions. Data-at-rest tablespace encryption is available in MySQL 5.7 and later.
4. Support for foreign keys is available in MySQL Cluster NDB 7.3 and later.
5. InnoDB support for FULLTEXT indexes is available in MySQL 5.6 and later.

6. InnoDB support for geospatial indexing is available in MySQL 5.7 and later.
7. InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.
8. See the discussion later in this section.

16.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an [ENGINE](#) table option to the [CREATE TABLE](#) statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the [ENGINE](#) option, the default storage engine is used. The default engine is [InnoDB](#) in MySQL 8.0. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for [TEMPORARY](#) tables created with [CREATE TEMPORARY TABLE](#) can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an [ALTER TABLE](#) statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 13.1.18, “CREATE TABLE Syntax”](#), and [Section 13.1.8, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses [InnoDB](#) tables for maximum safety, but the slave servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever [CREATE TABLE](#) or [ALTER TABLE](#) cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 5.1.10, “Server SQL Modes”](#).

MySQL may store a table's index and data in one or more other files, depending on the storage engine. Table and column definitions are stored in the MySQL data dictionary. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

16.2 The MyISAM Storage Engine

[MyISAM](#) is based on the older (and no longer available) [ISAM](#) storage engine but has many useful extensions.

Table 16.2 MyISAM Storage Engine Features

Feature	Support
B-tree indexes	Yes
Backup/point-in-time recovery (Implemented in the server, rather than in the storage engine.)	Yes
Cluster database support	No
Clustered indexes	No
Compressed data	Yes (Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.)
Data caches	No
Encrypted data (Implemented in the server via encryption functions. Data-at-rest tablespace encryption is available in MySQL 5.7 and later.)	Yes
Foreign key support	No
Full-text search indexes	Yes
Geospatial data type support	Yes
Geospatial indexing support	Yes
Hash indexes	No
Index caches	Yes
Locking granularity	Table
MVCC	No
Replication support (Implemented in the server, rather than in the storage engine.)	Yes
Storage limits	256TB
T-tree indexes	No
Transactions	No
Update statistics for data dictionary	Yes

Each [MyISAM](#) table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. The data file has an [.MYD](#) ([MYData](#)) extension. The index file has an [.MYI](#) ([MYIndex](#)) extension. The table definition is stored in the MySQL data dictionary.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an [ENGINE](#) table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 8.0, it is normally necessary to use [ENGINE](#) to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine.

You can check or repair [MyISAM](#) tables with the [mysqlcheck](#) client or [myisamchk](#) utility. You can also compress [MyISAM](#) tables with [myisampack](#) to take up much less space. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

In MySQL 8.0, the [MyISAM](#) storage engine provides no partitioning support. *Partitioned [MyISAM](#) tables created in previous versions of MySQL cannot be used in MySQL 8.0.* For more information, see [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#). For help with upgrading such tables so that they can be used in MySQL 8.0, see [Section 2.11.1.3, “Changes in MySQL 8.0”](#).

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of $(2^{32})^2$ (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an [AUTO_INCREMENT](#) column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one [AUTO_INCREMENT](#) column per table is supported. [MyISAM](#) automatically updates this column for [INSERT](#) and [UPDATE](#) operations. This makes [AUTO_INCREMENT](#) columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an [AUTO_INCREMENT](#) column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The [AUTO_INCREMENT](#) value can be reset with [ALTER TABLE](#) or [myisamchk](#).
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can [INSERT](#) new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 8.11.3, “Concurrent Inserts”](#).

- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 13.1.18, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Chapter 10, Character Sets, Collations, Unicode](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <https://forums.mysql.com/list.php?21>.

16.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.1.6, “Server Command Options”](#).

Table 16.3 MyISAM Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
bulk_insert_buffer_size	Yes	Yes	Yes		Both	Yes
concurrent_insert	Yes	Yes	Yes		Global	Yes
delay-key-write	Yes	Yes			Global	Yes
- Variable: delay_key_write			Yes		Global	Yes
have_rtree_keys			Yes		Global	No
key_buffer_size	Yes	Yes	Yes		Global	Yes
log-isam	Yes	Yes				
myisam-block-size	Yes	Yes				
myisam_data_pointer_size	Yes	Yes	Yes		Global	Yes
myisam_max_sort_file_size	Yes	Yes	Yes		Global	Yes

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dy
myisam_mmap_size	Yes	Yes	Yes		Global	No
myisam-recover-options	Yes	Yes				
- Variable: myisam_recover_options						
myisam_recover_options			Yes		Global	No
myisam_repair_threads	Yes	Yes	Yes		Both	Ye
myisam_sort_buffer_size	Yes	Yes	Yes		Both	Ye
myisam_stats_method	Yes	Yes	Yes		Both	Ye
myisam_use_mmap	Yes	Yes	Yes		Global	Ye
skip-concurrent-insert	Yes	Yes				
- Variable: concurrent_insert						
tmp_table_size	Yes	Yes	Yes		Both	Ye

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

Note

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with [myisamchk](#)) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.7, “Server System Variables”](#).

- [bulk_insert_buffer_size](#)

The size of the tree cache used in bulk insert optimization.

Note

This is a limit *per thread*!

- [myisam_max_sort_file_size](#)

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during [REPAIR TABLE](#), [ALTER TABLE](#), or [LOAD DATA INFILE](#)). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- [myisam_sort_buffer_size](#)

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

16.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as $(key_length + 4) / 0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

16.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 13.1.18, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed MyISAM tables using `myisamchk --unpack`; see [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

16.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7) / 8
             + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

16.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a [MyISAM](#) table contains any variable-length columns ([VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#)), or if the table was created with the [ROW_FORMAT=DYNAMIC](#) table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use [OPTIMIZE TABLE](#) or [myisamchk -r](#) to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain [NULL](#) values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- [NULL](#) columns require additional space in the row to record whether their values are [NULL](#). Each [NULL](#) column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run [OPTIMIZE TABLE](#) or [myisamchk -r](#) from time to time to improve performance. Use [myisamchk -ei](#) to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using [myisamchk -ed](#). All links may be removed with [OPTIMIZE TABLE](#) or [myisamchk -r](#).

16.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the [myisampack](#) tool. Compressed tables can be uncompressed with [myisamchk](#).

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).

- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
 - Suffix space compression.
 - Prefix space compression.
 - Numbers with a value of zero are stored using one bit.
 - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
 - If a column has only a small set of possible values, the data type is converted to `ENUM`.
 - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

**Note**

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

16.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

16.2.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 13.7.3.2, “CHECK TABLE Syntax”](#), [Section 13.7.3.5, “REPAIR TABLE Syntax”](#), and [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 28.5, “Debugging and Porting MySQL”](#).

16.2.4.2 Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

16.3 The MEMORY Storage Engine

The **MEMORY** storage engine (formerly known as **HEAP**) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

Table 16.4 MEMORY Storage Engine Features

Feature	Support
B-tree indexes	Yes
Backup/point-in-time recovery (Implemented in the server, rather than in the storage engine.)	Yes
Cluster database support	No
Clustered indexes	No
Compressed data	No
Data caches	N/A
Encrypted data (Implemented in the server via encryption functions. Data-at-rest tablespace encryption is available in MySQL 5.7 and later.)	Yes
Foreign key support	No
Full-text search indexes	No
Geospatial data type support	No
Geospatial indexing support	No
Hash indexes	Yes
Index caches	N/A
Locking granularity	Table
MVCC	No
Replication support (Implemented in the server, rather than in the storage engine.)	Limited (See the discussion later in this section.)
Storage limits	RAM
T-tree indexes	No
Transactions	No
Update statistics for data dictionary	Yes

- [Additional Resources](#)

When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the [MEMORY](#) storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the [MEMORY](#) engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in [MEMORY](#) tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the [MEMORY](#) engine with higher performance levels, and provides additional features not available with [MEMORY](#):

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including [BLOB](#) and [TEXT](#)) not supported by [MEMORY](#).

Partitioning

[MEMORY](#) tables cannot be partitioned.

Performance Characteristics

[MEMORY](#) performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for [MEMORY](#) tables, they are not necessarily faster than [InnoDB](#) tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of [MEMORY](#) tables from multiple sessions.

Depending on the kinds of queries performed on a [MEMORY](#) table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Characteristics of MEMORY Tables

The **MEMORY** storage engine does not create any files on disk. The table definition is stored in the MySQL data dictionary.

MEMORY tables have the following characteristics:

- Space for **MEMORY** tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. **MEMORY** tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- **MEMORY** tables use a fixed-length row-storage format. Variable-length types such as **VARCHAR** are stored using a fixed length.
- **MEMORY** tables cannot contain **BLOB** or **TEXT** columns.
- **MEMORY** includes support for **AUTO_INCREMENT** columns.
- Non-**TEMPORARY MEMORY** tables are shared among all clients, just like any other non-**TEMPORARY** table.

DDL Operations for MEMORY Tables

To create a **MEMORY** table, specify the clause **ENGINE=MEMORY** on the **CREATE TABLE** statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in the MySQL data dictionary, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
        SELECT ip,SUM(downloads) AS down
        FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of **MEMORY** tables is limited by the **max_heap_table_size** system variable, which has a default value of 16MB. To enforce different size limits for **MEMORY** tables, change the value of this variable. The value in effect for **CREATE TABLE**, or a subsequent **ALTER TABLE** or **TRUNCATE TABLE**, is the value used for the life of the table. A server restart also sets the maximum size of existing **MEMORY** tables to the global **max_heap_table_size** value. You can set the size for individual tables as described later in this section.

Indexes

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a **USING** clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
```

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

MEMORY tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

MEMORY tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain **NULL** values.

User-Created and Temporary Tables

MEMORY table contents are stored in memory, which is a property that **MEMORY** tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created **MEMORY** tables are never converted to disk tables.

Loading Data

To populate a **MEMORY** table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.6, “Server Command Options”](#), and [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

MEMORY Tables and Replication

A server's **MEMORY** tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave **MEMORY** tables, when a **MEMORY** table is used on a master for the first time since it was started, a **DELETE** statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the **MEMORY** table on the master at startup.

Managing Memory Use

The server needs sufficient memory to maintain all **MEMORY** tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a **MEMORY** table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a **MEMORY** table when you no longer require

its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <https://forums.mysql.com/list.php?92>.

16.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a data file. The data file name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
ENGINE = CSV;
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.05 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i | c |
+-----+-----+
| 1 | record one |
| 2 | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

16.4.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status | OK |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error | Corrupt |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text          |
+-----+-----+-----+-----+
| test.csvtest   | check | warning  | Table is marked as crashed |
| test.csvtest   | check | status   | OK                |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use [REPAIR](#), this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text          |
+-----+-----+-----+-----+
| test.csvtest   | repair | status   | OK                |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

16.4.2 CSV Limitations

The [CSV](#) storage engine does not support indexing.

The [CSV](#) storage engine does not support partitioning.

All tables that you create using the [CSV](#) storage engine must have the [NOT NULL](#) attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

16.5 The ARCHIVE Storage Engine

The [ARCHIVE](#) storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

Table 16.5 ARCHIVE Storage Engine Features

Feature	Support
B-tree indexes	No
Backup/point-in-time recovery (Implemented in the server, rather than in the storage engine.)	Yes
Cluster database support	No
Clustered indexes	No
Compressed data	Yes
Data caches	No
Encrypted data (Implemented in the server via encryption functions. Data-at-rest tablespace encryption is available in MySQL 5.7 and later.)	Yes

Feature	Support
Foreign key support	No
Full-text search indexes	No
Geospatial data type support	Yes
Geospatial indexing support	No
Hash indexes	No
Index caches	No
Locking granularity	Row
MVCC	No
Replication support (Implemented in the server, rather than in the storage engine.)	Yes
Storage limits	None
T-tree indexes	No
Transactions	No
Update statistics for data dictionary	Yes

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the [ARCHIVE](#) engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the [ARCHIVE](#) storage engine is available with the `SHOW ENGINES` statement.

When you create an [ARCHIVE](#) table, the storage engine creates files with names that begin with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The [ARCHIVE](#) engine supports [INSERT](#), [REPLACE](#), and [SELECT](#), but not [DELETE](#) or [UPDATE](#). It does support [ORDER BY](#) operations, [BLOB](#) columns, and basically all but spatial data types (see [Section 11.5.1](#), “Spatial Data Types”). The [ARCHIVE](#) engine uses row-level locking.

The [ARCHIVE](#) engine supports the [AUTO_INCREMENT](#) column attribute. The [AUTO_INCREMENT](#) column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The [ARCHIVE](#) engine also supports the [AUTO_INCREMENT](#) table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

[ARCHIVE](#) does not support inserting a value into an [AUTO_INCREMENT](#) column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The [ARCHIVE](#) engine ignores [BLOB](#) columns if they are not requested and scans past them while reading.

The [ARCHIVE](#) storage engine does not support partitioning.

Storage: Rows are compressed as they are inserted. The [ARCHIVE](#) engine uses [zlib](#) lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An [INSERT](#) statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A [SELECT](#) forces a flush to occur.

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 13.7.3.4, “OPTIMIZE TABLE Syntax”](#), [Section 13.7.3.5, “REPAIR TABLE Syntax”](#), and [Section 13.7.6.36, “SHOW TABLE STATUS Syntax”](#).

Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <https://forums.mysql.com/list.php?112>.

16.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates the table definition in the global data dictionary. There are no files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

The `BLACKHOLE` storage engine does not support partitioning.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is `BLACKHOLE`, depicted as follows:

Figure 16.1 Replication using BLACKHOLE for Filtering

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,  
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

16.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column data types and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.
- Comments for tables, columns, and indexes can differ.
- Table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` can differ.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files and enables some operations to be performed more efficiently. For more information, see [Chapter 22, Partitioning](#).

When you create a `MERGE` table, MySQL creates a `.MRG` file on disk that contains the names of the underlying `MyISAM` tables that should be used as one. The table format of the `MERGE` table is stored in the MySQL data dictionary. The underlying tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
```

+-----+	
a	message
+-----+	
1	Testing
2	table
3	t1
1	Testing
2	table
3	t2
+-----+	

To remap a [MERGE](#) table to a different collection of [MyISAM](#) tables, you can use one of the following methods:

- [DROP](#) the [MERGE](#) table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty [UNION](#) clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new [MERGE](#) tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the [MERGE](#) table. Conformance is checked when a table that is part of a [MERGE](#) table is opened, not when the [MERGE](#) table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a [MERGE](#) may cause a failure when the [MERGE](#) table is accessed. The conformance checks applied to each table are:

- The underlying table and the [MERGE](#) table must have the same number of columns.
- The column order in the underlying table and the [MERGE](#) table must match.
- Additionally, the specification for each corresponding column in the parent [MERGE](#) table and the underlying tables are compared and must satisfy these checks:
 - The column type in the underlying table and the [MERGE](#) table must be equal.
 - The column length in the underlying table and the [MERGE](#) table must be equal.
 - The column of the underlying table and the [MERGE](#) table can be [NULL](#).
- The underlying table must have at least as many indexes as the [MERGE](#) table. The underlying table may have more indexes than the [MERGE](#) table, but cannot have fewer.

Note

A known issue exists where indexes on the same columns must be in identical order, in both the [MERGE](#) table and the underlying [MyISAM](#) table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the [MERGE](#) table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the [MERGE](#) table must be the same.
- For each index part:

- Index part lengths must be equal.
- Index part types must be equal.
- Index part languages must be equal.
- Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at <https://forums.mysql.com/list.php?93>.

16.7.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.
- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 13.8.2, “EXPLAIN Syntax”](#).

16.7.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child `MyISAM` tables.

From versions 5.1.23, `MERGE` children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the `MyISAM` tables corrupted them.
- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
 - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
 - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield

unexpected results. To work around this problem, ensure that no [MERGE](#) tables remain open by issuing a [FLUSH TABLES](#) statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the [MERGE](#) table will report table corruption. If this occurs after one of the named operations on the underlying [MyISAM](#) tables, the corruption message is spurious. To deal with this, issue a [FLUSH TABLES](#) statement after modifying the [MyISAM](#) tables.

- [DROP TABLE](#) on a table that is in use by a [MERGE](#) table does not work on Windows because the [MERGE](#) storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all [MERGE](#) tables (with [FLUSH TABLES](#)) or drop the [MERGE](#) table before dropping the table.
- The definition of the [MyISAM](#) tables and the [MERGE](#) table are checked when the tables are accessed (for example, as part of a [SELECT](#) or [INSERT](#) statement). The checks ensure that the definitions of the tables and the parent [MERGE](#) table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the [MERGE](#) table and its underlying tables should be the same. If you use [ALTER TABLE](#) to add a [UNIQUE](#) index to a table used in a [MERGE](#) table, and then use [ALTER TABLE](#) to add a nonunique index on the [MERGE](#) table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because [ALTER TABLE](#) puts [UNIQUE](#) indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the [MyISAM](#) storage engine. Confirm that all of these tables are [MyISAM](#).
- The maximum number of rows in a [MERGE](#) table is 2^{64} (~1.844E+19; the same as for a [MyISAM](#) table). It is not possible to merge multiple [MyISAM](#) tables into a single [MERGE](#) table that would have more than this number of rows.
- Use of underlying [MyISAM](#) tables of differing row formats with a parent [MERGE](#) table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary [MERGE](#) table when [LOCK TABLES](#) is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary [MERGE](#) table.

- You cannot create a [MERGE](#) table with [CREATE ... SELECT](#), neither as a temporary [MERGE](#) table, nor as a nontemporary [MERGE](#) table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not [BASE TABLE](#).

- In some cases, differing [PACK_KEYS](#) table option values among the [MERGE](#) and underlying tables cause unexpected results if the underlying tables contain [CHAR](#) or [BINARY](#) columns. As a workaround, use [ALTER TABLE](#) to ensure that all involved tables have the same [PACK_KEYS](#) value. (Bug #50646)

16.8 The FEDERATED Storage Engine

The **FEDERATED** storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local **FEDERATED** table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the **FEDERATED** storage engine if you build MySQL from source, invoke **CMake** with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The **FEDERATED** storage engine is not enabled by default in the running server; to enable **FEDERATED**, you must start the MySQL server binary using the `--federated` option.

To examine the source for the **FEDERATED** engine, look in the `storage/federated` directory of a MySQL source distribution.

16.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as **MyISAM**, **CSV** or **InnoDB**), the table consists of the table definition and the associated data. When you create a **FEDERATED** table, the table definition is the same, but the physical storage of the data is handled on a remote server.

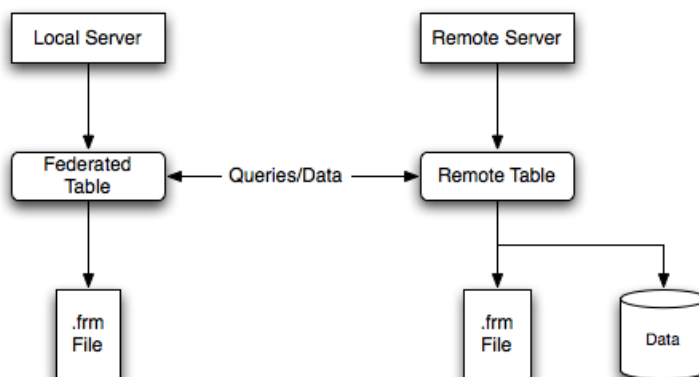

A **FEDERATED** table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the MySQL data dictionary) and the associated table. The table type of the remote table may be any type supported by the remote **mysqld** server, including **MyISAM** or **InnoDB**.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored in the data dictionary. There is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a **FEDERATED** table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a **FEDERATED** table setup is shown in [Figure 16.2, “FEDERATED Table Structure”](#).

Figure 16.2 FEDERATED Table Structure

When a client issues an SQL statement that refers to a [FEDERATED](#) table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the [FEDERATED](#) table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the [FEDERATED](#) engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

16.8.2 How to Create FEDERATED Tables

To create a [FEDERATED](#) table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the [SHOW CREATE TABLE](#) statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=utf8mb4;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

Important

When you create the local table it *must* have an identical field definition to the remote table.

Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote

server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

16.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

Note

`CONNECTION` replaces the `COMMENT` used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.
- *user_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- *password*: (Optional) The corresponding password for *user_name*.
- *host_name*: The host name or IP address of the remote server.
- *port_num*: (Optional) The port number for the remote server. The default is 3306.
- *db_name*: The name of the database holding the remote table.
- *tbl_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

16.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of [FEDERATED](#) tables on the same server, or if you want to simplify the process of creating [FEDERATED](#) tables, you can use the [CREATE SERVER](#) statement to define the server connection parameters, just as you would with the [CONNECTION](#) string.

The format of the [CREATE SERVER](#) statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The [server_name](#) is used in the connection string when creating a new [FEDERATED](#) table.

For example, to create a server connection identical to the [CONNECTION](#) string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a [FEDERATED](#) table that uses this connection, you still use the [CONNECTION](#) keyword, but specify the name you used in the [CREATE SERVER](#) statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection ([fedlink](#)) and the name of the table ([test_table](#)) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on [CREATE SERVER](#), see [Section 13.1.16, “CREATE SERVER Syntax”](#).

The [CREATE SERVER](#) statement accepts the same arguments as the [CONNECTION](#) string. The [CREATE SERVER](#) statement updates the rows in the [mysql.servers](#) table. See the following table for information on the correspondence between parameters in a connection string, options in the [CREATE SERVER](#) statement, and the columns in the [mysql.servers](#) table. For reference, the format of the [CONNECTION](#) string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	scheme	wrapper_name	Wrapper
Remote user	user_name	USER	Username

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Remote password	<i>password</i>	PASSWORD	Password
Remote host	<i>host_name</i>	HOST	Host
Remote port	<i>port_num</i>	PORT	Port
Remote database	<i>db_name</i>	DATABASE	Db

16.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

- **FEDERATED** accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
 - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
 - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.
- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables.

16.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the **FEDERATED** storage engine is available at <https://forums.mysql.com/list.php?105>.

16.9 The EXAMPLE Storage Engine

The **EXAMPLE** storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the **EXAMPLE** storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the **EXAMPLE** engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an **EXAMPLE** table, no files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
```

```
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

The `EXAMPLE` storage engine does not support partitioning.

16.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

16.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

16.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

16.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

17.4.5	How to Report Replication Bugs or Problems	3111

Replication enables data from one MySQL database server (the master) to be copied to one or more MySQL database servers (the slaves). Replication is asynchronous by default; slaves do not need to be connected permanently to receive updates from the master. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.

-
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
 - Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the master.

For information on how to use replication in such scenarios, see [Section 17.3, “Replication Solutions”](#).

MySQL 8.0 supports different methods of replication. The traditional method is based on replicating events from the master's binary log, and requires the log files and positions in them to be synchronized between master and slave. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between master and slave as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication in MySQL, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 17.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. In MySQL 8.0, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction; see [Section 17.3.10, “Semisynchronous Replication”](#). MySQL 8.0 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time; see [Section 17.3.11, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use NDB Cluster (see [MySQL NDB Cluster 7.5](#) and [NDB Cluster 7.6](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 17.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 17.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution, see [Section 17.4, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 8.0 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 17.2, “Replication Implementation”](#).

17.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the master and slaves.
- For a guide to setting up two or more servers for replication using GTID transactions, [Section 17.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 17.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 17.1.7, “Common Replication Administration Tasks”](#).

17.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Important

You cannot configure the master to log only certain events.

Each slave keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave records the current position within the binary log, it is possible for slaves to be disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's master info repository (see [Section 17.2.4, “Replication Relay and Status Logs”](#)).

17.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all setups:

- On the master, you must ensure that binary logging is enabled, and configure a unique server ID. This might require a server restart. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Section 17.1.2.2, “Setting the Replication Slave Configuration”](#).
- Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See [Section 17.1.2.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the master you should record the current position in the binary log. You need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on the master and want to use it to synchronize the slave, you need to create a data snapshot to copy the data to the slave. The storage engine you are using has an impact on how you create the snapshot. When you are using [MyISAM](#), you must stop processing statements on the master to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information will not match, resulting in inconsistent or corrupted databases on the slaves. For more information on replicating a [MyISAM](#) master, see [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#). If you are using [InnoDB](#), you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 15.18, “InnoDB and MySQL Replication”](#).
- Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Section 17.1.2.7, “Setting the Master Configuration on the Slave”](#).

Note

Certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a master and slaves that contain no data, see [Setting Up Replication with New Master and Slaves](#).
- To set up replication of a new master using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replication slaves to an existing replication environment, see [Section 17.1.2.8, “Adding Slaves to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Also familiarize yourself with the replication startup options described in [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

17.1.2.1 Setting the Replication Master Configuration

To configure a master to use binary log file position based replication, you must ensure that binary logging is enabled, and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging is required on the master because the binary log is the basis for replicating changes from the master to its slaves. Binary logging is enabled by default (the `log_bin` system variable is set to ON). The `--log-bin` option tells the server what base name to use for binary log files. It is recommended that you specify this option to give the binary log files a non-default base name, so that if the host name changes, you can easily continue to use the same binary log file names (see [Section B.5.7, “Known Issues in MySQL”](#)).

Each server within a replication topology must be configured with a unique server ID, which you can specify using the `--server-id` option. This server ID is used to identify individual servers within the replication topology, and must be a positive integer between 1 and $(2^{32})-1$. If you set a server ID of 0 on a master, it refuses any connections from slaves, and if you set a server ID of 0 on a slave, it refuses to connect to a master. Other than that, how you organize and select the numbers is your choice, so long as each server ID is different from every other server ID in use by any other server in the replication topology. The `server_id` system variable is set to 1 by default. A server can be started with this default server ID, but an informational message is issued if you did not specify a server ID explicitly.

Note

The following options also have an impact on the replication master:

- For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the replication master's `my.cnf` file.
- Ensure that the `skip-networking` option is not enabled on the replication master. If networking has been disabled, the slave cannot communicate with the master and replication fails.

17.1.2.2 Setting the Replication Slave Configuration

Each replication slave must have a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique nonzero `server-id` value that differs from that of the master and from any of the other slaves.

Binary logging is enabled by default on all servers. A slave is not required to have binary logging enabled for replication to take place. However, binary logging on a slave means that the slave's binary log can be used for data backups and crash recovery.

Slaves that have binary logging enabled can also be used as part of a more complex replication topology. For example, you might want to set up replication servers using this chained arrangement:

```
A -> B -> C
```

Here, **A** serves as the master for the slave **B**, and **B** serves as the master for the slave **C**. For this to work, **B** must be both a master *and* a slave. Updates received from **A** must be logged by **B** to its binary log, in order to be passed on to **C**. In addition to binary logging, this replication topology requires the `--log-slave-updates` option to be enabled. With this option, the slave writes updates that are received from a master server and performed by the slave's SQL thread to the slave's own binary log. The `--log-slave-updates` option is enabled by default.

If you need to disable binary logging or slave update logging on a slave server, you can do this by specifying the `--skip-log-bin` and `--skip-log-slave-updates` options for the slave.

17.1.2.3 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. The user name is specified by the `MASTER_USER` option on the `CHANGE MASTER TO` command when you set up a replication slave. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository table `mysql.slave_master_info` (see [Section 17.2.4.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `example.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com';
```

See [Section 13.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

Important

To connect to the replication master using a user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in [Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”](#), or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users created from MySQL 8.0 (for details, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#)). If the user account that you create or use for replication (as specified by the `MASTER_USER` option) uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection.

17.1.2.4 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need to note the master's current coordinates within its binary log.

Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

If you are planning to shut down the master to create a data snapshot, you can optionally skip this procedure and instead store a copy of the binary log index file along with the data snapshot. In that situation, the master creates a new binary log file on restart. The master binary log coordinates where the slave must start the replication process are therefore the start of that new file, which is the next binary log file on the master following after the files that are listed in the copied binary log index file.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
```

File	Position	Binlog_Do_DB	Binlog_Ignore_DB
mysql-bin.000003	73	test	manual,mysql

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously with binary logging disabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`' '`) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the master. Choose one of the following options:

- If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so

that the data copied to the slave is in synchrony with the master. Proceed to [Section 17.1.2.5, “Choosing a Method for Data Snapshots”](#).

- If you are setting up a new master and slave replication group, you can exit the first session to release the read lock. See [Setting Up Replication with New Master and Slaves](#) for how to proceed.

17.1.2.5 Choosing a Method for Data Snapshots

If the master database contains existing data it is necessary to copy this data to each slave. There are different ways to dump the data from the master database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a slave. This can be more efficient than using `mysqldump` and importing the file on each slave, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing master database, use the `mysqldump` tool. Once the data dump has been completed, import this data into the slave before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

For more information, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use [InnoDB](#) tables, you can use the [mysqlbackup](#) command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 29.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the master and slave have different values for [ft_stopword_file](#), [ft_min_word_len](#), or [ft_max_word_len](#) and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the [cold backup](#) technique to obtain a reliable binary snapshot of [InnoDB](#) tables: do a [slow shutdown](#) of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of [MyISAM](#) tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as [cp](#) or [copy](#), a remote copy tool such as [scp](#) or [rsync](#), an archiving tool such as [zip](#) or [tar](#), or a file system snapshot tool such as [dump](#). If you are replicating only certain databases, copy only those files that relate to those tables. For [InnoDB](#), all tables in all databases are stored in the [system tablespace](#) files, unless you have the [innodb_file_per_table](#) option enabled.

The following files are not required for replication:

- Files relating to the [mysql](#) database.
- The master info repository file [master.info](#), if used; the use of this file is now deprecated (see [Section 17.2.4, “Replication Relay and Status Logs”](#)).
- The master's binary log files, with the exception of the binary log index file if you are going to use this to locate the master binary log coordinates for the slave.
- Any relay log files.

Depending on whether you are using [InnoDB](#) tables or not, choose one of the following:

If you are using [InnoDB](#) tables, and also to get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using [InnoDB](#) tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

17.1.2.6 Setting Up Replication Slaves

The following sections describe how to set up slaves. Before you proceed, ensure that you have:

- Configured the MySQL master with the necessary configuration properties. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#).
- Obtained the master status information, or a copy of the master's binary log index file made during a shutdown for the data snapshot. See [Section 17.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- On the master, released the read lock:

```
mysql> UNLOCK TABLES;
```

- On the slave, edited the MySQL configuration. See [Section 17.1.2.2, “Setting the Replication Slave Configuration”](#).

The next steps depend on whether you have existing data to import to the slave or not. See [Section 17.1.2.5, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see [Setting Up Replication with New Master and Slaves](#).
- If you have a snapshot of a database to import, see [Setting Up Replication with Existing Data](#).

Setting Up Replication with New Master and Slaves

When there is no snapshot of a previous database to import, configure the slave to start the replication from the new master.

To set up replication between a master and a new slave:

1. Start up the MySQL slave.
2. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Section 17.1.2.7, “Setting the Master Configuration on the Slave”](#).

Perform these slave setup steps on each slave.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data is automatically replicated to the slaves.

If you are setting up a new replication environment using the data from a different existing database server to create a new master, run the dump file generated from that server on the new master. The database updates are automatically propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the master to the slave before starting replication. The process for importing data to the slave depends on how you created the snapshot of data on the master.

Choose one of the following:

If you used `mysqldump`:

1. Start the slave, using the `--skip-slave-start` option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

2. Start the slave, using the `--skip-slave-start` option so that replication does not start.
3. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Section 17.1.2.7, “Setting the Master Configuration on the Slave”](#).
4. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave connects to the master and replicates any updates that have occurred on the master since the snapshot was taken. Error messages are issued to the slave's error log if it is not able to replicate for any reason.

The slave uses information logged in its master info log and relay log info log to keep track of how much of the master's binary log it has processed. From MySQL 8.0, by default, the repositories for these slave status logs are tables named `slave_master_info` and `slave_relay_log_info` in the `mysql` database. The alternative settings `--master-info-repository=FILE` and `--relay-log-info-repository=FILE`, where the repositories are files named `master.info` and `relay-log.info` in the data directory, are now deprecated and will be removed in a future release.

Do *not* remove or edit these tables (or files, if used) unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave uses the values specified in the statement to

update the slave status logs automatically. See [Section 17.2.4, “Replication Relay and Status Logs”](#), for more information.

Note

The contents of the master info log override some of the server options specified on the command line or in `my.cnf`. See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

17.1.2.7 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, configure the slave with the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

Important

As noted in [Section 17.1.2.3, “Creating a User for Replication”](#), if you are not using a secure connection and the user account named in the `MASTER_USER` option authenticates with the `caching_sha2_password` plugin (the default from MySQL 8.0), you must specify the `MASTER_PUBLIC_KEY_PATH` or `GET_MASTER_PUBLIC_KEY` option in the `CHANGE MASTER TO` statement to enable RSA key pair-based password exchange.

17.1.2.8 Adding Slaves to a Replication Environment

You can add another slave to an existing replication configuration without stopping the master. To do this, you can set up the new slave by copying the data directory of an existing slave, and giving the new slave a different server ID (which is user-specified) and server UUID (which is generated at startup).

To duplicate an existing slave:

1. Stop the existing slave and record the slave status information, particularly the master binary log file and relay log file positions. You can view the slave status either in the Performance Schema replication tables (see [Section 25.11.11, “Performance Schema Replication Tables”](#)), or by issuing `SHOW SLAVE STATUS` as follows:

```
mysql> STOP SLAVE;
```

```
mysql> SHOW SLAVE STATUS\G
```

2. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

3. Copy the data directory from the existing slave to the new slave, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

Important

- Before copying, verify that all the files relating to the existing slave actually are stored in the data directory. For example, the `InnoDB` system tablespace, undo tablespace, and redo log might be stored in an alternative location. `InnoDB` tablespace files and file-per-table tablespaces might have been created in other directories. The binary logs and relay logs for the slave might be in their own directories outside the data directory. Check through the system variables that are set for the existing slave and look for any alternative paths that have been specified. If you find any, copy these directories over as well.
- During copying, if files have been used for the master info and relay log info repositories (see [Section 17.2.4, “Replication Relay and Status Logs”](#)), ensure that you also copy these files from the existing slave to the new slave. If tables have been used for the repositories, which is the default from MySQL 8.0, the tables are in the data directory.
- After copying, delete the `auto.cnf` file from the copy of the data directory on the new slave, so that the new slave is started with a different generated server UUID. The server UUID must be unique.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#), for more information about these options.

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`. If this is not possible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue `STOP SLAVE` on the new slave.

If you have already started the existing slave again, issue `STOP SLAVE` on the existing slave as well.
 - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
 - c. Proceed with the remaining steps in this section.
4. When copying is complete, restart the existing slave.
 5. On the new slave, edit the configuration and give the new slave a unique server ID (using the `server-id` option) that is not used by the master or any of the existing slaves.
 6. Start the new slave server, specifying the `--skip-slave-start` option so that replication does not start yet. Use the Performance Schema replication tables or issue `SHOW SLAVE STATUS` to confirm that the new slave has the correct settings when compared with the existing slave. Also display the server ID and server UUID and verify that these are correct and unique for the new slave.
 7. Start the slave threads by issuing a `START SLAVE` statement:

```
mysql> START SLAVE;
```

The new slave now uses the information in its master info repository to start the replication process.

17.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 17.2.1, “Replication Formats”](#)); however, for best results, we recommend that you use the row-based format.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see [Section 17.1.3.1, “GTID Format and Storage”](#)).
- The life cycle of a GTID (see [Section 17.1.3.2, “GTID Life Cycle”](#)).
- The auto-positioning function for synchronizing a slave and master that use GTIDs (see [Section 17.1.3.3, “GTID Auto-Positioning”](#)).
- A general procedure for setting up and starting GTID-based replication (see [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#)).

- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 17.1.3.5, “Using GTIDs for Failover and Scaleout”](#)).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 17.1.3.6, “Restrictions on Replication with GTIDs”](#)).
- Stored functions that you can use to work with GTIDs (see [Section 17.1.3.7, “Stored Function Examples to Manipulate GTIDs”](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 17.1.6.5, “Global Transaction ID Options and Variables”](#). See also [Section 12.17, “Functions Used with Global Transaction Identifiers \(GTIDs\)”](#), which describes SQL functions supported by MySQL 8.0 for use with GTIDs.

17.1.3.1 GTID Format and Storage

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (the master). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication topology.

GTID assignment distinguishes between client transactions, which are committed on the master, and replicated transactions, which are reproduced on a slave. When a client transaction is committed on the master, it is assigned a new GTID, provided that the transaction was written to the binary log. Client transactions are guaranteed to have monotonically increasing GTIDs without gaps between the generated numbers. If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID on the server of origin.

Replicated transactions retain the same GTID that was assigned to the transaction on the server of origin. The GTID is present before the replicated transaction begins to execute, and is persisted even if the replicated transaction is not written to the binary log on the slave, or is filtered out on the slave. The MySQL system table `mysql.gtid_executed` is used to preserve the assigned GTIDs of all the transactions applied on a MySQL server, except those that are stored in a currently active binary log file.

The auto-skip function for GTIDs means that a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency. Once a transaction with a given GTID has been committed on a given server, any attempt to execute a subsequent transaction with the same GTID is ignored by that server. No error is raised, and no statement in the transaction is executed.

If a transaction with a given GTID has started to execute on a server, but has not yet committed or rolled back, any attempt to start a concurrent transaction on the server with the same GTID will block. The server neither begins to execute the concurrent transaction nor returns control to the client. Once the first attempt at the transaction commits or rolls back, concurrent sessions that were blocking on the same GTID may proceed. If the first attempt rolled back, one concurrent session proceeds to attempt the transaction, and any other concurrent sessions that were blocking on the same GTID remain blocked. If the first attempt committed, all the concurrent sessions stop being blocked, and auto-skip all the statements of the transaction.

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source_id* identifies the originating server. Normally, the server's `server_uuid` is used for this purpose. The *transaction_id* is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has `1` as its *transaction_id*, and the tenth transaction to be committed on the same originating server is assigned

a *transaction_id* of 10. It is not possible for a transaction to have 0 as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID 3E11FA47-71CA-11E1-9E33-C80AA9429562 has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose *server_uuid* is 3E11FA47-71CA-11E1-9E33-C80AA9429562.

This format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
  uuid_set [, uuid_set] ...
  | ''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
  [0-9|A-F]

interval:
  n[-n]

  (n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input. When GTID sets are returned from server variables, UUIDs are in alphabetical order and numeric intervals are merged and in ascending order.

mysql.gtid_executed Table

GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when the MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
  interval_start BIGINT(20) NOT NULL,
  interval_end BIGINT(20) NOT NULL,
  PRIMARY KEY (source_uuid, interval_start)
)
```

Warning

As with other MySQL system tables, do not attempt to create or modify this table yourself.

The `mysql.gtid_executed` table enables a slave to use GTIDs when binary logging is disabled on the slave, and it enables retention of the GTID history when the binary logs have been lost.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. The point at which GTIDs are stored depends on whether binary logging is enabled or disabled:

- If binary logging is disabled (`log_bin` is `OFF`), or if `log_slave_updates` is disabled, the server stores the GTID belonging to each transaction together with the transaction in the table. In addition, the table is compressed periodically at a user-configurable rate; see [mysql.gtid_executed Table Compression](#), for more information. This situation can only apply on a replication slave where binary logging or slave update logging is disabled. It does not apply on a replication master, because on a master, binary logging must be enabled for replication to take place.
- If binary logging is enabled (`log_bin` is `ON`), whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the `mysql.gtid_executed` table. This situation applies on a replication master, or a replication slave where binary logging is enabled.

In the event of the server stopping unexpectedly, the set of GTIDs from the current binary log is not saved in the `mysql.gtid_executed` table. In this case, these GTIDs are added to the table and to the set of GTIDs in the `gtid_executed` system variable during recovery.

When binary logging is enabled, the `mysql.gtid_executed` table does not provide a complete record of the GTIDs for all executed transactions. That information is provided by the global value of the `gtid_executed` system variable.

The `mysql.gtid_executed` table is reset by `RESET MASTER`.

mysql.gtid_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a sequence, similar to what is shown here:

```
mysql> SELECT * FROM mysql.gtid_executed;
```

source_uuid	interval_start	interval_end
3E11FA47-71CA-11E1-9E33-C80AA9429562	37	37
3E11FA47-71CA-11E1-9E33-C80AA9429562	38	38
3E11FA47-71CA-11E1-9E33-C80AA9429562	39	39

3E11FA47-71CA-11E1-9E33-C80AA9429562	40	40	
3E11FA47-71CA-11E1-9E33-C80AA9429562	41	41	
3E11FA47-71CA-11E1-9E33-C80AA9429562	42	42	
3E11FA47-71CA-11E1-9E33-C80AA9429562	43	43	
...			

Considerable space can be saved if this table is compressed periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

source_uuid	interval_start	interval_end	
3E11FA47-71CA-11E1-9E33-C80AA9429562	37	43	
...			

When GTIDs are enabled, the server performs this type of compression on the `mysql.gtid_executed` table periodically. You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `gtid_executed_compression_period` system variable. This variable's default value is 1000; this means that, by default, compression of the table is performed after each 1000 transactions. Setting `gtid_executed_compression_period` to 0 prevents the compression from being performed at all; however, you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

Note

When binary logging is enabled, the value of `gtid_executed_compression_period` is *not* used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread named `thread/sql/compress_gtid_table`. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM performance_schema.threads WHERE NAME LIKE '%gtid%'\G
***** 1. row *****
      THREAD_ID: 26
        NAME: thread/sql/compress_gtid_table
        TYPE: FOREGROUND
  PROCESSLIST_ID: 1
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
  PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 1509
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
  PARENT_THREAD_ID: 1
          ROLE: NULL
    INSTRUMENTED: YES
          HISTORY: YES
CONNECTION_TYPE: NULL
   THREAD_OS_ID: 18677
```

The `thread/sql/compress_gtid_table` thread normally sleeps until `gtid_executed_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `gtid_executed_compression_period` transactions have taken place, then wakes up to perform the

compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up.

17.1.3.2 GTID Life Cycle

The life cycle of a GTID consists of the following steps:

1. A transaction is executed and committed on the master. This client transaction is assigned a GTID composed of the master's UUID and the smallest nonzero transaction sequence number not yet used on this server. The GTID is written to the master's binary log (immediately preceding the transaction itself in the log). If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID.
2. If a GTID was assigned for the transaction, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.
3. If a GTID was assigned for the transaction, the GTID is externalized non-atomically (very shortly after the transaction is committed) by adding it to the set of GTIDs in the `gtid_executed` system variable (`@global.gtid_executed`). This GTID set contains a representation of the set of all committed GTID transactions. With binary logging enabled (as required for the master), the set of GTIDs in the `gtid_executed` system variable is a complete record of the transactions applied, but the `mysql.gtid_executed` table is not, because the most recent history is still in the current binary log file.
4. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process, see [Section 17.2, "Replication Implementation"](#), for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID. It is important to note that the slave sets `gtid_next` in a session context.
5. The slave verifies that no thread has yet taken ownership of the GTID in `gtid_next` in order to process the transaction. By reading and checking the replicated transaction's GTID first, before processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. So if multiple clients attempt to apply the same transaction concurrently, the server resolves this by letting only one of them execute. The `gtid_owned` system variable (`@global.gtid_owned`) for the slave shows each GTIDs that is currently in use and the ID of the thread that owns it. If the GTID has already been used, no error is raised, and the auto-skip function is used to ignore the transaction.
6. If the GTID has not been used, the slave applies the replicated transaction. Because `gtid_next` is set to the GTID already assigned by the master, the slave does not attempt to generate a new GTID for this transaction, but instead uses the GTID stored in `gtid_next`.
7. If binary logging is enabled on the slave, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.
8. If binary logging is disabled on the slave, the GTID is persisted atomically by writing it directly into the `mysql.gtid_executed` table. MySQL appends a statement to the transaction to insert the GTID into the table. From MySQL 8.0, this operation is atomic for DDL statements as well as for DML statements. In this situation, the `mysql.gtid_executed` table is a complete record of the transactions applied on the slave.

9. Very shortly after the replicated transaction is committed on the slave, the GTID is externalized non-atomically by adding it to the set of GTIDs in the `gtid_executed` system variable (`@@global.gtid_executed`) for the slave. As for the master, this GTID set contains a representation of the set of all committed GTID transactions. If binary logging is disabled on the slave, the `mysql.gtid_executed` table is also a complete record of the transactions applied on the slave. If binary logging is enabled on the slave, meaning that some GTIDs are only recorded in the binary log, the set of GTIDs in the `gtid_executed` system variable is the only complete record.

Client transactions that are completely filtered out on the master are not assigned a GTID, therefore they are not added to the set of transactions in the `gtid_executed` system variable, or added to the `mysql.gtid_executed` table. However, replicated transactions that are completely filtered out on the slave are persisted. If binary logging is enabled on the slave, the filtered-out transaction is written to the binary log as a `Gtid_log_event` followed by an empty transaction containing only BEGIN and COMMIT statements. If binary logging is disabled, the GTID of the filtered-out transaction is written to the `mysql.gtid_executed` table. Preserving the GTIDs for filtered-out transactions ensures that the `mysql.gtid_executed` table and the set of GTIDs in the `gtid_executed` system variable can be compressed. It also ensures that the filtered-out transactions are not retrieved again if the slave reconnects to the master.

On a multithreaded replication slave (with `slave_parallel_workers > 0`), transactions can be applied in parallel, so replicated transactions can commit out of order (unless `slave_preserve_commit_order=1` is set). When that happens, the set of GTIDs in the `gtid_executed` system variable will contain multiple GTID ranges with gaps between them. (On a master or a single-threaded replication slave, there will be monotonically increasing GTIDs without gaps between the numbers.) Gaps on multithreaded replication slaves only occur among the most recently applied transactions, and are filled in as replication progresses. When replication threads are stopped cleanly using the `STOP SLAVE` statement, ongoing transactions are applied so that the gaps are filled in. In the event of a shutdown such as a server failure or the use of the `KILL` statement to stop replication threads, the gaps might remain.

It is possible for a client to simulate a replicated transaction by setting the variable `@@session.gtid_next` to a valid GTID (consisting of a UUID and a transaction sequence number, separated by a colon) before executing the transaction. This technique is used by `mysqlbinlog` to generate a dump of the binary log that the client can replay to preserve GTIDs. A simulated replicated transaction committed through a client is completely equivalent to a replicated transaction committed through a replication thread, and they cannot be distinguished after the fact.

gtid_purged

The set of GTIDs in the `gtid_purged` system variable (`@@global.gtid_purged`) contains the GTIDs of all the transactions that have been committed on the server, but do not exist in any binary log file on the server. The following categories of GTIDs are in this set:

- GTIDs of replicated transactions that were committed with binary logging disabled on the slave
- GTIDs of transactions that were written to a binary log file that has now been purged
- GTIDs that were added explicitly to the set by the statement `SET @@global.gtid_purged`

The set of GTIDs in the `gtid_purged` system variable is initialized when the server starts. Every binary log file begins with the event `Previous_gtid_log_event`, which contains the set of GTIDs in all previous binary log files (composed from the GTIDs in the preceding file's `Previous_gtid_log_event`, and the GTIDs of every `Gtid_log_event` in the file itself). The contents of `Previous_gtid_log_event` in the oldest binary log file are used to initialize the `gtid_purged` set when the server starts, and to maintain that set when a binary log file is purged.

17.1.3.3 GTID Auto-Positioning

GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. When GTIDs are in use, all the information that the slave needs for synchronizing with the master is obtained directly from the replication data stream.

To start a slave using GTID-based replication, you do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct the slave to replicate from a given master. These options specify the name of the log file and the starting position within the file, but with GTIDs the slave does not need this nonlocal data. Instead, you need to enable the `MASTER_AUTO_POSITION` option. For full instructions to configure and start masters and slaves using GTID-based replication, see [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#).

The `MASTER_AUTO_POSITION` option is disabled by default. If multi-source replication is enabled on the slave, you need to set the option for each applicable replication channel. Disabling the `MASTER_AUTO_POSITION` option again makes the slave revert to file-based replication, in which case you must also specify one or both of the `MASTER_LOG_FILE` or `MASTER_LOG_POS` options.

When a replication slave has GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE`) and the `MASTER_AUTO_POSITION` option enabled, auto-positioning is activated for connection to the master. The master must have `GTID_MODE=ON` set in order for the connection to succeed. In the initial handshake, the slave sends a GTID set containing the transactions that it has already received, committed, or both. This GTID set is equal to the union of the set of GTIDs in the `gtid_executed` system variable (`@@global.gtid_executed`), and the set of GTIDs recorded in the Performance Schema `replication_connection_status` table as received transactions (the result of the statement `SELECT RECEIVED_TRANSACTION_SET FROM PERFORMANCE_SCHEMA.replication_connection_status`).

The master responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the slave. This exchange ensures that the master only sends the transactions with a GTID that the slave has not already recorded or committed. If the slave receives transactions from more than one master, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. (The auto-skip function also ensures that the master skips the transactions sent by the slave in the initial handshake.)

If any of the transactions that should be sent by the master have been purged from the master's binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the master sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the slave, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the master's error log in the warning message `ER_FOUND_MISSING_GTIDS`. The slave cannot recover automatically from this error because parts of the transaction history that are needed to catch up with the master have been purged. Attempting to reconnect without the `MASTER_AUTO_POSITION` option enabled only results in the loss of the purged transactions on the slave. The correct approach to recover from this situation is for the slave to replicate the missing transactions listed in the `ER_FOUND_MISSING_GTIDS` message from another source, or for the slave to be replaced by a new slave created from a more recent backup. Consider revising the binary log expiration period (`binlog_expire_logs_seconds`) on the master to ensure that the situation does not occur again.

If during the exchange of transactions it is found that the slave has recorded or committed transactions with the master's UUID in the GTID, but the master itself has not committed them, the master sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the slave and replication does not start. This situation can occur if a slave is provisioned to become the new master, but you have not verified that that slave is more up to date than the other slaves. The correct approach to recover from this situation is to check manually whether the master and slave have diverged, and to perform manual conflict resolution

for individual transactions as required, or to remove either the master or the slave from the replication topology.

17.1.3.4 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 8.0. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see [Section 17.1.3.5, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

Note

`server_uuid` must exist for GTIDs to function correctly.

4. Instruct the slave to use the master as the replication data source and to use auto-positioning. The SQL statements needed to accomplish this step are described in the example that follows later in this section.
5. Take a new backup. Binary logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled, so backups taken before this point cannot be used with your new configuration.
6. Start the slave, then disable read-only mode on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 17.1.2.3, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 17.1.2.1, “Setting the Replication Master Configuration”](#) for information about setting the `server_id` variable. The following examples show how to store `mysqld` startup options in server's option file, see [Section 4.2.7, “Using Option Files”](#) for more information. Alternatively you can use startup options when running `mysqld`.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

Step 1: Synchronize the servers. This step is only required when working with servers which are already replicating without using GTIDs. For new servers proceed to Step 3. Make the servers read-only by setting the `read_only` system variable to `ON` on each server by issuing the following:

```
mysql> SET @@global.read_only = ON;
```

Wait for all ongoing transactions to commit or roll back. Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing transactions without GTIDs. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

Important

It is important to understand that logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled. Before proceeding, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

Step 2: Stop both servers. Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -uusername -p shutdown
```

Then supply this user's password at the prompt.

Step 3: Start both servers with GTIDs enabled. To enable GTID-based replication, each server must be started with GTID mode enabled by setting the `gtid_mode` variable to `ON`, and with the `enforce_gtid_consistency` variable enabled to ensure that only statements which are safe for GTID-based replication are logged. For example:

```
gtid_mode=ON
enforce-gtid-consistency=true
```

In addition, you should start slaves with the `--skip-slave-start` option before configuring the slave settings. For more information on GTID related options and variables, see [Section 17.1.6.5, “Global Transaction ID Options and Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs when using the [mysql.gtid_executed Table](#). Masters must always have binary logging enabled in order to be able to replicate. However, slave servers can use GTIDs but without binary logging. If you need to disable binary logging on a slave server, you can do this by specifying the `--skip-log-bin` and `--skip-log-slave-updates` options for the slave.

Step 4: Configure the slave to use GTID-based auto-positioning. Tell the slave to use the master with GTID based transactions as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Issue a `CHANGE MASTER TO` statement on the slave, including the `MASTER_AUTO_POSITION` option in the statement to tell the slave that the master's transactions are identified by GTIDs.

You may also need to supply appropriate values for the master's host name and port number as well as the user name and password for a replication user account which can be used by the slave to connect to the master; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
>     MASTER_HOST = host,
>     MASTER_PORT = port,
>     MASTER_USER = user,
>     MASTER_PASSWORD = password,
>     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error.

Step 5: Take a new backup. Existing backups that were made before you enabled GTIDs can no longer be used on these servers now that you have enabled GTIDs. Take a new backup at this point, so that you are not left without a usable backup.

For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Step 6: Start the slave and disable read-only mode. Start the slave like this:

```
mysql> START SLAVE;
```

The following step is only necessary if you configured a server to be read-only in Step 1. To allow the server to begin accepting updates again, issue the following statement:

```
mysql> SET @@global.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the master as before. [Section 17.1.3.5, “Using GTIDs for Failover and Scaleout”](#), discusses creation of new slaves when using GTIDs.

17.1.3.5 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new slave which can then be used for scaleout, being promoted to master as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the slave](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid_purged`](#)
- [Restoring GTID mode slaves](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

Simple replication. The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

Copying data and transactions to the slave. Executing the entire transaction history can be time-consuming when the source server has processed a large number of transactions previously, and this can represent a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source server contains can be imported to the new slave. The source server can be either the master or the slave, but you must ensure that the source has processed all required transactions before copying the data.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

Data Set

1. Create a dump file using `mysqldump` on the source server. Set the `mysqldump` option `--master-data` (with the default value of 1) to include a `CHANGE MASTER TO` statement with binary logging information. Set the `--set-gtid-purged` option to `AUTO` (the default) or `ON`, to include information about executed transactions in the dump. Then use the `mysql` client to import the dump file on the target server.
2. Alternatively, create a data snapshot of the source server using raw data files, then copy these files to the target server, following the instructions in [Section 17.1.2.5, “Choosing a Method for Data Snapshots”](#). If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 29.2, “MySQL Enterprise Backup Overview”](#) for detailed information.
3. Alternatively, stop both the source and target servers, copy the contents of the source's data directory to the new slave's data directory, then restart the slave. If you use this method, the slave must be configured for GTID-based replication, in other words with `gtid_mode=ON`. For instructions and important information for this method, see [Section 17.1.2.8, “Adding Slaves to a Replication Environment”](#).

Transaction History

If the source server has a complete transaction history in its binary logs (that is, the GTID set `@@global.gtid_purged` is empty), you can use these methods.

1. Import the binary logs from the source server to the new slave using `mysqlbinlog`, with the `--read-from-remote-server` and `--read-from-remote-master` options.
2. Alternatively, copy the source server's binary log files to the slave. You can make copies from the slave using `mysqlbinlog` with the

`--read-from-remote-server` and `--raw` options. These can be read into the slave by using `mysqlbinlog > file` (without the `--raw` option) to export the binary log files to SQL files, then passing these files to the `mysql` client for processing. Ensure that all of the binary log files are processed using a single `mysql` process, rather than multiple connections. For example:

```
shell> mysqlbinlog copied-binlog.000001 copied-binlog.000002 | mysql -u root
```

For more information, see [Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous, but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

Injecting empty transactions. The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;

BEGIN;
COMMIT;

SET GTID_NEXT= 'AUTOMATIC' ;
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

Excluding transactions with `gtid_purged`. The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the

previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

Restoring GTID mode slaves. When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*!*/;`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
mysql> START SLAVE;
```

17.1.3.6 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

Updates involving nontransactional storage engines. When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not. Also be aware that triggers that are defined to operate on nontransactional tables can be the cause of these problems.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

CREATE TABLE ... SELECT statements. `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

GTIDS and ALTER TABLE statements. For `ALTER TABLE ... ADD`, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error:

- With mixed-based or row-based replication, an `ER_BINLOG_UNSAFE_SYSTEM_FUNCTION` error occurs, regardless of GTID settings.
- With statement-based replication, the statement result depends on GTID settings:
 - For `gtid_mode=OFF` plus `enforce_gtid_consistency=OFF`, the statement is accepted.
 - For `gtid_mode=OFF` plus `enforce_gtid_consistency=WARN`, the statement is accepted with a warning.
 - For `gtid_mode=OFF` plus `enforce_gtid_consistency=ON`, an `ER_GTID_UNSAFE_ALTER_ADD_COL_WITH_DEFAULT_EXPRESSION` error occurs.
 - For `gtid_mode=ON_PERMISSIVE` plus `gtid_next=AUTOMATIC`, an `ER_GTID_UNSAFE_ALTER_ADD_COL_WITH_DEFAULT_EXPRESSION` error occurs.
 - For `gtid_mode=ON`, an `ER_GTID_UNSAFE_ALTER_ADD_COL_WITH_DEFAULT_EXPRESSION` error occurs.
 - For `gtid_next=UUID:NUMBER`, an `ER_GTID_UNSAFE_ALTER_ADD_COL_WITH_DEFAULT_EXPRESSION` error occurs.

Temporary tables. When `binlog_format` is set to `STATEMENT`, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements cannot be used inside transactions, procedures, functions, and triggers when GTIDs are in use on the server (that is, when the `enforce_gtid_consistency` system variable is set to `ON`). They can be used outside these contexts when GTIDs are in use, provided that `autocommit=1` is set. From MySQL 8.0.13, when `binlog_format` is set to `ROW` or `MIXED`, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are allowed inside a transaction, procedure, function, or trigger when GTIDs are in use. However, the statements are not written to the binary log and are therefore not replicated to slaves. If the removal of these statements from a transaction results in an empty transaction, the transaction is not written to the binary log. If a transaction involving these statements is rolled back, a warning message is issued stating that the creation or dropping of the temporary tables could not be rolled back.

Preventing execution of unsupported statements. To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

Note that `--enforce-gtid-consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For information about other required startup options when enabling GTIDs, see [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#).

Skipping transactions. `sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the master's `gtid_executed` variable instead; see [Injecting empty transactions](#), for more information.

Ignoring servers. The `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement is deprecated when using GTIDs, because transactions that have already been applied are automatically

ignored. Before starting GTID-based replication, check for and clear all ignored server ID lists that have previously been set on the servers involved. The `SHOW_SLAVE_STATUS` statement, which can be issued for individual channels, displays the list of ignored server IDs if there is one. If there is no list, the `Replicate_Ignore_Server_Ids` field is blank.

GTID mode and mysqldump. It is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

GTID mode and mysql_upgrade. When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade` (the `--write-binlog` option).

17.1.3.7 Stored Function Examples to Manipulate GTIDs

MySQL includes some built-in (native) functions for use with GTID-based replication. These functions are as follows:

<code>GTID_SUBSET(set1,set2)</code>	Given two sets of global transaction identifiers <code>set1</code> and <code>set2</code> , returns true if all GTIDs in <code>set1</code> are also in <code>set2</code> . Returns false otherwise.
<code>GTID_SUBTRACT(set1,set2)</code>	Given two sets of global transaction identifiers <code>set1</code> and <code>set2</code> , returns only those GTIDs from <code>set1</code> that are not in <code>set2</code> .
<code>WAIT_FOR_EXECUTED_GTID_SET(gtid_set[,timeout])</code>	Wait until the server has applied all of the transactions whose global transaction identifiers are contained in <code>gtid_set</code> . The optional <code>timeout</code> stops the function from waiting after the specified number of seconds have elapsed.
<code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[,channel])</code>	Like <code>WAIT_FOR_EXECUTED_GTID_SET()</code> , but for a single started replication channel. Use <code>WAIT_FOR_EXECUTED_GTID_SET()</code> instead to ensure all channels are covered in all states.

For details of these functions, see [Section 12.17, “Functions Used with Global Transaction Identifiers \(GTIDs\)”](#).

You can define your own stored functions to work with GTIDs. For information on defining stored functions, see [Chapter 23, Stored Programs and Views](#). The following examples show some useful stored functions that can be created based on the built-in `GTID_SUBSET()` and `GTID_SUBTRACT()` functions.

Note that in these stored functions, the delimiter command has been used to change the MySQL statement delimiter to a vertical bar, as follows:

```
mysql> delimiter |
```

All of these functions take string representations of GTID sets as arguments, so GTID sets must always be quoted when used with them.

This function returns nonzero (true) if two GTID sets are the same set, even if they are not formatted in the same way.

```
CREATE FUNCTION GTID_IS_EQUAL(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS INT
RETURN GTID_SUBSET(gtid_set_1, gtid_set_2) AND GTID_SUBSET(gtid_set_2, gtid_set_1)|
```

This function returns nonzero (true) if two GTID sets are disjoint.

```
CREATE FUNCTION GTID_IS_DISJOINT(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS INT
RETURN GTID_SUBSET(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2))|
```

This function returns nonzero (true) if two GTID sets are disjoint, and `sum` is the union of the two sets.

```
CREATE FUNCTION GTID_IS_DISJOINT_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT, sum LONGTEXT)
RETURNS INT
RETURN GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_1), gtid_set_2) AND
GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_2), gtid_set_1)|
```

This function returns a normalized form of the GTID set, in all uppercase, with no whitespace and no duplicates. The UUIDs are arranged in alphabetic order and intervals are arranged in numeric order.

```
CREATE FUNCTION GTID_NORMALIZE(g LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(g, '')|
```

This function returns the union of two GTID sets.

```
CREATE FUNCTION GTID_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_NORMALIZE(CONCAT(gtid_set_1, ',', gtid_set_2))|
```

This function returns the intersection of two GTID sets.

```
CREATE FUNCTION GTID_INTERSECTION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2))|
```

This function returns the symmetric difference between two GTID sets, that is, the GTIDs that exist in `gtid_set_1` but not in `gtid_set_2`, and also the GTIDs that exist in `gtid_set_2` but not in `gtid_set_1`.

```
CREATE FUNCTION GTID_SYMMETRIC_DIFFERENCE(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(CONCAT(gtid_set_1, ',', gtid_set_2), GTID_INTERSECTION(gtid_set_1, gtid_set_2))|
```

This function removes from a GTID set all the GTIDs from a specified origin, and returns the remaining GTIDs, if any. The UUID is the identifier used by the server where the transaction originated, which is normally the `server_uuid` value.

```
CREATE FUNCTION GTID_SUBTRACT_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set, CONCAT(UUID, ':1-', (1 << 63) - 2))|
```

This function reverses the previously listed function to return only those GTIDs from the GTID set that originate from the server with the specified identifier (UUID).

```
CREATE FUNCTION GTID_INTERSECTION_WITH_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set, GTID_SUBTRACT_UUID(gtid_set, uuid))|
```

Example 17.1 Verifying that a replication slave is up to date

The built-in functions `GTID_SUBSET` and `GTID_SUBTRACT` can be used to check that a replication slave has applied at least every transaction that a master has applied.

To perform this check with `GTID_SUBSET`, execute the following statement on the slave:

```
GTID_SUBSET(master_gtid_executed, slave_gtid_executed)
```

If this returns 0 (false), some GTIDs in `master_gtid_executed` are not present in `slave_gtid_executed`, so the master has applied some transactions that the slave has not applied, and the slave is therefore not up to date.

To perform the check with `GTID_SUBTRACT`, execute the following statement on the slave:

```
GTID_SUBTRACT(master_gtid_executed, slave_gtid_executed)
```

This statement returns any GTIDs that are in `master_gtid_executed` but not in `slave_gtid_executed`. If any GTIDs are returned, the master has applied some transactions that the slave has not applied, and the slave is therefore not up to date.

Example 17.2 Backup and restore scenario

The stored functions `GTID_IS_EQUAL`, `GTID_IS_DISJOINT`, and `GTID_IS_DISJOINT_UNION` could be used to verify backup and restore operations involving multiple databases and servers. In this example scenario, `server1` contains database `db1`, and `server2` contains database `db2`. The goal is to copy database `db2` to `server1`, and the result on `server1` should be the union of the two databases. The procedure used is to back up `server2` using `mysqldump` or `mysqlpump`, then restore this backup on `server1`.

Provided the backup program's option `--set-gtid-purged` was set to `ON` or the default of `AUTO`, the program's output contains a `SET @@global.gtid_purged` statement that will add the `gtid_executed` set from `server2` to the `gtid_purged` set on `server1`. The `gtid_purged` set contains the GTIDs of all the transactions that have been committed on a server but do not exist in any binary log file on the server. When database `db2` is copied to `server1`, the GTIDs of the transactions committed on `server2`, which are not in the binary log files on `server1`, must be added to `server1`'s `gtid_purged` set to make the set complete.

The stored functions can be used to assist with the following steps in this scenario:

- Use `GTID_IS_EQUAL` to verify that the backup operation computed the correct GTID set for the `SET @@global.gtid_purged` statement. On `server2`, extract that statement from the `mysqlpump` or `mysqldump` output, and store the GTID set into a local variable, such as `$gtid_purged_set`. Then execute the following statement:

```
server2> SELECT GTID_IS_EQUAL($gtid_purged_set, @@global.gtid_executed);
```

If the result is 1, the two GTID sets are equal, and the set has been computed correctly.

- Use `GTID_IS_DISJOINT` to verify that the GTID set in the `mysqlpump` or `mysqldump` output does not overlap with the `gtid_executed` set on `server1`. If there is any overlap, with identical GTIDs present on both servers for some reason, you will see errors when copying database `db2` to `server1`. To check, on `server1`, extract and store the `gtid_purged` set from the output into a local variable as above, then execute the following statement:

```
server1> SELECT GTID_IS_DISJOINT($gtid_purged_set, @@global.gtid_executed);
```

If the result is 1, there is no overlap between the two GTID sets, so no duplicate GTIDs are present.

- Use `GTID_IS_DISJOINT_UNION` to verify that the restore operation resulted in the correct GTID state on `server1`. Before restoring the backup, on `server1`, obtain the existing `gtid_executed` set by executing the following statement:

```
server1> SELECT @@global.gtid_executed;
```

Store the result in a local variable `$original_gtid_executed`. Also store the `gtid_purged` set in a local variable as described above. When the backup from `server2` has been restored onto `server1`, execute the following statement to verify the GTID state:

```
server1> SELECT GTID_IS_DISJOINT_UNION($original_gtid_executed,
                                     $gtid_purged_set,
                                     @@global.gtid_executed);
```

If the result is 1, the stored function has verified that the original `gtid_executed` set from `server1` (`$original_gtid_executed`) and the `gtid_purged` set that was added from `server2`

(`$gtid_purged_set`) have no overlap, and also that the updated `gtid_executed` set on `server1` now consists of the previous `gtid_executed` set from `server1` plus the `gtid_purged` set from `server2`, which is the desired result. Ensure that this check is carried out before any further transactions take place on `server1`, otherwise the new transactions in the `gtid_executed` set will cause it to fail.

Example 17.3 Selecting the most up-to-date slave for manual failover

The stored function `GTID_UNION` could be used to identify the most up-to-date replication slave from a set of slaves, in order to perform a manual failover operation after a replication master has stopped unexpectedly. If some of the slaves are experiencing replication lag, this stored function can be used to compute the most up-to-date slave without waiting for all the slaves to apply their existing relay logs, and therefore to minimize the failover time. The function can return the union of the `gtid_executed` set on each slave with the set of transactions received by the slave, which is recorded in the Performance Schema table `replication_connection_status`. You can compare these results to find which slave's record of transactions is the most up-to-date, even if not all of the transactions have been committed yet.

On each replication slave, compute the complete record of transactions by issuing the following statement:

```
SELECT GTID_UNION(RECEIVED_TRANSACTION_SET, @@global.gtid_executed)
FROM performance_schema.replication_connection_status
WHERE channel_name = 'name';
```

You can then compare the results from each slave to see which one has the most up-to-date record of transactions, and use this slave as the new replication master.

Example 17.4 Checking for extraneous transactions on a replication slave

The stored function `GTID_SUBTRACT_UUID` could be used to check whether a replication slave has received transactions that did not originate from its designated master or masters. If it has, there might be an issue with your replication setup, or with a proxy, router, or load balancer. This function works by removing from a GTID set all the GTIDs from a specified originating server, and returning the remaining GTIDs, if any.

For a replication slave with a single master, issue the following statement, giving the identifier of the originating replication master, which is normally the `server_uuid` value:

```
SELECT GTID_SUBTRACT_UUID(@@global.gtid_executed, server_uuid_of_master);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from the designated master.

For a slave in a multi-master replication topology, repeat the function, for example:

```
SELECT GTID_SUBTRACT_UUID(GTID_SUBTRACT_UUID(@@global.gtid_executed,
server_uuid_of_master_1),
server_uuid_of_master_2);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from any of the designated masters.

Example 17.5 Verifying that a server in a replication topology is read-only

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to verify that a server has not originated any GTIDs and is in a read-only state. The function returns only those GTIDs from the GTID set that originate from the server with the specified identifier. If any of the transactions in the server's `gtid_executed` set have the server's own identifier, the server itself originated those transactions. You can issue the following statement on the server to check:

```
SELECT GTID_INTERSECTION_WITH_UUID(@@global.gtid_executed, my_server_uuid);
```

Example 17.6 Validating an additional slave in a multi-master replication setup

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to find out if a slave attached to a multi-master replication setup has applied all the transactions originating from one particular master. In this scenario, `master1` and `master2` are both masters and slaves and replicate to each other. `master2` also has its own replication slave. The replication slave will also receive and apply `master1`'s transactions if `master2` is configured with `log_slave_updates=ON`, but it will not do so if `master2` uses `log_slave_updates=OFF`. Whatever the case, we currently only want to find out if the replication slave is up to date with `master2`. In this situation, the stored function `GTID_INTERSECTION_WITH_UUID` can be used to identify the transactions that `master2` originated, discarding the transactions that `master2` has replicated from `master1`. The built-in function `GTID_SUBSET` can then be used to compare the result to the `gtid_executed` set on the slave. If the slave is up to date with `master2`, the `gtid_executed` set on the slave contains all the transactions in the intersection set (the transactions that originated from `master2`).

To carry out this check, store `master2`'s `gtid_executed` set, `master2`'s server UUID, and the slave's `gtid_executed` set, into client-side variables as follows:

```
$master2_gtid_executed :=
  master2> SELECT @@global.gtid_executed;
$master2_server_uuid :=
  master2> SELECT @@global.server_uuid;
$slave_gtid_executed :=
  slave> SELECT @@global.gtid_executed;
```

Then use `GTID_INTERSECTION_WITH_UUID` and `GTID_SUBSET` with these variables as input, as follows:

```
SELECT GTID_SUBSET(GTID_INTERSECTION_WITH_UUID($master2_gtid_executed,
                                                $master2_server_uuid),
                  $slave_gtid_executed);
```

The server identifier from `master2` (`$master2_server_uuid`) is used with `GTID_INTERSECTION_WITH_UUID` to identify and return only those GTIDs from `master2`'s `gtid_executed` set that originated on `master2`, omitting those that originated on `master1`. The resulting GTID set is then compared with the set of all executed GTIDs on the slave, using `GTID_SUBSET`. If this statement returns nonzero (true), all the identified GTIDs from `master2` (the first set input) are also in the slave's `gtid_executed` set (the second set input), meaning that the slave has replicated all the transactions that originated from `master2`.

17.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, which enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

17.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See [Section 17.2.3, “Replication Channels”](#). The following sections describe how to set up multi-source replication.

17.1.4.2 Multi-Source Replication Tutorials

This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#) for how to configure a master using GTID based replication. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#) for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require [TABLE](#) repositories for the master info log and relay log info log, which are the default in MySQL 8.0. Multi-source replication is not compatible with [FILE](#) based repositories, and the `FILE` setting for the `--master-info-repository` and `--relay-log-info-repository` options is now deprecated.

To modify an existing replication slave that is using a [FILE](#) repository for the slave status logs to use [TABLE](#) repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;
SET GLOBAL master_info_repository = 'TABLE';
SET GLOBAL relay_log_info_repository = 'TABLE';
```

Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using `gtid_mode=ON`, enabled a replication user, and ensured that the slave is using [TABLE](#) based replication repositories. Use the [CHANGE MASTER TO](#) statement to add a new master to a channel by using a [FOR CHANNEL channel](#) clause. For more information on replication channels, see [Section 17.2.3, “Replication Channels”](#)

For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \
MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#) for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes that binary logging is enabled on the master (which is the default), the slave is using [TABLE](#) based replication repositories (which is the default in MySQL 8.0), and that you have enabled a replication user and noted the current binary log position. You need to know the current [MASTER_LOG_FILE](#) and [MASTER_LOG_POSITION](#). Use the [CHANGE MASTER TO](#) statement to add a new master to a channel by specifying a [FOR CHANNEL channel](#) clause. For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='' \
MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

Starting Multi-Source Replication Slaves

Once you have added all of the channels you want to use as replication masters, use a `START SLAVE thread_types` statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:

```
START SLAVE thread_types;
```

- To start only a named channel, use a `FOR CHANNEL channel` clause:

```
START SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to start on the slave. See [Section 13.4.2.6, “START SLAVE Syntax”](#) for more information.

Stopping Multi-Source Replication Slaves

The `STOP SLAVE` statement can be used to stop a multi-source replication slave. By default, if you use the `STOP SLAVE` statement on a multi-source replication slave all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
STOP SLAVE thread_types;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
STOP SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to stop on the slave. See [Section 13.4.2.7, “STOP SLAVE Syntax”](#) for more information.

Resetting Multi-Source Replication Slaves

The `RESET SLAVE` statement can be used to reset a multi-source replication slave. By default, if you use the `RESET SLAVE` statement on a multi-source replication slave all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
RESET SLAVE;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
RESET SLAVE FOR CHANNEL channel;
```

See [Section 13.4.2.4, “RESET SLAVE Syntax”](#) for more information.

17.1.4.3 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 25.11.11, “Performance Schema Replication Tables”](#).
- Using `SHOW SLAVE STATUS FOR CHANNEL channel`. By default, if the `FOR CHANNEL channel` clause is not used, this statement shows the slave status for all channels with one row per channel. The identifier `Channel_name` is added as a column in the result set. If a `FOR CHANNEL channel` clause is provided, the results show the status of only the named replication channel.

Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
***** 2. row *****
CHANNEL_NAME: master2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `master1` and `master2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE CHANNEL_NAME=channel` clause:

```
mysql> SELECT * FROM replication_connection_status WHERE CHANNEL_NAME='master1'\G
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE CHANNEL_NAME=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 25.11.11, “Performance Schema Replication Tables”](#).

17.1.4.4 Multi-Source Replication Error Messages

Error codes and messages provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel which generated the error. For example:

`Slave is already running` and `Slave is already stopped` have been replaced with `Replication thread(s) for channel channel_name are already running` and `Replication threads(s) for channel channel_name are already stopped` respectively.

The server log messages have also been changed to indicate which channel the log messages relate to. This makes debugging and tracing easier.

17.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline.

17.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
- Anonymous transactions do not have a GTID assigned, and MySQL ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions, anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

Transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set from a top-level statement by an account that has privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#). In MySQL 5.6 and earlier, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. When `gtid_mode=OFF_PERMISSIVE` then *new* transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then *new* transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

The fields related to GTIDs display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the `replication_applier_status_by_worker` Performance Schema table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see [Section 17.1.5.2, “Enabling GTID Transactions Online”](#).

The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical. The meaning of each entry is as follows:

- **Y**: the `gtid_mode` of master and slave is compatible
- **N**: the `gtid_mode` of master and slave is not compatible
- *****: auto-positioning can be used with this combination

Table 17.1 Valid Combinations of Master and Slave `gtid_mode`

<code>gtid_mode</code>	Master OFF	Master OFF_PERMISSIVE	Master ON_PERMISSIVE	Master ON
Slave OFF	Y	Y	N	N
Slave OFF_PERMISSIVE	Y	Y	Y	Y*
Slave ON_PERMISSIVE	Y	Y	Y	Y*
Slave ON	N	N	Y	Y*

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`. The meaning of each entry is as follows:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified UUID:NUMBER.
- **New GTID**: generate a GTID with an automatically generated number.

Table 17.2 Valid Combinations of `gtid_mode` and `gtid_next`

	<code>gtid_next</code> AUTOMATIC binary log on	<code>gtid_next</code> AUTOMATIC binary log off	<code>gtid_next</code> ANONYMOUS	<code>gtid_next</code> UUID:NUMBER
<code>gtid_mode OFF</code>	ANONYMOUS	ANONYMOUS	ANONYMOUS	Error
<code>gtid_mode OFF_PERMISSIVE</code>	ANONYMOUS	ANONYMOUS	ANONYMOUS	UUID:NUMBER
<code>gtid_mode ON_PERMISSIVE</code>	New GTID	ANONYMOUS	ANONYMOUS	UUID:NUMBER
<code>gtid_mode ON</code>	New GTID	ANONYMOUS	Error	UUID:NUMBER

When the binary log is off and `gtid_next` is set to **AUTOMATIC**, then no GTID is generated. This is consistent with the behavior of previous versions.

17.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless all servers which are in the topology are using this version.

- All servers have `gtid_mode` set to the default value `OFF`.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 17.1.5.3, “Disabling GTID Transactions Online”](#), the online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

Note

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

Important

This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

```
SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
```

Note

On a replication slave, it is theoretically possible that this shows zero and then nonzero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See [Section 17.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

Important

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

8. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON;
```

9. On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

17.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
 - All servers have `gtid_mode` set to `ON`.
1. Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

2. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

4. On each server, wait until the variable @@GLOBAL.GTID_OWNED is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

5. Wait for all transactions that currently exist in any binary log to replicate to all slaves. See [Section 17.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.
6. If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

7. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

8. On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

17.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

1. On the master, execute:

```
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

2. On every slave, use the file and position information from the master to execute:

```
SELECT MASTER_POS_WAIT(file, position);
```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle *twice*.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

17.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

Property	Value
Command-Line Format	<code>--server-id=#</code>
System Variable	<code>server_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.3$)	1
Default Value ($\leq 8.0.2$)	0

Property	Value
Minimum Value	0
Maximum Value	4294967295

Specifies the server ID. The `server_id` system variable is set to 1 by default. The server can be started with this default ID, but when binary logging is enabled, an informational message is issued if you did not specify a server ID explicitly using the `--server-id` option.

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. For additional information, see [Section 17.1.6.2, “Replication Master Options and Variables”](#), and [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

For more information, see [Section 17.1.2.2, “Setting the Replication Slave Configuration”](#).

`server_uuid`

The MySQL server generates a true UUID in addition to the default or user-supplied server ID set in the `server_id` system variable. This is available as the global, read-only variable `server_uuid`.

Note

The presence of the `server_uuid` system variable does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

Property	Value
System Variable	<code>server_uuid</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

**Important**

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

**Note**

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.
- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

17.1.6.1 Replication and Binary Logging Option and Variable Reference

The following two lists provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

The command-line options and system variables in the following list relate to replication masters and replication slaves. [Section 17.1.6.2, “Replication Master Options and Variables”](#), provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

- `abort-slave-event-count`: Option used by `mysql-test` for debugging and testing of replication
- `binlog_expire_logs_seconds`: Purge binary logs after this many seconds
- `binlog_gtid_simple_recovery`: Controls how binary logs are iterated during GTID recovery
- `Com_change_master`: Count of `CHANGE MASTER TO` statements
- `Com_show_master_status`: Count of `SHOW MASTER STATUS` statements
- `Com_show_new_master`: Count of `SHOW NEW MASTER` statements
- `Com_show_slave_hosts`: Count of `SHOW SLAVE HOSTS` statements
- `Com_show_slave_status`: Count of `SHOW SLAVE STATUS` statements
- `Com_show_slave_status_nonblocking`: Count of `SHOW SLAVE STATUS NONBLOCKING` statements
- `Com_slave_start`: Count of `START SLAVE` statements
- `Com_slave_stop`: Count of `STOP SLAVE` statements

- `disconnect-slave-event-count`: Option used by mysql-test for debugging and testing of replication
- `enforce-gtid-consistency`: Prevents execution of statements that cannot be logged in a transactionally safe manner
- `enforce_gtid_consistency`: Prevents execution of statements that cannot be logged in a transactionally safe manner
- `executed-gtids-compression-period`: Deprecated and will be removed in a future version; use the renamed `gtid-executed-compression-period` instead
- `executed_gtids_compression_period`: Deprecated and will be removed in a future version; use the renamed `gtid_executed_compression_period` instead
- `expire_logs_days`: Purge binary logs after this many days
- `gtid-executed-compression-period`: Compress `gtid_executed` table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.
- `gtid-mode`: Controls whether GTID based logging is enabled and what type of transactions the logs can contain
- `gtid_executed`: Global: All GTIDs in the binary log (global) or current transaction (session). Read-only.
- `gtid_executed_compression_period`: Compress `gtid_executed` table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.
- `gtid_mode`: Controls whether GTID based logging is enabled and what type of transactions the logs can contain
- `gtid_next`: Specifies the GTID for the next statement to execute; see documentation for details
- `gtid_owned`: The set of GTIDs owned by this client (session), or by all clients, together with the thread ID of the owner (global). Read-only.
- `gtid_purged`: The set of all GTIDs that have been purged from the binary log
- `init_slave`: Statements that are executed when a slave connects to a master
- `log-bin-trust-function-creators`: If equal to 0 (the default), then when `--log-bin` is used, creation of a stored function is allowed only to users having the SUPER privilege and only if the function created does not break binary logging
- `log-slave-updates`: Tells the slave to log the updates performed by its SQL thread to its own binary log
- `log_built_in_as_identified_by_password`: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion
- `log_slave_updates`: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the `--log-slave-updates` server option.
- `log_statements_unsafe_for_binlog`: Disables error 1592 warnings being written to the error log
- `master-info-file`: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs

- `master-info-repository`: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table
- `master-retry-count`: Number of tries the slave makes to connect to the master before giving up
- `master_info_repository`: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table
- `max_relay_log_size`: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by the value of `max_binlog_size`.
- `original_commit_timestamp`: The time when a transaction was committed on the original master
- `relay-log`: The location and base name to use for relay logs
- `relay-log-index`: The location and name to use for the file that keeps a list of the last relay logs
- `relay-log-info-file`: The location and name of the file that remembers where the SQL replication thread is in the relay logs
- `relay-log-info-repository`: Whether to write the replication SQL thread's location in the relay logs to a file or a table
- `relay-log-recovery`: Enables automatic recovery of relay log files from master at startup
- `relay_log_basename`: Complete path to relay log, including filename
- `relay_log_index`: The name of the relay log index file
- `relay_log_info_file`: The name of the file in which the slave records information about the relay logs
- `relay_log_info_repository`: Whether to write the replication SQL thread's location in the relay logs to a file or a table
- `relay_log_purge`: Determines whether relay logs are purged
- `relay_log_recovery`: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave
- `relay_log_space_limit`: Maximum space to use for all relay logs
- `replicate-do-db`: Tells the slave SQL thread to restrict replication to the specified database
- `replicate-do-table`: Tells the slave SQL thread to restrict replication to the specified table
- `replicate-ignore-db`: Tells the slave SQL thread not to replicate to the specified database
- `replicate-ignore-table`: Tells the slave SQL thread not to replicate to the specified table
- `replicate-rewrite-db`: Updates to a database with a different name than the original
- `replicate-same-server-id`: In replication, if set to 1, do not skip events having our server id
- `replicate-wild-do-table`: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern
- `replicate-wild-ignore-table`: Tells the slave thread not to replicate to the tables that match the given wildcard pattern
- `report-host`: Host name or IP of the slave to be reported to the master during slave registration

- `report-password`: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.
- `report-port`: Port for connecting to slave reported to the master during slave registration
- `report-user`: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.
- `Rpl_semi_sync_master_clients`: Number of semisynchronous slaves
- `rpl_semi_sync_master_enabled`: Whether semisynchronous replication is enabled on the master
- `Rpl_semi_sync_master_net_avg_wait_time`: The average time the master waited for a slave reply
- `Rpl_semi_sync_master_net_wait_time`: The total time the master waited for slave replies
- `Rpl_semi_sync_master_net_waits`: The total number of times the master waited for slave replies
- `Rpl_semi_sync_master_no_times`: Number of times the master turned off semisynchronous replication
- `Rpl_semi_sync_master_no_tx`: Number of commits not acknowledged successfully
- `Rpl_semi_sync_master_status`: Whether semisynchronous replication is operational on the master
- `Rpl_semi_sync_master_timefunc_failures`: Number of times the master failed when calling time functions
- `rpl_semi_sync_master_timeout`: Number of milliseconds to wait for slave acknowledgment
- `rpl_semi_sync_master_trace_level`: The semisynchronous replication debug trace level on the master
- `Rpl_semi_sync_master_tx_avg_wait_time`: The average time the master waited for each transaction
- `Rpl_semi_sync_master_tx_wait_time`: The total time the master waited for transactions
- `Rpl_semi_sync_master_tx_waits`: The total number of times the master waited for transactions
- `rpl_semi_sync_master_wait_for_slave_count`: How many slave acknowledgments the master must receive per transaction before proceeding
- `rpl_semi_sync_master_wait_no_slave`: Whether master waits for timeout even with no slaves
- `rpl_semi_sync_master_wait_point`: The wait point for slave transaction receipt acknowledgment
- `Rpl_semi_sync_master_wait_pos_backtraverse`: The total number of times the master waited for an event with binary coordinates lower than events waited for previously
- `Rpl_semi_sync_master_wait_sessions`: Number of sessions currently waiting for slave replies
- `Rpl_semi_sync_master_yes_tx`: Number of commits acknowledged successfully
- `rpl_semi_sync_slave_enabled`: Whether semisynchronous replication is enabled on slave
- `Rpl_semi_sync_slave_status`: Whether semisynchronous replication is operational on slave
- `rpl_semi_sync_slave_trace_level`: The semisynchronous replication debug trace level on the slave

- `rpl_read_size`: Set the minimum amount of data in bytes that is read from the binary log files and relay log files
- `rpl_stop_slave_timeout`: Set the number of seconds that STOP SLAVE waits before timing out
- `server_uuid`: The server's globally unique ID, automatically (re)generated at server start
- `show-slave-auth-info`: Show user name and password in SHOW SLAVE HOSTS on this master
- `simplified_binlog_gtid_recovery`: Controls how binary logs are iterated during GTID recovery
- `skip-slave-start`: If set, slave is not autostarted
- `slave-checkpoint-group`: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- `slave-checkpoint-period`: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- `slave-load-tmpdir`: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement
- `slave-max-allowed-packet`: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides `max_allowed_packet`
- `slave_net_timeout`: Number of seconds to wait for more data from a master/slave connection before aborting the read
- `slave-parallel-type`: Tells the slave to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions. The default is LOGICAL_CLOCK.
- `slave-parallel-workers`: Number of applier threads for executing replication transactions in parallel. The default is 4 applier threads. Set to 0 to disable slave multithreading. Not supported by MySQL Cluster.
- `slave-pending-jobs-size-max`: Maximum size of slave worker queues holding events not yet applied
- `slave-rows-search-algorithms`: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN
- `slave-skip-errors`: Tells the slave thread to continue replication when a query returns an error from the provided list
- `slave_checkpoint_group`: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- `slave_checkpoint_period`: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- `slave_compressed_protocol`: Use compression on master/slave protocol
- `slave_exec_mode`: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for NDB Cluster, where IDEMPOTENT is always used
- `Slave_heartbeat_period`: The slave's replication heartbeat interval, in seconds
- `slave_max_allowed_packet`: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides `max_allowed_packet`

- [Slave_open_temp_tables](#): Number of temporary tables that the slave SQL thread currently has open
- [slave_parallel_type](#): Tells the slave to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions.
- [slave_parallel_workers](#): Number of applier threads for executing replication transactions in parallel. A value of 0 disables slave multithreading. Not supported by MySQL Cluster.
- [slave_pending_jobs_size_max](#): Maximum size of slave worker queues holding events not yet applied
- [slave_preserve_commit_order](#): Ensures that all commits by slave workers happen in the same order as on the master to maintain consistency when using parallel applier threads.
- [Slave_retried_transactions](#): The total number of times since startup that the replication slave SQL thread has retried transactions
- [slave_rows_search_algorithms](#): Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN.
- [Slave_rows_last_search_algorithm_used](#): Search algorithm most recently used by this slave to locate rows for row-based replication (index, table, or hash scan)
- [Slave_running](#): The state of this server as a replication slave (slave I/O thread status)
- [slave_transaction_retries](#): Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping
- [slave_type_conversions](#): Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.
- [sql_log_bin](#): Toggle binary logging
- [sql_slave_skip_counter](#): Number of events from the master that a slave server should skip. Not compatible with GTID replication.
- [sync_binlog](#): Synchronously flush binary log to disk after every #th event
- [sync_master_info](#): Synchronize master.info to disk after every #th event
- [sync_relay_log](#): Synchronize relay log to disk after every #th event
- [sync_relay_log_info](#): Synchronize relay.info file to disk after every #th event
- [transaction_write_set_extraction](#): Defines the algorithm used to hash the writes extracted during a transaction

The command-line options and system variables in the following list relate to the binary log. [Section 17.1.6.4, “Binary Logging Options and Variables”](#), provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see [Section 5.4.4, “The Binary Log”](#).

- [binlog-checksum](#): Enable/disable binary log checksums
- [binlog-do-db](#): Limits binary logging to specific databases
- [binlog_format](#): Specifies the format of the binary log
- [binlog-ignore-db](#): Tells the master that updates to the given database should not be logged to the binary log

- `binlog-row-event-max-size`: Binary log max event size
- `binlog-rows-query-log-events`: Enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 slaves/readers.
- `Binlog_cache_disk_use`: Number of transactions that used a temporary file instead of the binary log cache
- `binlog_cache_size`: Size of the cache to hold the SQL statements for the binary log during a transaction
- `Binlog_cache_use`: Number of transactions that used the temporary binary log cache
- `binlog_checksum`: Enable/disable binary log checksums
- `binlog_direct_non_transactional_updates`: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.
- `binlog_error_action`: Controls what happens when the server cannot write to the binary log
- `binlog_group_commit_sync_delay`: Sets the number of microseconds to wait before synchronizing transactions to disk
- `binlog_group_commit_sync_no_delay_count`: Sets the maximum number of transactions to wait for before aborting the current delay specified by `binlog_group_commit_sync_delay`
- `binlog_max_flush_queue_time`: How long to read transactions before flushing to binary log
- `binlog_order_commits`: Whether to commit in same order as writes to binary log
- `binlog_row_image`: Use full or minimal images when logging row changes
- `binlog_row_metadata`: Configures the amount of table related metadata binary logged when using row-based logging.
- `binlog_row_value_options`: Enables binary logging of partial JSON updates for row-based replication.
- `binlog-rows-query-log-events`: When TRUE, enables logging of rows query log events in row-based logging mode. FALSE by default. Do not enable when producing logs for pre-5.6 replication slaves or other readers.
- `Binlog_stmt_cache_disk_use`: Number of nontransactional statements that used a temporary file instead of the binary log statement cache
- `binlog_stmt_cache_size`: Size of the cache to hold nontransactional statements for the binary log during a transaction
- `Binlog_stmt_cache_use`: Number of statements that used the temporary binary log statement cache
- `binlog_transaction_dependency_tracking`: Source of dependency information (commit timestamps or transaction write sets) from which to assess which transactions can be executed in parallel by slave's multithreaded applier.
- `binlog_transaction_dependency_history_size`: Number of row hashes kept for looking up transaction that last updated some row.
- `Com_show_binlog_events`: Count of SHOW BINLOG EVENTS statements
- `Com_show_binlogs`: Count of SHOW BINLOGS statements

- `log-bin-use-v1-row-events`: Use version 1 binary log row events
- `log_bin_basename`: Path and base name for binary log files
- `log_bin_use_v1_row_events`: Shows whether server is using version 1 binary log row events
- `master-verify-checksum`: Cause master to examine checksums when reading from the binary log
- `master_verify_checksum`: Cause master to read checksums from binary log
- `max-binlog-dump-events`: Option used by mysql-test for debugging and testing of replication
- `max_binlog_cache_size`: Can be used to restrict the total size used to cache a multi-statement transaction
- `max_binlog_size`: Binary log will be rotated automatically when size exceeds this value
- `max_binlog_stmt_cache_size`: Can be used to restrict the total size used to cache all nontransactional statements during a transaction
- `slave-sql-verify-checksum`: Cause slave to examine checksums when reading from the relay log
- `slave_sql_verify_checksum`: Cause slave to examine checksums when reading from relay log
- `sporadic-binlog-dump-fail`: Option used by mysql-test for debugging and testing of replication

For a listing of *all* command-line options, system and status variables used with `mysqld`, see [Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”](#).

17.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see [Section 17.1.6.4, “Binary Logging Options and Variables”](#).

Startup Options for Replication Masters

The following list describes startup options for controlling replication master servers. Replication-related system variables are discussed later in this section.

- `--show-slave-auth-info`

Property	Value
Command-Line Format	<code>--show-slave-auth-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- `auto_increment_increment`

Property	Value
System Variable	<code>auto_increment_increment</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Note

`auto_increment_increment` is intended for use with MySQL Cluster, which is not currently supported in MySQL 8.0.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoincl
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of

`AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto_increment_offset} + N \times \text{auto_increment_increment}$$

where N is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series $5 + N \times 10$, that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).

- `auto_increment_offset`

Property	Value
System Variable	auto_increment_offset
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

This variable has a default value of 1. For more information, see the description for [auto_increment_increment](#).

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Note

`auto_increment_offset` is intended for use with MySQL Cluster, which is not currently supported in MySQL 8.0.

- `rpl_semi_sync_master_enabled`

Property	Value
System Variable	rpl_semi_sync_master_enabled
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout`

Property	Value
System Variable	rpl_semi_sync_master_timeout
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value	10000

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

Property	Value
System Variable	<code>rpl_semi_sync_master_trace_level</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	32

The semisynchronous replication debug trace level on the master. Four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_for_slave_count`

Property	Value
System Variable	<code>rpl_semi_sync_master_wait_for_slave_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

The number of slave acknowledgments the master must receive per transaction before proceeding. By default `rpl_semi_sync_master_wait_for_slave_count` is 1, meaning that semisynchronous replication proceeds after receiving a single slave acknowledgment. Performance is best for small values of this variable.

For example, if `rpl_semi_sync_master_wait_for_slave_count` is 2, then 2 slaves must acknowledge receipt of the transaction before the timeout period configured by `rpl_semi_sync_master_timeout` for semisynchronous replication to proceed. If less slaves acknowledge receipt of the transaction during the timeout period, the master reverts to normal replication.

Note

This behavior also depends on `rpl_semi_sync_master_wait_no_slave`

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

Property	Value
System Variable	<code>rpl_semi_sync_master_wait_no_slave</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Controls whether the master waits for the timeout period configured by `rpl_semi_sync_master_timeout` to expire, even if the slave count drops to less than the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count` during the timeout period.

When the value of `rpl_semi_sync_master_wait_no_slave` is `ON` (the default), it is permissible for the slave count to drop to less than `rpl_semi_sync_master_wait_for_slave_count` during the timeout period. As long as enough slaves acknowledge the transaction before the timeout period expires, semisynchronous replication continues.

When the value of `rpl_semi_sync_master_wait_no_slave` is `OFF`, if the slave count drops to less than the number configured in `rpl_semi_sync_master_wait_for_slave_count` at any time during the timeout period configured by `rpl_semi_sync_master_timeout`, the master reverts to normal replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_point`

Property	Value
System Variable	<code>rpl_semi_sync_master_wait_point</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>AFTER_SYNC</code>
Valid Values	<code>AFTER_SYNC</code>

Property	Value
	AFTER_COMMIT

This variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- [AFTER_SYNC](#) (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- [AFTER_COMMIT](#): The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With [AFTER_SYNC](#), all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date. Note, however, that the master cannot be restarted in this scenario and must be discarded, because its binary log might contain uncommitted transactions that would cause a conflict with the slave when externalized after binary log recovery.

- With [AFTER_COMMIT](#), the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

This variable is available only if the master-side semisynchronous replication plugin is installed.

With the addition of [rpl_semi_sync_master_wait_point](#) in MySQL 5.7, a version compatibility constraint was created because it increments the semisynchronous interface version: Servers for MySQL 5.7 and higher do not work with semisynchronous replication plugins from older versions, nor do servers from older versions work with semisynchronous replication plugins for MySQL 5.7 and higher.

17.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and contains the following:

- [Startup Options for Replication Slaves](#)
- [Options for Logging Slave Status to Tables](#)
- [System Variables Used on Replication Slaves](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. Specify system variable values using [SET](#).

Server ID. On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example [my.cnf](#) file:

```
[mysqld]
server-id=3
```

Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. Others, such as the [--replicate-*](#) options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- [--log-slave-updates](#)

Property	Value
Command-Line Format	--log-slave-updates
System Variable	log_slave_updates
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value ($\geq 8.0.3$)	ON
Default Value ($\leq 8.0.2$)	OFF

This option makes a slave write updates that are received from a master server and performed by the slave's SQL thread to the slave's own binary log. Binary logging, which is controlled by the [--log-bin](#) option and is enabled by default, must also be enabled on the slave for updates to be logged. [--log-slave-updates](#) is enabled by default, unless you specify [--skip-log-bin](#) to disable binary logging, in which case MySQL also disables slave update logging by default. If you need to disable slave update logging when binary logging is enabled, specify [--skip-log-slave-updates](#).

[--log-slave-updates](#) enables replication servers to be chained. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, [A](#) serves as the master for the slave [B](#), and [B](#) serves as the master for the slave [C](#). For this to work, [B](#) must be both a master *and* a slave. With binary logging and the [--log-slave-updates](#) option enabled, which are the default settings, updates received from [A](#) are logged by [B](#) to its binary log, and can therefore be passed on to [C](#).

- [--master-info-file=file_name](#)

Property	Value
Command-Line Format	--master-info-file=file_name
Type	File name

Property	Value
Default Value	<code>master.info</code>

The name for the master info log, if `--master-info-repository=FILE` is set. The default name is `master.info` in the data directory. `--master-info-repository=FILE` is now deprecated. For information about the master info log, see [Section 17.2.4.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

Property	Value
Command-Line Format	<code>--master-retry-count=#</code>
Deprecated	Yes
Type	Integer
Default Value	<code>86400</code>
Minimum Value	<code>0</code>
Maximum Value (64-bit platforms)	<code>18446744073709551615</code>
Maximum Value (32-bit platforms)	<code>4294967295</code>

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

Property	Value
Command-Line Format	<code>--max-relay-log-size=#</code>
System Variable	<code>max_relay_log_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>0</code>
Minimum Value	<code>0</code>
Maximum Value	<code>1073741824</code>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 17.2.4.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

Property	Value
Command-Line Format	<code>--relay-log=file_name</code>
System Variable	<code>relay_log</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The base name for the relay log. The server creates relay log files in sequence by adding a numeric suffix to the base name.

For the default replication channel, the default base name for relay logs is `host_name-relay-bin`, using the name of the host machine. For non-default replication channels, the default base name for relay logs is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in this relay log.

The default location for relay log files is the data directory. You can use the `--relay-log` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index` options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.4, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

Property	Value
Command-Line Format	<code>--relay-log-index=file_name</code>
System Variable	<code>relay_log_index</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The name for the index file for the relay log. If you do not specify the `--relay-log-index` option, but the `--relay-log` option is specified, its value is used as the default base name for the relay log index file. If the `--relay-log` option is also not specified, then for the default replication channel, the default name is `host_name-relay-bin.index`, using the name of the host machine. For non-default replication channels, the default name is `host_name-relay-bin-channel.index`, where `channel` is the name of the replication channel recorded in this relay log index.

The default location for relay log files is the data directory, or any other location that was specified using the `--relay-log` option. You can use the `--relay-log-index` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index` options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.4, “Specifying Program Options”](#).

- `--relay-log-info-file=file_name`

Property	Value
Command-Line Format	<code>--relay-log-info-file=file_name</code>
Type	File name
Default Value	<code>relay-log.info</code>

The name for the relay log info file, if `--relay-log-info-repository` is set to `FILE`. The default name is `relay-log.info` in the data directory. `--relay-log-info-repository=FILE` is now deprecated. For information about the relay log info log, see [Section 17.2.4.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

Property	Value	
Command-Line Format	<code>--relay-log-purge</code>	
System Variable	<code>relay_log_purge</code>	
Scope	Global	2949

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	TRUE

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option risks data consistency and is therefore not crash-safe.

- `--relay-log-recovery={0|1}`

Property	Value
Command-Line Format	<code>--relay-log-recovery</code>
Type	Boolean
Default Value	FALSE

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

To provide a crash-safe slave, this option must be enabled (set to 1), `--relay-log-info-repository` must be set to `TABLE`, and `relay-log-purge` must be enabled. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe. See [Making replication resilient to unexpected halts](#), for more information.

When using a multithreaded slave (in other words `slave_parallel_workers` is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the `--relay-log-recovery` option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, which brings the server to a more consistent state, then issue `RESET SLAVE` to remove the relay logs. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `--relay-log-space-limit=size`

Property	Value
Command-Line Format	<code>--relay-log-space-limit=#</code>
System Variable	<code>relay_log_space_limit</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

Property	Value
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Property	Value
Command-Line Format	<code>--replicate-do-db=name</code>
Type	String

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

The precise effect of this replication filter depends on whether statement-based or row-based replication is in use.

Statement-based replication. Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Row-based replication. Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

Property	Value
Command-Line Format	<code>--replicate-ignore-db=name</code>
Type	String

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-ignore-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

Statement-based replication. Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Row-based replication. Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

Property	Value
Command-Line Format	<code>--replicate-do-table=name</code>
Type	String

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

Property	Value
Command-Line Format	<code>--replicate-ignore-table=name</code>
Type	String

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-ignore-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

Property	Value
Command-Line Format	<code>--replicate-rewrite-db=old_name->new_name</code>
Type	String

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. Specify the channel name followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, and any subsequent colons are interpreted as literal colons. For example, to configure a channel specific replication filter on a channel named `channel_1`, use:

```
shell> mysqld --replicate-rewrite-db=channel_1:db_name1->db_name2
```

If you use a colon but do not specify a channel name, the option configures the replication filter for the default replication channel. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.

3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

- `--replicate-same-server-id`

Property	Value
Command-Line Format	<code>--replicate-same-server-id</code>
Type	Boolean
Default Value	<code>FALSE</code>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. The option cannot be set to 1 when `--log-slave-updates` is enabled, which is the default.

By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Property	Value
Command-Line Format	<code>--replicate-wild-do-table=name</code>
Type	String

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

As an example, `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Property	Value
Command-Line Format	<code>--replicate-wild-ignore-table=name</code>
Type	String

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-ignore:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 17.2.5.4, “Replication Channel Based Filters”](#) for more information.

Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

As an example, `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`. For information about how matching works, see the description of the `--replicate-wild-do-table`

option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

Property	Value
Command-Line Format	<code>--report-host=host_name</code>
System Variable	<code>report_host</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

Property	Value
Command-Line Format	<code>--report-password=name</code>
System Variable	<code>report_password</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

Property	Value
Command-Line Format	<code>--report-port=#</code>
System Variable	<code>report_port</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	[slave_port]
Minimum Value	0
Maximum Value	65535

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

Property	Value
Command-Line Format	<code>--report-user=name</code>
System Variable	<code>report_user</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--slave-checkpoint-group=#`

Property	Value
Command-Line Format	<code>--slave-checkpoint-group=#</code>
Type	Integer
Default Value	512
Minimum Value	32
Maximum Value	524280
Block Size	8

Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `--slave-checkpoint-period=#`

Property	Value
Command-Line Format	<code>--slave-checkpoint-period=#</code>
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	4G

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `--slave-parallel-workers`

Property	Value
Command-Line Format	<code>--slave-parallel-workers=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1024

Enables multithreading on the slave and sets the number of slave applier threads for executing replication transactions in parallel. When the value is a number greater than 0, the slave is a multithreaded slave with the specified number of applier threads, plus a coordinator thread to manage them. If you are using multiple replication channels, each channel has this number of threads.

Retrying of transactions is supported when multithreading is enabled on a slave. When `slave_preserve_commit_order=1`, transactions on a slave are externalized on the slave in the same order as they appear in the slave's relay log. The way in which transactions are distributed among applier threads is configured by `--slave-parallel-type`.

To disable parallel execution, set this option to 0, which gives the slave a single applier thread and no coordinator thread. With this setting, the `--slave-parallel-type` and `slave_preserve_commit_order` options have no effect and are ignored.

- `--slave-pending-jobs-size-max=#`

Property	Value
Command-Line Format	<code>--slave-pending-jobs-size-max=#</code>
Type	Integer
Default Value ($\geq 8.0.12$)	128M
Default Value ($\leq 8.0.11$)	16M
Minimum Value	1024
Maximum Value	16EiB
Block Size	1024

For multithreaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multithreading is not enabled.

The minimum possible value for this option is 1024 bytes; the default is 128MB. The maximum possible value is 18446744073709551615 (16 exbibytes). Values that are not exact multiples of 1024 bytes are rounded down to the next lower multiple of 1024 bytes prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- `--skip-slave-start`

Property	Value
Command-Line Format	<code>--skip-slave-start</code>
Type	Boolean
Default Value	FALSE

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

Property	Value
Command-Line Format	<code>--slave-compressed-protocol</code>
System Variable	<code>slave_compressed_protocol</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

Property	Value
Command-Line Format	<code>--slave-load-tmpdir=dir_name</code>
System Variable	<code>slave_load_tmpdir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	<code>/tmp</code>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

Property	Value
Command-Line Format	<code>--slave-max-allowed-packet=#</code>
Type	Integer
Default Value	1073741824
Minimum Value	1024
Maximum Value	1073741824

This option sets the maximum packet size in bytes that the slave SQL and I/O threads can handle. It is possible for a replication master to write binary log events longer than its `max_allowed_packet` setting once the event header is added. The setting for `slave_max_allowed_packet` must be larger than the `max_allowed_packet` setting on the master, so that large updates using row-based replication do not cause replication to fail.

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

Property	Value
Command-Line Format	<code>--slave-net-timeout=#</code>
System Variable	<code>slave_net_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default value is 60 seconds (one minute).

- `--slave-parallel-type=type`

Property	Value
Command-Line Format	<code>--slave-parallel-type=type</code>
Type	Enumeration
Default Value	<code>DATABASE</code>
Valid Values	<code>DATABASE</code> <code>LOGICAL_CLOCK</code>

When using a multithreaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The option has no effect on slaves for which multithreading is not enabled. The possible values are:

- `LOGICAL_CLOCK`: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. The dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible. When this value is set, the `binlog_transaction_dependency_tracking` system variable can be used on the master to specify that write sets are used for parallelization in place of timestamps, if a write set is available for the transaction and gives improved results compared to timestamps.
- `DATABASE`: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. There must be no cross-database constraints, as such constraints may be violated on the slave.

When `slave_preserve_commit_order=1` is set, you can only use `LOGICAL_CLOCK`.

If your replication topology uses multiple levels of slaves, `LOGICAL_CLOCK` may achieve less parallelization for each level the slave is away from the master. You can reduce this effect by using `binlog_transaction_dependency_tracking` on the master to specify that write sets are used instead of timestamps for parallelization where possible.

- `slave-rows-search-algorithms=list`

Property	Value
Command-Line Format	<code>--slave-rows-search-algorithms=list</code>
Type	Set
Default Value (>= 8.0.2)	<code>INDEX_SCAN,HASH_SCAN</code>
Default Value (<= 8.0.1)	<code>TABLE_SCAN,INDEX_SCAN</code>
Valid Values	<code>TABLE_SCAN,INDEX_SCAN</code> <code>INDEX_SCAN,HASH_SCAN</code> <code>TABLE_SCAN,HASH_SCAN</code> <code>TABLE_SCAN,INDEX_SCAN,HASH_SCAN</code> (equivalent to <code>INDEX_SCAN,HASH_SCAN</code>)

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. The option sets the initial value for the `slave_rows_search_algorithms` system variable.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	<code>INDEX_SCAN,HASH_SCAN</code> or <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code>	<code>INDEX_SCAN, TABLE_SCAN</code>	<code>TABLE_SCAN, HASH_SCAN</code>
<i>Primary key or unique key</i>	Index scan	Index scan	Hash scan over index
<i>(Other) Key</i>	Hash scan over index	Index scan	Hash scan over index
<i>No index</i>	Hash scan	Table scan	Hash scan

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

- The default value is `INDEX_SCAN,HASH_SCAN`. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`.
- To force hashing for *all* searches, set this option to `TABLE_SCAN, HASH_SCAN`.
- To remove hashing, set this option to `TABLE_SCAN, INDEX_SCAN`. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

**Note**

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

Property	Value
Command-Line Format	<code>--slave-skip-errors=name</code>
System Variable	<code>slave_skip_errors</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	OFF
Valid Values	OFF [<code>list of error codes</code>] all ddl_exist_errors

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

The shorthand value `ddl_exist_errors` is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

Property	Value
Command-Line Format	<code>--slave-sql-verify-checksum=value</code>
Type	Boolean
Default Value	1
Valid Values	0 1

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count`

Property	Value
Command-Line Format	<code>--abort-slave-event-count=#</code>
Type	Integer
Default Value	0
Minimum Value	0

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays *Yes* in both the *Slave_IO_Running* and the *Slave_SQL_Running* columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count`

Property	Value
Command-Line Format	<code>--disconnect-slave-event-count=#</code>
Type	Integer
Default Value	0

Options for Logging Slave Status to Tables

Replication slave status information is logged to an InnoDB table in the `mysql` database. Before MySQL 8.0, this information could alternatively be logged to a file in the data directory, but the use of that format is now deprecated. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={TABLE|FILE}`

Property	Value
Command-Line Format	<code>--master-info-repository=FILE TABLE</code>
Type	String
Default Value (>= 8.0.2)	TABLE
Default Value (<= 8.0.1)	FILE
Valid Values	FILE TABLE

This option determines whether the slave server logs master status and connection information to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the master info log is named `mysql.slave_master_info`. The `TABLE` setting is required when multiple replication channels are configured.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the master info log is named `master.info` by default, and you can change this name using the `--master-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_master_info` system variable. You can only change the setting when no replication threads are executing.

- `--relay-log-info-repository={TABLE|FILE}`

Property	Value
Command-Line Format	<code>--relay-log-info-repository=FILE TABLE</code>
Type	String
Default Value (>= 8.0.2)	TABLE
Default Value (<= 8.0.1)	FILE
Valid Values	FILE TABLE

This option determines whether the slave server logs its position in the relay logs to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the relay log info log is named `mysql.slave_relay_log_info`. The `TABLE` setting is required when multiple replication channels are configured. The `TABLE` setting for the relay log info log is also required to make replication resilient to unexpected halts, for which the `--relay-log-recovery` option must also be enabled. See [Making replication resilient to unexpected halts](#) for more information.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the relay log info log is named `relay-log.info` by default, and you can change this name using the `--relay-log-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable. You can only change the setting when no replication threads are executing.

The slave status log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see [Section 17.2.4, “Replication Relay and Status Logs”](#).

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

Property	Value
Command-Line Format	<code>--init-slave=name</code>
System Variable	<code>init_slave</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 13.4.2.6, “START SLAVE Syntax”](#), for more information.

- `log_slow_slave_statements`

Property	Value
System Variable	<code>log_slow_slave_statements</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

Note that all statements logged in row format in the master will not be logged in the slave's slow log, even if `log_slow_slave_statements` is enabled.

- `master_info_repository`

Property	Value
Command-Line Format	<code>--master-info-repository=FILE TABLE</code>
System Variable	<code>master_info_repository</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value ($\geq 8.0.2$)	TABLE
Default Value ($\leq 8.0.1$)	FILE
Valid Values	FILE TABLE

The setting of this variable determines whether the slave server logs master status and connection information to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the master info log is named `mysql.slave_master_info`. The `TABLE` setting is required when multiple replication channels are configured.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the master info log is named `master.info` by default, and you can change this name using the `--master-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_master_info` system variable. You can only change the setting when no replication threads are executing.

- `max_relay_log_size`

Property	Value
Command-Line Format	<code>--max-relay-log-size=#</code>
System Variable	<code>max_relay_log_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1073741824

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 17.2.2, “Replication Implementation Details”](#).

- `relay_log`

Property	Value
Command-Line Format	<code>--relay-log=file_name</code>
System Variable	<code>relay_log</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The base name for relay log files, with no paths and no file extension. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in this relay log.

- `relay_log_basename`

Property	Value
System Variable	<code>relay_log_basename</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>datadir + '/' + hostname + '-relay-bin'</code>

Holds the name and complete path to the relay log file.

- `relay_log_index`

Property	Value
Command-Line Format	<code>--relay-log-index</code>
System Variable	<code>relay_log_index</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>*host_name*-relay-bin.index</code>

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index`.

- `relay_log_info_file`

Property	Value
Command-Line Format	<code>--relay-log-info-file=file_name</code>
System Variable	<code>relay_log_info_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>relay-log.info</code>

The name of the relay log info log, when `relay_log_info_repository=FILE` is set. The default name is `relay-log.info` in the data directory. `relay_log_info_repository=FILE` is now deprecated.

- `relay_log_info_repository`

Property	Value
System Variable	<code>relay_log_info_repository</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.2)	<code>TABLE</code>
Default Value (<= 8.0.1)	<code>FILE</code>
Valid Values	<code>FILE</code> <code>TABLE</code>

The setting of this variable determines whether the slave server logs its position in the relay logs to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the relay log info log is named `mysql.slave_relay_log_info`. The `TABLE` setting is required when multiple replication channels are configured. The `TABLE` setting for the relay log info log is also required to make replication resilient to unexpected halts, for which the `--relay-log-recovery` option must also be enabled. See [Making replication resilient to unexpected halts](#) for more information.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the relay log info log is named `relay-log.info` by default, and you can change this name using the `--relay-log-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable. You can only change the setting when no replication threads are executing.

- `relay_log_purge`

Property	Value
Command-Line Format	<code>--relay-log-purge</code>
System Variable	<code>relay_log_purge</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>TRUE</code>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_recovery`

Property	Value
Command-Line Format	<code>--relay-log-recovery</code>
System Variable	<code>relay_log_recovery</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>FALSE</code>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This global variable is read-only; its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-safe slave. The default value is 0 (disabled).

This variable also interacts with `relay-log-purge`, which controls purging of logs when they are no longer needed. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multithreaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `relay_log_space_limit`

Property	Value
Command-Line Format	<code>--relay-log-space-limit=#</code>
System Variable	<code>relay_log_space_limit</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum amount of space to use for all relay logs.

- `report_host`

Property	Value
Command-Line Format	<code>--report-host=host_name</code>
System Variable	<code>report_host</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The value of the `--report-host` option.

- `report_password`

Property	Value
Command-Line Format	<code>--report-password=name</code>
System Variable	<code>report_password</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The value of the `--report-password` option. Not the same as the password used for the MySQL replication user account.

- `report_port`

Property	Value
Command-Line Format	<code>--report-port=#</code>
System Variable	<code>report_port</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	[slave_port]
Minimum Value	0
Maximum Value	65535

The value of the `--report-port` option.

- `report_user`

Property	Value
Command-Line Format	<code>--report-user=name</code>
System Variable	<code>report_user</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- `rpl_read_size`

Property	Value
Command-Line Format	<code>--rpl-read-size=#</code>
Introduced	8.0.11
System Variable	<code>rpl_read_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	8192
Maximum Value	4294967295

The `rpl_read_size` system variable controls the minimum amount of data in bytes that is read from the binary log files and relay log files. If heavy disk I/O activity for these files is impeding performance for the database, increasing the read size might reduce file reads and I/O stalls when the file data is not currently cached by the operating system.

The minimum and default value for `rpl_read_size` is 8192 bytes. The value must be a multiple of 4KB. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves. Setting a large value might therefore have an impact on memory consumption for servers.

- `rpl_semi_sync_slave_enabled`

Property	Value
System Variable	rpl_semi_sync_slave_enabled
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to [ON](#) or [OFF](#) (or 1 or 0), respectively. The default is [OFF](#).

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [rpl_semi_sync_slave_trace_level](#)

Property	Value
System Variable	rpl_semi_sync_slave_trace_level
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	32

The semisynchronous replication debug trace level on the slave. See [rpl_semi_sync_master_trace_level](#) for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [rpl_stop_slave_timeout](#)

Property	Value
Command-Line Format	--rpl-stop-slave-timeout=seconds
System Variable	rpl_stop_slave_timeout
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	31536000
Minimum Value	2
Maximum Value	31536000

You can control the length of time (in seconds) that [STOP SLAVE](#) waits before timing out by setting this variable. This can be used to avoid deadlocks between [STOP SLAVE](#) and other slave SQL statements using different client connections to the slave.

The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements.

This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the slave threads to stop, but the slave threads continue to try to stop, and the `STOP SLAVE` instruction remains in effect. Once the slave threads are no longer busy, the `STOP SLAVE` statement is executed and the slave stops.

- `slave_allow_batching`

Property	Value
Command-Line Format	<code>--slave-allow-batching</code>
System Variable	<code>slave_allow_batching</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>off</code>

Whether or not batched updates are enabled on replication slaves.

Setting this variable has an effect only when using replication with the `NDB` storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Starting NDB Cluster Replication \(Single Replication Channel\)](#).

- `slave_checkpoint_group`

Property	Value
Command-Line Format	<code>--slave-checkpoint-group=#</code>
System Variable	<code>slave_checkpoint_group=#</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>512</code>
Minimum Value	<code>32</code>
Maximum Value	<code>524280</code>
Block Size	<code>8</code>

Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

Property	Value
Command-Line Format	<code>--slave-checkpoint-period=#</code>
System Variable	<code>slave_checkpoint_period=#</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	4G

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `slave_compressed_protocol`

Property	Value
Command-Line Format	<code>--slave-compressed-protocol</code>
System Variable	<code>slave_compressed_protocol</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to use compression of the slave/master protocol if both the slave and the master support it. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- `slave_exec_mode`

Property	Value
Command-Line Format	<code>--slave-exec-mode=mode</code>
System Variable	<code>slave_exec_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>IDEMPOTENT</code> (NDB) <code>STRICT</code> (Other)
Valid Values	<code>IDEMPOTENT</code> <code>STRICT</code>

Controls how a slave thread resolves conflicts and errors during replication. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors; `STRICT` means no such suppression takes place.

`IDEMPOTENT` mode is intended for use in multi-master replication, circular replication, and some other special replication scenarios. *This mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored.* It is meant to be used in fail-over scenarios where multi-master replication or circular replication is employed, and is not recommended for use in other cases.

Setting this variable takes immediate effect for all replication channels, including running channels.

- `slave_load_tmpdir`

Property	Value
Command-Line Format	<code>--slave-load-tmpdir=dir_name</code>
System Variable	<code>slave_load_tmpdir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	<code>/tmp</code>

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_max_allowed_packet`

Property	Value
System Variable	<code>slave_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	1024
Maximum Value	1073741824

This option sets the maximum packet size in bytes that the slave SQL and I/O threads can handle. Setting this variable takes effect for all replication channels immediately, including running channels. It is possible for a replication master to write binary log events longer than its `max_allowed_packet` setting once the event header is added. The setting for `slave_max_allowed_packet` must be larger than the `max_allowed_packet` setting on the master, so that large updates using row-based replication do not cause replication to fail.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

Property	Value
Command-Line Format	<code>--slave-net-timeout=#</code>
System Variable	<code>slave_net_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1

The number of seconds to wait for more data from a master/slave connection before aborting the read. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

- `slave_parallel_type=type`

Property	Value
Command-Line Format	<code>--slave-parallel-type=type</code>
Type	Enumeration

Property	Value
Default Value	DATABASE
Valid Values	DATABASE LOGICAL_CLOCK

When using a multithreaded slave (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The variable has no effect on slaves for which multithreading is not enabled. The possible values are:

- **LOGICAL_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. The dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible. When this value is set, the `binlog_transaction_dependency_tracking` system variable can be used on the master to specify that write sets are used for parallelization in place of timestamps, if a write set is available for the transaction and gives improved results compared to timestamps.
- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. There must be no cross-database constraints, as such constraints may be violated on the slave.

When `slave_preserve_commit_order=1` is set, you can only use **LOGICAL_CLOCK**.

If your replication topology uses multiple levels of slaves, **LOGICAL_CLOCK** may achieve less parallelization for each level the slave is away from the master. You can reduce this effect by using `binlog_transaction_dependency_tracking` on the master to specify that write sets are used instead of timestamps for parallelization where possible.

- `slave_parallel_workers`

Property	Value
Command-Line Format	<code>--slave-parallel-workers=#</code>
System Variable	<code>slave_parallel_workers</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1024

Enables multithreading on the slave and sets the number of slave applier threads for executing replication transactions in parallel. When the value is a number greater than 0, the slave is a multithreaded slave with the specified number of applier threads, plus a coordinator thread to manage them. If you are using multiple replication channels, each channel has this number of threads.

Retrying of transactions is supported when multithreading is enabled on a slave. When `slave_preserve_commit_order=1`, transactions on a slave are externalized on the slave in the

same order as they appear in the slave's relay log. The way in which transactions are distributed among applier threads is configured by `--slave-parallel-type`.

To disable parallel execution, set this option to 0, which gives the slave a single applier thread and no coordinator thread. With this setting, the `--slave-parallel-type` and `slave_preserve_commit_order` options have no effect and are ignored.

Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

- `slave_pending_jobs_size_max`

Property	Value
Command-Line Format	<code>--slave-pending-jobs-size-max=#</code>
System Variable	<code>slave_pending_jobs_size_max</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (>= 8.0.12)	128M
Default Value (<= 8.0.11)	16M
Minimum Value	1024
Maximum Value	16EiB
Block Size	1024

For multithreaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024 bytes; the default is 128MB. The maximum possible value is 18446744073709551615 (16 exbibytes). Values that are not exact multiples of 1024 bytes are rounded down to the next lower multiple of 1024 bytes prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- `slave_preserve_commit_order`

Property	Value
Command-Line Format	<code>--slave-preserve-commit-order=value</code>
System Variable	<code>slave_preserve_commit_order</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	0

Property	Value
Valid Values	0 1

For multithreaded slaves, the setting 1 for this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave's relay log, and prevents gaps in the sequence of transactions that have been executed from the relay log. This variable has no effect on slaves for which multithreading is not enabled.

`slave_preserve_commit_order=1` requires that `--log-bin` and `--log-slave-updates` are enabled on the slave, and `--slave-parallel-type` is set to `LOGICAL_CLOCK`.

With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as `Waiting for preceding transaction to commit`. With this mode, a multithreaded slave never enters a state that the master was not in. This supports the use of replication for read scale-out. See [Section 17.3.5, “Using Replication for Scale-Out”](#).

Before changing this variable, all replication threads (for all replication channels if you are using multiple replication channels) must be stopped. If `slave_preserve_commit_order=0` is set, the transactions that the slave applies in parallel may commit out of order. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. There is a chance of gaps in the sequence of transactions that have been executed from the slave's relay log. This has implications for logging and recovery when using a multithreaded slave. Note that the setting `slave_preserve_commit_order=1` prevents gaps, but does not prevent gap-free low-watermark positions (where `Exec_master_log_pos` is behind the position up to which transactions have been executed). See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `slave_rows_search_algorithms`

Property	Value
System Variable	<code>slave_rows_search_algorithms=list</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Set
Default Value (>= 8.0.2)	<code>INDEX_SCAN, HASH_SCAN</code>
Default Value (<= 8.0.1)	<code>TABLE_SCAN, INDEX_SCAN</code>
Valid Values	<code>TABLE_SCAN, INDEX_SCAN</code> <code>INDEX_SCAN, HASH_SCAN</code> <code>TABLE_SCAN, HASH_SCAN</code> <code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code>)

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary

or unique key, some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels. The initial setting for the system variable can be specified using the `--slave-rows-search-algorithms` option.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The value is expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	<code>INDEX_SCAN,HASH_SCAN</code> or <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code>	<code>INDEX_SCAN, TABLE_SCAN</code>	<code>TABLE_SCAN, HASH_SCAN</code>
Primary key or unique key	Index scan	Index scan	Hash scan over index
(Other) Key	Hash scan over index	Index scan	Hash scan over index
No index	Hash scan	Table scan	Hash scan

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

- The default value is `INDEX_SCAN, HASH_SCAN`. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`.
- To force hashing for *all* searches, set this option to `TABLE_SCAN, HASH_SCAN`.
- To remove hashing, set this option to `TABLE_SCAN, INDEX_SCAN`. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

Note

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `slave_skip_errors`

Property	Value
Command-Line Format	<code>--slave-skip-errors=name</code>
System Variable	<code>slave_skip_errors</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	String
Default Value	OFF
Valid Values	OFF [list of error codes] all ddl_exist_errors

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_sql_verify_checksum`

Property	Value
System Variable	<code>slave_sql_verify_checksum</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	1
Valid Values	0 1

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

Note

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- `slave_transaction_retries`

Property	Value
Command-Line Format	<code>--slave-transaction-retries=#</code>
System Variable	<code>slave_transaction_retries</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10

Property	Value
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Sets the maximum number of times for replication slave SQL threads on a single-threaded or multithreaded slave to automatically retry failed transactions before stopping. Setting this variable takes effect for all replication channels immediately, including running channels. The default value is 10. Setting the variable to 0 disables automatic retrying of transactions.

If a replication slave SQL thread fails to execute a transaction because of an [InnoDB](#) deadlock or because the transaction's execution time exceeded [InnoDB's innodb_lock_wait_timeout](#), it automatically retries [slave_transaction_retries](#) times before stopping with an error. Transactions with a non-temporary error are not retried.

The Performance Schema table [replication_applier_status](#) shows the number of retries that took place on each replication channel, in the [COUNT_TRANSACTIONS_RETRIES](#) column. The Performance Schema table [replication_applier_status_by_worker](#) shows detailed information on transaction retries by individual applier threads on a single-threaded or multithreaded replication slave, and identifies the errors that caused the last transaction and the transaction currently in progress to be reattempted.

- [slave_type_conversions](#)

Property	Value
Command-Line Format	<code>--slave-type-conversions=set</code>
System Variable	slave_type_conversions
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Set
Default Value	
Valid Values	ALL_LOSSY ALL_NON_LOSSY ALL_SIGNED ALL_UNSIGNED

Controls the type conversion mode in effect on the slave when using row-based replication. Its value is a comma-delimited set of zero or more elements from the list: [ALL_LOSSY](#), [ALL_NON_LOSSY](#), [ALL_SIGNED](#), [ALL_UNSIGNED](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- [sql_slave_skip_counter](#)

Property	Value
System Variable	<code>sql_slave_skip_counter</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a nonzero value and there are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `--gtid-mode=ON`. If you need to skip transactions when employing GTIDs, use `gtid_executed` from the master instead. See [Injecting empty transactions](#), for information about how to do this.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

- `sync_master_info`

Property	Value
Command-Line Format	<code>--sync-master-info=#</code>
System Variable	<code>sync_master_info</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

master_info_repository = FILE. If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatsync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

master_info_repository = TABLE. If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

- `sync_relay_log`

Property	Value
Command-Line Format	<code>--sync-relay-log=#</code>
System Variable	<code>sync_relay_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatsync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

Property	Value
Command-Line Format	<code>--sync-relay-log-info=#</code>
System Variable	<code>sync_relay_log_info</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

The effects of this variable on the replication slave depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`). If the setting is `TABLE`, the effects of the variable also depend on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not transactional (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are as follows:

- | | |
|---|---|
| <code>sync_relay_log_info = 0</code> | <ul style="list-style-type: none">• If <code>relay_log_info_repository</code> is set to <code>FILE</code>, the MySQL server performs no synchronization of the <code>relay-log.info</code> file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.• If <code>relay_log_info_repository</code> is set to <code>TABLE</code>, and the storage engine for that table is transactional, the table is updated after each transaction. (The <code>sync_relay_log_info</code> setting is effectively ignored in this case.)• If <code>relay_log_info_repository</code> is set to <code>TABLE</code>, and the storage engine for that table is not transactional, the table is never updated. |
| <code>sync_relay_log_info = N</code>
<code>> 0</code> | <ul style="list-style-type: none">• If <code>relay_log_info_repository</code> is set to <code>FILE</code>, the slave synchronizes its <code>relay-log.info</code> file to disk (using <code>fdatsync()</code>) after every <code>N</code> transactions.• If <code>relay_log_info_repository</code> is set to <code>TABLE</code>, and the storage engine for that table is transactional, the table is updated after each transaction. (The <code>sync_relay_log_info</code> setting is effectively ignored in this case.)• If <code>relay_log_info_repository</code> is set to <code>TABLE</code>, and the storage engine for that table is not transactional, the table is updated after every <code>N</code> events. |

17.1.6.4 Binary Logging Options and Variables

- [Startup Options Used with Binary Logging](#)
- [System Variables Used with Binary Logging](#)

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.6, “Server Command Options”](#), and [Section 5.1.7, “Server System Variables”](#).

Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Property	Value
Command-Line Format	<code>--binlog-row-event-max-size=#</code>
Type	Integer
Default Value	8192
Minimum Value	256
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See [Section 17.2.1, “Replication Formats”](#).

- `--binlog-rows-query-log-events`

Property	Value
Command-Line Format	<code>--binlog-rows-query-log-events</code>
Type	Boolean
Default Value	FALSE

This option enables `binlog_rows_query_log_events`, which causes the MySQL Server to write informational log events such as row query log events into its binary log.

- `--log-bin[=base_name]`

Property	Value
Command-Line Format	<code>--log-bin</code>
System Variable	<code>log_bin</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Specifies the base name to use for binary log files. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. The `--log-bin` option value is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name.

If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path

recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

Binary logging is enabled by default (the `log_bin` system variable is set to ON). The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default. It is possible to enable binary logging in this case by specifying the `--log-bin` option.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

The `--log-slave-updates` and `--slave-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--skip-log-slave-updates` and `--skip-slave-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-slave-updates` or `--slave-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

In MySQL 5.7, a server ID had to be specified when binary logging was enabled, or the server would not start. In MySQL 8.0, the `server_id` system variable is set to 1 by default. The server can now be started with this default server ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `--server-id` option. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

For information on the format and management of the binary log, see [Section 5.4.4, “The Binary Log”](#).

- `--log-bin-index[=file_name]`

Property	Value
Command-Line Format	<code>--log-bin-index=file_name</code>
Type	File name

The name for the index file for the binary log. The binary log index file contains the names of all used binary log files. By default, it has the same location and base name as you specified for the binary log files using the `--log-bin` option, plus the extension `.index`. If you did not supply the `--log-bin` option, the default name for the binary log index file is `binlog.index`. If you supplied the `--log-bin` option with no string or an empty string, the default name for the binary log index file is `host_name-bin.index`, using the name of the host machine.

For information on the format and management of the binary log, see [Section 5.4.4, “The Binary Log”](#).

- `--log-bin-trust-function-creators[={0|1}]`

Property	Value
Command-Line Format	<code>--log-bin-trust-function-creators</code>
System Variable	<code>log_bin_trust_function_creators</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	<code>FALSE</code>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 23.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

Property	Value
Command-Line Format	<code>--log-bin-use-v1-row-events[={0 1}]</code>
System Variable	<code>log_bin_use_v1_row_events</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	0

MySQL 8.0 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in those releases, and thus produce binary logs that can be read by slaves at those releases. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

Property	Value
Command-Line Format	<code>--binlog-do-db=name</code>
Type	String

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

Row-based logging. Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

Property	Value
Command-Line Format	<code>--binlog-ignore-db=name</code>
Type	String

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

When there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

Row-based format. Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Checksum options. MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

Property	Value
Command-Line Format	<code>--binlog-checksum=type</code>
Type	String
Default Value	<code>CRC32</code>
Valid Values	<code>NONE</code> <code>CRC32</code>

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only `CRC32` checksums are supported, and `CRC32` is the default. You cannot change the setting for this option within a transaction.

- `--master-verify-checksum={0|1}`

Property	Value
Command-Line Format	<code>--master-verify-checksum=name</code>
Type	Boolean
Default Value	<code>OFF</code>

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

Property	Value
Command-Line Format	<code>--max-binlog-dump-events=#</code>

Property	Value
Type	Integer
Default Value	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Property	Value
Command-Line Format	<code>--sporadic-binlog-dump-fail</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

Property	Value
Command-Line Format	<code>--binlog-cache-size=#</code>
System Variable	<code>binlog_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The size of the cache to hold changes to the binary log during a transaction. When binary logging is enabled on the server (with the `log_bin` system variable set to ON), a binary log cache is allocated for each client if the server supports any transactional storage engines. If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

Property	Value
System Variable	<code>binlog_checksum</code>

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	CRC32
Valid Values	NONE CRC32

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`. You cannot change the value of `binlog_checksum` within a transaction.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

Property	Value
Command-Line Format	<code>--binlog-direct-non-transactional-updates[=value]</code>
System Variable	<code>binlog_direct_non_transactional_updates</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format, that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

This variable has no effect when the binary log format is `ROW` or `MIXED`.

- `binlog_error_action`

Property	Value
Command-Line Format	<code>--binlog-error-action[=value]</code>
System Variable	<code>binlog_error_action</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>ABORT_SERVER</code>
Valid Values	<code>IGNORE_ERROR</code> <code>ABORT_SERVER</code>

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's log to become inconsistent and replication slaves to lose synchronization.

This variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. Upon server restart, all of the previously prepared and binary logged transactions are committed, while any transactions which were prepared but not binary logged due to the error are aborted.

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again. This provides backward compatibility with older versions of MySQL.

- `binlog_expire_logs_seconds`

Property	Value
Command-Line Format	<code>--binlog-expire-logs-seconds=#</code>
Introduced	8.0.1
System Variable	<code>binlog_expire_logs_seconds</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.11$)	2592000
Default Value ($\leq 8.0.4$)	0
Minimum Value	0
Maximum Value	4294967295

Sets the binary log expiration period in seconds. After their expiration period ends, binary log files can be automatically removed. Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.4, “MySQL Server Logs”](#).

The default binary log expiration period is 2592000 seconds, which equals 30 days ($30 \times 24 \times 60 \times 60$ seconds). The default applies if neither `binlog_expire_logs_seconds` nor the deprecated system variable `expire_logs_days` has a value set at startup. If a non-zero value for one of the variables `binlog_expire_logs_seconds` or `expire_logs_days` is set at startup, this value is used as the binary log expiration period. If a non-zero value for both of those variables is set at startup, the value for `binlog_expire_logs_seconds` is used as the binary log expiration period, and the value for `expire_logs_days` is ignored with a warning message.

To disable automatic purging of the binary log, specify a value of 0 explicitly for `binlog_expire_logs_seconds`, and do not specify a value for `expire_logs_days`. For compatibility with earlier releases, automatic purging is also disabled if you specify a value of 0 explicitly for `expire_logs_days` and do not specify a value for `binlog_expire_logs_seconds`. In that case, the default for `binlog_expire_logs_seconds` is not applied.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `binlog_format`

Property	Value
Command-Line Format	<code>--binlog-format=format</code>
System Variable	<code>binlog_format</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>ROW</code>
Valid Values	<code>ROW</code>

Property	Value
	STATEMENT
	MIXED

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 17.2.1, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

The default is `ROW`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see [Section 23.7, “Binary Logging of Stored Programs”](#).

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@session.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@global.binlog_format` or `SET @@persist.binlog_format`).
- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@global.binlog_format` or `SET @@persist.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (`SET @@persist_only.binlog_format`) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

Property	Value
Command-Line Format	<code>--binlog-group-commit-sync-delay=#</code>
System Variable	<code>binlog_group_commit_sync_delay</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000000

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group.

When `sync_binlog=0` or `sync_binlog=1` is set, the delay specified by `binlog_group_commit_sync_delay` is applied for every binary log commit group before synchronization (or in the case of `sync_binlog=0`, before proceeding). When `sync_binlog` is set to a value *n* greater than 1, the delay is applied after every *n* binary log commit groups.

Setting `binlog_group_commit_sync_delay` can increase the number of parallel committing transactions on any server that has (or might have after a failover) a replication slave, and therefore can increase parallel execution on the replication slaves. To benefit from this effect, the slave servers must have `slave_parallel_type=LOGICAL_CLOCK` set, and the effect is more significant when `binlog_transaction_dependency_tracking=COMMIT_ORDER` is also set. It is important to take into account both the master's throughput and the slaves' throughput when you are tuning the setting for `binlog_group_commit_sync_delay`.

Setting `binlog_group_commit_sync_delay` can also reduce the number of `fsync()` calls to the binary log on any server (master or slave) that has a binary log.

Note that setting `binlog_group_commit_sync_delay` increases the latency of transactions on the server, which might affect client applications. Also, on highly concurrent workloads, it is possible for the delay to increase contention and therefore reduce throughput. Typically, the benefits of setting a delay outweigh the drawbacks, but tuning should always be carried out to determine the optimal setting.

- `binlog_group_commit_sync_no_delay_count`

Property	Value
Command-Line Format	<code>--binlog-group-commit-sync-no-delay-count=#</code>
System Variable	<code>binlog_group_commit_sync_no_delay_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000000

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog_group_commit_sync_delay`. If `binlog_group_commit_sync_delay` is set to 0, then this option has no effect.

- `binlog_max_flush_queue_time`

Property	Value
Deprecated	Yes
System Variable	<code>binlog_max_flush_queue_time</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100000

`binlog_max_flush_queue_time` is deprecated, and is marked for eventual removal in a future MySQL release. Formerly, this system variable controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. It no longer has any effect.

- `binlog_order_commits`

Property	Value
System Variable	<code>binlog_order_commits</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

When this variable is enabled on a master (the default), transactions are externalized in the same order as they are written to the binary log. If disabled, transactions may be committed in parallel. In some cases, disabling this variable might produce a performance increment.

- `binlog_row_image`

Property	Value
Command-Line Format	<code>--binlog-row-image=image_type</code>
System Variable	<code>binlog_row_image=image_type</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>full</code>
Valid Values	<code>full</code> (Log all columns) <code>minimal</code> (Log only changed columns, and columns needed to identify rows) <code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns)

For MySQL row-based replication, this variable determines how row images are written to the binary log.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- **full**: Log all columns in both the before image and the after image.
- **minimal**: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.
- **noblob**: Log all columns (same as **full**), except for **BLOB** and **TEXT** columns that are not required to identify rows, or that have not changed.

The default value is **full**.

When using **minimal** or **noblob**, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is **STATEMENT**. When **binlog_format** is **MIXED**, the setting for **binlog_row_image** is applied to changes that are logged using row-based format, but this setting has no effect on changes logged as statements.

Setting **binlog_row_image** on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- **binlog_row_metadata**

Property	Value
Command-Line Format	<code>--binlog-row-metadata=metadata_type</code>
Introduced	8.0.1
System Variable	<code>binlog_row_metadata=metadata_type</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	MINIMAL
Valid Values	FULL (All metadata is included.) MINIMAL (Limit included metadata.)

Configures the amount of table metadata added to the binary log when using row-based logging. When set to **MINIMAL**, the default, only metadata related to **SIGNED** flags, column character set and geometry

types are logged. When set to `FULL` complete metadata for tables is logged, such as column name, `ENUM` or `SET` string values, `PRIMARY KEY` information, and so on.

The extended metadata serves the following purposes:

- Slaves use the metadata to transfer data when its table structure is different from the master's.
- External software can use the metadata to decode row events and store the data into external databases, such as a data warehouse.
- `binlog_row_value_options`

Property	Value
Command-Line Format	<code>--binlog-row-value-options=#</code>
Introduced	8.0.3
System Variable	<code>binlog_row_value_options</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	<code>''</code>
Valid Values	<code>PARTIAL_JSON</code>

When set to `PARTIAL_JSON`, this enables use of a space-efficient binary log format for updates that modify only a small portion of a JSON document, which causes row-based replication to write only the modified parts of the JSON document to the after-image for the update in the binary log (rather than writing the full document). This works for an `UPDATE` statement which modifies a JSON column using any sequence of `JSON_SET()`, `JSON_REPLACE()`, and `JSON_REMOVE()`. If the modification requires more space than the full document, or if the server is unable to generate a partial update, the full document is used instead.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

`PARTIAL_JSON` is the only supported value; to unset `binlog_row_value_options`, set its value to the empty string.

`binlog_row_value_options=PARTIAL_JSON` takes effect only when binary logging is enabled and `binlog_format` is set to `ROW` or `MIXED`. Statement-based replication *always* logs only the modified parts of the JSON document, regardless of any value set for `binlog_row_value_options`. To maximize the amount of space saved, use `binlog_row_image=NOBLOB` or `binlog_row_image=MINIMAL` together with this option. `binlog_row_image=FULL` saves less space than either of these, since the full JSON document is stored in the before-image, and the partial update is stored only in the after-image.

`binlog_row_value_options=PARTIAL_JSON` overrides any setting for the `log_bin_use_v1_row_events` variable. If that option is enabled, the event format required by `binlog_row_value_options=PARTIAL_JSON` is still used.

`mysqlbinlog` output includes partial JSON updates in the form of events encoded as base-64 strings using `BINLOG` statements. If the `--verbose` option is specified, `mysqlbinlog` displays the partial JSON updates as readable JSON using pseudo-SQL statements.

MySQL Replication generates an error if a modification cannot be applied to the JSON document on the slave. This includes a failure to find the path. Be aware that, even with this and other safety checks, if a JSON document on a slave has diverged from that on the master and a partial update is applied, it remains theoretically possible to produce a valid but unexpected JSON document on the slave.

Replicating to older MySQL versions. When replicating to a slave that uses MySQL 8.0.2 or a previous version from a master running MySQL 8.0.3 or later, `binlog_row_value_options` must be disabled (that is, set to `' '`). This is because logging of JSON partial updates uses a binary log event type introduced in MySQL 8.0.3; this event type is not recognized by previous versions of MySQL.

- `binlog_rows_query_log_events`

Property	Value
Command-Line Format	<code>--binlog-rows-query-log-events</code>
System Variable	<code>binlog_rows_query_log_events</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>FALSE</code>

The `binlog_rows_query_log_events` system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's `--verbose` option twice, either as `-vv` or `--verbose --verbose`.

- `binlog_stmt_cache_size`

Property	Value
Command-Line Format	<code>--binlog-stmt-cache-size=#</code>
System Variable	<code>binlog_stmt_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>32768</code>
Minimum Value	<code>4096</code>
Maximum Value (64-bit platforms)	<code>18446744073709551615</code>
Maximum Value (32-bit platforms)	<code>4294967295</code>

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. When binary logging is enabled on the server (with the `log_bin` system variable set to ON), separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines. If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `binlog_transaction_dependency_tracking`

Property	Value
Command-Line Format	<code>--binlog-transaction-dependency-tracking=value</code>
Introduced	8.0.1
System Variable	<code>binlog_transaction_dependency_tracking</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>COMMIT_ORDER</code>
Valid Values	<code>COMMIT_ORDER</code> <code>WRITESET</code> <code>WRITESET_SESSION</code>

The source of dependency information that the master uses to determine which transactions can be executed in parallel by the slave's multithreaded applier. This variable can take one of the three values described in the following list:

- `COMMIT_ORDER`: Dependency information is generated from the master's commit timestamps. This is the default. This mode is also used for any transactions without write sets, even if this variable's is `WRITESET` or `WRITESET_SESSION`; this is also the case for transactions updating tables without primary keys and transactions updating tables having foreign key constraints.
- `WRITESET`: Dependency information is generated from the master's write set, and any transactions which write different tuples can be parallelized.
- `WRITESET_SESSION`: Dependency information is generated from the master's write set, but no two updates from the same session can be reordered.

`WRITESET` and `WRITESET_SESSION` modes do not deliver any transaction dependencies that are newer than those that would have been returned in `COMMIT_ORDER` mode.

The value of this variable cannot be set to anything other than `COMMIT_ORDER` if `transaction_write_set_extraction` is `OFF`. You should also note that the value of `transaction_write_set_extraction` cannot be changed if the current value of `binlog_transaction_dependency_tracking` is `WRITESET` or `WRITESET_SESSION`.

The number of row hashes to be kept and checked for the latest transaction to have changed a given row is determined by the value of `binlog_transaction_dependency_history_size`.

- `binlog_transaction_dependency_history_size`

Property	Value
Command-Line Format	<code>--binlog-transaction-dependency-history-size=#</code>
Introduced	8.0.1
System Variable	<code>binlog_transaction_dependency_history_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	1
Maximum Value	1000000

Sets an upper limit on the number of row hashes which are kept in memory and used for looking up the transaction that last modified a given row. Once this number of hashes has been reached, the history is purged.

- `expire_logs_days`

Property	Value
Command-Line Format	<code>--expire-logs-days=#</code>
Deprecated	8.0.3
System Variable	<code>expire_logs_days</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.11$)	0
Default Value ($\geq 8.0.2, \leq 8.0.4$)	30
Default Value ($\leq 8.0.1$)	0
Minimum Value	0
Maximum Value	99

Specifies the number of days before automatic removal of binary log files. `expire_logs_days` is deprecated, and will be removed in a future release. Instead, use `binlog_expire_logs_seconds`, which sets the binary log expiration period in seconds. If you do not set a value for either system variable, the default expiration period is 30 days. Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.4, “MySQL Server Logs”](#).

Any non-zero value that you specify for `expire_logs_days` is ignored if `binlog_expire_logs_seconds` is also specified, and the value of `binlog_expire_logs_seconds` is used instead as the binary log expiration period. A warning message is issued in this situation. A non-zero value for `expire_logs_days` is only applied as the binary log expiration period if `binlog_expire_logs_seconds` is not specified or is specified as 0.

To disable automatic purging of the binary log, specify a value of 0 explicitly for `binlog_expire_logs_seconds`, and do not specify a value for `expire_logs_days`. For compatibility with earlier releases, automatic purging is also disabled if you specify a value of 0 explicitly for `expire_logs_days` and do not specify a value for `binlog_expire_logs_seconds`. In that case, the default for `binlog_expire_logs_seconds` is not applied.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `log_bin`

Property	Value
System Variable	<code>log_bin</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Whether binary logging is enabled or disabled. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. `ON` means that the binary log is available, `OFF` means that it is not in use.

Binary logging is enabled by default, with the `log_bin` system variable set to `ON`. The `--log-bin` option is used to specify a base name and location for the binary log.

If the `--skip-log-bin` or `--disable-log-bin` option is specified at startup, binary logging is disabled, with the `log_bin` system variable set to `OFF`.

For information on the format and management of the binary log, see [Section 5.4.4, “The Binary Log”](#).

- `log_bin_basename`

Property	Value
System Variable	<code>log_bin_basename</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Holds the base name and path for the binary log files, which can be set with the `--log-bin` server option. In MySQL 8.0, if the `--log-bin` option is not supplied, the default base name is `binlog`. For compatibility with MySQL 5.7, if the `--log-bin` option is supplied with no string or with an empty string, the default base name is `host_name-bin`, using the name of the host machine. The default location is the data directory.

- `log_bin_index`

Property	Value
System Variable	log_bin_index
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option.

- [log_bin_trust_function_creators](#)

Property	Value
Command-Line Format	<code>--log-bin-trust-function-creators</code>
System Variable	log_bin_trust_function_creators
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>FALSE</code>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the [SUPER](#) privilege in addition to the [CREATE ROUTINE](#) or [ALTER ROUTINE](#) privilege. A setting of 0 also enforces the restriction that a function must be declared with the [DETERMINISTIC](#) characteristic, or with the [READS SQL DATA](#) or [NO SQL](#) characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 23.7](#), “Binary Logging of Stored Programs”.

- [log_bin_use_v1_row_events](#)

Property	Value
Command-Line Format	<code>--log-bin-use-v1-row-events[={0 1}]</code>
System Variable	log_bin_use_v1_row_events
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>0</code>

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

- `log_builtin_as_identified_by_password`

Property	Value
Command-Line Format	<code>--log-builtin-as-identified-by-password[={OFF ON}]</code>
Removed	8.0.11
System Variable	<code>log_builtin_as_identified_by_password</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This system variable was removed in MySQL 8.0.11.

- `log_slave_updates`

Property	Value
Command-Line Format	<code>--log-slave-updates</code>
System Variable	<code>log_slave_updates</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value ($\geq 8.0.3$)	TRUE
Default Value ($\leq 8.0.2$)	FALSE

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

This system variable is set on by default, and is read-only. If you need to prevent the slave server from logging updates, specify `--skip-log-slave-updates` when you start the slave, or specify `log_slave_updates=OFF` in the configuration file for the slave.

- `log_statements_unsafe_for_binlog`

Property	Value
System Variable	<code>log_statements_unsafe_for_binlog</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	ON

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- `master_verify_checksum`

Property	Value
System Variable	<code>master_verify_checksum</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enabling this variable causes the master to examine checksums when reading from the binary log. `master_verify_checksum` is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- `max_binlog_cache_size`

Property	Value
Command-Line Format	<code>--max-binlog-cache-size=#</code>
System Variable	<code>max_binlog_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	18446744073709551615
Minimum Value	4096
Maximum Value	18446744073709551615

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EiB (exbibytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

The visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value affects only new sessions that are started after the value is changed.

- `max_binlog_size`

Property	Value
Command-Line Format	<code>--max-binlog-size=#</code>
System Variable	<code>max_binlog_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	4096
Maximum Value	1073741824

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

Property	Value
Command-Line Format	<code>--max-binlog-stmt-cache-size=#</code>
System Variable	<code>max_binlog_stmt_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	18446744073709547520
Minimum Value	4096
Maximum Value	18446744073709547520

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `original_commit_timestamp`

Property	Value
Introduced	8.0.1
System Variable	<code>original_commit_timestamp</code>
Scope	Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Numeric

For internal use by replication. When re-executing a transaction on a slave, this is set to the time when the transaction was committed on the original master, measured in microseconds since the epoch. This allows the original commit timestamp to be propagated throughout a replication topology.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `sql_log_bin`

Property	Value
System Variable	<code>sql_log_bin</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the master you do not want replicated to the slave.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

- `sync_binlog`

Property	Value
Command-Line Format	<code>--sync-binlog=#</code>
System Variable	<code>sync_binlog</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>1</code>

Property	Value
Minimum Value	0
Maximum Value	4294967295

Controls how often the MySQL server synchronizes the binary log to disk.

- `sync_binlog=0`: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.
- `sync_binlog=1`: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.
- `sync_binlog=N`, where *N* is a value other than 0 or 1: The binary log is synchronized to disk after *N* binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses [InnoDB](#) with transactions, use these settings:

- `sync_binlog=1`.
- `innodb_flush_log_at_trx_commit=1`.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `transaction_write_set_extraction`

Property	Value
Command-Line Format	<code>--transaction-write-set-extraction=[value]</code>
System Variable	<code>transaction_write_set_extraction</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration

Property	Value
Default Value ($\geq 8.0.2$)	XXHASH64
Default Value	OFF
Valid Values	OFF MURMUR32 XXHASH64

Defines the algorithm used to hash the writes extracted during a transaction. If you are using Group Replication, this variable must be set to [XXHASH64](#) because the process of extracting the writes from a transaction is required for conflict detection on all group members. See [Section 18.7.1, “Group Replication Requirements”](#).

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Note

The value of this variable cannot be changed when [binlog_transaction_dependency_tracking](#) is set to either of [WRITESET](#) or [WRITESET_SESSION](#).

17.1.6.5 Global Transaction ID Options and Variables

- [Startup Options Used with GTID Replication](#)
- [System Variables Used with GTID Replication](#)

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

Startup Options Used with GTID Replication

The following server startup options are used with GTID-based replication:

- [--enforce-gtid-consistency](#)

Property	Value
Command-Line Format	--enforce-gtid-consistency[=value]
System Variable	enforce_gtid_consistency
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF ON

Property	Value
	WARN

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this option to [ON](#) before enabling GTID based replication.

The values that [--enforce-gtid-consistency](#) can be configured to are:

- [OFF](#): all transactions are allowed to violate GTID consistency.
- [ON](#): no transaction is allowed to violate GTID consistency.
- [WARN](#): all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

Setting [--enforce-gtid-consistency](#) without a value is an alias for [--enforce-gtid-consistency=ON](#). This impacts on the behavior of the variable, see [enforce_gtid_consistency](#).

Only statements that can be logged using GTID safe statements can be logged when [enforce-gtid-consistency](#) is set to [ON](#), so the operations listed here cannot be used with this option:

- [CREATE TABLE ... SELECT](#) statements
- [CREATE TEMPORARY TABLE](#) or [DROP TEMPORARY TABLE](#) statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

[--enforce-gtid-consistency](#) only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For more information, see [Section 17.1.3.6, “Restrictions on Replication with GTIDs”](#).

- [--executed-gtids-compression-period](#)

Property	Value
Command-Line Format	--executed-gtids-compression-period=#
Deprecated	Yes
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- [--gtid-mode](#)

Property	Value
Command-Line Format	--gtid-mode=MODE

Property	Value
System Variable	gtid_mode
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF OFF_PERMISSIVE ON_PERMISSIVE ON

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. The `gtid_mode` variable is dynamic and enables GTID based replication to be configured online. Before using this feature, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

- `--gtid-executed-compression-period`

Property	Value
Command-Line Format	<code>--gtid-executed-compression-period=#</code>
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See [mysql.gtid_executed Table Compression](#), for more information.

System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

Property	Value
Command-Line Format	<code>--binlog-gtid-simple-recovery</code>
System Variable	binlog_gtid_simple_recovery
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	TRUE

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtid_log_event`. All GTIDs from `Previous_gtid_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtid_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtid_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default, the server iterates only the oldest and the newest binary log files and the values of `gtid_purged` and `gtid_executed` are computed based only on `Previous_gtid_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

- `enforce_gtid_consistency`

Property	Value
Command-Line Format	<code>--enforce-gtid-consistency[=value]</code>

Property	Value
System Variable	enforce_gtid_consistency
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF ON WARN

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to [ON](#) before enabling GTID based replication.

The values that [enforce_gtid_consistency](#) can be configured to are:

- [OFF](#): all transactions are allowed to violate GTID consistency.
- [ON](#): no transaction is allowed to violate GTID consistency.
- [WARN](#): all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

[enforce_gtid_consistency](#) only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For more information on statements that can be logged using GTID based replication, see [--enforce-gtid-consistency](#).

Prior to MySQL 5.7 and in early releases in that release series, the boolean [enforce_gtid_consistency](#) defaulted to [OFF](#). To maintain compatibility with these earlier releases, the enumeration defaults to [OFF](#), and setting [--enforce-gtid-consistency](#) without a value is interpreted as setting the value to [ON](#). The variable also has multiple textual aliases for the values: [0=OFF=FALSE](#), [1=ON=TRUE](#), [2=WARN](#). This differs from other enumeration types but maintains compatibility with the boolean type used in previous releases. These changes impact on what is returned by the variable. Using [SELECT @@ENFORCE_GTID_CONSISTENCY](#), [SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'](#), and [SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'](#), all return the textual form, not the numeric form. This is an incompatible change, since [@@ENFORCE_GTID_CONSISTENCY](#) returns the numeric form for booleans but returns the textual form for [SHOW](#) and the Information Schema.

- [executed_gtids_compression_period](#)

Property	Value
Deprecated	Yes
System Variable	executed_gtids_compression_period
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `gtid_executed`

Property	Value
System Variable	<code>gtid_executed</code>
System Variable	<code>gtid_executed</code>
Scope	Global
Scope	Global, Session
Dynamic	No
Dynamic	No
SET_VAR Hint Applies	No
SET_VAR Hint Applies	No
Type	String

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@global.gtid_executed` is initialized. See [binlog_gtid_simple_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@global.gtid_executed, @@global.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

In some older releases, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope is now deprecated.

- `gtid_executed_compression_period`

Property	Value
System Variable	<code>gtid_executed_compression_period</code>

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See [mysql.gtid_executed Table Compression](#), for more information.

- `gtid_mode`

Property	Value
System Variable	<code>gtid_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF OFF_PERMISSIVE ON_PERMISSIVE ON

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. You must have privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#). `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

Logged transactions can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The different modes are:

- **OFF**: Both new and replicated transactions must be anonymous.
- **OFF_PERMISSIVE**: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- **ON_PERMISSIVE**: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- **ON**: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

The values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values.

- `gtid_next`

Property	Value
System Variable	<code>gtid_next</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>AUTOMATIC</code>
Valid Values	<code>AUTOMATIC</code> <code>ANONYMOUS</code> <code>UUID:NUMBER</code>

This variable is used to specify whether and how the next GTID is obtained.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

`gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.
- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in `UUID:NUMBER` format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see [Section 17.1.5.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is `OFF`.

After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

`DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines.

- `gtid_owned`

Property	Value
System Variable	<code>gtid_owned</code>
Scope	Global, Session

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	String

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- `gtid_purged`

Property	Value
System Variable	<code>gtid_purged</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, the global value of `gtid_purged` is initialized to a set of GTIDs. See [binlog_gtid_simple_recovery](#) for more information on how binary logs are iterated to populate `gtid_purged`. Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

There are two ways to set `gtid_purged`. When `gtid_set` is a superset of `gtid_purged`, and goes not intersect with `gtid_subtract(gtid_executed - gtid_purged)` use:

```
SET @@GLOBAL.GTID_PURGED = 'gtid_set'
```

The result is that `GTID_PURGED` is set equal to `gtid_set`, and `GTID_EXECUTED` becomes the union of `gtid_set` and the previous value of `GTID_EXECUTED`.

When `gtid_set` does not intersect with `gtid_executed` use:

```
SET @@GLOBAL.GTID_PURGED = '+gtid_set'
```

The result is that `gtid_set` is added to both `gtid_executed` and `gtid_purged`.

If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that `gtid_purged` may be computed incorrectly with `binlog_gtid_simple_recovery=TRUE`. See [binlog_gtid_simple_recovery](#) for more information.

- `simplified_binlog_gtid_recovery`

Property	Value
Command-Line Format	<code>--simplified-binlog-gtid-recovery</code>
Deprecated	Yes
System Variable	<code>simplified_binlog_gtid_recovery</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	FALSE

This option is deprecated and will be removed in a future MySQL release. Use the renamed [binlog_gtid_simple_recovery](#) to control how MySQL iterates through binary log files after a crash.

17.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

17.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master.

The [SHOW SLAVE STATUS](#) statement, which you must execute on each slave, provides information about the configuration and status of the connection between the slave server and the master server. From MySQL 5.7, the Performance Schema has replication tables that provide this information in a more accessible form. See [Section 25.11.11, “Performance Schema Replication Tables”](#).

The [SHOW STATUS](#) statement also provided some information relating specifically to replication slaves. From MySQL 5.7, the following status variables previously monitored using [SHOW STATUS](#) were deprecated and moved to the Performance Schema replication tables:

- [Slave_retried_transactions](#)
- [Slave_last_heartbeat](#)
- [Slave_received_heartbeats](#)
- [Slave_heartbeat_period](#)
- [Slave_running](#)

The replication heartbeat information shown in the Performance Schema replication tables lets you check that the replication connection is active even if the master has not sent events to the slave recently. The master sends a heartbeat signal to a slave if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The [MASTER_HEARTBEAT_PERIOD](#) setting on the master (set by the [CHANGE MASTER TO](#) statement) specifies the frequency of the heartbeat, which defaults to half of the connection timeout interval for the slave ([slave_net_timeout](#)). The [replication_connection_status](#) Performance Schema table shows when the most recent heartbeat signal was received by a replication slave, and how many heartbeat signals it has received.

If you are using the [SHOW SLAVE STATUS](#) statement to check on the status of an individual slave, the statement provides the following information:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
```

```

Slave_IO_State: Waiting for master to send event
Master_Host: master1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 931
Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
Last_IO_Errno: 0
Last_IO_Error:
Last_SQL_Errno: 0
Last_SQL_Error:
Replicate_Ignore_Server_Ids: 0

```

The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See [Section 8.14.4, “Replication Slave I/O Thread States”](#), and [Section 8.14.5, “Replication Slave SQL Thread States”](#), for more information.
- **Slave_IO_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.
- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last_IO_Error**, **Last_SQL_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds_Behind_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave_net_timeout** has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_File`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
      Id: 10
      User: root
      Host: slave1:58371
      db: NULL
      Command: Binlog Dump
      Time: 777
      State: Has sent all binlog to slave; waiting for binlog to be updated
      Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
| 10        | slave1 | 3306 | 0                 | 1         |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

17.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;  
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;  
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 17.2.2, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 8.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 17.2.4, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

17.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called *statement-based replication* (which can be abbreviated as *SBR*), which corresponds to the MySQL statement-based binary logging format.
- When using row-based logging, the master writes *events* to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called *row-based replication* (which can be abbreviated as *RBR*).

Row-based logging is the default method.

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 5.4.4.2, “Setting The Binary Log Format”](#).

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 23.7, “Binary Logging of Stored Programs”](#).

17.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
Not all statements which modify data (such as [INSERT](#), [DELETE](#), [UPDATE](#), and [REPLACE](#) statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
 - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 17.4.1.16, “Replication of Invoked Features”](#), for more information.
 - [DELETE](#) and [UPDATE](#) statements that use a [LIMIT](#) clause without an [ORDER BY](#) are nondeterministic. See [Section 17.4.1.18, “Replication and LIMIT”](#).
 - Locking read statements ([SELECT ... FOR UPDATE](#) and [SELECT ... FOR SHARE](#)) that use [NOWAIT](#) or [SKIP LOCKED](#) options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).
 - Deterministic UDFs must be applied on the slaves.
 - Statements using any of the following functions cannot be replicated properly using statement-based replication:

- `LOAD_FILE()`
- `UUID()`, `UUID_SHORT()`
- `USER()`
- `FOUND_ROWS()`
- `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
- `GET_LOCK()`
- `IS_FREE_LOCK()`
- `IS_USED_LOCK()`
- `MASTER_POS_WAIT()`
- `RAND()`
- `RELEASE_LOCK()`
- `SLEEP()`
- `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 17.4.1.14, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For **InnoDB**: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 17.4.1.29, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.

- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

Note

Statements that update the information in the `mysql` database—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
 - `INSERT ... SELECT`
 - `INSERT` statements with `AUTO_INCREMENT`
 - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

17.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 17.2.1, “Replication Formats”](#), and [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 17.4.1.31, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format or (from MySQL 8.0.4) mixed format. For more information, see [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based or mixed format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

You can switch from statement-based to row-based binary logging format at runtime even when temporary tables have been created. However, from MySQL 8.0.4, you cannot switch from row-based or mixed format for binary logging to statement-based format at runtime, because any `CREATE TEMPORARY TABLE` statements will have been omitted from the binary log in the previous mode.

From MySQL 8.0, the MySQL server tracks the logging mode that was in effect when each temporary table was created. When a given client session ends, the server logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the `DROP TEMPORARY TABLE IF EXISTS` statement is not logged. Before MySQL 8.0, the `DROP TEMPORARY TABLE IF EXISTS` statement was logged regardless of the logging mode that was in effect.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the slave's copy of the table, this may or may not be effective.
- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 13.7.7.1, “BINLOG Syntax”](#)). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.7, “Server System Variables”](#).

**Note**

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value. For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient, and is the default value.

- **Filtering based on server ID not supported.** You can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats, but is deprecated for use when `GTID_MODE=ON` is set. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.
- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

17.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL replication refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 17.4.1.12, “Replication and Floating-Point Values”](#)).

Handling of safe and unsafe statements. A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. If a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL has a warning suppression mechanism. Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 17.2.1, “Replication Formats”](#).

Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**

These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

Nondeterministic functions not considered unsafe. Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 17.4.1.14, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 17.4.1.39, “Replication and Variables”](#). For exceptions, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).
- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL.
- **Trigger or stored program updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 17.4.1.1, “Replication and `AUTO_INCREMENT`”](#).

- **`INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 17.4.1.18, “Replication and LIMIT”](#).
- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 17.4.1.35, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA INFILE statements.** `LOAD DATA INFILE` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.
- **XA transactions.** If two XA transactions committed in parallel on the master are being prepared on the slave in the inverse order, locking dependencies can occur with statement-based replication that cannot be safely resolved, and it is possible for replication to fail with deadlock on the slave. When `binlog_format=STATEMENT` is set, DML statements inside XA transactions are flagged as being unsafe and generate a warning. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

For additional information, see [Section 17.4.1, “Replication Features and Issues”](#).

17.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 8.14.3, “Replication Master Thread States”](#). For slave states, see [Section 8.14.4, “Replication Slave I/O Thread States”](#), and [Section 8.14.5, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
      Id: 2
      User: root
      Host: localhost:32931
      db: NULL
Command: Binlog Dump
      Time: 94
      State: Has sent all binlog to slave; waiting for binlog to
            be updated
      Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
      Id: 10
      User: system user
      Host:
      db: NULL
Command: Connect
      Time: 11
      State: Waiting for master to send event
      Info: NULL
***** 2. row *****
      Id: 11
      User: system user
      Host:
      db: NULL
Command: Connect
```

```
Time: 11
State: Has read all relay log; waiting for the slave I/O
      thread to update it
Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section A.13, “MySQL 8.0 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.7, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 17.1.7.1, “Checking Replication Status”](#).

17.2.3 Replication Channels

Replication channels represent the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string (`""`). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see [Section 17.2.3.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O) thread, they are added to the channel's relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port. In MySQL 8.0, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name (see [Section 17.2.3.4, “Replication Channel Naming Conventions”](#)). Channels can be configured independently.

17.2.3.1 Commands for Operations on a Single Channel

To enable MySQL replication operations to act on individual replication channels, use the `FOR CHANNEL channel` clause with the following replication statements:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`

- `FLUSH RELAY LOGS`
- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel` parameter is introduced for the following functions:

- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

The following statements are disallowed for the `group_replication_recovery` channel.

- `START SLAVE`
- `STOP SLAVE`

17.2.3.2 Compatibility with Previous Replication Statements

When a replication slave has multiple channels and a `FOR CHANNEL channel` option is not specified, a valid statement generally acts on all available channels.

For example, the following statements behave as expected:

- `START SLAVE` starts replication threads for all channels, except the `group_replication_recovery` channel.
- `STOP SLAVE` stops replication threads for all channels, except the `group_replication_recovery` channel.
- `SHOW SLAVE STATUS` reports the status for all channels.
- `FLUSH RELAY LOGS` flushes the relay logs for all channels.
- `RESET SLAVE` resets all channels.

Warning

Use `RESET SLAVE` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the slave. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE MASTER TO`
- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`
- `WAIT_FOR_EXECUTED_GTID_SET()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

17.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

- `--relay-log-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`. The `FILE` setting is now deprecated, and `TABLE` is the default.

- `--master-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`. The `FILE` setting is now deprecated, and `TABLE` is the default.

The following startup options now affect *all* channels in a replication topology.

- `--log-slave-updates`

All transactions received by the slave (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`

The specified number of transaction retries can take place on all applier threads of all channels.

- `--skip-slave-start`

No replication threads start on any channels.

- `--slave-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For *N* channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--slave-parallel-workers=value`

Number of slave parallel workers per channel.

- `--slave-checkpoint-group`

Waiting time by an I/O thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 17.2.3.4, “Replication Channel Naming Conventions”](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 17.2.3.4, “Replication Channel Naming Conventions”](#).

- `--slave_net_timeout=N`

This value is set per channel, so that each channel waits for *N* seconds to check for a broken connection.

- `--slave-skip-counter=N`

This value is set per channel, so that each channel skips *N* events from its master.

17.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `relay_log_basename-channel.xxxxxx`, where `relay_log_basename` is a base name specified using the `--relay-log` option, and `channel` is the name of the channel logged to this file. If you do not specify the `--relay-log` option, a default file name is used that also includes the name of the channel.

17.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log. The master info log is written to the `mysql.slave_master_info` table.
- The *relay log info log* holds status information about the execution point within the slave's relay log. The relay log is written to the `mysql.slave_relay_log_info` table.

In MySQL 8.0, a warning is given when `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

In MySQL 8.0, execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

Important

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported.

Making replication resilient to unexpected halts. The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine InnoDB. Updates to the relay log info log table are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the slave to guarantee resilience. For more details, see [Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

17.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files. The default location for relay log files is the data directory.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

For the default replication channel, relay log file names have the default form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. For non-default replication channels, the default base name is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in the relay log.

The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` for the default channel, and `host_name-relay-bin-channel.index` for non-default replication channels.

The default relay log file and relay log index file names and locations can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes too large, which is determined as follows:
 - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
 - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

17.2.4.2 Slave Status Logs

A replication slave server creates two slave status logs in the form of InnoDB tables in the `mysql` database: the master info log `slave_master_info`, and the relay log info log `slave_relay_log_info`.

The two slave status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). The slave status logs survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log table should be protected because it contains the password for connecting to the master. See [Section 6.1.2.3, “Passwords and Logging”](#).

Before MySQL 8.0, to create the slave status logs as tables, it was necessary to specify the options `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE` at server startup. Otherwise, the logs were created as files in the data directory named `master.info` and `relay-log.info`, or with alternative names and locations specified by the `--master-info-file` and `--relay-log-info-file` options. From MySQL 8.0, creating the slave status logs as tables is the default, and creating the slave status logs as files is deprecated. For more information, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine InnoDB. Updates to the relay log info log table are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the slave to guarantee resilience. For more details, see [Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

One additional slave status log is created primarily for internal use, and holds status information about worker threads on a multithreaded replication slave. This slave worker log includes the names and positions for the relay log file and master binary log file for each worker thread. If the relay log info log for the slave is created as a table, which is the default, the slave worker log is written to the `mysql.slave_worker_info` table. If the relay log info log is written to a file, the slave worker log is written to the `worker-relay-log.info` file. For external use, status information for worker threads is presented in the Performance Schema table `replication_applier_status_by_worker`.

The slave I/O thread updates the master info log. The following table shows the correspondence between the columns in the `mysql.slave_master_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the deprecated `master.info` file.

<code>slave_master_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	<code>master.info</code> File Line	Description
<code>Number_of_lines</code>	[None]	1	Number of columns in the table (or lines in the file)
<code>Master_log_name</code>	<code>Master_Log_File</code>	2	The name of the master binary log currently being read from the master
<code>Master_log_pos</code>	<code>Read_Master_Log_Pos</code>	3	The current position within the master binary log that has been read from the master
<code>Host</code>	<code>Master_Host</code>	4	The host name of the master
<code>User_name</code>	<code>Master_User</code>	5	The user name used to connect to the master
<code>User_password</code>	Password (not shown by <code>SHOW SLAVE STATUS</code>)	6	The password used to connect to the master
<code>Port</code>	<code>Master_Port</code>	7	The network port used to connect to the master
<code>Connect_retry</code>	<code>Connect_Retry</code>	8	The period (in seconds) that the slave will wait before trying to reconnect to the master
<code>Enabled_ssl</code>	<code>Master_SSL_Allowed</code>	9	Indicates whether the server supports SSL connections
<code>Ssl_ca</code>	<code>Master_SSL_CA_File</code>	10	The file used for the Certificate Authority (CA) certificate
<code>Ssl_capath</code>	<code>Master_SSL_CA_Path</code>	11	The path to the Certificate Authority (CA) certificates

<code>slave_master_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	<code>master.info</code> File Line	Description
<code>Ssl_cert</code>	<code>Master_SSL_Cert</code>	12	The name of the SSL certificate file
<code>Ssl_cipher</code>	<code>Master_SSL_Cipher</code>	13	The list of possible ciphers used in the handshake for the SSL connection
<code>Ssl_key</code>	<code>Master_SSL_Key</code>	14	The name of the SSL key file
<code>Ssl_verify_server_cert</code>	<code>Master_SSL_Verify_Server_Cert</code>	15	Whether to verify the server certificate
<code>Heartbeat</code>	[None]	16	Interval between replication heartbeats, in seconds
<code>Bind</code>	<code>Master_Bind</code>	17	Which of the slave's network interfaces should be used for connecting to the master
<code>Ignored_server_ids</code>	<code>Replicate_Ignore_Server_Ids</code>	18	The list of server IDs to be ignored. Note that for <code>Ignored_server_ids</code> the list of server IDs is preceded by the total number of server IDs to ignore.
<code>Uuid</code>	<code>Master_UUID</code>	19	The master's unique ID
<code>Retry_count</code>	<code>Master_Retry_Count</code>	20	Maximum number of reconnection attempts permitted
<code>Ssl_crl</code>	[None]	21	Path to an ssl certificate revocation list file
<code>Ssl_crl_path</code>	[None]	22	Path to a directory containing ssl certificate revocation list files
<code>Enabled_auto_position</code>	<code>Auto_position</code>	23	If autopositioning is in use or not
<code>Channel_name</code>	<code>Channel_name</code>	24	The name of the replication channel

slave_master_info Table Column	SHOW SLAVE STATUS Column	master.info File Line	Description
Tls_Version	Master_TLS_Version	25	TLS version on master
Master_public_key_path	Master_public_key_path	26	Name of RSA public key file
Get_master_public_key	Get_master_public_key	27	Whether to request RSA public key from master

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the columns in the `mysql.slave_relay_log_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the deprecated `relay-log.info` file.

slave_relay_log_info Table Column	SHOW SLAVE STATUS Column	Line in relay-log.info File	Description
Number_of_lines	[None]	1	Number of columns in the table or lines in the file
Relay_log_name	Relay_Log_File	2	The name of the current relay log file
Relay_log_pos	Relay_Log_Pos	3	The current position within the relay log file; events up to this position have been executed on the slave database
Master_log_name	Relay_Master_Log_File	4	The name of the master binary log file from which the events in the relay log file were read
Master_log_pos	Exec_Master_Log_Pos	5	The equivalent position within the master's binary log file of events that have already been executed
Sql_delay	SQL_Delay	6	The number of seconds that the slave must lag the master
Number_of_workers	[None]	7	The number of slave applier threads for executing replication events (transactions) in parallel

<code>slave_relay_log_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Line in <code>relay-log.info</code> File	Description
<code>Id</code>	[None]	8	ID used for internal purposes; currently this is always 1
<code>Channel_name</code>	<code>Channel_name</code>	9	The name of the replication channel

When you back up the replication slave's data, ensure that you back up the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables containing the slave status logs, because they are needed to resume replication after you restore the data from the slave. If you lose the relay log files, but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

17.2.5 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).) The filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the slave server is running by `CHANGE REPLICATION FILTER`. Note that replication filters cannot be used on Group Replication-specific channels on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 17.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

Note

All replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

17.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a `USE` statement) is the database that is checked.

Note

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when `binlog_format=ROW`. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a `USE` statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?
 - **STATEMENT.** Test the default database.
 - **ROW.** Test the database affected by the changes.
2. Are there any `--replicate-do-db` options?
 - **Yes.** Does the database match any of them?
 - **Yes.** Continue to Step 4.
 - **No.** Ignore the update and exit.
 - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-db` options?
 - **Yes.** Does the database match any of them?
 - **Yes.** Ignore the update and exit.
 - **No.** Continue to step 4.
 - **No.** Continue to step 4.

4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 17.2.5.2, “Evaluation of Table-Level Replication Options”](#).

Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
 - **Yes.** Continue to step 2.
 - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
 - **Yes.** Continue to step 3.
 - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
 - **Yes.** Do any of them match the database?
 - **Yes.** Log the statement and exit.
 - **No.** Ignore the statement and exit.
 - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
 - **Yes.** Ignore the statement and exit.
 - **No.** Log the statement and exit.

Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

17.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.

- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

1. Are there any table replication options?
 - **Yes.** Continue to step 2.
 - **No.** Execute the update and exit.
2. Which logging format is used?
 - **STATEMENT.** Carry out the remaining steps for each statement that performs an update.
 - **ROW.** Carry out the remaining steps for each update of a table row.
3. Are there any `--replicate-do-table` options?
 - **Yes.** Does the table match any of them?
 - **Yes.** Execute the update and exit.
 - **No.** Continue to step 4.
 - **No.** Continue to step 4.
4. Are there any `--replicate-ignore-table` options?
 - **Yes.** Does the table match any of them?
 - **Yes.** Ignore the update and exit.
 - **No.** Continue to step 5.

- **No.** Continue to step 5.
5. Are there any `--replicate-wild-do-table` options?
- **Yes.** Does the table match any of them?
 - **Yes.** Execute the update and exit.
 - **No.** Continue to step 6.
 - **No.** Continue to step 6.
6. Are there any `--replicate-wild-ignore-table` options?
- **Yes.** Does the table match any of them?
 - **Yes.** Ignore the update and exit.
 - **No.** Continue to step 7.
 - **No.** Continue to step 7.
7. Is there another table to be tested?
- **Yes.** Go back to step 3.
 - **No.** Continue to step 8.
8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
- **Yes.** Ignore the update and exit.
 - **No.** Execute the update and exit.

Note

Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The slave must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

17.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No <code>--replicate-*</code> options at all:	The slave executes all events that it receives from the master.

Condition (Types of Options)	Outcome
<code>--replicate-*-db</code> options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
<code>--replicate-*-table</code> options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

Statement-based replication. The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

Row-based replication. The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

17.2.5.4 Replication Channel Based Filters

This section explains how to work with replication filters when multiple replication channels exist, for example in a multi-source replication topology. Before MySQL 8.0, replication filters were global - filters were applied to all replication channels. From MySQL 8.0, replication filters can be global or channel specific, enabling you to configure multi-source replication slaves with replication filters on specific replication channels. Channel specific replication filters are particularly useful in a multi-source replication topology when the same database or table is present on multiple masters, and the slave is only required to replicate it from one master.

For more background information, see [Section 17.1.4, “MySQL Multi-Source Replication”](#) and [Section 17.2.3, “Replication Channels”](#).

Important

On a MySQL server instance that is configured for Group Replication, channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels. Filtering on these channels would make the group unable to reach agreement on a consistent state.

Overview of Replication Filters and Channels

When multiple replication channels exist, for example in a multi-source replication topology, replication filters are applied as follows:

- Any global replication filter specified is added to the global replication filters of the filter type (`do_db`, `do_ignore_table`, and so on).
- Any channel specific replication filter adds the filter to the specified channel's replication filters for the specified filter type.
- Each slave replication channel copies global replication filters to its channel specific replication filters if no channel specific replication filter of this type is configured.
- Each channel uses its channel specific replication filters to filter the replication stream.

The syntax to create channel specific replication filters extends the existing SQL statements and command options. When a replication channel is not specified the global replication filter is configured to ensure backwards compatibility. The `CHANGE REPLICATION FILTER` statement supports the `FOR CHANNEL` clause to configure channel specific filters online. The `--replicate-*` command options to configure filters can specify a replication channel using the form `--replicate-filter_type=channel_name:filter_details`. For example, suppose channels `channel_1` and `channel_2` exist before the server starts, starting the slave with the command line options `--replicate-do-db=db1 --replicate-do-db=channel_1:db2 --replicate-do-db=db3 --replicate-ignore-db=db4 --replicate-ignore-db=channel_2:db5` would result in:

- *Global replication filters:* `do_db=db1,db3`, `ignore_db=db4`
- *Channel specific filters on channel_1:* `do_db=db2`, `ignore_db=db4`
- *Channel specific filters on channel_2:* `do_db=db1,db3`, `ignore_db=db5`

To monitor the replication filters in such a setup use the `replication_applier_global_filters` and `replication_applier_filters` tables.

Configuring Channel Specific Replication Filters at Startup

The replication filter related command options can take an optional `channel` followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, subsequent colons are interpreted as literal colons. The following command options support channel specific replication filters using this format:

- `--replicate-do-db=channel:database_id`
- `--replicate-ignore-db=channel:database_id`
- `--replicate-do-table=channel:table_id`
- `--replicate-ignore-table=channel:table_id`

- `--replicate-rewrite-db=channel:db1-db2`
- `--replicate-wild-do-table=channel:table regexid`
- `--replicate-wild-ignore-table=channel:table regexid`

If you use a colon but do not specify a `channel` for the filter option, for example `--replicate-do-db=:database_id`, the option configures the replication filter for the default replication channel. The default replication channel is the replication channel which always exists once replication has been started, and differs from multi-source replication channels which you create manually. When neither the colon nor a `channel` is specified the option configures the global replication filters, for example `--replicate-do-db=database_id` configures the global `--replicate-do-db` filter.

If you configure multiple `rewrite-db=from_name->to_name` options with the same `from_name` database, all filters are added together (put into the `rewrite_do` list) and the first one takes effect.

Changing Channel Specific Replication Filters Online

In addition to the `--replicate-*` options, replication filters can be configured using the `CHANGE REPLICATION FILTER` statement. This removes the need to restart the server, but the slave applier thread must be stopped while making the change. To make this statement apply the filter to a specific channel, use the `FOR CHANNEL channel` clause. For example:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB=(db1) FOR CHANNEL channel_1;
```

When a `FOR CHANNEL` clause is provided, the statement acts on the specified channel's replication filters. If multiple types of filters (`do_db`, `do_ignore_table`, `wild_do_table`, and so on) are specified, only the specified filter types are replaced by the statement. In a replication topology with multiple channels, for example on a multi-source replication slave, when no `FOR CHANNEL` clause is provided, the statement acts on the global replication filters and all channels' replication filters, using a similar logic as the `FOR CHANNEL` case. For more information see [Section 13.4.2.2, "CHANGE REPLICATION FILTER Syntax"](#).

Removing Channel Specific Replication Filters

When channel specific replication filters have been configured, you can remove the filter by issuing an empty filter type statement. For example to remove all `REPLICATE_REWRITE_DB` filters from a replication channel named `channel_1` issue:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=() FOR CHANNEL channel_1;
```

Any `REPLICATE_REWRITE_DB` filters previously configured, using either command options or `CHANGE REPLICATION FILTER`, are removed.

The `RESET SLAVE ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the slave are copied to them, and no channel specific replication filters are applied.

17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 17.3.1, "Using Replication for Backups"](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 17.3.4, "Using Replication with Different Master and Slave Storage Engines"](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 17.3.5, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 17.3.6, “Replicating Different Databases to Different Slaves”](#)

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 17.3.7, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 17.3.8, “Switching Masters During Failover”](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”](#).

17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 17.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 17.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 17.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

17.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 17.1.7.1, “Checking Replication Status”](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 17.3.6, “Replicating Different Databases to Different Slaves”](#).

17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), in addition to the data, you need to have the master info repository and relay log info repository, and the relay log

files. These items are needed to resume replication after you restore the slave's data. If tables have been used for the master info and relay log info repositories (see [Section 17.2.4, “Replication Relay and Status Logs”](#)), which is the default in MySQL 8.0, these tables are backed up along with the data directory. If files have been used for the repositories, you must back these up separately. The relay log files must also be backed up separately if they have been placed in a different location to the data directory.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

17.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact

of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a slave, upon restart the slave's SQL thread must recover which transactions have been executed already. The information required for recovery is stored in the slave's relay log info log. From MySQL 8.0, this log is created by default as an `InnoDB` table named `mysql.slave_relay_log_info` (with the system variable `relay_log_info_repository` set to the default of `TABLE`). By using this transactional storage engine the information is always recoverable upon restart.

Updates to the relay log info log table are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. Previously, this information was stored by default in a file in the data directory that was updated after the transaction had been applied. This held the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the file itself. The setting `relay_log_info_repository = FILE` is now deprecated, and will be removed in a future release. For further information on the slave logs, see [Section 17.2.4, “Replication Relay and Status Logs”](#).

When the relay log info log is stored in the `mysql.slave_relay_log_info` table, DML transactions and also atomic DDL make the following three updates together, atomically:

- Apply the transaction on the database.
- Update the replication positions in the `mysql.slave_relay_log_info` table.
- Update the GTID in the `mysql.gtid_executed` table (when GTIDs are enabled and the binary log is disabled on the server).

In all other cases, including DDL statements that are not fully atomic, and exempted storage engines that do not support atomic DDL, the `mysql.slave_relay_log_info` table might be missing updates associated with replicated data if the server halts unexpectedly. Restoring updates in this case is a manual process. For details on atomic DDL support in MySQL 8.0, and the resulting behavior for the replication of certain statements, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multithreaded, the setting of variables such as `relay_log_recovery`, and whether features such as `MASTER_AUTO_POSITION` are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

Table 17.3 Factors Influencing Single-threaded Replication Slave Recovery

Configuration	GTID	Atomic DDL	Atomic DML	Atomic DDL + Atomic DML
<code>MASTER_AUTO_POSITION = 1</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes
<code>MASTER_AUTO_POSITION = 0</code>	Yes	Yes	Yes	Yes

As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery. Note that to guarantee recovery, `sync_binlog=1` (which is the default) must also be set on the slave, so that the slave's binary log is synchronized to disk at each write. Otherwise, committed transactions might not be present in the slave's binary log.
- When using file position based replication, set `relay_log_recovery=1` and `relay_log_info_repository=TABLE`.

Note

During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multithreaded slave recovers from an unexpected halt.

Table 17.4 Factors Influencing Multithreaded Replication Slave Recovery

Configuration	Impact
<code>sync_binlog=1</code>	Guaranteed
<code>sync_relay_log=1</code>	Guaranteed
<code>relay_log_recovery=1</code>	Guaranteed
<code>relay_log_info_repository=TABLE</code>	Guaranteed
<code>relay_log_recovery=0</code>	Not guaranteed
<code>relay_log_info_repository=TABLE</code>	Not guaranteed
<code>relay_log_recovery=1</code>	Not guaranteed
<code>relay_log_info_repository=TABLE</code>	Not guaranteed
<code>sync_binlog=1</code>	Not guaranteed
<code>sync_relay_log=1</code>	Not guaranteed
<code>relay_log_recovery=1</code>	Not guaranteed
<code>relay_log_info_repository=TABLE</code>	Not guaranteed

As the table shows, when using a multithreaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.
- When using file position based replication, set `relay_log_recovery=1`, `sync_relay_log=1`, and `relay_log_info_repository=TABLE`.

Note

During recovery the relay log is lost.

It is important to note the impact of `sync_relay_log=1`, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without `sync_relay_log=1`, the effect of an unexpected halt depends on how the relay log is handled by the

operating system. Also note that when `relay_log_recovery=0`, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multithreaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#). If the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multithreaded slave are filled.

17.3.3 Monitoring Row-based Replication

The current progress of the replication applier (SQL) thread when using row-based replication is monitored through Performance Schema instrument stages, enabling you to track the processing of operations and check the amount of work completed and work estimated. When these Performance Schema instrument stages are enabled the `events_stages_current` table shows stages for applier threads and their progress. For background information, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

To track progress of all three row-based replication event types (write, update, delete):

- Enable the three Performance Schema stages by issuing:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME LIKE 'stage/sql/Applying batch of row changes%';
```

- Wait for some events to be processed by the replication applier thread and then check progress by looking into the `events_stages_current` table. For example to get progress for `update` events issue:

```
mysql> SELECT WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
-> WHERE EVENT_NAME LIKE 'stage/sql/Applying batch of row changes (update)';
```

- If `binlog_rows_query_log_events` is enabled, information about queries is stored in the binary log and is exposed in the `processlist_info` field. To see the original query that triggered this event:

```
mysql> SELECT db, processlist_state, processlist_info FROM performance_schema.threads
-> WHERE processlist_state LIKE 'stage/sql/Applying batch of row changes%' AND thread_id = N;
```

17.3.4 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` system variable is not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 17.3.5, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;  
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

17.3.5 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 17.1, “Using Replication to Improve Performance During Scale-Out”](#).

Figure 17.1 Using Replication to Improve Performance During Scale-Out

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take

advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

17.3.6 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

Figure 17.2 Using Replication to Replicate Databases to Separate Replication Slaves

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

Note

This does not work with [InnoDB](#) databases unless you use `innodb_file_per_table`.

17.3.7 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 17.3, “Using an Additional Replication Host to Improve Performance”](#).

Figure 17.3 Using an Additional Replication Host to Improve Performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging is enabled on both masters, which is the default.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 has the `--log-slave-updates` option enabled (which is the default). With this option, replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

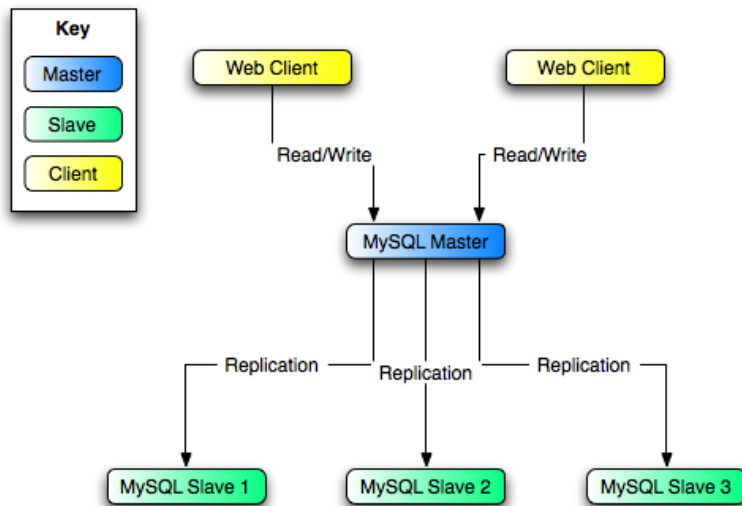

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If heavy disk I/O activity for reads of the binary log file and relay log files is an issue, consider increasing the value of the `rpl_read_size` system variable. This system variable controls the minimum amount of data read from the log files, and increasing it might reduce file reads and I/O stalls when the file data is not currently cached by the operating system. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves. Setting a large value might therefore have an impact on memory consumption for servers.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 17.3.6, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 17.3.4, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you may switch off `--log-slave-updates` on the slaves. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

17.3.8 Switching Masters During Failover

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the slaves should also be run with `--skip-log-slave-updates` (logging slave updates is the default). In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 17.4, “Redundancy Using Replication, Initial Structure”](#).

Figure 17.4 Redundancy Using Replication, Initial Structure

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 17.3.5, “Using Replication for Scale-Out”](#).

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with binary logging enabled, and with `--skip-log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log when `--skip-log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave with `--skip-log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, which is the default, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all update statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 17.5, “Redundancy Using Replication, After Master Failure”](#).

Figure 17.5 Redundancy Using Replication, After Master Failure

When **Master** becomes available again, you should make it a slave of **Slave 1**. To do this, issue on **Master** the same `CHANGE MASTER TO` statement as that issued on **Slave 2** and **Slave 3** previously. **Master** then becomes a slave of **Slave 1** and picks up the **Web Client** writes that it missed while it was offline.

To make **Master** a master again, use the preceding procedure as if **Slave 1** was unavailable and **Master** was to be the new master. During this procedure, do not forget to run `RESET MASTER` on **Master** before making **Slave 1**, **Slave 2**, and **Slave 3** slaves of **Master**. If you fail to do this, the slaves may pick up stale writes from the **Web Client** applications dating from before the point at which **Master** became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

17.3.9 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see [Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”](#).

To enable encrypted connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the server public key certificate file. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key`: The path name of the server private key file.

To enable encrypted connections on the slave, use the `CHANGE MASTER TO` statement. You can either name the slave certificate and SSL private key files required for the encrypted connection in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement. For more information on the `CHANGE MASTER TO` statement, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

- Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, and add the `MASTER_SSL` option to connect using encryption:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='repl',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

Setting `MASTER_SSL=1` for a replication connection and then setting no further `MASTER_SSL_XXX` options corresponds to setting `--ssl-mode=REQUIRED` for the client, as described in [Section 6.4.2, “Command Options for Encrypted Connections”](#). With `MASTER_SSL=1`, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the `--ssl-mode=PREFERRED` setting for replication. If `MASTER_SSL=0` is set, this corresponds to `--ssl-mode=DISABLED`.

- To name the slave certificate and SSL private key files using the `CHANGE MASTER TO` statement, if you did not do this in the slave's `my.cnf` file, add the appropriate `MASTER_SSL_XXX` options:

```
-> MASTER_SSL_CA = 'ca_file_name',  
-> MASTER_SSL_CAPATH = 'ca_directory_name',  
-> MASTER_SSL_CERT = 'cert_file_name',  
-> MASTER_SSL_KEY = 'key_file_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Section 6.4.2, “Command Options for Encrypted Connections”](#). For these options to take effect, `MASTER_SSL=1` must also be set. For a replication connection, specifying a value for either of `MASTER_SSL_CA` or `MASTER_SSL_CAPATH`, or specifying these options in the slave's `my.cnf` file, corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt only succeeds if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `MASTER_SSL_VERIFY_SERVER_CERT` option:

```
-> MASTER_SSL_VERIFY_SERVER_CERT=1,
```

This option corresponds to the `--ssl-verify-server-cert` option, which was deprecated from MySQL 5.7 and removed in MySQL 8.0. For a replication connection, specifying `MASTER_SSL_VERIFY_SERVER_CERT=1` corresponds to setting `--ssl-mode=VERIFY_IDENTITY`, as described in [Section 6.4.2, “Command Options for Encrypted Connections”](#). For this option to take effect, `MASTER_SSL=1` must also be set. Host name identity verification does not work with self-signed certificates.

- To activate certificate revocation list (CRL) checks, add the `MASTER_SSL_CRL` or `MASTER_SSL_CRLPATH` option:

```
-> MASTER_SSL_CRL = 'crl_file_name',  
-> MASTER_SSL_CRLPATH = 'crl_directory_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Section 6.4.2, “Command Options for Encrypted Connections”](#). If they are not specified, no CRL checking takes place.

- To specify lists of permitted ciphers and encryption protocols for the replication connection, add the `MASTER_SSL_CIPHER` and `MASTER_TLS_VERSION` options:

```
-> MASTER_SSL_CIPHER = 'cipher_list',  
-> MASTER_TLS_VERSION = 'protocol_list',
```

The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted for the replication connection. The format is like that for the `tls_version` system variable, with one or more protocol names separated by commas. The `MASTER_SSL_CIPHER` option specifies the list of permitted ciphers for the replication connection, with one or more cipher names separated by colons. The protocols and ciphers that you can use in these lists depend on the SSL library used to compile MySQL. For information on how to specify these options, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

- Requiring encrypted connections on the slave does not ensure that the master requires encrypted connections from slaves. If you want to ensure that the master only accepts replication slaves that connect using encrypted connections, create a replication user account on the master using the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'  
-> REQUIRE SSL;  
mysql> GRANT REPLICATION SLAVE ON *.*  
-> TO 'repl'@'%.example.com';
```

If you have an existing replication user account on the master, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.example.com' REQUIRE SSL;
```

17.3.10 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 8.0 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

The number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

17.3.10.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_XXX` system variables are described at [Section 5.1.7, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 5.1.9, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

17.3.10.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 17.1, “Configuring Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 17.2.3, “Replication Channels”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <https://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%semi%';
```

PLUGIN_NAME	PLUGIN_STATUS
rpl_semi_sync_master	ACTIVE

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value *N* is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;  
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]  
rpl_semi_sync_master_enabled=1  
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]  
rpl_semi_sync_slave_enabled=1
```

17.3.10.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

17.3.11 Delayed Replication

MySQL supports delayed replication such that a slave server deliberately executes transactions later than the master by at least a specified amount of time. This section describes how to configure a replication delay on a slave, and how to monitor replication delay.

In MySQL 8.0, the method of delaying replication depends on two timestamps, `immediate_commit_timestamp` and `original_commit_timestamp` (see [Replication Delay Timestamps](#)). If all servers in the replication topology are running MySQL 8.0.1 or above, delayed replication is measured using these timestamps. If either the immediate master or slave is not using these timestamps, the implementation of delayed replication from MySQL 5.7 is used (see [Delayed Replication](#)). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use the `CHANGE MASTER TO MASTER_DELAY=N` statement to set the delay to `N` seconds. A transaction received from the master is not executed until at least `N` seconds later than its commit on the immediate master. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

Note

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

The `replication_applier_configuration` Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `MASTER_DELAY` option. The `replication_applier_status` Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. With a delay you can roll back a delayed slave to the time just before the mistake.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.
- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a slave with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

Replication Delay Timestamps

MySQL 8.0 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- `original_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original master.

- `immediate_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate master.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined timezone for better readability. For example:

```
#170404 10:48:05 server id 1  end_log_pos 233 CRC32 0x016ce647      GTID      last_committed=0
\ sequence_number=1      original_committed_timestamp=1491299285661130      immediate_commit_timestamp=1491299285661130
# original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
# immediate_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
/*!80001 SET @@session.original_commit_timestamp=1491299285661130*//*!*/;
SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:1'/*!*/;
# at 233
```

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In master-slave replication, the `original_commit_timestamp` of a transaction in the (original) master's binary log is always the same as its `immediate_commit_timestamp`. In the slave's relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the master's binary log; whereas in its own binary log, the transaction's `immediate_commit_timestamp` corresponds to when the slave committed the transaction.

In a Group Replication setup, when the original master is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original master and its write set is ready to be sent to all members of the group for certification. Therefore, the same `original_commit_timestamp` is replicated to all servers (regardless of whether it is a group member or slave replicating from a member) applying the transaction and each stores in its binary log the local commit time using `immediate_commit_timestamp`.

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each server but share the same GTID (so, they are not first executed in a master and then replicated to the group, but all members of the group execute and apply the same transaction). Since there is no original master, these transactions have their `original_commit_timestamp` set to zero.

Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW SLAVE STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional master-slave setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the master, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multithreaded slave, provides information on the last transaction buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering.
- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the master, provides information about the transactions applied by the applier thread, or by each worker when using a multithreaded slave.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction's GTID
- a transaction's `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the slave's relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW SLAVE STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE MASTER TO MASTER_DELAY=N`, measured in seconds.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

17.4 Replication Notes and Tips

17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In other words, successful statement-based replication requires that any SQL features used be supported by both the master and the slave servers. If you use a feature on the master server that is available only in the current version of MySQL, you cannot replicate to a slave that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 8.0 and a previous MySQL release series, it is a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 23.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 5.4.4.1, “Binary Logging Formats”](#), and [Section 17.2.1, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 15.18, “InnoDB and MySQL Replication”](#). For information relating to replication with NDB Cluster, see [NDB Cluster Replication](#).

17.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is carried out subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)
- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the `InnoDB` storage engine, since an `InnoDB` table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

17.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the [BLACKHOLE](#) storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

17.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

17.4.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

The statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

17.4.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 17.4.1.7, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master.

17.4.1.7 Replication of CREATE TABLE ... SELECT Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 13.3.3, “Statements That Cause an Implicit Commit”](#)).
- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
 - `STATEMENT` or `MIXED` format: The statement is logged as written.
 - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the `CREATE TABLE ... SELECT` statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

- If the destination table exists and `IF NOT EXISTS` is given, MySQL 8.0 ignores the statement completely; nothing is inserted or logged.

When statement-based replication is in use, MySQL 8.0 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

17.4.1.8 Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the master and the slave when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the master is replicated to the slave as metadata, and the slave applies the statement to the current user named in the metadata, rather than to the current user on the slave.

17.4.1.9 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 17.4.1.24, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (  
    c1 INT,  
    c2 INT,  
    c3 INT  
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 11.7, “Data Type Default Values”](#).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication. When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Row-based replication: attribute promotion and demotion. Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions. In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

Type conversion modes (slave_type_conversions variable). The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following list, which describes the effects of each mode on the slave's type-conversion behavior:

<code>ALL_LOSSY</code>	<p>In this mode, type conversions that would mean loss of information are permitted.</p> <p>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</p>
<code>ALL_NON_LOSSY</code>	<p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to</p>

	<code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.
<code>ALL_LOSSY,ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
<code>ALL_SIGNED</code>	Treat promoted integer types as signed values (the default behavior).
<code>ALL_UNSIGNED</code>	Treat promoted integer types as unsigned values.
<code>ALL_SIGNED,ALL_UNSIGNED</code>	Treat promoted integer types as signed if possible, otherwise as unsigned.
[empty]	When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.
This mode is the default.	

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. You can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

Supported conversions. Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where $D' \geq D$ and $(M' - D') \geq (M - D)$ is non-lossy; for any case where $M' < M$, $D' < D$, or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 12.23.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* characters of the string on the slave, where *N* is the width of the target column.

**Important**

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* bytes of the string on the slave, where *N* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where $M' > M$, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the *M* bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where $M' < M$, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

17.4.1.10 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.10, “Server SQL Modes”](#).

17.4.1.11 Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 12.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

17.4.1.13 Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 13.7.7.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

17.4.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 17.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 17.4.1.8, “Replication of CURRENT_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also [Section 17.4.1.33, “Replication and Time Zones”](#)

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
```

```

+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)

```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 17.4.1.33, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

17.4.1.15 Replication and Fractional Seconds Support

MySQL 8.0 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.3.6, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a master server that understands fractional seconds to a slave using a version earlier than MySQL 5.6 that does not understand them. For `CREATE TABLE` statements containing columns that have an *fsp* (fractional seconds precision) value greater than 0, replication will fail due to parser errors, and some expression results will differ on master and slave. Statements that use temporal data types with an *fsp* value of 0 will work for with statement-based logging but not row-based logging. Note, however, that replicating from a newer master to an older slave is not a recommended configuration.

17.4.1.16 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
 - `CREATE EVENT`
 - `ALTER EVENT`
 - `DROP EVENT`
 - `CREATE PROCEDURE`
 - `DROP PROCEDURE`

- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
 - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
 - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 24.9, “The INFORMATION_SCHEMA EVENTS Table”](#), and [Section 13.7.6.18, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
```

```
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

17.4.1.17 Replication of JSON Documents

Before MySQL 8.0, an update to a JSON column was always written to the binary log as the complete document. In MySQL 8.0, it is possible to log partial updates to JSON documents (see [Partial Updates of JSON Values](#)), which is more efficient. The logging behavior depends on the format used, as described here:

Statement-based replication. JSON partial updates are always logged as partial updates. This cannot be disabled when using statement-based logging.

Row-based replication. JSON partial updates are not logged as such by default, but instead are logged as complete documents. To enable logging of partial updates, set `binlog_row_value_options=PARTIAL_JSON`. If a replication master has this variable set, partial updates received from that master are handled and applied by a replication slave regardless of the slave's own setting for the variable.

Servers running MySQL 8.0.2 or earlier do not recognize the log events used for JSON partial updates. For this reason, when replicating to such a server from a server running MySQL 8.0.3 or later, `binlog_row_value_options` must be disabled on the master by setting this variable to `''` (empty string). See the description of this variable for more information.

17.4.1.18 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

17.4.1.19 Replication and `LOAD DATA INFILE`

`LOAD DATA INFILE` is considered unsafe for statement-based logging (see [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA INFILE` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA INFILE` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

17.4.1.20 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded slave (with `slave_parallel_workers > 0`), ensure that the `slave_pending_jobs_size_max` system variable is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the master. The default setting for `slave_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the master will send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.

The replication slave actually accepts packets up to the limit set by its `slave_max_allowed_packet` setting, which defaults to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `slave_pending_jobs_size_max` controls the memory that is made available on the slave to hold incoming packets. The specified memory is shared among all the slave worker queues.

The value of `slave_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `slave_pending_jobs_size_max` can be processed, the delay to clear the queues of all the slave workers and the wait to queue subsequent

transactions can cause lag on the replication slave and decreased concurrency of the slave workers. `slave_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

17.4.1.21 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 17.4.1.39, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 16.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

17.4.1.22 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

17.4.1.23 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not

a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 17.4.1.18, “Replication and LIMIT”](#), for a detailed discussion of these.

17.4.1.24 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

17.4.1.25 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

17.4.1.26 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. For example, a table column named `rank` on a MySQL 5.7 master that is replicating to a MySQL 8.0 slave could cause a problem because `RANK` is a reserved word beginning in MySQL 8.0.

Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected. Only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 9.2, “Schema Object Names”](#).

17.4.1.27 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 13.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 5.1.14, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.7 help content into a MySQL 5.7 master server, but not necessarily replicate that content to a MySQL 8.0 slave server for which 8.0 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that the help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <https://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version:

```
mysql mysql < fill_help_tables.sql
```

Loading Help Table Content With Replication to Slaves

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
```

```
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url         | char(128)   |
| help_topic   | url         | char(128)   |
+-----+-----+-----+
```

For tables with the new structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url         | text        |
| help_topic   | url         | text        |
+-----+-----+-----+
```

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=OFF;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

17.4.1.28 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data

from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the InnoDB redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 17.4.1.31, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

17.4.1.29 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

Note

If a temporary error is recorded in the slave's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the slave SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the slave, unless the slave SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as [MyISAM](#), it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since [MyISAM](#) ignores foreign key constraints, an [INSERT](#) or [UPDATE](#) statement accessing an [InnoDB](#) table on the master might cause a foreign key violation but the same statement performed on a [MyISAM](#) version of the same table on the slave would produce no such error, causing replication to stop.

17.4.1.30 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same [INSERT](#) statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.10, “Server SQL Modes”](#).

17.4.1.31 Replication and Temporary Tables

In MySQL 8.0, when [binlog_format](#) is set to [ROW](#) or [MIXED](#), statements that exclusively use temporary tables are not logged on the master, and therefore the temporary tables are not replicated. Statements that involve a mix of temporary and nontemporary tables are logged on the master only for the operations on nontemporary tables, and the operations on temporary tables are not logged. This means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

When [binlog_format](#) is set to [STATEMENT](#), operations on temporary tables are logged on the master and replicated on the slave, provided that the statements involving temporary tables can be logged safely using statement-based format. In this situation, loss of replicated temporary tables on the slave can be an issue. In statement-based replication mode, [CREATE TEMPORARY TABLE](#) and [DROP TEMPORARY TABLE](#) statements cannot be used inside a transaction, procedure, function, or trigger when GTIDs are in use on the server (that is, when the [enforce_gtid_consistency](#) system variable is set to [ON](#)). They can be used outside these contexts when GTIDs are in use, provided that [autocommit=1](#) is set.

Because of the differences in behavior between row-based or mixed replication mode and statement-based replication mode regarding temporary tables, you cannot switch the replication format at runtime, if the change applies to a context (global or session) that contains any open temporary tables. For more details, see the description of the [binlog_format](#) option.

Safe slave shutdown when using temporary tables. In statement-based replication mode, temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, with statement-based replication, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replication slave always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

17.4.1.32 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` sets the maximum number of times for applier threads on a single-threaded or multithreaded replication slave to automatically retry failed transactions before stopping. Transactions are automatically retried when the SQL thread fails to execute them because of an InnoDB deadlock, or when the transaction's execution time exceeds the `InnoDB innodb_lock_wait_timeout` value. If a transaction has a non-temporary error that will prevent it from ever succeeding, it is not retried.

The default setting for `slave_transaction_retries` is 10, meaning that a failing transaction with an apparently temporary error is retried 10 times before the applier thread stops. Setting the variable to 0 disables automatic retrying of transactions. On a multithreaded slave, the specified number of transaction retries can take place on all applier threads of all channels. The Performance Schema table `replication_applier_status` shows the total number of transaction retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

The process of retrying transactions can cause lag on a replication slave or on a Group Replication group member, which can be configured as a single-threaded or multithreaded slave. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by the applier threads on a single-threaded or multithreaded slave. This data includes timestamps showing how long it took the applier thread to apply the last transaction from start to finish (and when the transaction currently in progress was started), and how long this was after the commit on the original master and the immediate master. The data also shows the number of retries for the last transaction and the transaction currently in progress, and enables you to identify the transient errors that caused the transactions to be retried. You can use this information to see whether transaction retries are the cause of replication lag, and investigate the root cause of the failures that led to the retries.

17.4.1.33 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using

the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 17.4.1.14, “Replication and System Functions”](#).

17.4.1.34 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multithreaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that binary logging (the `log_bin` system variable) and slave update logging (the `--log-slave-updates`) are also enabled.
- *Gap-free low-watermark position.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multithreaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multithreaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multithreaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multithreaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

17.4.1.35 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates *any* of the tables involved is considered a “mixed” statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is `OFF`

For more information, see [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

Note

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave. It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Changing the binary logging format within transactions. The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

**Note**

For restrictions that apply specifically to XA transactions, see [Section C.6, “Restrictions on XA Transactions”](#).

17.4.1.36 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 8.0 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

Upgrades. Multiple triggers are not supported in versions earlier than MySQL 5.7. If you upgrade servers in a replication topology that use a version earlier than MySQL 5.7, upgrade the replication slaves first and then upgrade the master. If an upgraded replication master still has old slaves using MySQL versions that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time.

Downgrades. If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see [Table Trigger Storage](#).

- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

17.4.1.37 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 13.1.34](#), “`TRUNCATE TABLE` Syntax” governing such tables. (Bug #36763)

17.4.1.38 Replication and User Name Length

The maximum length of MySQL user names is 32 characters. Replication of user names longer than 16 characters to a slave earlier than MySQL 5.7 that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

17.4.1.39 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`

- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 17.4.1.21, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
```

```
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 17.2.1, “Replication Formats”](#).

The following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems. The `lower_case_table_names` setting can only be configured when initializing the server.

17.4.1.40 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.6 to a slave running MySQL 5.7, from a master running MySQL 5.7 to a slave running MySQL 8.0, and so on. However, you might encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are

using a chained or circular replication setup, you cannot use MySQL 8.0.1, MySQL 8.0.2, and MySQL 8.0.4 concurrently, although you could use any two of these releases together.

Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves might be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 17.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 17.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 17.4.1, “Replication Features and Issues”](#).

17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#)

When you upgrade a master to 8.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 8.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 8.0.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 8.0 format.

Changes affecting operations in strict SQL mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`) may result in replication failure on an upgraded slave. If you use statement-based logging (`binlog_format=STATEMENT`), if a slave is upgraded before the master, the nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

The default character set has changed to `utf8mb4` in MySQL 8.0. In a replicated setting, when upgrading from MySQL 5.7 to 8.0, it is advisable to change the default character set back to the character set used in MySQL 5.7 before upgrading. After the upgrade is completed, the default character set can be changed to

`utf8mb4`. Assuming that the previous defaults were used, one way to preserve them is to start the server with these lines in the `my.cnf` file:

```
[mysqld]
character_set_server=latin1
collation_server=latin1_swedish_ci
```

After the slaves have been upgraded, shut down the master, upgrade it to the same 8.0.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 8.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 8.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 8.0 format. These too are recognized by the 8.0 slaves.

In other words, when upgrading to MySQL 8.0, the slaves must be MySQL 8.0 before you can upgrade the master to 8.0. Note that downgrading from 8.0 to older versions does not work so simply: You must ensure that any 8.0 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.11.1.3, “Changes in MySQL 8.0”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = OFF` statement. Alternatively, stop the master and restart it with the `--skip-log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to `OFF` earlier, execute a `SET sql_log_bin = ON` statement. If you restarted the master to disable the binary log, restart it without `--skip-log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. See [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade`.

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled.

Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. Binary logging is enabled by default. If binary logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are not running the master with any settings that disable binary logging, such as the `--skip-log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 17.2.2, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
 - Verify the privileges for the user being used for replication on the master.
 - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
 - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
 - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
 - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 17.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 17.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
 1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.

2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Ensure that the slave is running with binary logging enabled (the `log_bin` system variable), and with the `--log-slave-updates` option enabled, which causes the slave to log the updates that it receives from the master into its own binary logs. These settings are the defaults.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
 - All binary log files from the master
 - All binary log files from the slave
 - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
 - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
 - Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- [Section 18.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.
- [Section 18.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 18.3, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 18.5, “Group Replication Security”](#) explains how to secure a group.
- [Section 18.9, “Group Replication Technical Details”](#) provides in-depth information about how Group Replication works.

18.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

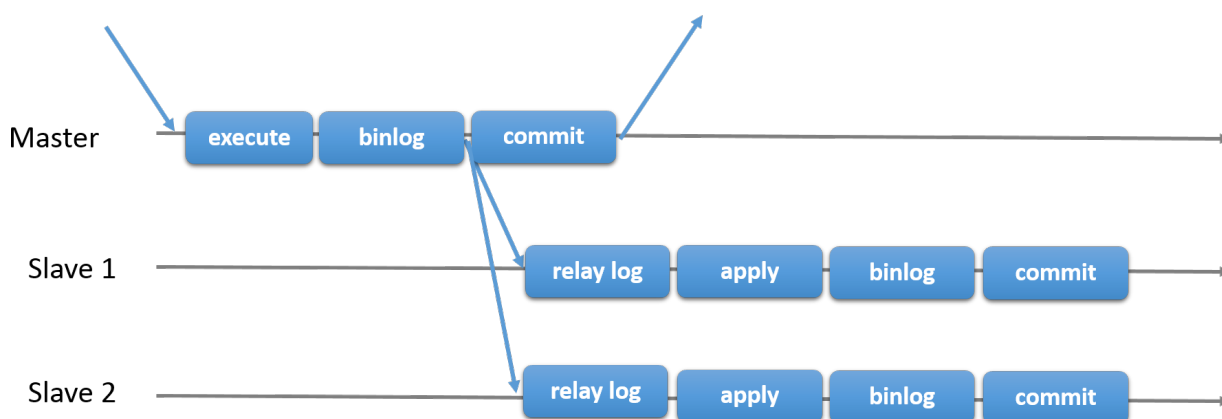

18.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

18.1.1.1 Primary-Secondary Replication

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

Figure 18.1 MySQL Asynchronous Replication

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has *received* the transaction. Only then does the Primary resume the commit operation.

Figure 18.2 MySQL Semisynchronous Replication

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Diagonal arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

18.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called *certification*. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.

Figure 18.3 MySQL Group Replication Protocol

Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

18.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see [MySQL Router 8.0](#).

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

18.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Master-Slave replication* - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

18.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

18.1.3.1 Failure Detection

There is a failure detection mechanism provided that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have

consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

18.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a *view*. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

18.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers (n) needed to tolerate f failures is then $n = 2 \times f + 1$.

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

Majority	Failures Tolerated
1	0
2	0
3	1
4	1
5	2
6	2
7	3

The next Chapter covers technical aspects of Group Replication.

18.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

18.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.

Figure 18.4 Group Architecture

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

18.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 5.7.17 and later. For more background information on MySQL plugins, see [Section 5.6, “MySQL Server Plugins”](#). This procedure assumes that MySQL Server was downloaded and unpacked into the directory named `mysql-8.0`. The following procedure uses one physical machine, therefore each MySQL server instance requires a specific data directory for the instance. Create the data directories in a directory named `data` and initialize each one.

```
mkdir data
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s1
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s2
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 18.5, “Group Replication Security”](#).

18.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 18.7.2, “Group Replication Limitations”](#).

Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in the instance's configuration file. See [Section 4.2.7, “Using Option Files”](#) for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as `s1` in this procedure. The following section shows an example server configuration.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-8.0/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication depends on a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers, to allow execution of only statements that can be safely logged using a GTID, and to disable writing checksums for events written to the binary log.

If you are using a version of MySQL earlier than 8.0.3, where the defaults were improved for replication, you need to add these lines to the member's option file.

```
log_bin=binlog
log_slave_updates=ON
binlog_format=ROW
master_info_repository=TABLE
relay_log_info_repository=TABLE
```

These settings instruct the server to turn on binary logging, use row-based format, to store replication metadata in system tables instead of files and disable binary log event checksums. For more details see [Section 18.7.1, “Group Replication Requirements”](#).

Group Replication Settings

At this point the `my.cnf` file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24901"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group=off
```

Note

The `loose-` prefix used for the `group_replication` variables above instructs the server to continue to start if the Group Replication plugin has not been loaded at the time the server is started.

- Configuring `transaction_write_set_extraction` instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm. From MySQL 8.0.2, this setting is the default, so this line can be omitted.
- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa".

The value of `group_replication_group_name` must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log. Use `SELECT UUID()` to generate a UUID.

- Configuring `group_replication_start_on_boot` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to on so that Group Replication starts automatically upon server boot.
- Configuring `group_replication_local_address` tells the plugin to use the network address 127.0.0.1 and port 24901 for internal communication with other members in the group.

**Important**

Group Replication uses this address for internal member-to-member connections using XCom. This address must be different to the hostname and port used for SQL and it must not be used for client applications. It must be reserved for internal communication between the members of the group while running Group Replication.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address you could use the IP of the machine, such as 10.0.0.1. If you use hostnames then you must use a fully qualified name and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. The recommended port for `group_replication_local_address` is 33061. In this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used for the internal communication network address.

- Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed at `performance_schema.replication_group_members`. Usually the `group_replication_group_seeds` list contains the `hostname:port` of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

**Important**

The `hostname:port` listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the SQL `hostname:port` used for client connections, and shown for example in `performance_schema.replication_group_members` table.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

**Warning**

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not.

Important

This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

18.2.1.3 User Credentials

Group Replication uses the asynchronous replication protocol to achieve [Section 18.9.5, “Distributed Recovery”](#), synchronizing group members before joining them to the group. The distributed recovery process relies on a replication channel named `group_replication_recovery` which is used to transfer transactions from donor members to members that join the group. Therefore you need to set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member recovery replication channels.

Start the server using the options file:

```
mysql-8.0/bin/mysqld --defaults-file=data/s1/s1.cnf
```

Create a MySQL user with the `REPLICATION-SLAVE` privilege. This process can be captured in the binary log and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. To disable binary logging, connect to server `s1` and issue the following statements:

```
mysql> SET SQL_LOG_BIN=0;
```

In the following example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password.

```
mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

If binary logging was disabled, enable it again once the user has been created.

```
mysql> SET SQL_LOG_BIN=1;
```

Once the user has been configured, use the `CHANGE MASTER TO` statement to configure the server to use the given credentials for the `group_replication_recovery` replication channel the next time it needs to recover its state from another member. Issue the following, replacing `rpl_user` and `password` with the values used when creating the user.

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\\
    FOR CHANNEL 'group_replication_recovery';
```

Distributed recovery is the first step taken by a server that joins the group and does not have the same set of transactions as the group members. If these credentials are not set correctly for the `group_replication_recovery` replication channel and the `rpl_user` as shown, the server cannot connect to the donor members and run the distributed recovery process to gain synchrony with the other group members, and hence ultimately cannot join the group.

Similarly, if the server cannot correctly identify the other members via the server's `hostname` the recovery process can fail. It is recommended that operating systems running MySQL have a properly configured unique `hostname`, either using DNS or local settings. This `hostname` can be verified in the `Member_host` column of the `performance_schema.replication_group_members` table. If multiple group members externalize a default `hostname` set by the operating system, there is a chance of the member not resolving to the correct member address and not being able to join the group. In such a situation use `report_host` to configure a unique `hostname` to be externalized by each of the servers.

Using Group Replication and the Caching SHA-2 User Credentials Plugin

By default, users created in MySQL 8 use [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#). If the `rpl_user` you configure for distributed recovery uses the caching SHA-2 authentication plugin and you are not using [Section 18.5.2, “Secure Socket Layer Support \(SSL\)”](#) for the `group_replication_recovery` replication channel, RSA key-pairs are used for password exchange, see [Section 6.4.3, “Creating SSL and RSA Certificates and Keys”](#). You can either copy the public key of the `rpl_user` to the member that should recover its state from the group, or configure the donors to provide the public key when requested.

The more secure approach is to copy the public key of the `rpl_user` to the member that should recover the group state from the donors. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the member joining the group with the path to the public key for the `rpl_user`.

Optionally, a less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the `rpl_user` to members when they join the group. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

18.2.1.4 Launching Group Replication

Once server `s1` has been configured and started, install the Group Replication plugin. Connect to the server and issue the following command:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Important

The `mysql.session` user must exist before you can load Group Replication. `mysql.session` was added in MySQL version 8.0.2. If your data dictionary was initialized using an earlier version you must run the `mysql_upgrade` procedure. If the upgrade is not run, Group Replication fails to start with the error message `There was an error when trying to access the server with user: mysql.session@localhost. Make sure the user is present in the server and that mysql_upgrade was ran after a server update..`

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	PROPRIETARY
(...)				
group_replication	ACTIVE	GROUP REPLICATION	group_replication.so	PROPRIETARY

To start the group, instruct server `s1` to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATUS
group_replication_applier	ce9be252-2b71-11e6-b8f4-00212844f856	myhost	24801	ONLINE

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
```

c1	c2
1	Luis

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	1	123	Server ver: 8.0.2-gr080-log, Binlog ver
binlog.000001	123	Previous_gtid	1	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa
binlog.000001	211	Query	1	270	BEGIN

binlog.000001	270	View_change	1	369	view_id=14724817264259180:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PRIMARY
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa
binlog.000001	831	Query	1	899	BEGIN
binlog.000001	899	Table_map	1	942	table_id: 108 (test.t1)
binlog.000001	942	Write_rows	1	984	table_id: 108 flags: STMT_END_F
binlog.000001	984	Xid	1	1011	COMMIT /* xid=38 */

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

18.2.1.5 Adding Instances to the Group

At this point, the group has one member in it, server s1, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the location of the data directory, the ports that s2 is going to be listening on or its `server_id`. These different lines are highlighted in the listing below.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s2
basedir=<full_path_to_bin>/mysql-8.0/

port=24802
socket=<full_path_to_sock_dir>/s2.sock

#
# Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE

#
# Group Replication configuration
#
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24902"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server.

```
mysql-8.0/bin/mysqld --defaults-file=data/s2/s2.cnf
```

Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. Issue the following statements on s2.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\\
FOR CHANNEL 'group_replication_recovery';
```

**Tip**

If you are using the caching SHA-2 authentication plugin, the default in MySQL 8, see [Using Group Replication and the Caching SHA-2 User Credentials Plugin](#).

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

**Tip**

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to ON in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as read-write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when the `super_read_only` variable is set to ON then it is set to OFF upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two *ONLINE* servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATUS
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	myhost	24801	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	myhost	24802	ONLINE

As server s2 is also marked as *ONLINE*, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

```
mysql> SELECT * FROM test.t1;
```

```
+-----+
| c1 | c2 |
+-----+
| 1 | Luis |
+-----+
```

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	2	123	Server ver: 8.0.3-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	2	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PRIMAR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=30 */
binlog.000001	1002	Gtid	1	1063	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	1063	Query	1	1122	BEGIN
binlog.000001	1122	View_change	1	1261	view_id=14724832985483517:2
binlog.000001	1261	Query	1	1326	COMMIT

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-8.0/

port=24803
socket=<full_path_to_sock_dir>/s3.sock

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE

#
```

```
# Group Replication configuration
#
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24903"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

2. Start the server

```
mysql-8.0/bin/mysqld --defaults-file=data/s3/s3.cnf
```

3. Configure the recovery credentials for the group_replication_recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\\
FOR CHANNEL 'group_replication_recovery';
```

4. Install the Group Replication plugin and start it.

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATUS
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	myhost	24801	ONLINE
group_replication_applier	7eb217ff-6df3-11e6-966c-00212844f856	myhost	24803	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	myhost	24802	ONLINE

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

```
mysql> SELECT * FROM test.t1;
```

c1	c2
1	Luis

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
----------	-----	------------	-----------	-------------	------

binlog.000001	4	Format_desc	3	123	Server ver: 8.0.3-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	3	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1

18.3 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that the Performance Schema is enabled. Group Replication adds the following tables:

- [performance_schema.replication_group_member_stats](#)
- [performance_schema.replication_group_members](#)

These Performance Schema replication tables also show information about Group Replication:

- [performance_schema.replication_connection_status](#)
- [performance_schema.replication_applier_status](#)

The replication channels created by the Group Replication plugin are named:

- [group_replication_recovery](#) - This channel is used for the replication changes that are related to the distributed recovery phase.
- [group_replication_applier](#) - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe the information available in each of these tables.

18.3.1 Replication_group_member_stats

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The [performance_schema.replication_group_member_stats](#) table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can

be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made.

Table 18.1 replication_group_member_stats

Field	Description
Channel_name	The name of the Group Replication channel.
View_id	The current view identifier for this group.
Member_id	The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.
Count_transactions_in_queue	The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.
Count_transactions_checked	The number of transactions that have been checked for conflicts.
Count_conflicts_detected	The number of transactions that did not pass the conflict detection check.
Count_transactions_rows_validating	The current size of the conflict detection database (against which each transaction is certified).
Transactions_committed_all_members	The transactions that have been successfully committed on all members of the replication group. This is updated at a fixed time interval.
Last_conflict_free_transaction	The transaction identifier of the last conflict free transaction checked.
Count_transactions_remote_in_applier_queue	The number of transactions that this member has received from the replication group which are waiting to be applied.
Count_transactions_remote_applied	The number of transactions that this member has received from the replication group which have been applied.
Count_transactions_local_proposed	The number of transactions that this member originated and sent to the replication group for coordination.
Count_transactions_local_rollback	The number of transactions that this member originated that were rolled back after being sent to the replication group.

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members is delayed and is not able to keep up to date with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

18.3.2 Replication_group_members

This table is used for monitoring the status of the different server instances that are tracked in the current view, or in other words are part of the group and as such are tracked by the membership service. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member.

Table 18.2 replication_group_members

Field	Description
Channel_name	The name of the Group Replication channel.
Member_id	The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.
Member_host	The network address of the group member.
Member_port	The MySQL connection port on which the group member is listening.
Member_state	The current state of the group member (which can be ONLINE , ERROR , RECOVERING , OFFLINE or UNREACHABLE).
Member_role	The role of the member in the group, either PRIMARY or SECONDARY .
Member_version	The MySQL version of the group member.

For more information about the [Member_host](#) value and its impact on the distributed recovery process, see [Section 18.2.1.3, “User Credentials”](#).

18.3.3 Replication_connection_status

When connected to a group, some fields in this table show information regarding Group Replication. For instance, the transactions that have been received from the group and queued in the applier queue (the relay log).

Table 18.3 replication_connection_status

Field	Description
Channel_name	The name of the Group Replication channel.
Group_name	Shows the value of the name of the group. It is always a valid UUID.
Source_UUID	Shows the identifier for the group. It is similar to the group name and it is used as the UUID for all the transactions that are generated during group replication.
Service_state	Shows whether the member is a part of the group or not. The possible values of service state can be {ON, OFF and CONNECTING};
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

18.3.4 Replication_applier_status

The state of the Group Replication related channels and threads can be observed using the regular `replication_applier_status` table as well. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

Table 18.4 replication_applier_status

Field	Description
Channel_name	The name of the Group Replication channel.

Field	Description
Service_state	Shows whether the applier service is ON or OFF.
Remaining_delay	Shows whether there is some applier delay configured.
Count_transactions_retries	The number of retries performed while applying a transaction.
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

18.3.5 Group Replication Server States

The table `replication_group_members` is updated whenever there is a view change, for example when the configuration of the group is dynamically changed. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together.

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information may be reported, depending on which server is queried. Note that if the server has left the group then obviously it cannot report updated information about other servers' state. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

Table 18.5 Server State

Field	Description	Group Synchronized
ONLINE	The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.	Yes
RECOVERING	The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.	No
OFFLINE	The plugin is loaded but the member does not belong to any group.	No
ERROR	The state of the member. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.	No
UNREACHABLE	Whenever the local failure detector suspects that a given server is not reachable, because maybe it has crashed or was disconnected involuntarily, it shows that server's state as 'unreachable'.	No

Important

Once an instance enters `ERROR` state, the `super_read_only` option is set to `ON`. To leave the `ERROR` state you must manually configure the instance with `super_read_only=OFF`.

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

18.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups. .

18.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or router.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

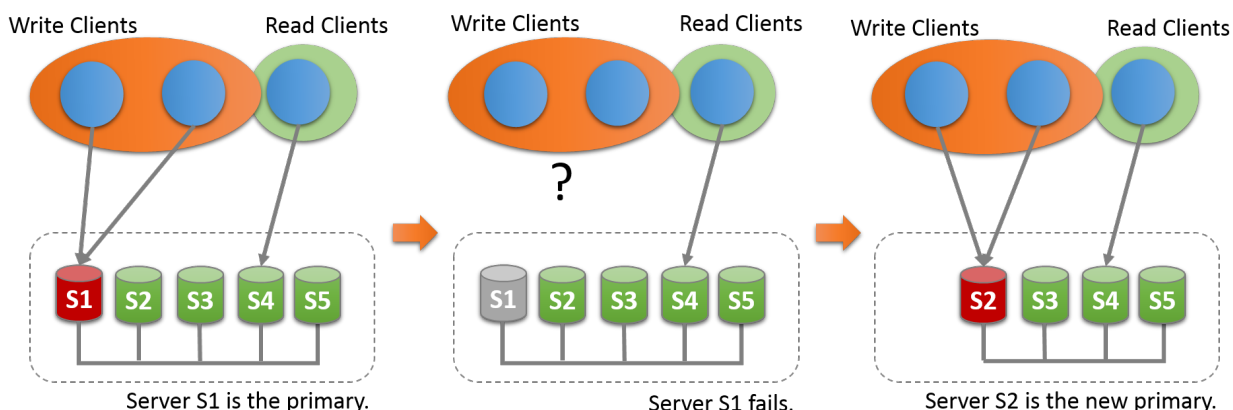

These checks can be deactivated by setting the option

`group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

18.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (with `super-read-only=ON`). This happens automatically. The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

Figure 18.5 New Primary Election

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single server writes to the group. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode they are not. Upon primary member failure, an automatic primary election mechanism chooses the new primary member. The election process is performed by looking at the new view, and ordering the potential new primaries based on the value of `group_replication_member_weight`. Assuming the group is operating with all members running the same MySQL version, then the member with the highest value for `group_replication_member_weight` is elected as the new primary. In the event that multiple servers have the same `group_replication_member_weight`, the servers are then prioritized based on their `server_uuid` in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-write and the other secondaries remain as secondaries, and as such, read-only.

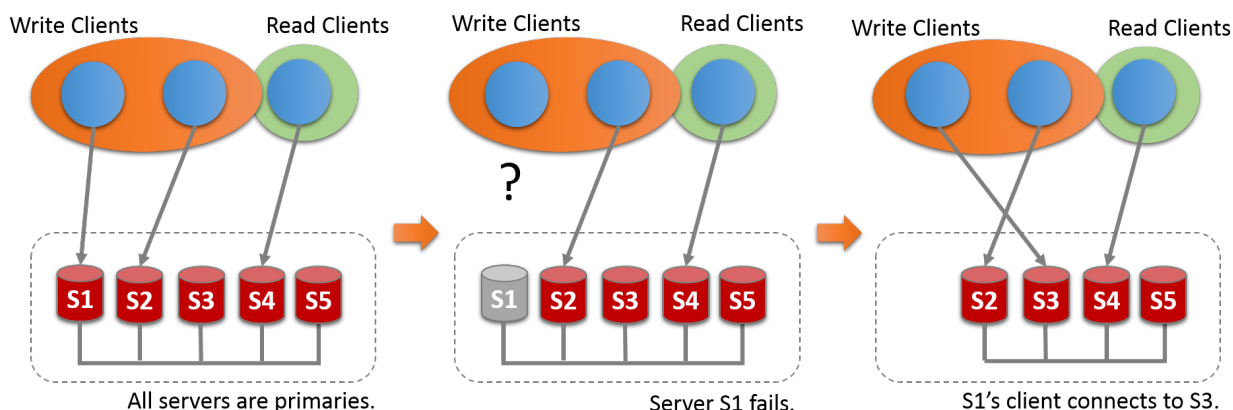

If the group is operating with members that are running different versions of MySQL then the election process can be impacted. For example, if any member does not support `group_replication_member_weight`, then the primary is chosen based on `server_uuid` order from the members of the lower major version. Alternatively, if all members running different MySQL versions do support `group_replication_member_weight`, the primary is chosen based on `group_replication_member_weight` from the members of the lower major version.

It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing the client applications to it.

18.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure since there is no server playing any special role.

Figure 18.6 Client Failover

All servers are set to read-write mode when joining the group.

18.4.1.3 Finding the Primary

To find out which server is currently the primary when deployed in single-primary mode, use the `MEMBER_ROLE` column in the `performance_schema.replication_group_members` table. For example:

```
sql> SELECT MEMBER_HOST, MEMBER_ROLE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_HOST | MEMBER_ROLE |
```

remote1.example.com	PRIMARY
remote2.example.com	SECONDARY
remote3.example.com	SECONDARY

Warning

The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

Alternatively use the `group_replication_primary_member` status variable.

```
mysql> SHOW STATUS LIKE 'group_replication_primary_member'
```

18.4.2 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

Note

A donor is picked randomly from the list of online members in the current view.

Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a server joining the group already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the server joining the group.

One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

**Note**

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

Number of Attempts

The number of attempts a server joining the group makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable. The following command sets the maximum number of attempts to connect to a donor to 10.

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the server joining the group makes connecting to each one of the suitable donors.

Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the server joining the group is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A does not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the server joining the group has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

18.4.3 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

**Note**

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

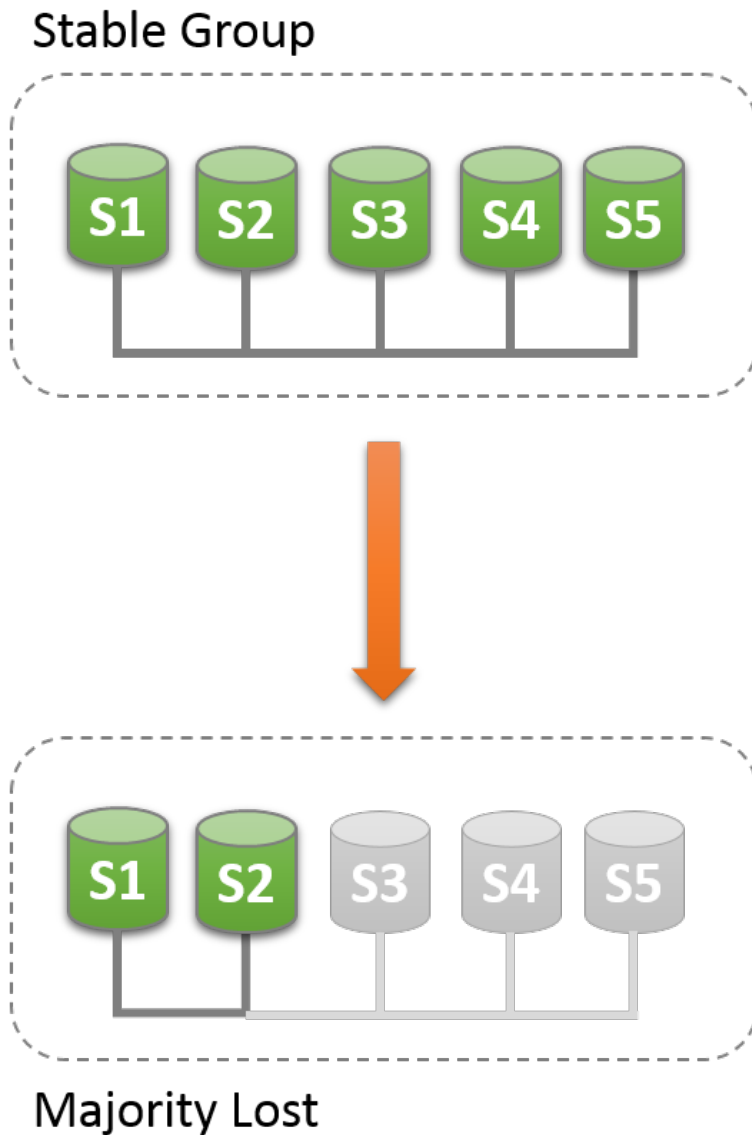

**Tip**

A primary that has been excluded from a group after a majority loss followed by a reconfiguration can contain extra transactions that are not included in the new group. If this happens, the attempt to add back the excluded member from the group results in an error with the message `This member has more executed transactions than those present in the group.`

Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 18.7 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier [199b2df7-4aaf-11e6-bb16-28b2bd168d07](#)
- Server s2 with member identifier [199bb88e-4aaf-11e6-babe-28b2bd168d07](#)
- Server s3 with member identifier [1999b9fb-4aaf-11e6-bb54-28b2bd168d07](#)
- Server s4 with member identifier [19ab72fc-4aaf-11e6-bb51-28b2bd168d07](#)
- Server s5 with member identifier [19b33846-4aaf-11e6-ba81-28b2bd168d07](#)

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	ONLINE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	ONLINE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	ONLINE

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

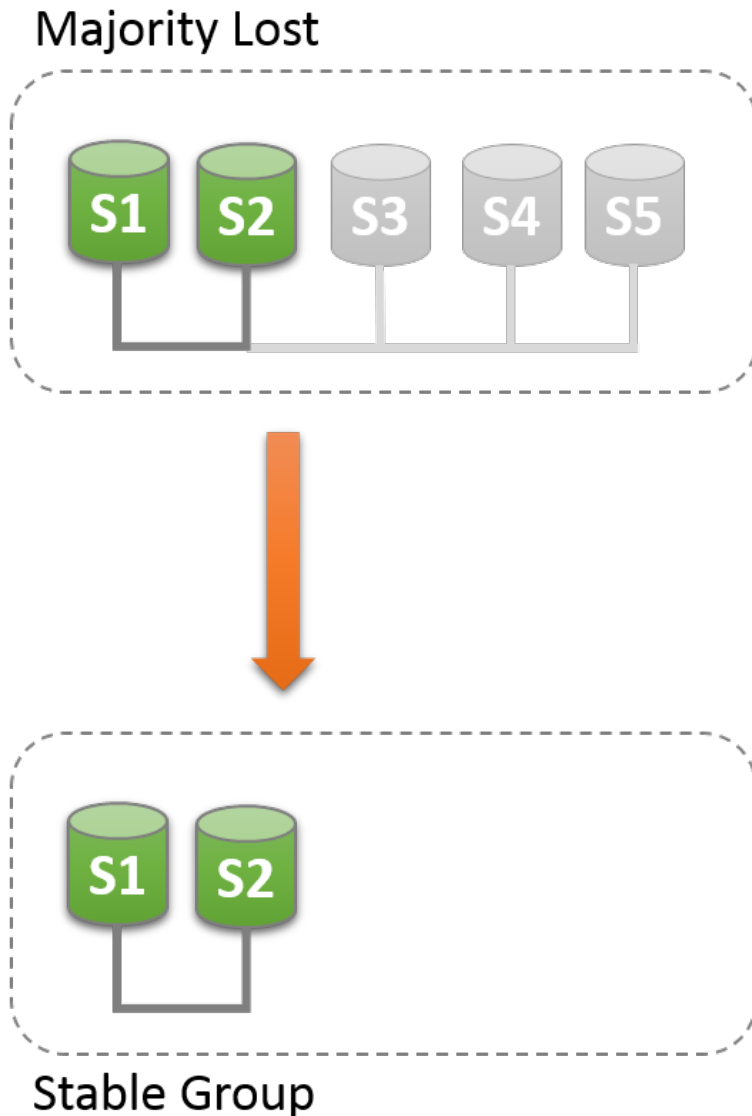

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	UNREACHABLE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	UNREACHABLE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	UNREACHABLE

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could chose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 18.8 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	UNREACHABLE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	UNREACHABLE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	UNREACHABLE

The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
```

@@group_replication_local_address
127.0.0.1:10000

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
```

@@group_replication_local_address
127.0.0.1:10001

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	b5ffe505-4ab6-11e6-b04b-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	b60907e7-4ab6-11e6-afb7-28b2bd168d07	127.0.0.1	13001	ONLINE

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	b5ffe505-4ab6-11e6-b04b-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	b60907e7-4ab6-11e6-afb7-28b2bd168d07	127.0.0.1	13001	ONLINE

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable

but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

18.4.4 Using MySQL Enterprise Backup with Group Replication

This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup; the same technique can be used to quickly add a new member to a group. Generally, backing up a Group Replication member is no different to backing up a stand-alone MySQL instance. The recommended process is to use MySQL Enterprise Backup image backups and a subsequent restore, for more information see [Backup Operations](#).

The required steps can be summarized as:

- Use MySQL Enterprise Backup to create a backup of the source server instance with simple timestamps.
- Copy the backup to the destination server instance.
- Use MySQL Enterprise Backup to restore the backup to the destination server instance.

The following procedure demonstrates this process. Consider the following group:

```
mysql> SELECT * member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

member_host	member_port	member_state
node1	3306	ONLINE
node2	3306	ONLINE
node3	3306	ONLINE

In this example the group is operating in single-primary mode and the primary group member is `node1`. This means that `node2` and `node3` are secondaries, operating in read-only mode (`super_read_only=ON`). Using MySQL Enterprise Backup, a recent backup has been taken of `node2` by issuing:

```
mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
--backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -pmYsecr3t \
--host=127.0.0.1 --no-history-logging backup-to-image
```

The `--no-history-logging` option is used because `node2` is a secondary, and because it is read-only MySQL Enterprise Backup cannot write status and metadata tables to the instance.

Assume that the primary member, `node1`, encounters irreconcilable corruption. After a period of time the server instance is rebuilt but all the data on the member was lost. The most recent backup of member `node2` can be used to rebuild `node1`. This requires copying the backup files from `node2` to `node1` and then using MySQL Enterprise Backup to restore the backup to `node1`. The exact way you copy the backup files depends on the operating system and tools available to you. In this example we assume Linux servers and use SCP to copy the files between servers:

```
node2/backups # scp my.mbi_2206_1429 node1:/backups
```

Connect to the destination server, in this case `node1`, and restore the backup using MySQL Enterprise Backup by issuing:

```
mysqlbackup --defaults-file=/etc/my.cnf \
--backup-image=/backups/my.mbi_2206_1429 \
```

```
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

The backup is restored to the destination server.

If your group is using multi-primary mode, extra care must be taken to prevent writes to the database during the MySQL Enterprise Backup restore stage and the Group Replication recovery phase. Depending on how the group is accessed by clients, there is a possibility of DML being executed on the newly joined instance the moment it is accessible on the network, even prior to applying the binary log before rejoining the group. To avoid this, configure the member's option file with:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

This ensures that Group Replication is not started on boot, that the member defaults to read-only and that the event_scheduler is turned off while the member catches up with the group during the recovery phase. Adequate error handling must be configured on the clients to recognise that they are, temporarily, prevented from performing DML during this period.

Start the server instance and connect an SQL client. The restored backup has old binary log files and related metadata that are specific to the instance that was backed up. To reset all of that issue:

```
mysql> RESET MASTER;
```

The restored backup has the relay log files associated with the source instance, in this case `node2`. Therefore reset the logs, metadata, and configuration for all replication channels by issuing:

```
mysql> RESET SLAVE ALL;
```

For the restored instance to be able to recover automatically using Group Replication's built-in distributed recovery (see [Section 18.9.5, “Distributed Recovery”](#)), configure the `gtid_executed` variable. The MySQL Enterprise Backup backup from `node2` includes the `backup_gtid_executed.sql` file, usually at the path `datadir/meta/`, which contains the information required to configure `node1`. Disable binary logging and then use this file to configure the `gtid_executed` variable by issuing:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/meta/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Configure the [Section 18.2.1.3, “User Credentials”](#) and start Group Replication, for example:

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' /
FOR CHANNEL 'group_replication_recovery';
mysql> START GROUP_REPLICATION;
```

The instance attempts to join the group, executing the restored binary logs from the correct location. Once the instance gains synchrony with the group, it joins as a secondary, with `super_read_only=ON`. Reset the temporary configuration changes made during the restore. Turn the event scheduler back on in the running process:

```
mysql> SET global event_scheduler=ON;
```

Edit the following system variables in the instance's option file:

```
group_replication_start_on_boot=ON
super_read_only=ON
event_scheduler=ON
```

18.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

18.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server `s1`, then when server `s2` is establishing a connection to `s1` for the purpose of engaging group communication, then `s1` first checks the whitelist before accepting the connection from `s2`. If `s2` is in the whitelist, then `s1` accepts the connection, otherwise `s1` rejects the connection attempt by `s2`.

If you do not specify a whitelist explicitly, the server automatically sets the whitelist to the private networks that the server has an interface on. This means that a server, even if it has interfaces on public IPs, does not by default allow connections from external hosts.

Whenever the IP whitelist is set to `AUTOMATIC`, an entry is added in the error log, similar to:

```
2017-10-07T06:40:49.320686Z 4 [Note] Plugin group_replication reported: '[GCS] Added automatically IP rang
```

You can improve the security of the group further by manually setting the list of hosts that are permitted to use group communication connections. You can specify host names (from MySQL 8.0.4), simple IP addresses, or CIDR notation, in any combination. A comma must separate each entry. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,example.org,w
mysql> START GROUP_REPLICATION;
```

The localhost IP address (127.0.0.1) is always added to the whitelist. If not explicitly, it is implicitly and automatically added. IPv6 addresses, and host names that resolve to IPv6 addresses, are not supported.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

To join a replication group, a server only needs to be whitelisted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `--loose-group_replication_group_seeds` option

in the configuration for the server joining the group. However, note that when the replication group is reconfigured, the group members re-establish connections between themselves. If a group member is only whitelisted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not whitelist it. To avoid this scenario entirely, specify the same whitelist for all servers that are members of the replication group.

Note

It is possible to configure different whitelists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different whitelists to meet your security requirements, ensure that there is sufficient overlap between the whitelists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

18.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports OpenSSL and wolfSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the server joining the group establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the server joining the group connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the server joining the group to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '../cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group

Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see [Section 6.4.2, "Command Options for Encrypted Connections"](#). The options which configure Group Replication are shown in the following table.

Table 18.6 SSL Options

Option	Description
<code>ssl_key</code>	Path of key file. To be used as client and server certificate.
<code>ssl_cert</code>	Path of certificate file. To be used as client and server certificate.
<code>ssl_ca</code>	Path of file with SSL Certificate Authorities that are trusted.
<code>ssl_capath</code>	Path of directory containing certificates for SSL Certificate Authorities that

Plugin
Configuration
Description
are trusted.
<code>ssl_crl</code> Path of file containing the certificate revocation lists.
<code>ssl_crlpath</code> Path of directory containing revoked certificate lists.
<code>ssl_cipher</code> List of ciphers to use while encrypting data over the connection.
<code>ssl_version</code> Version of communication will use this version and its protocols.

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

Table 18.7 `group_replication_ssl_mode` configuration values

Description
<code>DISABLED</code> An

Description

unencrypted
connection
(*default*).

REQUIRED

a
secure
connection
if
the
server
supports
secure
connections.

VERIFY_CA

REQUIRED,
but
additionally
verify
the
server
TLS
certificate
against
the
configured
Certificate
Authority
(CA)
certificates.

VERIFY_IDENTITY

VERIFY_CA,
but
additionally
verify
that
the
server
certificate
matches
the
host
to
which
the
connection
is
attempted.

The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

18.5.3 Virtual Private Networks (VPN)

There is nothing preventing Group Replication from operating over a virtual private network. At its core, it just relies on an IPv4 socket to establish connections between servers for the purpose of propagating messages between them.

18.6 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "group_replication".

Important

Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.

- `group_replication_allow_local_disjoint_gtids_join`

Property	Value
Command-Line Format	<code>--group-replication-allow-local-disjoint-gtids-join=value</code>
Deprecated	Yes (removed in 8.0.4)
System Variable	<code>group_replication_allow_local_disjoint_gtids_join</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Removed in version 8.0.4. Allow the current server to join the group even if it has transactions not present in the group.

Warning

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- `group_replication_allow_local_lower_version_join`

Property	Value
Command-Line Format	<code>--group-replication-allow-local-lower-version-join=value</code>
System Variable	<code>group_replication_allow_local_lower_version_</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_auto_increment_increment`

Property	Value
Command-Line Format	<code>--group-replication-auto-increment-increment=value</code>
System Variable	<code>group_replication_auto_increment_increment</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	7
Minimum Value	1
Maximum Value	65535

Determines the interval between successive column values for transactions that execute on this server instance.

- `group_replication_bootstrap_group`

Property	Value
Command-Line Format	<code>--group-replication-bootstrap-group=value</code>
System Variable	<code>group_replication_bootstrap_group</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two

servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_communication_debug_options`

Property	Value
Command-Line Format	<code>--group-replication-communication-debug-options=value</code>
Introduced	8.0.3
System Variable	<code>group_replication_communication_debug_options</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>GCS_DEBUG_NONE</code>
Valid Values	<code>GCS_DEBUG_NONE</code> <code>GCS_DEBUG_BASIC</code> <code>GCS_DEBUG_TRACE</code> <code>XCOM_DEBUG_BASIC</code> <code>XCOM_DEBUG_TRACE</code> <code>GCS_DEBUG_ALL</code>

Configures the level of debugging messages to provide for the different Group Replication components, such as Group Communication System (GCS) and XCOM. The debug information is stored in the `GCS_DEBUG_TRACE` file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- `GCS_DEBUG_NONE` disables all debugging levels for both GCS and XCOM
- `GCS_DEBUG_BASIC` enables basic debugging information in GCS
- `GCS_DEBUG_TRACE` enables trace information in GCS
- `XCOM_DEBUG_BASIC` enables basic debugging information in XCOM
- `XCOM_DEBUG_TRACE` enables trace information in XCOM
- `GCS_DEBUG_ALL` enables all debugging levels for both GCS and XCOM

Setting the debug level to `GCS_DEBUG_NONE` only has an effect when provided without any other option. Setting the debug level to `GCS_DEBUG_ALL` overrides all other options.

- `group_replication_components_stop_timeout`

Property	Value
Command-Line Format	<code>--group-replication-components-stop-timeout=value</code>
System Variable	<code>group_replication_components_stop_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	31536000
Minimum Value	2
Maximum Value	31536000

Timeout, in seconds, that Group Replication waits for each of the components when shutting down.

- `group_replication_compression_threshold`

Property	Value
Command-Line Format	<code>--group-replication-compression-threshold=value</code>
System Variable	<code>group_replication_compression_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000000
Minimum Value	0
Maximum Value	4294967295

The value in bytes above which (LZ4) compression is enforced. When set to zero, deactivates compression.

- `group_replication_enforce_update_everywhere_checks`

Property	Value
Command-Line Format	<code>--group-replication-enforce-update-everywhere-checks=value</code>
System Variable	<code>group_replication_enforce_update_everywhere_checks</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enable or disable strict consistency checks for multi-primary update everywhere.

- `group_replication_exit_state_action`

Property	Value
Command-Line Format	<code>--group-replication-exit-state-action=value</code>
System Variable	<code>group_replication_exit_state_action</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>ABORT_SERVER</code>
Valid Values	<code>ABORT_SERVER</code> <code>READ_ONLY</code>

Configures how Group Replication behaves when a server instance leaves the group unintentionally, for example after encountering an applier error. When `group_replication_exit_state_action` is set to `ABORT_SERVER`, the instance shuts itself down, and when `group_replication_exit_state_action` is set to `READ_ONLY` the server switches itself to super read only mode instead.

- `group_replication_flow_control_applier_threshold`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-applier-threshold=value</code>
System Variable	<code>group_replication_flow_control_applier_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>25000</code>
Minimum Value	<code>0</code>
Maximum Value	<code>2147483647</code>

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_certifier_threshold`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-certifier-threshold=value</code>
System Variable	<code>group_replication_flow_control_certifier_threshol</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	0
Maximum Value	2147483647

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_hold_percent`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-hold-percent=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_hold_percent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	100

Defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_max_commit_quota`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-max-commit-quota=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_max_commit_quota</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

Defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. Cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-member-quota-percent=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_member_quota_percent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100

Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-min-quota=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_min_quota</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

Controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_min_recovery_quota`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-min-recovery-quota=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_min_recovery_</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

Controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_mode`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-mode=value</code>
System Variable	<code>group_replication_flow_control_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>QUOTA</code>
Valid Values	<code>DISABLED</code> <code>QUOTA</code>

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_period`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-period=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_period</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	60

Defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

- `group_replication_flow_control_release_percent`

Property	Value
Command-Line Format	<code>--group-replication-flow-control-release-percent=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_flow_control_release_percent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	1000

Defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- `group_replication_force_members`

Property	Value
Command-Line Format	<code>--group-replication-force-members=value</code>
System Variable	<code>group_replication_force_members</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

A list of peer addresses as a comma separated list such as `host1:port1,host2:port2`. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked. You need to manually kill the excluded servers. Any invalid host names in the list could

cause subsequent `START GROUP_REPLICATION` statements to fail because they could block group membership.

- `group_replication_group_name`

Property	Value
Command-Line Format	<code>--group-replication-group-name=value</code>
System Variable	<code>group_replication_group_name</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The name of the group which this server instance belongs to. Must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log.

Important

A unique UUID must be used.

- `group_replication_group_seeds`

Property	Value
Command-Line Format	<code>--group-replication-group-seeds=value</code>
System Variable	<code>group_replication_group_seeds</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

A list of group members that provide a member which joins the group with the data required for the joining member to gain synchrony with the group. The list consists of the seed member's network addresses specified as a comma separated list, such as `host1:port1,host2:port2`.

Important

These addresses must not be the member's SQL hostname and port.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid host names, issuing `START GROUP_REPLICATION` fails.

- `group_replication_gtid_assignment_block_size`

Property	Value
Command-Line Format	<code>--group-replication-gtid-assignment-block-size=value</code>
System Variable	<code>group_replication_gtid_assignment_block_size</code>

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000000
Minimum Value	1
Maximum Value (64-bit platforms)	9223372036854775807
Maximum Value (32-bit platforms)	4294967295

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserves more when needed.

- [group_replication_ip_whitelist](#)

Property	Value
Command-Line Format	<code>--group-replication-ip-whitelist=value</code>
System Variable	group_replication_ip_whitelist
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	AUTOMATIC

Specifies which hosts are permitted to connect to the group. By default, this system variable is set to [AUTOMATIC](#), which permits connections from private subnetworks active on the host. Active interfaces on the host are scanned and those with addresses on private subnetworks are automatically added to the permitted list.

Alternatively, you can specify a whitelist of permitted hosts as a comma separated list of IPv4 addresses, subnet CIDR notation, or (from MySQL 8.0.4) host names, in any combination. For example:

```
192.0.2.22,198.51.100.0/24,example.org,www.example.com/24
```

Address 127.0.0.1 is always permitted to connect, even when not specified explicitly. IPv6 addresses, and host names that resolve to IPv6 addresses, are not supported.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as

DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

Property	Value
Command-Line Format	<code>--group-replication-local-address=value</code>
System Variable	<code>group_replication_local_address</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be reachable by all members of the group because it is used by XCOM, the internal group communication system.

Warning

Do not use this address for communication with the member.

Other Group Replication members contact this member through this `host:port` for all internal group communication. This is not the MySQL server SQL protocol host and port.

- `group_replication_member_weight`

Property	Value
Command-Line Format	<code>--group-replication-member-weight=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_member_weight</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	100

A percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- `member-1`: `group_replication_member_weight=30`, `server_uuid=aaaa`
- `member-2`: `group_replication_member_weight=40`, `server_uuid=bbbb`
- `member-3`: `group_replication_member_weight=40`, `server_uuid=cccc`
- `member-4`: `group_replication_member_weight=40`, `server_uuid=dddd`

during election of a new primary the members above would be sorted as `member-2`, `member-3`, `member-4`, and `member-1`. This results in `member-2` being chosen as the new primary in the event of failover. For more information, see [Section 18.4.1.1, “Single-Primary Mode”](#).

- `group_replication_member_expel_timeout`

Property	Value
Command-Line Format	<code>--group-replication-member-expel-timeout=value</code>
Introduced	8.0.13
System Variable	<code>group_replication_member_expel_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000

The period of time in seconds that a member waits before expelling from the group any member suspected of having failed. A member is expelled when its suspicion timeout has elapsed. On slow networks, or when there are expected machine slowdowns, increase the value of this option.

- `group_replication_poll_spin_loops`

Property	Value
Command-Line Format	<code>--group-replication-poll-spin-loops=value</code>
System Variable	<code>group_replication_poll_spin_loops</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_complete_at`

Property	Value
Command-Line Format	<code>--group-replication-recovery-complete-at=value</code>
System Variable	<code>group_replication_recovery_complete_at</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>TRANSACTIONS_APPLIED</code>
Valid Values	<code>TRANSACTIONS_CERTIFIED</code> <code>TRANSACTIONS_APPLIED</code>

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before it joined the group (`TRANSACTIONS_CERTIFIED`) or after it has received and applied them (`TRANSACTIONS_APPLIED`).

- `group_replication_recovery_get_public_key`

Property	Value
Command-Line Format	<code>--group-replication-recovery-get-public-key</code>
Introduced	8.0.4
System Variable	<code>group_replication_recovery_get_public_key</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to request from the master the public key required for RSA key pair-based password exchange. This variable applies to slaves that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the master does not send the public key unless requested.

If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`.

- `group_replication_recovery_public_key_path`

Property	Value
Command-Line Format	<code>--group-replication-recovery-public-key-path</code>

Property	Value
Introduced	8.0.4
System Variable	group_replication_recovery_public_key_path
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The path name to a file containing a slave-side copy of the public key required by the master for RSA key pair-based password exchange. The file must be in PEM format. This variable applies to slaves that authenticate with the [sha256_password](#) or [caching_sha2_password](#) authentication plugin. (For [sha256_password](#), setting [group_replication_recovery_public_key_path](#) applies only if MySQL was built using OpenSSL.)

If [group_replication_recovery_public_key_path](#) is set to a valid public key file, it takes precedence over [group_replication_recovery_get_public_key](#).

- [group_replication_recovery_reconnect_interval](#)

Property	Value
Command-Line Format	<code>--group-replication-recovery-reconnect-interval=value</code>
System Variable	group_replication_recovery_reconnect_interval
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	31536000

The sleep time, in seconds, between reconnection attempts when no donor was found in the group.

- [group_replication_recovery_retry_count](#)

Property	Value
Command-Line Format	<code>--group-replication-recovery-retry-count=value</code>
System Variable	group_replication_recovery_retry_count
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10

Property	Value
Minimum Value	0
Maximum Value	31536000

The number of times that the member that is joining tries to connect to the available donors before giving up.

- `group_replication_recovery_ssl_ca`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-ca=value</code>
System Variable	<code>group_replication_recovery_ssl_ca</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The path to a file that contains a list of trusted SSL certificate authorities.

- `group_replication_recovery_ssl_capath`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-capath=value</code>
System Variable	<code>group_replication_recovery_ssl_capath</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The path to a directory that contains trusted SSL certificate authority certificates.

- `group_replication_recovery_ssl_cert`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-cert=value</code>
System Variable	<code>group_replication_recovery_ssl_cert</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The name of the SSL certificate file to use for establishing a secure connection.

- `group_replication_recovery_ssl_cipher`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-cipher=value</code>
System Variable	<code>group_replication_recovery_ssl_cipher</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The list of permitted ciphers for SSL encryption.

- `group_replication_recovery_ssl_crl`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-crl=value</code>
System Variable	<code>group_replication_recovery_ssl_crl</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_crlpath`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-crlpath=value</code>
System Variable	<code>group_replication_recovery_ssl_crlpath</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_key`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-key=value</code>
System Variable	<code>group_replication_recovery_ssl_key</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	String

The name of the SSL key file to use for establishing a secure connection.

- `group_replication_recovery_ssl_verify_server_cert`

Property	Value
Command-Line Format	<code>--group-replication-recovery-ssl-verify-server-cert=value</code>
System Variable	<code>group_replication_recovery_ssl_verify_server_cert</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Make the recovery process check the server's Common Name value in the donor sent certificate.

- `group_replication_recovery_use_ssl`

Property	Value
Command-Line Format	<code>--group-replication-recovery-use-ssl=value</code>
System Variable	<code>group_replication_recovery_use_ssl</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether Group Replication recovery connection should use SSL or not.

- `group_replication_single_primary_mode`

Property	Value
Command-Line Format	<code>--group-replication-single-primary-mode=value</code>
System Variable	<code>group_replication_single_primary_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_ssl_mode`

Property	Value
Command-Line Format	<code>--group-replication-ssl-mode=value</code>
System Variable	<code>group_replication_ssl_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	DISABLED
Valid Values	DISABLED REQUIRED VERIFY_CA VERIFY_IDENTITY

Specifies the security state of the connection between Group Replication members.

- `group_replication_start_on_boot`

Property	Value
Command-Line Format	<code>--group-replication-start-on-boot=value</code>
System Variable	<code>group_replication_start_on_boot</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether the server should start Group Replication or not during server start.

- `group_replication_transaction_size_limit`

Property	Value
Command-Line Format	<code>--group-replication-transaction-size-limit=value</code>
System Variable	<code>group_replication_transaction_size_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value (>= 8.0.2)	150000000
Default Value	0
Minimum Value	0
Maximum Value	2147483647

Configures the maximum transaction size in bytes which the group accepts. Transactions larger than this size are rolled back. Use this option to avoid large transactions causing the group to fail. A large transaction can cause problems for a group, either in terms of memory allocation or network bandwidth consumption, which may cause the failure detector to trigger because a given member is unreachable while it is busy processing the large transaction. When set to 0 there is no limit to the size of transactions the group accepts, and there may be the risk of large transactions causing the group to fail. Adjust the value of this variable depending on the size of workload you require from the group.

- `group_replication_unreachable_majority_timeout`

Property	Value
Command-Line Format	<code>--group-replication-unreachable-majority-timeout=value</code>
Introduced	8.0.2
System Variable	<code>group_replication_unreachable_majority_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000

Configures how long members that suffer a network partition and cannot connect to the majority wait before leaving the group. By default set to 0, which means that members that find themselves in a minority due to a network partition wait forever to connect the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits forever for a network reconnection. Any transactions processed by the minority group are blocked until Group Replication is stopped using `STOP GROUP REPLICATION` on the members of the minority.

If configured to a number of seconds, members wait for this amount of time after losing contact with the majority of members before leaving the group. All pending transactions processed by the minority are rolled back and the servers in the minority partition move to the `ERROR` state and set themselves to `super_read_only=ON` mode.

**Warning**

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members shut down and enter `ERROR` state.

Group Replication Status Variable

This section describes the status variables which provide information about Group Replication. The variable has the following meaning:

- `group_replication_primary_member`

Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

**Warning**

The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

See [Section 18.4.1.3, “Finding the Primary”](#).

18.7 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

18.7.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the `InnoDB` transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, `InnoDB` provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.
- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified.
- **IPv4 Network.** The group communication engine used by MySQL Group Replication only supports IPv4. Therefore, Group Replication requires an IPv4 network infrastructure.
- **Network Performance.** Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other, and is impacted by both network latency as well as network bandwidth.

Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be on for it to operate. This option is enabled by default. See [Section 5.4.4, “The Binary Log”](#).
- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs from participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself. This option is enabled by default.
- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See [Section 17.2.1, “Replication Formats”](#).
- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).
- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. From MySQL 8.0.2, these options are set to `TABLE` by default, and from MySQL 8.0.3, the `FILE` setting is deprecated. See [Section 17.2.4.2, “Slave Status Logs”](#).
- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts. This option is enabled by default.
- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded slaves, enabling transactions to be applied in parallel. A nonzero value for `slave_parallel_workers` enables the multithreaded applier on the member, and up to 1024 parallel applier threads can be specified. Setting `slave_preserve_commit_order=1` ensures that the final commit of parallel transactions is in the same order as the original transactions, as required for Group Replication, which relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transaction in the same order. Finally, the setting `slave_parallel_type=LOGICAL_CLOCK`, which specifies the policy used to decide which transactions are allowed to execute in parallel on the slave, is required with `slave_preserve_commit_order=1`. Setting `slave_parallel_workers=0` disables parallel execution and gives the slave a single applier thread and no coordinator thread. With that setting, the `slave_parallel_type` and `slave_preserve_commit_order` options have no effect and are ignored.

18.7.2 Group Replication Limitations

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

**Tip**

Group Replication is built on GTID based replication, therefore you should also be aware of [Section 17.1.3.6, “Restrictions on Replication with GTIDs”](#).

- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.
- **Gap Locks.** The certification process does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

**Note**

Unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”](#)) or named locks (see [GET_LOCK\(\)](#)).
- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Very Large Transactions.** Individual transactions that result in GTID contents which are large enough that it cannot be copied between group members over the network within a 5 second window can cause failures in the group communication. To avoid this issue try and limit the size of your transactions as much as possible. For example, split up files used with [LOAD DATA INFILE](#) into smaller chunks.
- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, [SELECT .. FOR UPDATE](#) statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.
- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the

group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

18.8 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then [Section 18.9.7.2, "Message Compression"](#) can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 2 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port, configured by `group_replication_local_address`, for `mysqld` so that it can bind to it and listen there. To see which ports MySQL is currently allowed to use, issue `semanage port -l | grep mysqld`. Assuming the port configured is 33061, add the necessary port to those permitted by SELinux by issuing `semanage port -a -t mysqld_port_t -p tcp 33061`.

How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in master to slave replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See [Section 17.2.4.1, “The Slave Relay Log”](#) for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, the Group Replication recovery procedure is based on asynchronous replication which uses the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the new member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If a you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

Important

The assigned value is used directly and is not affected by the `--skip-name-resolve` option.

To configure `MEMBER_PORT` on a server, specify it using the `--report-port` option.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See [Section 18.4.1.3, “Finding the Primary”](#)

18.9 Group Replication Technical Details

This section provides more technical details about MySQL Group Replication.

18.9.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

Figure 18.9 Group Replication Plugin Block Diagram

The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.

The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine. The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see [Section 18.1, “Group Replication Background”](#)). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

18.9.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at [Section 18.1.3.2, “Group Membership”](#) powers all of this.

18.9.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

18.9.4 Data Definition Statements

In a Group Replication topology, care needs to be taken when executing data definition statements, also commonly known as data definition language (DDL).

MySQL 8.0 introduces support for atomic Data Definition Language (DDL) statements, where the complete DDL statement is either committed or rolled back as a single atomic transaction. However, DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a `COMMIT` before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as `START TRANSACTION ... COMMIT`, or combined with other statements within the same transaction.

Group Replication is based on an optimistic replication paradigm, where statements are optimistically executed and rolled back later if necessary. Each server executes and commits without securing group agreement first. Therefore, more care needs to be taken when replicating DDL statements in multi-primary mode. If you make schema changes (using DDL) and changes to the data that an object contains (using DML) for the same object, the changes need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency when operations are interrupted or only partially completed. If the group is deployed in single-primary mode this issue does not occur, because all changes are performed through the same server, the primary.

For details on atomic DDL support in MySQL 8.0, and the resulting changes in behavior for the replication of certain statements, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

18.9.5 Distributed Recovery

This section describes the process through which a member joining a group catches up with the remaining servers in the group, called distributed recovery.

18.9.5.1 Distributed Recovery Basics

This section is a high level summary. The following sections provide additional detail, by describing the phases of the procedure in more detail.

Group Replication distributed recovery can be summarized as the process through which a server gets missing transactions from the group so that it can then join the group having processed the same set of transactions as the other group members. During distributed recovery, the server joining the group buffers any transactions and membership events that happen while the server joining the group is receiving the transactions required from the group. Once the server joining the group has received all of the group's transactions, it applies the transactions that were buffered during the recovery process. At the end of this process the server then joins the group as an online member.

Phase 1

In the first phase, the server joining the group selects one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for providing the server joining the group all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between the donor and the server joining the group, see [Section 17.2.3, “Replication Channels”](#). Through this replication channel, the donor's binary logs are replicated until the point that the view change happened when the server joining the group became part of the group. The server joining the group applies the donor's binary logs as it receives them.

While the binary log is being replicated, the server joining the group also caches every transaction that is exchanged within the group. In other words it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the server joining the group then starts phase two: the catch up.

Phase 2

In this phase, the server joining the group proceeds to the execution of the cached transactions. When the number of transactions queued for execution finally reaches zero, the member is declared online.

Resilience

The recovery procedure withstands donor failures while the server joining the group is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the server joining the group fails over

to a new donor and resumes from that one. When that happens the server joining the group closes the connection to the failed server joining the group explicitly and opens a connection to a new donor. This happens automatically.

18.9.5.2 Recovering From a Point-in-time

To synchronize the server joining the group with the donor up to a specific point in time, the server joining the group and donor make use of the MySQL Global Transaction Identifiers (GTIDs) mechanism. See [Section 17.1.3, “Replication with Global Transaction Identifiers”](#). However, GTIDS only provide a means to realize which transactions the server joining the group is missing, they do not help marking a specific point in time to which the server joining the group must catch up, nor do they help conveying certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, provisioning the server joining the group with missing certification related data.

View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the "view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

18.9.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log, The following steps are taken:

Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

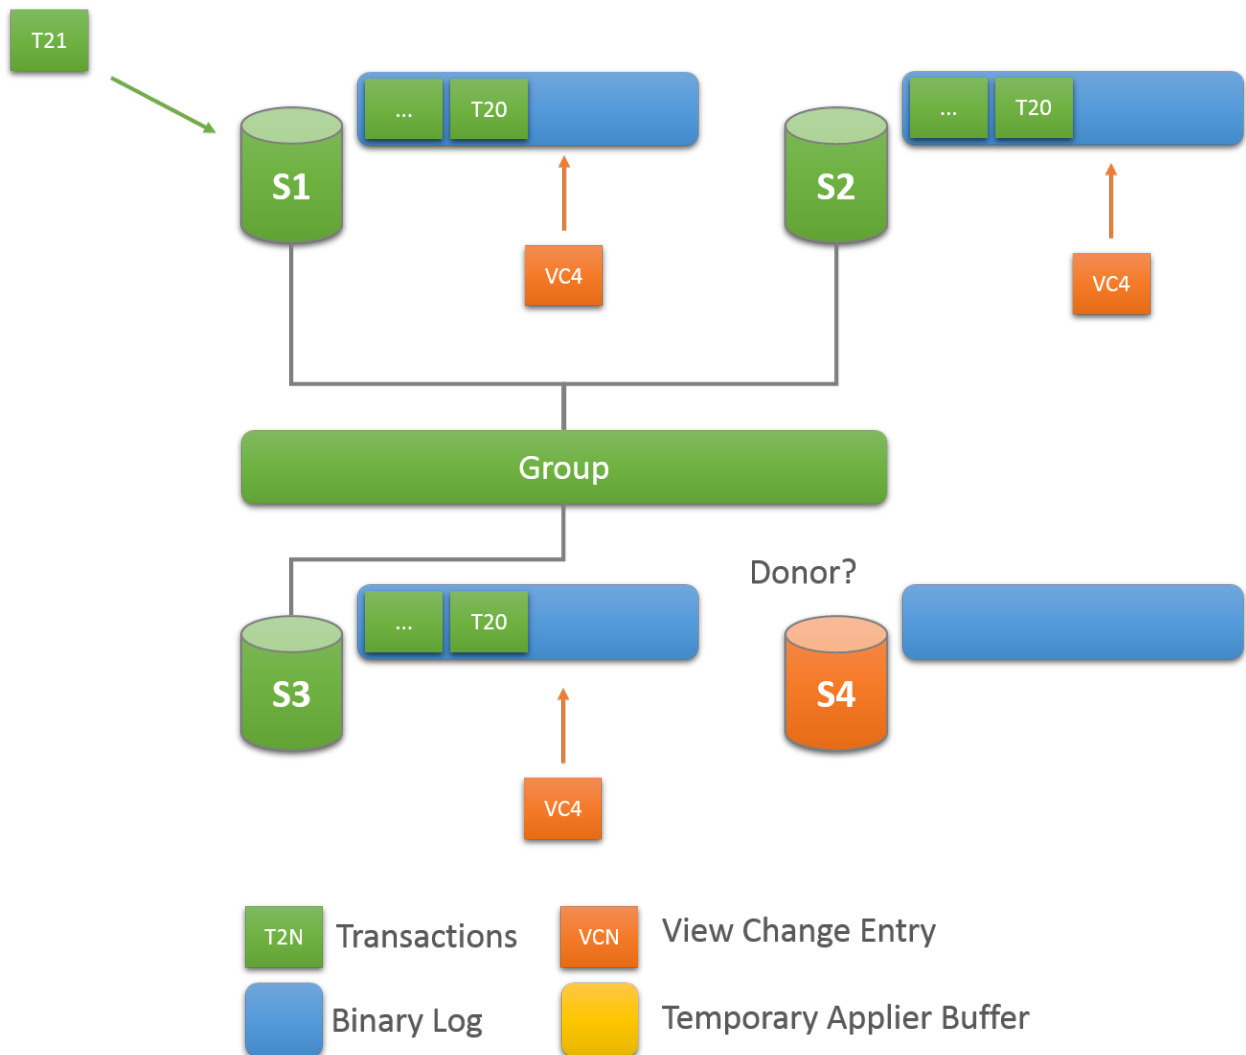

Figure 18.10 Stable Group

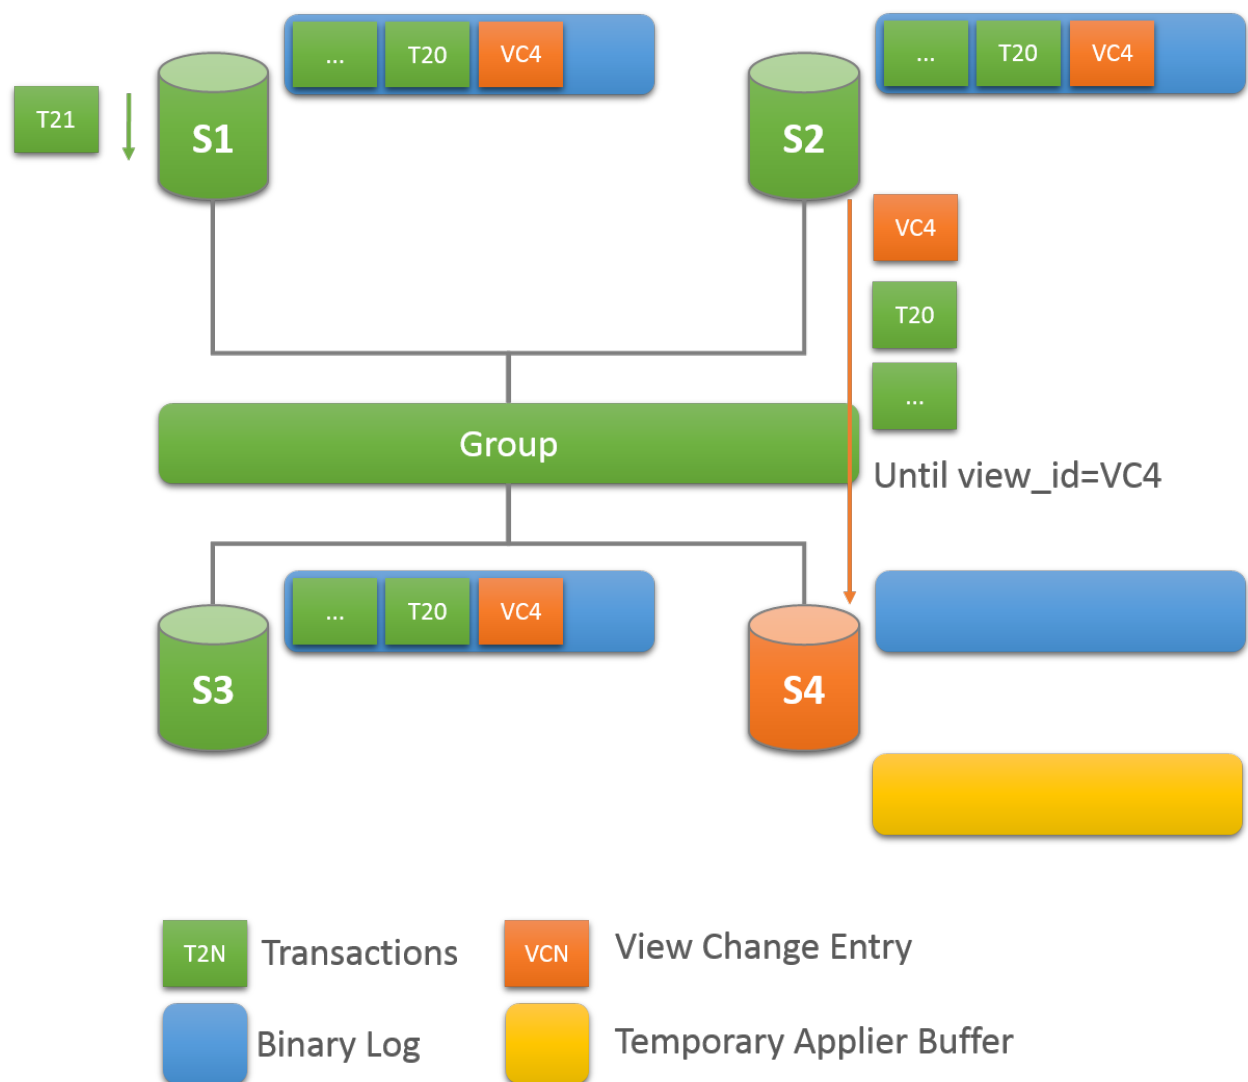

View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the server joining the group selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

Figure 18.11 A Member Joins**State Transfer: Catching Up**

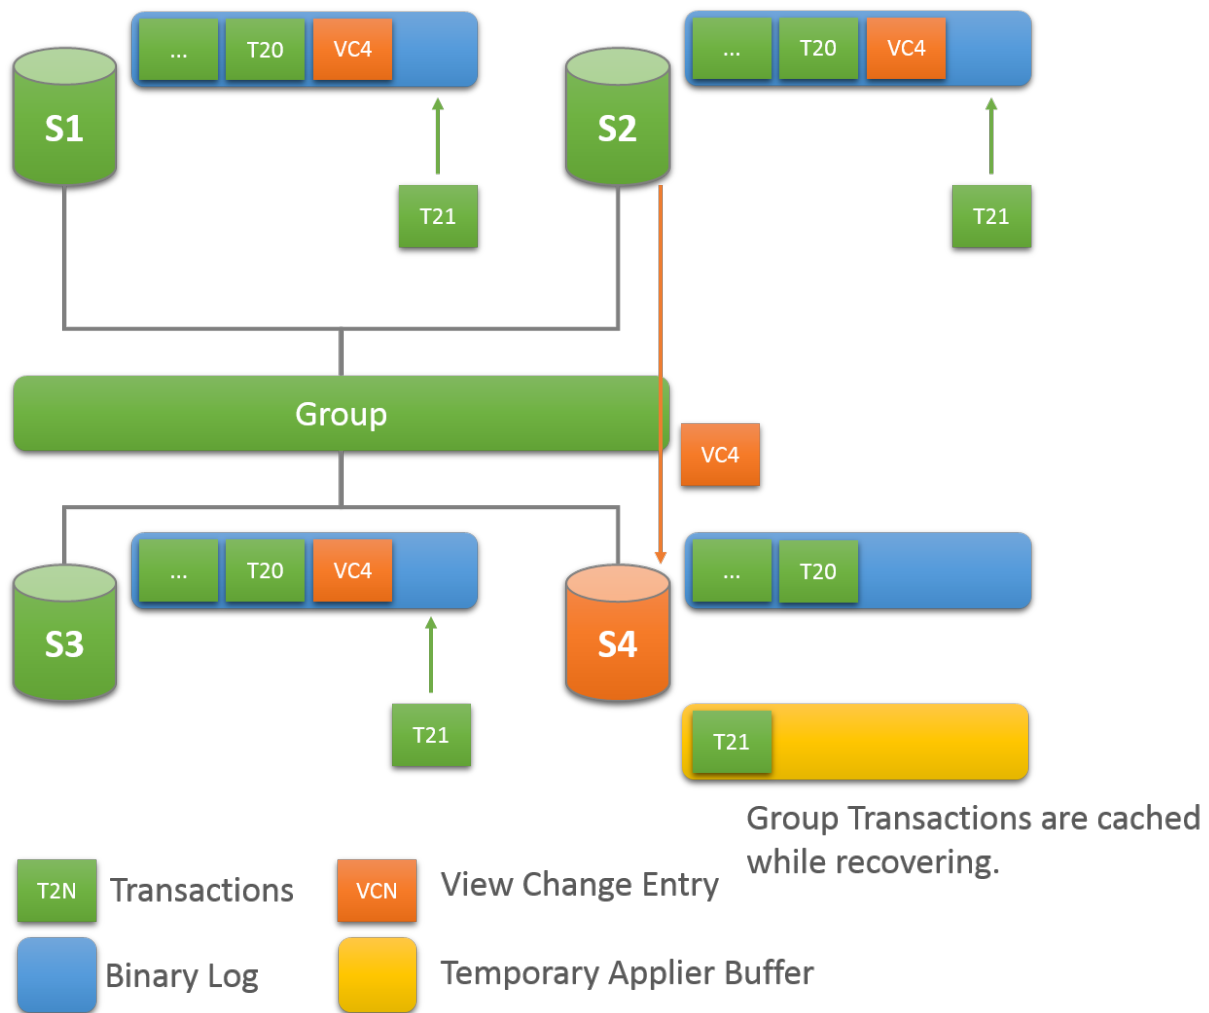

Once the server joining the group has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

Figure 18.12 State Transfer: Catching Up

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 18.13 Queued Transactions

Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

Figure 18.14 Instance Online

18.9.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the server joining the group is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

18.9.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group

Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 18.3, “Monitoring Group Replication”](#).

18.9.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

18.9.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

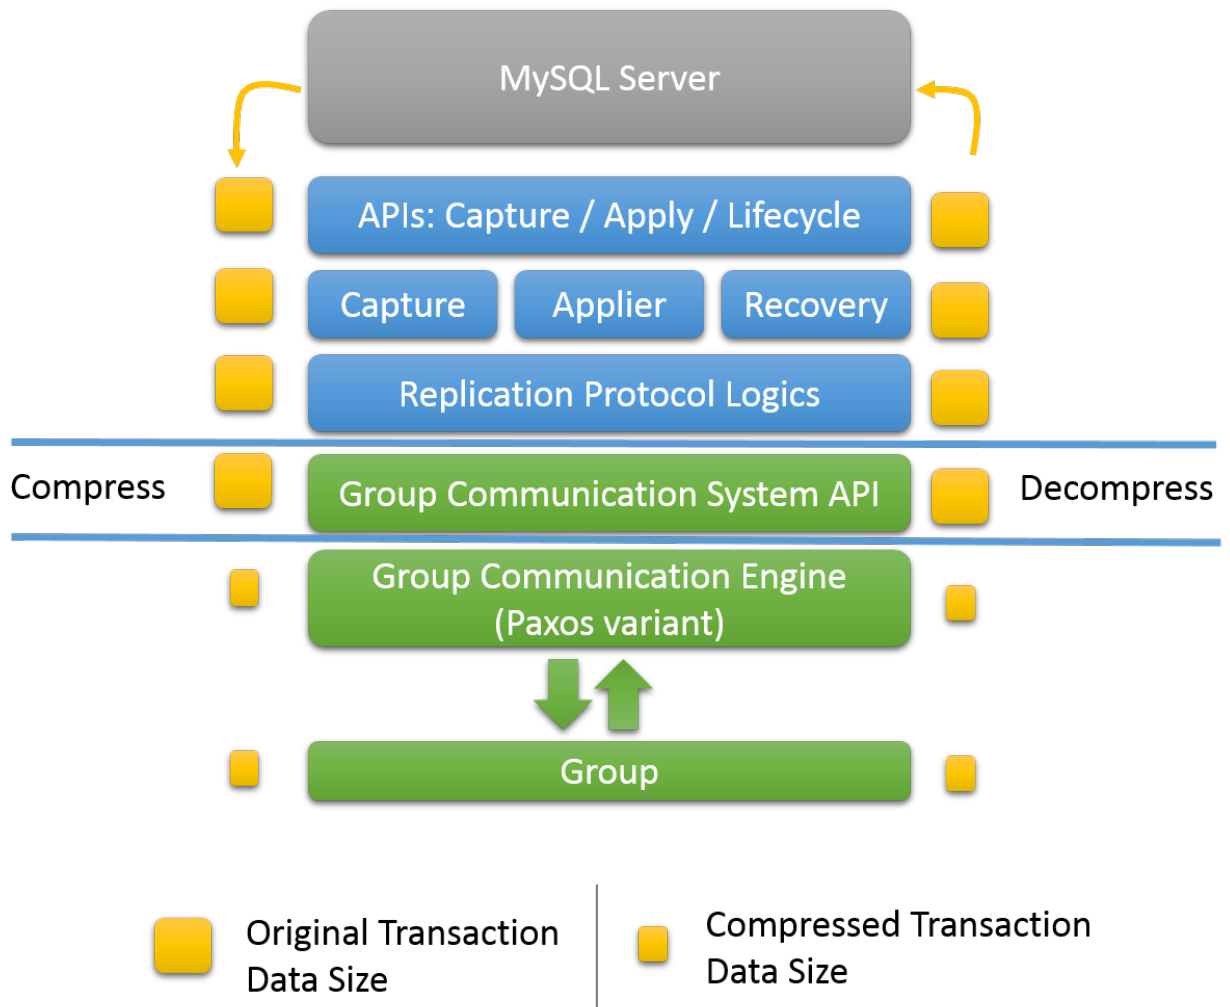

18.9.7.2 Message Compression

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

Table 18.8 LZ4 Compression Ratios for Different Binary Log Formats

Ratio	load
for	
SOWT	
4.5	mysqlslapd
3.9	sysbench

The TCP peer-to-peer nature of the interconnections between N participants on the group makes the sender send the same amount of data N times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.

Figure 18.15 Compression Support

Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```

This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

18.9.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the *certification* queue; (ii) and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;

- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

Chapter 19 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at <https://dev.mysql.com/doc/mysql-shell/en/>.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables you to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. For more information, see [Chapter 20, Using MySQL as a Document Store](#). For documentation on the concepts and usage of X DevAPI, see [X DevAPI User Guide](#).
- The AdminAPI enables you to work with InnoDB cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. See [Chapter 21, InnoDB Cluster](#).

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

20.5.2 Disabling X Plugin	3241
20.5.3 Using Secure Connections with X Plugin	3241
20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin	3242
20.5.5 X Plugin Options and Variables	3242
20.5.6 Monitoring X Plugin	3259

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Relational databases such as MySQL usually required a document schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. When using MySQL as a document store, to create documents describing products you do not need to know and define all possible attributes of any products before storing them and operating with them. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

These sections cover the usage of MySQL as a document store:

- The [Section 20.1, “Key Concepts”](#) section covers concepts like Document, Collection, Session, and Schema to help you understand how to use MySQL as a document store.
- The [Section 20.2, “Setting Up MySQL as a Document Store”](#) section explains how to configure X Plugin on a MySQL Server, so it can function as a document store, and how to install MySQL Shell to use as a client.

- The MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use the MySQL Shell to prototype applications, execute queries and update data. The *quick-start guides (tutorials)* help you to get started using MySQL Shell.

The quick-start guide for JavaScript is here: [Section 20.3, “Quick-Start Guide: MySQL Shell for JavaScript”](#).

The quick-start guide for Python is here: [Section 20.4, “Quick-Start Guide: MySQL Shell for Python”](#).

- [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) provides more detailed information about using MySQL Shell.
- *X DevAPI User guide*.

Clients that communicate with a MySQL Server using the X Protocol can use the X DevAPI to develop applications. For example MySQL Shell and MySQL Connectors provide this ability by implementing the X DevAPI. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. See [X DevAPI User Guide](#) for in-depth tutorials on using X DevAPI.

- The following MySQL products support the X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store.
 - MySQL Shell provides implementations of X DevAPI in JavaScript and Python.
 - Connector/C++
 - Connector/J
 - Connector/Node.js
 - Connector/NET
 - Connector/Python

20.1 Key Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

Document

A Document is a set of key and value pairs, as represented by a JSON object. A Document is represented internally using the MySQL binary JSON object, through the JSON MySQL datatype. The values of fields can contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  }
}
```

```
    },  
    "government": {  
      "GovernmentForm": "Monarchy",  
      "HeadOfState": "Michael Bates"  
    }  
  }  
}
```

Collection

A Collection is a container that may be used to store Documents in a MySQL database.

CRUD Operations

Create, Read, Update and Delete (CRUD) operations are the four basic operations that can be performed on a database Collection or Table. In terms of MySQL this means:

- Create a new entry (insertion or addition)
- Read entries (queries)
- Update entries
- Delete entries

X Plugin

The MySQL Server plugin which enables communication using X Protocol. Supports clients that implement X DevAPI and enables you to use MySQL as a document store.

X Protocol

A protocol to communicate with a MySQL Server running X Plugin. X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer.

20.2 Setting Up MySQL as a Document Store

This section describes how to set up MySQL Server with X Plugin, and how to install MySQL Shell.

The X Plugin is enabled by default as of MySQL 8.0, enabling MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. Clients compatible with X Protocol include MySQL Shell and MySQL 8.0 Connectors.

20.2.1 Installing MySQL Shell

Important

For the Community and Commercial versions of MySQL Shell: Before installing MySQL Shell, make sure you have the Visual C++ Redistributable for Visual Studio 2015 (available at the [Microsoft Download Center](#)) installed on your Windows system.

This section describes how to download, install, and start MySQL Shell, which is an interactive JavaScript, Python, or SQL interface supporting development and administration for MySQL Server. MySQL Shell is a component that you can install separately.

Requirements

MySQL Shell is available on Microsoft Windows, Linux, and macOS for 64-bit platforms.

20.2.1.1 Installing MySQL Shell on Microsoft Windows

To install MySQL Shell on Microsoft Windows using the MSI Installer, do the following:

1. Download the **Windows (x86, 64-bit), MSI Installer** package from <http://dev.mysql.com/downloads/shell/>.
2. When prompted, click **Run**.
3. Follow the steps in the Setup Wizard.

20.2.1.2 Installing MySQL Shell on Linux

Note

Installation packages for MySQL Shell are available only for a limited number of Linux distributions, and only for 64-bit systems.

For supported Linux distributions, the easiest way to install MySQL Shell on Linux is to use the [MySQL APT repository](#) or [MySQL Yum repository](#). For systems not using the MySQL repositories, MySQL Shell can also be downloaded and installed directly.

Installing MySQL Shell with the MySQL APT Repository

For Linux distributions supported by the [MySQL APT repository](#), follow one of the paths below:

- If you do not yet have the [MySQL APT repository](#) as a software repository on your system, do the following:
 - Follow the steps given in [Adding the MySQL APT Repository](#), paying special attention to the following:
 - During the installation of the configuration package, when asked in the dialogue box to configure the repository, make sure you choose MySQL 8.0 as the release series you want.
 - Make sure you do not skip the step for updating package information for the MySQL APT repository:

```
sudo apt-get update
```

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

- If you already have the [MySQL APT repository](#) as a software repository on your system, do the following:
 - Update package information for the MySQL APT repository:

```
sudo apt-get update
```

- Update the MySQL APT repository configuration package with the following command:

```
sudo apt-get install mysql-apt-config
```

When asked in the dialogue box to configure the repository, make sure you choose MySQL 8.0 as the release series you want.

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

Installing MySQL Shell with the MySQL Yum Repository

For Linux distributions supported by the [MySQL Yum repository](#), follow these steps to install MySQL Shell:

- Do one of the following:
 - If you already have the [MySQL Yum repository](#) as a software repository on your system and the repository was configured with the new release package `mysql80-community-release`.
 - If you already have the [MySQL Yum repository](#) as a software repository on your system but have configured the repository with the old release package `mysql-community-release`, it is easiest to install MySQL Shell by first reconfiguring the MySQL Yum repository with the new `mysql80-community-release` package. To do so, you need to remove your old release package first, with the following command :

```
sudo yum remove mysql-community-release
```

For dnf-enabled systems, do this instead:

```
sudo dnf erase mysql-community-release
```

Then, follow the steps given in [Adding the MySQL Yum Repository](#) to install the new release package, `mysql80-community-release`.

- If you do not yet have the [MySQL Yum repository](#) as a software repository on your system, follow the steps given in [Adding the MySQL Yum Repository](#).
- Install MySQL Shell with this command:

```
sudo yum install mysql-shell
```

For dnf-enabled systems, do this instead:

```
sudo dnf install mysql-shell
```

Installing MySQL Shell from Direct Downloads from the MySQL Developer Zone

RPM, Debian, and source packages for installing MySQL Shell are also available for download at [Download MySQL Shell](#).

20.2.1.3 Installing MySQL Shell on OS X

To install MySQL Shell on OS X, do the following:

1. Download the package from <http://dev.mysql.com/downloads/shell/>.
2. Double-click the downloaded DMG to mount it. Finder opens.

3. Double-click the `.pkg` file shown in the Finder window.
4. Follow the steps in the installation wizard.
5. When the installer finishes, eject the DMG. (It can be deleted.)

20.2.2 Starting MySQL Shell

You need an account name and password to establish a session using MySQL Shell. Replace `user` with your account name.

Open a terminal window (command prompt on Windows) and start MySQL Shell with the following command:

```
mysqlsh --uri user@localhost
```

You are prompted to input your password.

To get started using MySQL Shell and MySQL as a document store, see the following quick-start guides:

- [Quick-Start Guide: MySQL Shell for JavaScript](#)
- [Quick-Start Guide: MySQL Shell for Python](#)

20.3 Quick-Start Guide: MySQL Shell for JavaScript

This quick-start guide provides instructions to begin prototyping database applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

Available Quick-Start Guides

- [MySQL Shell for Python](#)
- [MySQL for Visual Studio](#)

Related Information

- [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) provides more in-depth information about MySQL Shell.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI.

20.3.1 Introduction

The MySQL Shell for JavaScript quick start provides a short but comprehensive introduction to the database functionality including the new X DevAPI, which offers a modern, integrative way to work with relational and document data, without requiring SQL knowledge from application developers.

In MySQL, tables are the native data storage container type and collections are stored internally using tables.

JSON Documents and Collections

A JSON [document](#) is a data structure composed of field/value pairs stored within a [collection](#). The values of fields often contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
```

Relational Tables

A [table](#) in MySQL enables you to store data organized in rows and columns. The structure of a table is defined by one or more columns with user-defined names and data types. Every row stored in the table has the same structure.

ID	Name	CountryCode	District	Info
1	Kabul	AFG	Kabul	{"Population": 1780000}
2	Qandahar	AFG	Qandahar	{"Population": 237500}
3	Herat	AFG	Herat	{"Population": 186800}
4	Mazar-e-Sharif	AFG	Balkh	{"Population": 127800}
5	Amsterdam	NLD	Noord-Holland	{"Population": 731200}
6	Rotterdam	NLD	Zuid-Holland	{"Population": 593321}

Related Information

- [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) provides a general overview.
- See [X DevAPI User Guide](#) for development reference documentation.

20.3.2 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection
 - `countryinfo`: Information about countries in the world.
- Tables
 - `country`: Minimal information about countries of the world.

- city: Information about some of the cities in those countries.
- countrylanguage: Languages spoken in each country.

Requirements

You must install MySQL Shell with the X Protocol enabled. For instructions, see [Section 20.2, “Setting Up MySQL as a Document Store”](#).

Start the server before you load the `world_x` database for this guide.

Download world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Create the schema with the following command:

```
mysqlsh -u root --sql < /tmp/world_x-db/world_x.sql
Enter password: ****
```

Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Replace `/tmp/` with the path to the `world_x.sql` file on your system.

Related Information

- [MySQL Shell Sessions](#) explains session types.
- See [Chapter 2, Installing and Upgrading MySQL](#) for general installation assistance.

20.3.3 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the local MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using the X Protocol.

On the same system where the server instance is running, open a terminal window and start MySQL Shell with the following command:

```
mysqlsh name@localhost/world_x
Creating a Session to 'root@localhost/world_x'
Enter password: ****
```

You may need to specify the path as appropriate.

In addition:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.3.2, “Import Database Sample”](#).

The `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. To specify a different host or port number, as well as other options, see the option descriptions at [mysqlsh — The MySQL Shell](#).

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** enters the current input line.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-js> \quit
```

Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.

- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

20.3.4 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you create, list, and drop.

The examples in this section use the `countryinfo` collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.3.2, “Import Database Sample”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

```
{field1: "value", field2 : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript:

```
[{Name: "Aruba", _id: "ABW"}, {Name: "Angola", _id: "AGO"}]
```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (false and true)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema that you specified on the command line. You can type <code>db</code> in

Object form	Description
	MySQL Shell to print a description of the object, which in this case will be the name of the schema it represents.
<code>db.getCollections()</code>	<code>db.getCollections()</code> holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.3.4.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `createCollection()` method. The following example creates in the `world_x` database a collection called `flags`.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `getCollections()` method on the schema object. Collections returned by the server appear between brackets.

```
mysql-js> db.getCollections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `dropCollection()` method on the session object. For example, to drop the `flags` collection from the `world_x` database, type:

```
mysql-js> session.dropCollection("world_x", "flags")
Query OK (0.04 sec)
```

Related Information

- See [Connections in JavaScript and Python](#) to learn more about the session object.
- See [Collection Objects](#) for more examples.

20.3.4.2 Add Documents

You can use the `add()` method to insert one document or a list documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
<Schema:world_x>
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
Schema `world_x` accessible through db.
```

Add a Document

Insert the following document into the `countryinfo` collection. Press **Enter** twice to insert the document.

```
mysql-js> db.countryinfo.add(
{
  GNP: .6,
  IndepYear: 1967,
  Name: "Sealand",
  _id: "SEA",
  demographics: {
    LifeExpectancy: 79,
    Population: 27
  },
  geography: {
```

```

        Continent: "Europe",
        Region: "British Islands",
        SurfaceArea: 193
    },
    government: {
        GovernmentForm: "Monarchy",
        HeadOfState: "Michael Bates"
    }
}
)
Query OK, 1 item affected (0.02 sec)

```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL Shell 1.0.11 (which was part of MySQL 5.7), if the document passed to the `add()` method did not contain the `_id` field, MySQL Shell as the client automatically inserted a field into the document and set the value to a generated universal unique identifier (UUID). In MySQL Shell 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not now automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`.

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.

20.3.4.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR` (`|`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```

mysql-js> db.countryinfo.find()
[
  {
    "GNP": 828,
    "IndepYear": null,
    "Name": "Aruba",
    "_id": "ABW",
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    }
  }
]

```

```

    }
    ...
  }
]
240 documents in set (0.00 sec)

```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional [MySQL](#). You must enclose all expressions in quotes.

All examples in this section use the `countryinfo` collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition consists of the `_id` field and unique identifier of a document. The following example returns a single document matching the identifier string:

```

mysql-js> db.countryinfo.find("_id = 'AUS'")
[
  {
    "GNP": 351182,
    "IndepYear": 1901,
    "Name": "Australia",
    "_id": "AUS",
    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    },
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  }
]
1 document in set (0.01 sec)

```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```

mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)

```

The `Population` field in the following query is embedded within the `demographics` object. To access the embedded field, use a period between `demographics` and `Population` to identify the relationship. Document and field names are case-sensitive.

```
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the countryinfo collection have a population value of zero. Warning messages appear at the end of the output.

```
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *country*. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
  {
    "GNP": 1161755,
    "IndepYear": 1861,
    "Name": "Italy",
    "_id": "ITA",
    "demographics": {
      "LifeExpectancy": 79,
      "Population": 57680000
    },
    "geography": {
      "Continent": "Europe",
      "Region": "Southern Europe",
      "SurfaceArea": 301316
    },
    "government": {
      "GovernmentForm": "Republic",
      "HeadOfState": "Carlo Azeglio Ciampi"
    }
  }
]
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```
mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```
mysql-js> db.countryinfo.find().
fields(mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).
limit(2)
[
  {
    "GNPPerCapita": 8038.834951456311,
    "Name": "ARUBA"
  },
  {
    "GNPPerCapita": 263.0281690140845,
    "Name": "AFGHANISTAN"
  }
]
2 documents in set (0.00 sec)
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the countryinfo collection.

```
mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
```

```
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.3.4.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-js> db.countryinfo.modify("_id = 'SEA'").
set("demographics", {LifeExpectancy: 78, Population: 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-js> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
[
  {
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
      "LifeExpectancy": 78,
```

```

    "Population": 28
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
]
1 document in set (0.00 sec)

```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```

mysql-js> db.countryinfo.modify("true").set("Airports", [])
Query OK, 240 items affected (0.07 sec)

```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```

mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)

```

Use `db.countryinfo.find("Name = 'France'")` to see the change.

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```

mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)

```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```

mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)

```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.3.4.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-js> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying any search condition.

Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 20.3.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.3.4.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `createIndex()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `false`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.createIndex("pop").
field("demographics.Population", "INTEGER", false).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `createIndex()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country "Name" is another common field in the countryinfo collection to index. In the following example, `Text(40)` represents the number of characters to index and `true` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.createIndex("name", mysqlx.IndexType.UNIQUE).
field("Name", "TEXT(40)", true).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `dropIndex()` method the name of the index to drop. For example, you can drop the "pop" index as follows:

```
mysql-js> db.countryinfo.dropIndex("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See [Collection Index Management Functions](#) for the full syntax definition.

20.3.5 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

Show All Tables

To display all relational tables in the `world_x` database, use the `getTables()` method on the schema object.

```
mysql-js> db.getTables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The <code>insert()</code> method inserts one or more records into the named table.
<code>db.name.select()</code>	The <code>select()</code> method returns some or all records in the named table.
<code>db.name.update()</code>	The <code>update()</code> method updates records in the named table.
<code>db.name.delete()</code>	The <code>delete()</code> method deletes one or more records from the named table.

Related Information

- See [Working with Relational Tables](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.3.2, "Import Database Sample"](#) for instructions on setting up the `world_x` database sample.

20.3.5.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").
values(null, "Olympia", "USA", "Washington", '{"Population": 5000}')
Query OK, 1 item affected (0.01 sec)
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").
values(null, "Little Falls", "USA").values(null, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.3.5.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (||)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-js> db.city.select()
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1 | Kabul | AFG | Kabul | {"Population": 1780000} |
| 2 | Qandahar | AFG | Qandahar | {"Population": 237500} |
| 3 | Herat | AFG | Herat | {"Population": 186800} |
| ... | ... | ... | ... | ... |
| 4079 | Rafah | PSE | Rafah | {"Population": 92020} |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-js> db.city.select(["Name", "CountryCode"])
```

Name	CountryCode
Kabul	AFG
Qandahar	AFG
Herat	AFG
Mazar-e-Sharif	AFG
Amsterdam	NLD
...	...
Rafah	PSE
Olympia	USA
Little Falls	USA
Happy Valley	USA

4082 rows in set (0.00 sec)

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

Name	CountryCode
Zaanstad	NLD
Zoetermeer	NLD
Zwolle	NLD
Zenica	BIH
Zagazig	EGY
Zaragoza	ESP
Zamboanga	PHL
Zahedan	IRN
Zanjan	IRN
Zabol	IRN
Zama	JPN
Zhezqazghan	KAZ
Zhengzhou	CHN
...	...
Zelevnogorsk	RUS

59 rows in set (0.00 sec)

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%' "` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.city.select(["Name", "CountryCode"]).
  where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
           where("Name like 'Z%' and CountryCode = 'CHN'")
```

Name	CountryCode
Zhengzhou	CHN
Zibo	CHN
Zhangjiakou	CHN
Zhuzhou	CHN
Zhangjiang	CHN
Zigong	CHN
Zaozhuang	CHN
...	...
Zhangjiagang	CHN

22 rows in set (0.01 sec)

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
           where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
```

Name	CountryCode
Zhengzhou	CHN
Zibo	CHN
Zhangjiakou	CHN
Zhuzhou	CHN
...	...
Zelevnogorsk	RUS

29 rows in set (0.01 sec)

Limit, Order, and Offset Results

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-js> db.country.select(["Code", "Name"]).limit(5)
```

Code	Name
ABW	Aruba
AFG	Afghanistan
AGO	Angola
AIA	Anguilla
ALB	Albania

5 rows in set (0.00 sec)

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZWE  | Zimbabwe  |
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
| YEM  | Yemen     |
+-----+-----+
3 rows in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.3.5.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID   | Name   | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1891 | Beijing | CHN         | Peking   | {"Population": 7472000}                |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.3.5.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.3.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.3.6 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` database.

city Table Description

The city table has five columns (or fields).

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			
Info	json	YES		null	

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-js> db.city.insert().
values(null, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).
  where("CountryCode = :country and Info->'$.Population' > 1000000").
  bind('country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

```
9 rows in set (0.01 sec)
```

Related Information

- See [Working with Relational Tables and Documents](#) for a general overview.
- See [Section 11.6, “The JSON Data Type”](#) for a detailed description of the data type.

20.4 Quick-Start Guide: MySQL Shell for Python

This quick-start guide provides instructions to begin prototyping database applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

Available Quick-Start Guides

- [MySQL Shell for JavaScript](#)
- [MySQL for Visual Studio](#)

Related Information

- [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) provides more in-depth information about MySQL Shell.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI.

20.4.1 Introduction

The MySQL Shell for Python quick start provides a short but comprehensive introduction to the database functionality including the new X DevAPI, which offers a modern, integrative way to work with relational and document data, without requiring SQL knowledge from application developers.

In MySQL, tables are the native data storage container type and collections are stored internally using tables.

JSON Documents and Collections

A JSON [document](#) is a data structure composed of field/value pairs stored within a [collection](#). The values of fields often contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
```

Relational Tables

A [table](#) in MySQL enables you to store data organized in rows and columns. The structure of a table is defined by one or more columns with user-defined names and data types. Every row stored in the table has the same structure.

ID	Name	CountryCode	District	Info
1	Kabul	AFG	Kabul	{"Population": 1780000}
2	Qandahar	AFG	Qandahar	{"Population": 237500}
3	Herat	AFG	Herat	{"Population": 186800}
4	Mazar-e-Sharif	AFG	Balkh	{"Population": 127800}
5	Amsterdam	NLD	Noord-Holland	{"Population": 731200}
6	Rotterdam	NLD	Zuid-Holland	{"Population": 593321}

Related Information

- [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) provides a general overview.

- See [X DevAPI User Guide](#) for development reference documentation.

20.4.2 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection
 - `countryinfo`: Information about countries in the world.
- Tables
 - `country`: Minimal information about countries of the world.
 - `city`: Information about some of the cities in those countries.
 - `countrylanguage`: Languages spoken in each country.

Requirements

You must install MySQL Shell with the X Protocol enabled. For instructions, see [Section 20.2, “Setting Up MySQL as a Document Store”](#).

Start the server before you load the `world_x` database for this guide.

Download world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Create the schema with the following command:

```
mysqlsh -u root --sql < /tmp/world_x-db/world_x.sql
Enter password: ****
```

Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Replace `/tmp/` with the path to the `world_x.sql` file on your system.

Related Information

- [MySQL Shell Sessions](#) explains session types.
- See [Chapter 2, Installing and Upgrading MySQL](#) for general installation assistance.

20.4.3 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the local MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using the X Protocol.

On the same system where the server instance is running, open a terminal window and start MySQL Shell with the following command:

```
mysqlsh name@localhost/world_x --py
Creating a Session to name@localhost/world_x
Enter password: ****
```

You may need to specify the path as appropriate.

In addition:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The `--py` option starts MySQL Shell in Python mode. If you omit `--py`, MySQL Shell starts in JavaScript mode.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.4.2, “Import Database Sample”](#).

The `mysql-py>` prompt indicates that the active language for this session is Python.

```
mysql-py>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. To specify a different host or port number, as well as other options, see the option descriptions at [mysqlsh — The MySQL Shell](#).

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** enters the current input line.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-py> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-py> \quit
```

Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

20.4.4 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you create, list, and drop.

The examples in this section use the `countryinfo` collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.4.2, “Import Database Sample”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2" : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for Python:

```
[{"Name": "Aruba", "_id": "ABW"}, {"Name": "Angola", "_id": "AGO"}]
```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values

- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema that you set on the command line. You can type <code>db</code> in MySQL Shell to print a description of the object, which in this case will be the name of the schema it represents.
<code>db.get_collections()</code>	<code>db.get_collections()</code> holds a list of collections in the schema. Use the list references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.4.4.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-py> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `create_collection()` method. The following example creates in the `world_x` database a collection called `flags`.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `get_collections()` method on the schema object. Collections returned by the server appear between brackets.

```
mysql-py> db.get_collections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `drop_collection()` method on the session object. For example, to drop the `flags` collection from the `world_x` database, type:

```
mysql-py> session.drop_collection("world_x", "flags")
Query OK (0.04 sec)
```

Related Information

- See [Connections in JavaScript and Python](#) to learn more about the session object.
- See [Collection Objects](#) for more examples.

20.4.4.2 Add Documents

You can use the `add()` method to insert one document or a list documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
<Schema:world_x>
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Add a Document

Insert the following document into the `countryinfo` collection. Press **Enter** twice to insert the document.

```
mysql-py> db.countryinfo.add(
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
)
Query OK, 1 item affected (0.02 sec)
```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL Shell 1.0.11 (which was part of MySQL 5.7), if the document passed to the `add()` method did not contain the `_id` field, MySQL Shell as the client automatically inserted a field into the document and set the value to a generated universal unique identifier (UUID). In MySQL Shell 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not now automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`.

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.

20.4.4.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find()
```

```
[
  {
    "GNP": 828,
    "IndepYear": null,
    "Name": "Aruba",
    "_id": "ABW",
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    }
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional [MySQL](#). You must enclose all expressions in quotes.

All examples in this section use the `countryinfo` collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition consists of the `_id` field and unique identifier of a document. The following example returns a single document matching the identifier string:

```
mysql-py> db.countryinfo.find("_id = 'AUS'")
[
  {
    "GNP": 351182,
    "IndepYear": 1901,
    "Name": "Australia",
    "_id": "AUS",
    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    },
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  }
]
```

```
}
]
1 document in set (0.01 sec)
```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The `Population` field in the following query is embedded within the `demographics` object. To access the embedded field, use a period between `demographics` and `Population` to identify the relationship. Document and field names are case-sensitive.

```
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the `countryinfo` collection have a population value of zero. Warning messages appear at the end of the output.

```
mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
  {
    "GNP": 1161755,
    "IndepYear": 1861,
    "Name": "Italy",
    "_id": "ITA",
    "demographics": {
      "LifeExpectancy": 79,
      "Population": 57680000
    },
    "geography": {
      "Continent": "Europe",
      "Region": "Southern Europe",
      "SurfaceArea": 301316
    }
  },
]
```

```

    "government": {
      "GovernmentForm": "Republic",
      "HeadOfState": "Carlo Azeglio Ciampi"
    }
  }
]
1 document in set (0.01 sec)

```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-py> db.countryinfo.find().\
fields(mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}' )).\
limit(2)
[
  {
    "GNPPerCapita": 8038.834951456311,
    "Name": "ARUBA"
  },
  {
    "GNPPerCapita": 263.0281690140845,
    "Name": "AFGHANISTAN"
  }
]
2 documents in set (0.00 sec)

```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.4.4.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested `demographics` object.

```
mysql-py> db.countryinfo.modify("_id = 'SEA'").\
set("demographics", {"LifeExpectancy": 78, "Population": 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand']").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
[
  {
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
      "LifeExpectancy": 78,
      "Population": 28
    },
    "geography": {
      "Continent": "Europe",
      "Region": "British Islands",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Monarchy",
      "HeadOfState": "Michael Bates"
    }
  }
]
1 document in set (0.00 sec)
```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the countryinfo collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```
mysql-py> db.countryinfo.modify(True).set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the Airports field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the Airports field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use `db.countryinfo.find("Name = 'France'")` to see the change.

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-py> db.countryinfo.modify("Name = 'France']").array_insert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```
mysql-py> db.countryinfo.modify("Name = 'France']").array_delete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.4.4.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove(True).limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-py> db.countryinfo.remove(True).sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove(True)` method without specifying a search condition.

Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 20.4.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.4.4.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `create_index()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the `Population` field inside the `demographics` object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `False`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.create_index("pop").\
field("demographics.Population", "INTEGER", False).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `create_index()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country `"Name"` is another common field in the `countryinfo` collection to index. In the following example, `"Text(40)"` represents the number of characters to index and `True` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.create_index("name", mysqlx.IndexType.UNIQUE).\
field("Name", "TEXT(40)", True).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `drop_index()` method the name of the index to drop. For example, you can drop the `"pop"` index as follows:

```
mysql-js> db.countryinfo.drop_index("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See [Collection Index Management Functions](#) for the full syntax definition.

20.4.5 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use [InnoDB](#) tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
<Schema:world_x>
```

If the schema value is not the `Schema:world_x` database, then set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the `world_x` database, use the `get_tables()` method on the schema object.

```
mysql-py> db.get_tables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The insert() method inserts one or more records into the named table.
<code>db.name.select()</code>	The select() method returns some or all records in the named table.
<code>db.name.update()</code>	The update() method updates records in the named table.
<code>db.name.delete()</code>	The delete() method deletes one or more records from the named table.

Related Information

- See [Working with Relational Tables](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

- See [Section 20.4.2, “Import Database Sample”](#) for instructions on setting up the `world_x` database sample.

20.4.5.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").\
values(None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

Query OK, 1 item affected (0.01 sec)

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").\
values(None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

Query OK, 2 item affected (0.03 sec)

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.4.5.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-py> db.city.select()
```

ID	Name	CountryCode	District	Info
1	Kabul	AFG	Kabul	{"Population": 1780000}
2	Qandahar	AFG	Qandahar	{"Population": 237500}
3	Herat	AFG	Herat	{"Population": 186800}
...
4079	Rafah	PSE	Rafah	{"Population": 92020}

4082 rows in set (0.01 sec)

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(["Name", "CountryCode"])
```

Name	CountryCode
Kabul	AFG
Qandahar	AFG
Herat	AFG
Mazar-e-Sharif	AFG
Amsterdam	NLD
...	...
Rafah	PSE
Olympia	USA
Little Falls	USA
Happy Valley	USA

4082 rows in set (0.00 sec)

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

Name	CountryCode
Zaanstad	NLD
Zoetermeer	NLD
Zwolle	NLD
Zenica	BIH
Zagazig	EGY
Zaragoza	ESP
Zamboanga	PHL
Zahedan	IRN
Zanjan	IRN
Zabol	IRN
Zama	JPN
Zhezqazghan	KAZ
Zhengzhou	CHN

```
...
| Zeleznogorsk      | RUS      |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%'"` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like 'Z%' and CountryCode = 'CHN'")
```

Name	CountryCode
Zhengzhou	CHN
Zibo	CHN
Zhangjiakou	CHN
Zhuzhou	CHN
Zhangjiang	CHN
Zigong	CHN
Zaozhuang	CHN
...	...
Zhangjiagang	CHN

```
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
```

Name	CountryCode
Zhengzhou	CHN
Zibo	CHN
Zhangjiakou	CHN
Zhuzhou	CHN
...	...
Zeleznogorsk	RUS

```
+-----+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
+-----+
| Code | Name |
+-----+
| ABW  | Aruba |
| AFG  | Afghanistan |
| AGO  | Angola |
| AIA  | Anguilla |
| ALB  | Albania |
+-----+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
+-----+
| Code | Name |
+-----+
| ZWE  | Zimbabwe |
| ZMB  | Zambia |
| YUG  | Yugoslavia |
+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
+-----+
| Code | Name |
+-----+
| ZMB  | Zambia |
| YUG  | Yugoslavia |
| YEM  | Yemen |
+-----+
3 rows in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.4.5.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID   | Name   | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1891 | Beijing | CHN         | Peking   | {"Population": 7472000}                |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.4.5.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.4.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.4.6 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the `city` table in the `world_x` database.

city Table Description

The `city` table has five columns (or fields).

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			
Info	json	YES		null	

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the `Info` column.

```
mysql-py> db.city.insert().\
values(None, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).\
where("CountryCode = :country and Info->'$.Population' > 1000000").\
bind('country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

9 rows in set (0.01 sec)

Related Information

- See [Working with Relational Tables and Documents](#) for a general overview.
- See [Section 11.6, “The JSON Data Type”](#) for a detailed description of the data type.

20.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

20.5.1 Checking X Plugin Installation

Because X Plugin is enabled by default, installing or upgrading to MySQL 8 makes the plugin available. The following shows how to use MySQL Shell and a standard MySQL Client to check if the plugin is installed:

Check the X Plugin Installation

Verify that the X Plugin is installed.

An installed X Plugin is listed in the plugins list on the MySQL server, for example:

MySQL Shell command:

```
shell> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

MySQL Client program command:

```
shell> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+-----+-----+-----+-----+-----+
| Name           | Status | Type           | Library | License |
+-----+-----+-----+-----+-----+
...
| mysqlx         | ACTIVE | DAEMON         | NULL    | GPL      |
...
+-----+-----+-----+-----+-----+
```

20.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `-DWITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

20.5.3 Using Secure Connections with X Plugin

This section explains how to configure X Plugin to use secure connections. For more background information, see [Section 6.4, “Using Encrypted Connections”](#).

X Plugin has its own SSL settings which can differ from those used with MySQL Server. This means that X Plugin can be configured with a different SSL key, certificate, and certificate authorities file than MySQL Server. Similarly, X Plugin has its own SSL status variables calculated independently from the MySQL Server SSL related variables. By default the X Plugin SSL configuration is taken from the `mysqlx_ssl_*` variables, described at [Section 20.5.5.2, “X Plugin System Variables and Options”](#). If no configuration is provided using the `mysqlx_ssl_*` variables, X Plugin falls back to using the MySQL Server SSL system variables. This means you can choose to either have separate SSL configurations for MySQL Protocol and X Protocol connections by configuring each separately, or share the SSL configuration between MySQL Protocol and X Protocol connections by only configuring the `ssl-*` variables.

On a server with X Plugin installed, to configure MySQL Protocol and X Protocol connections with separate SSL configurations use both the `ssl-*` and `mysqlx-ssl-*` variables in `my.cnf`:

```
[mysqld]
ssl-ca=ca1.pem
ssl-cert=server-cert1.pem
ssl-key=server-key1.pem

mysqlx-ssl-ca=ca2.pem
mysqlx-ssl-cert=server-cert2.pem
mysqlx-ssl-key=server-key2.pem
```

The available `mysqlx_ssl_*` variables mirror the SSL variables in MySQL Server, so the files and techniques described for configuring MySQL Server to use SSL at [Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”](#) are relevant to configuring X Plugin to use secure connections.

You can configure the TLS versions used by X Protocol SSL connections using the `tls_version` system variable. The TLS version used by MySQL Protocol and X Protocol connections is therefore the same TLS version.

Encryption per connection is optional, but a specific user can be forced to use encryption for X Protocol and MySQL Protocol connections. You configure such a user by issuing a `GRANT` statement with the `REQUIRE` option. For more details see [Section 13.7.1.6, “GRANT Syntax”](#). Alternatively all X Protocol and MySQL Protocol connections can be forced to use encryption by setting `require_secure_transport`.

20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL accounts created with the [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#) plugin. You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the caching SHA-2 authentication plugin holds an authentication cache, to use such accounts with X Plugin the X Plugin authentication cache plugin named `mysqlx_cache_cleaner` is used. Like X Plugin, it is enabled by default.

Before you can use non-SSL connections to authenticate an account which uses the `caching_sha2_password` plugin, the account must have authenticated at least once over an SSL connection to store the password in the X Plugin authentication cache. This means that the first use of an account must be done using an SSL connection with the X Plugin authentication cache enabled. Once this initial authentication over SSL has succeeded non-SSL connections can be used.

20.5.5 X Plugin Options and Variables

This section describes the command options and system variables which configure X Plugin. If values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.5.5.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, and system and status variables provided by X Plugin.

Table 20.1 X Plugin Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dyn Var
mysqlx	Yes	Yes	Yes		Global	No
Mysqlx_aborted_clients				Yes	Global	No
Mysqlx_address				Yes	Global	No
mysqlx-bind-address	Yes	Yes	Yes		Global	No
mysqlx_bind_address	Yes	Yes	Yes		Global	No

mysqlx_write_timeout	Yes	Yes	Yes		Session	Yes

20.5.5.2 X Plugin System Variables and Options

The following command options configure X Plugin:

- `--mysqlx[={OFF|ON}]`

Property	Value
Command-Line Format	<code>--mysqlx[={OFF ON}]</code>

Property	Value
Introduced	8.0.11
System Variable	mysqlx
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether the X Plugin should be disabled. Defaults to [ON](#), set to [OFF](#) to disable X Plugin.

- [--mysqlx-bind-address\[=value\]](#)

Property	Value
Command-Line Format	--mysqlx-bind-address=#
System Variable	mysqlx_bind_address
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	*

Specifies the network address which X Plugin uses for connections.

By default X Plugin listens for connections on a single IPv4 TCP/IP network socket. Use this option to configure where X Plugin listens for connections, such as binding to an IPv6 address, all IPv4 and IPv6 addresses or a default IPv6 address with a fallback IPv4 address.

X Plugin treats different types of addresses as follows:

- If the address is [*](#), X Plugin accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default.
- If the address is [0.0.0.0](#), X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. This value is the default.
- If the address is [::](#), X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is [*](#), X Plugin accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections for X Plugin.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to [::ffff:127.0.0.1](#), a client such as MySQL Shell can connect using [--host=127.0.0.1](#) or [--host>::ffff:127.0.0.1](#).
- If the address is a “regular” IPv4 or IPv6 address (such as [127.0.0.1](#) or [::1](#)), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

- `--mysqlx-connect-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-connect-timeout=#</code>
System Variable	<code>mysqlx_connect_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	1000000000

Number of seconds X Plugin waits for the first packet to be received from newly connected clients. The X Plugin equivalent of `connect_timeout`.

- `--mysqlx-idle-worker-thread-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-idle-worker-thread-timeout=#</code>
System Variable	<code>mysqlx_idle_worker_thread_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	3600

Time in seconds after which an idle worker thread is terminated.

- `--mysqlx-interactive-timeout=value]`

Property	Value
Command-Line Format	<code>--mysqlx-interactive-timeout=#</code>
Introduced	8.0.4
System Variable	<code>mysqlx_interactive_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1

Property	Value
Maximum Value	2147483

Default value of the `mysqlx_wait_timeout` session variable for interactive clients.

- `--mysqlx-max-allowed-packet[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-max-allowed-packet=#</code>
System Variable	<code>mysqlx_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1048576
Minimum Value	512
Maximum Value	1073741824

Maximum size of a network packet that X Plugin can process.

- `--mysqlx-max-connections[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-max-connections=#</code>
System Variable	<code>mysqlx_max_connections</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value	65535

Maximum number of concurrent client connections the X Plugin can accept. When modifying this variable, if the new value is smaller than the current number of connections, the new limit is only taken into account for new connections.

- `--mysqlx-min-worker-threads[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-min-worker-threads=value</code>
System Variable	<code>mysqlx_min_worker_threads</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	100

The minimum number of worker threads the X Plugin uses for handling client requests.

- `--mysqlx-port[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-port=#</code>
System Variable	<code>mysqlx_port</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	33060
Minimum Value	1
Maximum Value	65535

Specifies the port where the X Plugin listens for connections. The equivalent of `port` for X Plugin.

- `--mysqlx-port-open-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-port-open-timeout=#</code>
System Variable	<code>mysqlx_port_open_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	1
Maximum Value	120

The amount of time in seconds which X Plugin waits for a TCP/IP port to become free.

- `--mysqlx-read-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-read-timeout=#</code>
Introduced	8.0.4
System Variable	<code>mysqlx_port_read_timeout</code>

Property	Value
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	30
Maximum Value	2147483

Number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, the connection is aborted.

- `--mysqlx-socket[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-socket=file_name</code>
System Variable	<code>mysqlx_socket</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>/tmp/mysqlx.sock</code>

The path to a Unix socket file which X Plugin uses for connections. Only used by MySQL Server when running on Unix operating systems. Clients can then use this socket to connect to MySQL Server using the X Plugin.

The value of `mysqlx_socket` depends on the value of `socket`. By default `socket` is `/tmp/mysql.sock` and therefore `mysqlx_socket` is `/tmp/mysqlx.sock`. If `socket` is set to `/sockets/mysql.sock` and `mysqlx_socket` has not been manually configured, then `mysqlx_socket` is set to `/sockets/mysqlx.sock`. In other words the path and filename of `socket` is used and an `x` is appended to the filename, this enables you to conveniently store the sockets used by MySQL server at a single path. To define separate paths or unique filenames for the MySQL and X Plugin sockets, configure both the `socket` and the `mysqlx_socket` system variables. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

Alternatively, X Plugin can be configured at compile time to use a specific socket with the `MYSQLX_UNIX_ADDR` option. If the X Plugin `MYSQLX_UNIX_ADDR` compile option is not set, the value is based on the `MYSQL_UNIX_ADDR` and adds an `x` to the file name, for example resulting in `/tmp/mysqlx.sock`.

- `--mysqlx-ssl-ca[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-ca=file-name</code>

Property	Value
System Variable	<code>mysqlx_ssl_ca</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The equivalent of `ssl_ca` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-capath[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-capath=dir_name</code>
System Variable	<code>mysqlx_ssl_capath</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The equivalent of `ssl_capath` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-cert[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-cert=name</code>
System Variable	<code>mysqlx_ssl_cert</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The equivalent of `ssl_cert` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-cipher[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-cipher=name</code>
Type	String

The equivalent of `ssl_cipher` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-crl[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-crl=file_name</code>
System Variable	<code>mysqlx_ssl_crl</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The equivalent of `ssl_crl` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-crlpath[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-crlpath=directory_name</code>
System Variable	<code>mysqlx_ssl_crlpath</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The equivalent of `ssl_crlpath` for X Plugin, see that variable for more information.

- `--mysqlx-ssl-key[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-ssl-key=file-name</code>
System Variable	<code>mysqlx_ssl_key</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The equivalent of `ssl_key` for X Plugin, see that variable for more information.

- `--mysqlx-wait-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-wait-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_wait_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1

Property	Value
Maximum Value	2147483

Number of seconds that X Plugin waits for activity on a connection. After this time, if the read-operation is not successful, the connection is aborted. If the client is non-interactive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- `--mysqlx-write-timeout[=value]`

Property	Value
Command-Line Format	<code>--mysqlx-write-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_write_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	2147483

Number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, the connection is aborted.

When X Plugin is running the following system variables are available.

- `mysqlx`

Property	Value
Command-Line Format	<code>--mysqlx[={OFF ON}]</code>
Introduced	8.0.11
System Variable	<code>mysqlx</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether the X Plugin should be disabled. Defaults to `ON`, set to `OFF` to disable X Plugin.

- `mysqlx_bind_address`

Property	Value
Command-Line Format	<code>--mysqlx-bind-address=value</code>
System Variable	<code>mysqlx_bind_address</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	*

The network address which X Plugin uses for connections. The equivalent of `bind_address` for X Plugin, see that variable for more information. This variable is not dynamic and can only be configured at start up.

- `mysqlx_connect_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-connect-timeout=value</code>
System Variable	<code>mysqlx_connect_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	1000000000

Number of seconds X Plugin waits for the first packet to be received from newly connected clients. The equivalent of `connect_timeout` for X Plugin.

- `mysqlx_document_id_unique_prefix`

Property	Value
Command-Line Format	<code>--mysqlx-document-id-unique-prefix=value</code>
System Variable	<code>mysqlx_document_id_unique_prefix</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See [Understanding Document IDs](#).

- `mysqlx_idle_worker_thread_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-idle-worker-thread-timeout=value</code>
System Variable	<code>mysqlx_idle_worker_thread_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	3600

Number of seconds after which an idle worker thread is terminated.

- `mysqlx_interactive_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-interactive-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_interactive_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value	2147483

Default value of the `mysqlx_wait_timeout` session variable for interactive clients.

- `mysqlx_max_allowed_packet`

Property	Value
Command-Line Format	<code>--mysqlx-max-allowed-packet=value</code>
System Variable	<code>mysqlx_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1048576
Minimum Value	512
Maximum Value	1073741824

Maximum size of a network packet that can be received by X Plugin. The X Plugin equivalent of `max_allowed_packet`.

- `mysqlx_min_worker_threads`

Property	Value
Command-Line Format	<code>--mysqlx-min-worker-threads=value</code>
System Variable	<code>mysqlx_min_worker_threads</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	100

Minimum number of worker threads the X Plugin uses for handling client requests.

- `mysqlx_max_connections`

Property	Value
Command-Line Format	<code>--mysqlx-max-connections=value</code>
System Variable	<code>mysqlx_max_connections</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value	65535

Maximum number of concurrent client connections X Plugin can accept. The X Plugin equivalent of `max_connections`.

- `mysqlx_port`

Property	Value
Command-Line Format	<code>--mysqlx-port=value</code>
System Variable	<code>mysqlx_port</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	33060

Property	Value
Minimum Value	1
Maximum Value	65535

The network port which X Plugin uses for connections. The X Plugin equivalent of `port`.

- `mysqlx_port_open_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-port-open-timeout=value</code>
System Variable	<code>mysqlx_port_open_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100

The amount of time in seconds which X Plugin waits for a TCP/IP port to become free.

- `mysqlx_read_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-read-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_read_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	30
Maximum Value	2147483

Number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, the connection is aborted.

- `mysqlx_socket`

Property	Value
Command-Line Format	<code>--mysqlx-socket=file_name</code>
System Variable	<code>mysqlx_socket</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	String
Default Value	<code>/tmp/mysqlx.sock</code>

The socket where X Plugin listens for connections.

- `mysqlx_wait_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-wait-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_wait_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value	2147483

Number of seconds that X Plugin waits for activity on a connection. After this time, if the read-operation is not successful, the connection is aborted. If the client is non-interactive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- `mysqlx_write_timeout`

Property	Value
Command-Line Format	<code>--mysqlx-write-timeout=value</code>
Introduced	8.0.4
System Variable	<code>mysqlx_write_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	2147483

Number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, the connection is aborted.

20.5.6 Monitoring X Plugin

This section describes how to monitor X Plugin. There are two available methods of monitoring, using Performance Schema tables or status variables.

20.5.6.1 Status Variables for X Plugin

The status variables have the following meanings.

- `Mysqlx_aborted_clients`

The number of clients that were disconnected because of an input or output error.

- `Mysqlx_address`

The network address which X Plugin is bound to. If the bind has failed, or if the `skip_networking` option has been used, the value shows `UNDEFINED`.

- `Mysqlx_bytes_sent`

The number of bytes sent through the network.

- `Mysqlx_bytes_received`

The number of bytes received through the network.

- `Mysqlx_stmt_execute_sql`

The number of StmtExecute requests received for the SQL namespace.

- `Mysqlx_stmt_execute_xplugin`

The number of StmtExecute requests received for the X Plugin namespace.

- `Mysqlx_stmt_create_collection`

The number of create collection statements received.

- `Mysqlx_stmt_create_collection_index`

The number of create collection index statements received.

- `Mysqlx_stmt_drop_collection`

The number of drop collection statements received.

- `Mysqlx_stmt_drop_collection_index`

The number of drop collection index statements received.

- `Mysqlx_stmt_ensure_collection`

The number of ensure collection statements received.

- `Mysqlx_stmt_execute_mysqlx`

The number of StmtExecute messages received with namespace set to `mysqlx`.

- `Mysqlx_stmt_list_objects`

The number of list object statements received.

- `Mysqlx_stmt_enable_notices`

The number of enable notice statements received.

- `Mysqlx_stmt_disable_notices`

The number of disable notice statements received.

- `Mysqlx_stmt_list_notices`

The number of list notice statements received.

- `Mysqlx_stmt_list_clients`

The number of list client statements received.

- `Mysqlx_stmt_kill_client`

The number of kill client statements received.

- `Mysqlx_stmt_ping`

The number of ping statements received.

- `Mysqlx_crud_insert`

The number of insert requests received.

- `Mysqlx_crud_update`

The number of update requests received.

- `Mysqlx_crud_create_view`

The number of create view requests received.

- `Mysqlx_crud_drop_view`

The number of drop view requests received.

- `Mysqlx_crud_modify_view`

The number of modify view requests received.

- `Mysqlx_crud_delete`

The number of delete requests received.

- `Mysqlx_crud_find`

The number of find requests received.

- `Mysqlx_expect_open`

The number of expectation blocks opened.

- `Mysqlx_expect_close`

The number of expectation blocks closed.

- `Mysqlx_rows_sent`

The number of rows sent back to clients.

- `Mysqlx_notice_warning_sent`

The number of warning notices sent back to clients.

- `Mysqlx_notice_other_sent`

The number of other types of notices sent back to clients.

- `Mysqlx_port`

The TCP port which X Plugin is listening to. If a network bind has failed, or if the `--skip-networking` option has been used, the value shows `UNDEFINED`.

- `Mysqlx_socket`

The Unix socket which X Plugin is listening to.

- `Mysqlx_ssl_cipher`

The current SSL cipher (empty for non-SSL connections).

- `Mysqlx_ssl_cipher_list`

A list of possible SSL ciphers (empty for non-SSL connections).

- `Mysqlx_ssl_verify_depth`

The certificate verification depth for SSL connections.

- `Mysqlx_ssl_verify_mode`

The certificate verification mode for SSL connections.

- `Mysqlx_ssl_version`

The name of the protocol used for SSL connections.

- `Mysqlx_sessions`

The number of sessions that have been opened.

- `Mysqlx_sessions_closed`

The number of sessions that have been closed.

- `Mysqlx_sessions_fatal_error`

The number of sessions that have closed with a fatal error.

- `Mysqlx_init_error`

The number of errors during initialisation.

- `Mysqlx_sessions_accepted`

The number of session attempts which have been accepted.

- `Mysqlx_sessions_rejected`

The number of session attempts which have been rejected.

- `Mysqlx_sessions_killed`

The number of sessions which have been killed.

- `Mysqlx_connections_closed`

The number of connections which have been closed.

- `Mysqlx_connections_accepted`

The number of connections which have been accepted.

- `Mysqlx_connections_rejected`

The number of connections which have been rejected.

- `Mysqlx_connection_accept_errors`

The number of connections which have caused accept errors.

- `Mysqlx_connection_errors`

The number of connections which have caused errors.

- `Mysqlx_worker_threads`

The number of worker threads available.

- `Mysqlx_worker_threads_active`

The number of worker threads currently used.

- `Mysqlx_ssl_active`

If SSL is active.

- `Mysqlx_ssl_ctx_verify_depth`

The certificate verification depth limit currently set in ctx.

- `Mysqlx_ssl_ctx_verify_mode`

The certificate verification mode currently set in ctx.

- `Mysqlx_ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Mysqlx_ssl_accepts`

The number of accepted SSL connections.

- `Mysqlx_ssl_server_not_after`

The last date for which the SSL certificate is valid.

- `Mysqlx_ssl_server_not_before`

The first date for which the SSL certificate is valid.

- `Mysqlx_ssl_accept_renegotiates`

The number of negotiations needed to establish the connection.

- `Mysqlx_errors_sent`

The number of errors sent to clients.

Chapter 21 InnoDB Cluster

21.3	Using MySQL Router with InnoDB Cluster	3282
21.4	Working with InnoDB Cluster	3285
21.5	Known Limitations	3298

This chapter covers MySQL InnoDB cluster, which combines MySQL technologies to enable you to create highly available clusters of MySQL server instances.

21.1 Introducing InnoDB Cluster

MySQL InnoDB cluster provides a complete high availability solution for MySQL. [MySQL Shell](#) includes AdminAPI which enables you to easily configure and administer a group of at least three MySQL server instances to function as an InnoDB cluster. Each MySQL server instance runs MySQL Group Replication, which provides the mechanism to replicate data within InnoDB clusters, with built-in failover. AdminAPI removes the need to work directly with Group Replication in InnoDB clusters, but for more information see [Chapter 18, Group Replication](#) which explains the details. [MySQL Router](#) can automatically configure itself based on the cluster you deploy, connecting client applications transparently to the server instances. In the event of an unexpected failure of a server instance the cluster reconfigures automatically. In the default single-primary mode, an InnoDB cluster has a single read-write server instance - the primary. Multiple secondary server instances are replicas of the primary. If the primary fails, a secondary is automatically promoted to the role of primary. MySQL Router detects this and forwards client applications to the new primary. Advanced users can also configure a cluster to have multiple-primaries.

Important

InnoDB cluster does not provide support for MySQL NDB Cluster. NDB Cluster depends on the [NDB](#) storage engine as well as a number of programs specific to NDB Cluster which are not furnished with MySQL Server 8.0; [NDB](#) is available only as part of the MySQL NDB Cluster distribution. In addition, the MySQL server binary ([mysqld](#)) that is supplied with MySQL Server 8.0 cannot be used with NDB Cluster. For more information about MySQL NDB Cluster, see [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#). [MySQL Server Using InnoDB Compared with NDB Cluster](#), provides information about the differences between the [InnoDB](#) and [NDB](#) storage engines.

The following diagram shows an overview of how these technologies work together:

Figure 21.1 InnoDB cluster overview

Using AdminAPI

MySQL Shell includes the AdminAPI, which is accessed through the `dba` global variable and its associated methods. The `dba` variable's methods enable you to deploy, configure, and administer InnoDB clusters. For example, use the `dba.createCluster()` method to create an InnoDB cluster.

Important

MySQL Shell enables you to connect to servers over a socket connection, but AdminAPI requires TCP connections to a server instance. Socket based connections are not supported in AdminAPI.

MySQL Shell provides online help for the AdminAPI. To list all available `dba` commands, use the `dba.help()` method. For online help on a specific method, use the general format `object.help('methodname')`. For example:

```
mysql-js> dba.help('getCluster')
```

Retrieves a cluster from the Metadata Store.

SYNTAX

```
dba.getCluster([name][, options])
```

WHERE

name: Parameter to specify the name of the cluster to be returned.
options: Dictionary with additional options.

RETURNS

The cluster object identified by the given name or the default cluster.

DESCRIPTION

If name is not specified or is null, the default cluster will be returned.

If name is specified, and no cluster with the indicated name is found, an error will be raised.

The options dictionary accepts the `connectToPrimary` option, which defaults to true and indicates the shell to automatically connect to the primary member of the cluster.

EXCEPTIONS

MetadataError in the following scenarios:

- If the Metadata is inaccessible.
- If the Metadata update operation failed.

ArgumentError in the following scenarios:

- If the Cluster name is empty.
- If the Cluster name is invalid.
- If the Cluster does not exist.

RuntimeError in the following scenarios:

- If the current connection cannot be used for Group Replication.

21.2 Creating an InnoDB Cluster

This section explains the different ways you can create an InnoDB cluster, the requirements for server instances and the software you need to install to deploy a cluster.

21.2.1 Deployment Scenarios

InnoDB cluster supports the following deployment scenarios:

- *Production deployment:* if you want to use InnoDB cluster in a full production environment you need to configure the required number of machines and then deploy your server instances to the machines. A production deployment enables you to exploit the high availability features of InnoDB cluster to their full potential. See [Section 21.2.4, “Production Deployment of InnoDB Cluster”](#) for instructions.
- *Sandbox deployment:* if you want to test out InnoDB cluster before committing to a full production deployment, the provided sandbox feature enables you to quickly set up a cluster on your local machine. Sandbox server instances are created with the required configuration and you can experiment with InnoDB cluster to become familiar with the technologies employed. See [Section 21.2.5, “Sandbox Deployment of InnoDB Cluster”](#) for instructions.

Important

A sandbox deployment is not suitable for use in a full production environment.

21.2.2 InnoDB Cluster Requirements

Before installing a production deployment of InnoDB cluster, ensure that the server instances you intend to use meet the following requirements.

- InnoDB cluster uses Group Replication and therefore your server instances must meet the same requirements. See [Section 18.7.1, “Group Replication Requirements”](#). AdminAPI provides the `dba.checkInstanceConfiguration()` method to verify that an instance meets the Group Replication requirements, and the `dba.configureInstance()` method to configure an instance to meet the requirements.

Note

When using a sandbox deployment the instances are configured to meet these requirements automatically.

- Group Replication members can contain tables using a storage engine other than [InnoDB](#), for example [MyISAM](#). Such tables cannot be written to by Group Replication, and therefore when using InnoDB cluster. To be able to write to such tables with InnoDB cluster, convert all such tables to [InnoDB](#) before using the instance in a InnoDB cluster.
- The provisioning scripts that MySQL Shell uses to configure servers for use in InnoDB cluster require access to Python version 2.7. For a sandbox deployment Python is required on the single machine used for the deployment, production deployments require Python on each server instance which should run MySQL Shell locally, see [Persisting Settings](#).

On Windows MySQL Shell includes Python and no user configuration is required. On Unix Python must be found as part of the shell environment. To check that your system has Python configured correctly issue:

```
$ /usr/bin/env python
```

If a Python interpreter starts, no further action is required. If the previous command fails, create a soft link between `/usr/bin/python` and your chosen Python binary.

21.2.3 Methods of Installing

The method you use to install InnoDB cluster depends on the type of deployment you intend to use. For a sandbox deployment install the components of InnoDB cluster to a single machine. A sandbox deployment is local to a single machine, therefore the install needs to only be done once on the local machine. For a production deployment install the components to each machine that you intend to add to your cluster. A production deployment uses multiple remote host machines running MySQL server instances, so you need to connect to each machine using a tool such as SSH or Windows remote desktop to carry out tasks such as installing components. The following methods of installing InnoDB cluster are available:

- Downloading and installing the components using the following documentation:
 - MySQL Server - see [Chapter 2, Installing and Upgrading MySQL](#).
 - MySQL Shell - see [Section 20.2.1, “Installing MySQL Shell”](#).
 - MySQL Router - see [Installing MySQL Router](#).
- On Windows you can use the MySQL Installer for Windows for a sandbox deployment. For details, see [Group Replication](#).

Once you have installed the software required by InnoDB cluster choose to follow either [Section 21.2.5, “Sandbox Deployment of InnoDB Cluster”](#) or [Section 21.2.4, “Production Deployment of InnoDB Cluster”](#).

21.2.4 Production Deployment of InnoDB Cluster

When working in a production environment, the MySQL server instances which make up an InnoDB cluster run on multiple host machines as part of a network rather than on single machine as described in [Section 21.2.5, “Sandbox Deployment of InnoDB Cluster”](#). Before proceeding with these instructions you must install the required software to each machine that you intend to add as a server instance to your cluster, see [Section 21.2.3, “Methods of Installing”](#).

The following diagram illustrates the scenario you work with in this section:

Important

Unlike a sandbox deployment, where all instances are deployed locally to one machine which AdminAPI has local file access to and can persist configuration changes, for a production deployment you must persist any configuration changes on the instance. How you do this depends on the version of MySQL running on the instance, see [Persisting Settings](#).

To pass a server's connection information to AdminAPI use URI type strings or a data dictionary, see [Section 4.2.3, "Connecting Using a Path"](#). In this documentation URI type strings are shown.

User Privileges

The user account used to administer an instance does not have to be the root account, however the user needs to be assigned full read and write privileges on the InnoDB cluster metadata tables in addition to full MySQL administrator privileges (`SUPER`, `GRANT OPTION`, `CREATE`, `DROP` and so on). The preferred method to create users to administer the cluster is using the `clusterAdmin` option with the `dba.configureInstance()`, and `Cluster.addInstance()` operations. In this procedure the user `ic` is shown in examples.

If only read operations are needed (such as for monitoring purposes), an account with more restricted privileges can be used. To give the user `your_user` the privileges needed to monitor InnoDB cluster issue:

```
GRANT SELECT ON mysql_innodb_cluster_metadata.* TO your_user@'%';
GRANT SELECT ON performance_schema.global_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_coordinator TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_worker TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_member_stats TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_members TO your_user@'%';
GRANT SELECT ON performance_schema.threads TO your_user@'%' WITH GRANT OPTION;
```

User Accounts Created by InnoDB Cluster

As part of using Group Replication, InnoDB cluster creates internal users which enable replication between the servers in the cluster. These users are internal to the cluster, and the user name of the generated users follows a naming scheme of `mysql_innodb_cluster_r[10_numbers]`. The hostname used for the internal users depends on whether the `ipWhitelist` option has been configured. If `ipWhitelist` is not configured, it defaults to `AUTOMATIC` and the internal users are created using both the wildcard `%` character and `localhost` for the hostname value. When `ipWhitelist` has been configured, for each address in the `ipWhitelist` list an internal user is created. For more information, see [Creating a Whitelist of Servers](#).

Each internal user has a randomly generated password. The randomly generated users are given the following grants:

```
GRANT REPLICATION SLAVE ON *.* to internal_user;
```

The internal user accounts are created on the seed instance and then replicated to the other instances in the cluster. The internal users are:

- generated when creating a new cluster by issuing `dba.createCluster()`

- generated when adding a new instance to the cluster by issuing `Cluster.addInstance()`.

In addition, the `Cluster.rejoinInstance()` operation can also result in a new internal user being generated when the `ipWhitelist` option is used to specify a hostname. For example by issuing:

```
Cluster.rejoinInstance({ipWhitelist: "192.168.1.1/22"});
```

all previously existing internal users are removed and a new internal user is created, taking into account the `ipWhitelist` value used.

For more information on the internal users required by Group Replication, see [Section 18.2.1.3, “User Credentials”](#).

Configuring Hostname

The production instances which make up a cluster run on separate machines, therefore each machine must have a unique host name and be able to resolve the host names of the other machines which run server instances in the cluster. If this is not the case, you can:

- configure each machine to map the IP of each other machine to a hostname. See your operating system documentation for details. This is the recommended solution.
- set up a DNS service
- configure the `report_host` variable in the MySQL configuration of each instance to a suitable externally reachable address

In this procedure the host name `ic-number` is used in examples.

To verify whether the hostname of a MySQL server is correctly configured, execute the following query to see how the instance reports its own address to other servers and try to connect to that MySQL server from other hosts using the returned address:

```
SELECT coalesce(@report_host, @@hostname);
```

Persisting Settings

The AdminAPI commands you use to work with a cluster and its server instances modify the configuration of the instance. Depending on the way MySQL Shell is connected to the instance and the version of MySQL installed on the instance, these configuration changes can be persisted to the instance automatically. Persisting settings to the instance ensures that configuration changes are retained after the instance restarts, for background information see [SET PERSIST](#). This is essential for reliable cluster usage, for example if settings are not persisted then an instance which has been added to a cluster does not rejoin the cluster after a restart because configuration changes are lost. Persisting changes is required after the following operations:

- `dba.configureInstance()`
- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.removeInstance()`
- `Cluster.rejoinInstance()`

Instances which meet the following requirements support persisting configuration changes automatically:

- the instance is running MySQL version 8.0.11 or later
- `persisted_globals_load` is set to `ON`

Instances which do not meet these requirements do not support persisting configuration changes automatically, when AdminAPI operations result in changes to the instance's settings to be persisted you receive warnings such as:

```
WARNING: On instance 'localhost:3320' membership change cannot be persisted since MySQL version 5.7.21 does not support the SET PERSIST command (MySQL version >= 8.0.5 required). Please use the <Db>.configureLocalInstance command locally to persist the changes.
```

When AdminAPI commands are issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, MySQL Shell persists configuration changes directly to the instance. On local instances which support persisting configuration changes automatically, configuration changes are persisted to the instance's `mysqld-auto.cnf` file and the configuration change does not require any further steps. On local instances which do not support persisting configuration changes automatically, you need to make the changes locally, see [Configuring Local Instances](#).

When run against a remote instance, in other words an instance other than the one which MySQL Shell is currently running on, if the instance supports persisting configuration changes automatically, the AdminAPI commands persist configuration changes to the instance's `mysql-auto.conf` option file. If a remote instance does not support persisting configuration changes automatically, the AdminAPI commands can not automatically configure the instance's option file. This means that AdminAPI commands can read information from the instance, for example to display the current configuration, but changes to the configuration cannot be persisted to the instance's option file. In this case, you need to persist the changes locally, see [Configuring Local Instances](#).

Verbose Logging

When working with a production deployment it can be useful to configure verbose logging for MySQL Shell, the information in the log can help you to find and resolve any issues that might occur when you are preparing server instances to work as part of InnoDB cluster. To start MySQL Shell with a verbose logging level use the `--log-level` option:

```
shell> mysqlsh --log-level=DEBUG3
```

The `DEBUG3` is recommended, see `--log-level` for more information. When `DEBUG3` is set the MySQL Shell log file contains lines such as `Debug: execute_sql(...)` which contain the SQL queries that are executed as part of each AdminAPI call. The log file generated by MySQL Shell is located in `~/.mysqlsh/mysqlsh.log` for Unix-based systems; on Microsoft Windows systems it is located in `%APPDATA%\MySQL\mysqlsh\mysqlsh.log`. See [MySQL Shell Application Log](#) for more information.

In addition to enabling the MySQL Shell log level, you can configure the amount of output AdminAPI provides in MySQL Shell after issuing each command. To enable the amount of AdminAPI output, in MySQL Shell issue:

```
mysql-js> dba.verbose=2
```

This enables the maximum output from AdminAPI calls. The available levels of output are:

- 0 or OFF is the default. This provides minimal output and is the recommended level when not troubleshooting.
- 1 or ON adds verbose output from each call to the AdminAPI.

- 2 adds debug output to the verbose output providing full information about what each call to AdminAPI executes.

Configuring Production Instances

AdminAPI provides the `dba.configureInstance()` function that checks if an instance is suitably configured for InnoDB cluster usage, and configures the instance if it finds any settings which are not compatible with InnoDB cluster. You run the `dba.configureInstance()` command against an instance and it checks all of the settings required to enable the instance to be used for InnoDB cluster usage. If the instance does not require configuration changes, there is no need to modify the configuration of the instance, and the `dba.configureInstance()` command output confirms that the instance is ready for InnoDB cluster usage. If any changes are required to make the instance compatible with InnoDB cluster, a report of the incompatible settings is displayed, and you can choose to let the command make the changes to the instance's option file. Depending on the way MySQL Shell is connected to the instance, and the version of MySQL running on the instance, you can make these changes permanent by persisting them to a remote instance's option file, see [Persisting Settings](#). Instances which do not support persisting configuration changes automatically require that you configure the instance locally, see [Configuring Local Instances](#). Alternatively you can make the changes to the instance's option file manually, see [Section 4.2.7, "Using Option Files"](#) for more information. Regardless of the way you make the configuration changes, you might have to restart MySQL to ensure the configuration changes are detected.

The syntax of the `dba.configureInstance()` command is:

```
dba.configureInstance([instance][, options])
```

where *instance* is an instance definition, and *options* is a data dictionary with additional options to configure the operation. The command returns a descriptive text message about the operation's result.

The instance definition is the connection data for the instance. If the target instance already belongs to an InnoDB cluster an error is generated and the process fails.

The options dictionary can contain the following:

- `mycnfPath` - the path to the MySQL option file of the instance.
- `outputMycnfPath` - alternative output path to write the MySQL option file of the instance.
- `password` - the password to be used by the connection.
- `clusterAdmin` - the name of an InnoDB cluster administrator user to be created. The supported format is the standard MySQL account name format. Supports identifiers or strings for the user name and host name. By default if unquoted it assumes input is a string.
- `clusterAdminPassword` - the password for the InnoDB cluster administrator account being created using `clusterAdmin`.
- `clearReadOnly` - a boolean value used to confirm that `super_read_only` should be set to off, see [Super Read-only and Instances](#).
- `interactive` - a boolean value used to disable the interactive wizards in the command execution, so that prompts are not provided to the user and confirmation prompts are not shown.
- `restart` - a boolean value used to indicate that a remote restart of the target instance should be performed to finalize the operation.

The connection password can be contained in the instance definition. Alternatively, it can be overwritten by specifying it using the `password` option.

Once `dba.configureInstance()` is issued against an instance, the command checks if the instance's settings are suitable for InnoDB cluster usage. A report is displayed which shows the settings required by InnoDB cluster. If the instance does not require any changes to its settings you can use it in an InnoDB cluster, and can proceed to [Creating the Cluster](#). If the instance's settings are not valid for InnoDB cluster usage the `dba.configureInstance()` command displays the settings which require modification. Before configuring the instance you are prompted to confirm the changes shown in a table with the following information:

- **Variable** - the invalid configuration variable.
- **Current Value** - the current value for the invalid configuration variable.
- **Required Value** - the required value for the configuration variable.

How you proceed depends on whether the instance supports persisting settings, see [Persisting Settings](#). When `dba.configureInstance()` is issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, it attempts to automatically configure the instance. When `dba.configureInstance()` is issued against a remote instance, if the instance supports persisting configuration changes automatically, you can choose to do this. If a remote instance does not support persisting the changes to configure it for InnoDB cluster usage, you have to configure the instance locally. See [Configuring Local Instances](#).

In general, a restart of the instance is not required after `dba.configureInstance()` configures the option file, but for some specific settings a restart might be required. This information is shown in the report generated after issuing `dba.configureInstance()`. If the instance supports the `RESTART` statement, MySQL Shell can shutdown and then start the instance. This ensures that the changes made to the instance's option file are detected by `mysqld`. For more information see [RESTART](#).

**Note**

After executing a `RESTART` statement, the current connection to the instance is lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

The `dba.configureInstance()` method verifies that a suitable user is available for cluster usage, which is used for connections between members of the cluster, see [User Privileges](#). The recommended way to add a suitable user is to use the `clusterAdmin` and `clusterAdminPassword` options, which enable you to configure the cluster user and password when calling the function. For example:

```
mysql-js> dba.configureInstance('ic@ic-1:3306', \
{clusterAdmin: 'icadmin@ic-1%',clusterAdminPassword: 'password'});
```

This user is granted the privileges to be able to administer the cluster. The format of the user names accepted follows the standard MySQL account name format, see [Section 6.2.4, "Specifying Account Names"](#).

If you do not specify a user to administer the cluster, in interactive mode a wizard enables you to choose one of the following options:

- enable remote connections for the root user
- create a new user, the equivalent of specifying the `clusterAdmin` and `clusterAdminPassword` options
- no automatic configuration, in which case you need to manually create the user

The following example demonstrates the option to create a new user for cluster usage.

```
mysql-js> dba.configureLocalInstance('root@localhost:3306')

Please provide the password for 'root@localhost:3306':

Please specify the path to the MySQL configuration file: /etc/mysql/mysql.conf.d/mysqld.cnf
Validating instance...

The configuration has been updated but it is required to restart the server.
{

    }
  ],
  "errors": [],
  "restart_required": true,
  "status": "error"
}
mysql-js>
```

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

Creating the Cluster

Once you have prepared your instances, use the `dba.createCluster()` function to create the cluster. The machine which you are running MySQL Shell on is used as the seed instance for the cluster. The seed instance is replicated to the other instances which you add to the cluster, making them replicas of the seed instance.

MySQL Shell must be connected to an instance before you can create a cluster because when you issue `dba.createCluster(name)` MySQL Shell creates a MySQL protocol session to the server instance connected to the MySQL Shell's current global session. Use the `dba.createCluster(name)` function to create the cluster and assign the returned cluster to a variable called `cluster`:

```
mysql-js> var cluster = dba.createCluster('testCluster')

Validating instance at ic@ic-1:3306...

This instance reports its own address as ic-1

Instance configuration is suitable.
Creating InnoDB cluster 'testCluster' on 'ic@ic-1:3306'...

Adding Seed Instance...
Cluster successfully created. Use Cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to
one server failure.
```

The returned Cluster object uses a new session, independent from the MySQL Shell's main session. This ensures that if you change the MySQL Shell global session, the Cluster object maintains its session to the instance.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

Note

If you encounter an error related to metadata being inaccessible you might have the loopback network interface configured. For correct InnoDB cluster usage disable the loopback interface.

To check the cluster has been created, use the cluster instance's `status()` function. See [Checking the InnoDB Cluster Status](#).

Tip

Once server instances belong to a cluster it is important to only administer them using MySQL Shell and AdminAPI. Attempting to manually change the configuration of Group Replication on an instance once it has been added to a cluster is not supported. Similarly, modifying server variables critical to InnoDB cluster, such as `server_uuid` after an instance is configured using AdminAPI is not supported.

Adding Instances to a Cluster

Use the `cluster.addInstance(instance)` function to add more instances to the cluster, where `instance` is connection information to a configured instance, see [Configuring Production Instances](#). You need a minimum of three instances in the cluster to make it tolerant to the failure of one instance. Adding further instances increases the tolerance to failure of an instance. To add an instance to the cluster issue:

```
mysql-js> cluster.addInstance('ic@ic-2:3306')
A new instance will be added to the InnoDB cluster. Depending on the amount of
data on the cluster this might take from a few seconds to several hours.

Please provide the password for 'ic@ic-2:3306': *****
Adding instance to the cluster ...

Validating instance at ic-2:3306...

This instance reports its own address as ic-2

Instance configuration is suitable.

The instance 'ic@ic-2:3306' was successfully added to the cluster.
```

To verify the instance has been added, use the cluster instance's `status()` function. For example this is the status output of a sandbox cluster after adding a second instance:

```
mysql-js> cluster.status()
{
  "clusterName": "testCluster",
  "defaultReplicaSet": {
    "name": "default",
    "primary": "localhost:3310",
    "ssl": "REQUIRED",
    "status": "OK_NO_TOLERANCE",
    "statusText": "Cluster is NOT tolerant to any failures.",
    "topology": {
      "localhost:3310": {
        "address": "localhost:3310",
        "mode": "R/W",
        "readReplicas": {},
        "role": "HA",
        "status": "ONLINE"
      },
      "localhost:3320": {
        "address": "localhost:3320",
        "mode": "R/O",
        "readReplicas": {},
        "role": "HA",
        "status": "ONLINE"
      }
    }
  },
  "groupInformationSourceMember": "mysql://root@localhost:3310"
}
```

How you proceed depends on whether the instance is local or remote to the instance MySQL Shell is running on, and whether the instance supports persisting configuration changes automatically, see [Persisting Settings](#). If the instance supports persisting configuration changes automatically, you do not need to persist the settings manually and can either add more instances or continue to the next step. If the instance does not support persisting configuration changes automatically, you have to configure the instance locally. See [Configuring Local Instances](#). This is essential to ensure that instances rejoin the cluster in the event of leaving the cluster.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see [Section 21.3, “Using MySQL Router with InnoDB Cluster”](#).

21.2.5 Sandbox Deployment of InnoDB Cluster

This section explains how to set up a sandbox InnoDB cluster deployment. You create and administer your InnoDB clusters using MySQL Shell with the included AdminAPI. This section assumes familiarity with MySQL Shell, see [MySQL Shell 8.0 \(part of MySQL 8.0\)](#) for further information.

Initially deploying and using local sandbox instances of MySQL is a good way to start your exploration of InnoDB cluster. You can fully test out InnoDB cluster locally, prior to deployment on your production servers. MySQL Shell has built-in functionality for creating sandbox instances that are correctly configured to work with Group Replication in a locally deployed scenario.

Important

Sandbox instances are only suitable for deploying and running on your local machine for testing purposes. In a production environment the MySQL Server instances are deployed to various host machines on the network. See [Section 21.2.4, “Production Deployment of InnoDB Cluster”](#) for more information.

This tutorial shows how to use MySQL Shell to create an InnoDB cluster consisting of three MySQL server instances.

- [Deploying Sandbox Instances](#)
- [Creating the Sandbox InnoDB Cluster](#)
- [Adding Instances to an InnoDB Cluster](#)
- [Persisting the Sandbox Configuration](#)

Deploying Sandbox Instances

MySQL Shell includes the AdminAPI that adds the `dba` global variable, which provides functions for administration of sandbox instances. In this example setup, you create three sandbox instances using `dba.deploySandboxInstance()`.

Start MySQL Shell from a command prompt by issuing the command:

```
shell> mysqlsh
```

MySQL Shell provides two scripting language modes, JavaScript and Python, in addition to a native SQL mode. Throughout this guide MySQL Shell is used primarily in JavaScript mode. When MySQL Shell starts it is in JavaScript mode by default. Switch modes by issuing `\js` for JavaScript mode, `\py` for Python mode, and `\sql` for SQL mode. Ensure you are in JavaScript mode by issuing the `\js` command, then execute:

```
mysql-js> dba.deploySandboxInstance(3310)
```

Note

Terminating commands with a semi-colon is not required in JavaScript and Python modes.

The argument passed to `deploySandboxInstance()` is the TCP port number where the MySQL Server instance listens for connections. By default the sandbox is created in a directory named `$HOME/mysql-`

`sandboxes/port` on Unix systems. For Microsoft Windows systems the directory is `%userprofile%\MySQL\mysql-sandboxes\port`.

The root user's password for the instance is prompted for.

Important

Each instance has its own password. Defining the same password for all sandboxes in this tutorial makes it easier, but remember to use different passwords for each instance in production deployments.

To deploy further sandbox server instances, repeat the steps followed for the sandbox instance at port 3310, choosing different port numbers. For each additional sandbox instance issue:

```
mysql-js> dba.deploySandboxInstance(port_number)
```

To follow this tutorial, use port numbers 3310, 3320 and 3330 for the three sandbox server instances. Issue:

```
mysql-js> dba.deploySandboxInstance(3320)
mysql-js> dba.deploySandboxInstance(3330)
```

Creating the Sandbox InnoDB Cluster

The next step is to create the InnoDB cluster while connected to the seed MySQL Server instance. The seed instance contains the data that you want to replicate to the other instances. In this example the sandbox instances are blank, therefore we can choose any instance.

Connect MySQL Shell to the seed instance, in this case the one at port 3310:

```
mysql-js> \connect root@localhost:3310
```

The `\connect` MySQL Shell command is a shortcut for the `shell.connect()` method:

```
mysql-js> shell.connect('root@localhost:3310')
```

Once you have connected, AdminAPI can write to the local instance's option file. This is different to working with a production deployment, where you would need to connect to the remote instance and run the MySQL Shell application locally on the instance before AdminAPI can write to the instance's option file.

Use the `dba.createCluster()` method to create the InnoDB cluster with the currently connected instance as the seed:

```
mysql-js> var cluster = dba.createCluster('testCluster')
```

The `createCluster()` method deploys the InnoDB cluster metadata to the selected instance, and adds the instance you are currently connected to as the seed instance. The `createCluster()` method returns the created cluster, in the example above this is assigned to the `cluster` variable. The parameter passed to the `createCluster()` method is a symbolic name given to this InnoDB cluster, in this case `testCluster`.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

Adding Instances to an InnoDB Cluster

The next step is to add more instances to the InnoDB cluster. Any transactions that were executed by the seed instance are re-executed by each secondary instance as it is added. This tutorial uses the sandbox instances that were created earlier at ports 3320 and 3330.

The seed instance in this example was recently created, so it is nearly empty. Therefore, there is little data that needs to be replicated from the seed instance to the secondary instances. In a production environment, where you have an existing database on the seed instance, you could use a tool such as MySQL Enterprise Backup to ensure that the secondaries have matching data before replication starts. This avoids the possibility of lengthy delays while data replicates from the primary to the secondaries. See [Section 18.4.4, “Using MySQL Enterprise Backup with Group Replication”](#).

Add the second instance to the InnoDB cluster:

```
mysql-js> cluster.addInstance('root@localhost:3320')
```

The root user's password is prompted for.

Add the third instance:

```
mysql-js> cluster.addInstance('root@localhost:3330')
```

The root user's password is prompted for.

At this point you have created a cluster with three instances: a primary, and two secondaries.

Tip

You can only specify `localhost` in `addInstance()` if the instance is a sandbox instance. This also applies to the implicit `addInstance()` after issuing `createCluster()`.

Persisting the Sandbox Configuration

Once the sandbox instances have been added to the cluster, the configuration required for InnoDB cluster must be persisted to each of the instance's option files. How you proceed depends on whether the instance supports persisting configuration changes automatically, see [Persisting Settings](#). When the MySQL instance which you are using supports persisting configuration changes automatically, adding the instance automatically configures the instance. When the MySQL instance which you are using does not support persisting configuration changes automatically, you have to configure the instance locally. See [Configuring Local Instances](#).

To check the cluster has been created, use the cluster instance's `status()` function. See [Checking the InnoDB Cluster Status](#).

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see [Section 21.3, “Using MySQL Router with InnoDB Cluster”](#).

21.2.6 Adopting a Group Replication Deployment

If you have an existing deployment of Group Replication and you want to use it to create a cluster, pass the `adoptFromGR` option to the `dba.createCluster()` function. The created InnoDB cluster matches whether the replication group is running as single-primary or multi-primary.

To adopt an existing Group Replication group, connect to a group member using MySQL Shell. In the following example a single-primary group is adopted. We connect to `gr-member-2`, a secondary instance, while `gr-member-1` is functioning as the group's primary. Create a cluster using `dba.createCluster()`, passing in the `adoptFromGR` option. For example:

```
mysql-js> var cluster = dba.createCluster('prodCluster', {adoptFromGR: true});

A new InnoDB cluster will be created on instance 'root@gr-member-2:3306'.

Creating InnoDB cluster 'prodCluster' on 'root@gr-member-2:3306'...
Adding Seed Instance...

Cluster successfully created. Use cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to
one server failure.
```

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

The new cluster matches the mode of the group. If the adopted group was running in single-primary mode then a single-primary cluster is created. If the adopted group was running in multi-primary mode then a multi-primary cluster is created.

21.3 Using MySQL Router with InnoDB Cluster

This section describes how to use MySQL Router with InnoDB cluster to achieve high availability. Regardless of whether you have deployed a sandbox or production cluster, MySQL Router can configure itself based on the InnoDB cluster's metadata using the `--bootstrap` option. This configures MySQL Router automatically to route connections to the cluster's server instances. Client applications connect to the ports MySQL Router provides, without any need to be aware of the InnoDB cluster topology. In the event of an unexpected failure, the InnoDB cluster adjusts itself automatically and MySQL Router detects the change. This removes the need for your client application to handle failover. For more information, see [Routing for MySQL InnoDB cluster](#).

Note

Do not attempt to configure MySQL Router manually to redirect to the ports of an InnoDB cluster. Always use the `--bootstrap` option as this ensures that MySQL Router takes its configuration from the InnoDB cluster's metadata. See [Cluster Metadata and State](#).

The recommended deployment of MySQL Router is on the same host as the application. When using a sandbox deployment, everything is running on a single host, therefore you deploy MySQL Router to the same host. When using a production deployment, we recommend deploying one MySQL Router instance to each machine used to host one of your client applications. It is also possible to deploy MySQL Router to a common machine through which your application instances connect.

Assuming MySQL Router is already installed (see [Installing MySQL Router](#)), use the `--bootstrap` option to provide the location of a server instance that belongs to the InnoDB cluster. MySQL Router uses the included metadata cache plugin to retrieve the InnoDB cluster's metadata, consisting of a list of server instance addresses which make up the InnoDB cluster and their role in the cluster. You pass the URI type string of the server that MySQL Router should retrieve the InnoDB cluster metadata from. For example:

```
shell> mysqlrouter --bootstrap ic@ic-1:3306 --user=mysqlrouter
```

You are prompted for the instance password and encryption key for MySQL Router to use. This encryption key is used to encrypt the instance password used by MySQL Router to connect to the cluster. The ports you can use to connect to the InnoDB cluster are also displayed. The MySQL Router bootstrap process creates a `mysqlrouter.conf` file, with the settings based on the cluster metadata retrieved from the address passed to the `--bootstrap` option, in the above example `ic@ic-1:3306`. Based on the InnoDB cluster metadata retrieved, MySQL Router automatically configures the `mysqlrouter.conf` file, including a `metadata_cache` section with `bootstrap_server_addresses` containing the addresses for all server instances in the cluster. For example:

```
[metadata_cache:prodCluster]
router_id=1
bootstrap_server_addresses=mysql://ic@ic-1:3306,mysql://ic@ic-2:3306,mysql://ic@ic-3:3306
user=mysql_router1_jy95yozko3k2
metadata_cluster=prodCluster
ttl=300
```

Tip

When you change the topology of a cluster by adding another server instance after you have bootstrapped MySQL Router, you need to update `bootstrap_server_addresses` based on the updated metadata. Either restart MySQL Router using the `--bootstrap` option, or manually edit the `bootstrap_server_addresses` section of the `mysqlrouter.conf` file and restart MySQL Router.

The generated MySQL Router configuration creates TCP ports which you use to connect to the cluster. Ports for communicating with the cluster using both Classic MySQL protocol and X Protocol are created. To use X Protocol the server instances must have X Plugin installed and configured. For a sandbox deployment, instances have X Plugin set up automatically. For a production deployment, if you want to use X Protocol you need to install and configure X Plugin on each instance, see [Section 20.2, “Setting Up MySQL as a Document Store”](#). The default available TCP ports are:

- **6446** - for Classic MySQL protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- **6447** - for Classic MySQL protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.
- **64460** - for X Protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- **64470** - for X Protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

Depending on your MySQL Router configuration the port numbers might be different to the above. For example if you use the `--conf-base-port` option, or the `group_replication_single_primary_mode` variable. The exact ports are listed when you start MySQL Router.

The way incoming connections are redirected depends on the type of cluster being used. When using a single-primary cluster, by default MySQL Router publishes a X Protocol and a classic protocol port, which clients connect to for read-write sessions and which are redirected to the cluster's single primary. With a multi-primary cluster read-write sessions are redirected to one of the primary instances in a round-robin fashion. For example, this means that the first connection to port 6446 would be redirected to the

ic-1 instance, the second connection to port 6446 would be redirected to the ic-2 instance, and so on. For incoming read-only connections MySQL Router redirects connections to one of the secondary instances, also in a round-robin fashion. To modify this behavior see the [routing_strategy](#) option.

Once bootstrapped and configured, start MySQL Router. If you used a system wide install with the `--bootstrap` option then issue:

```
shell> mysqlrouter &
```

If you installed MySQL Router to a directory using the `--directory` option, use the `start.sh` script found in the directory you installed to. Alternatively set up a service to start MySQL Router automatically when the system boots, see [Starting MySQL Router](#). You can now connect a MySQL client, such as MySQL Shell to one of the incoming MySQL Router ports as described above and see how the client gets transparently connected to one of the InnoDB cluster instances.

```
shell> mysqlsh --uri root@localhost:6442
```

To verify which instance you are actually connected to, simply issue an SQL query against the `port` status variable.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-sql> select @@port;
+-----+
| @@port |
+-----+
| 3310   |
+-----+
```

Testing High Availability

To test if high availability works, simulate an unexpected halt by killing an instance. The cluster detects the fact that the instance left the cluster and reconfigures itself. Exactly how the cluster reconfigures itself depends on whether you are using a single-primary or multi-primary cluster, and the role the instance serves within the cluster.

In single-primary mode:

- If the current primary leaves the cluster, one of the secondary instances is elected as the new primary, with instances prioritized by the lowest `server_uuid`. MySQL Router redirects read-write connections to the newly elected primary.
- If a current secondary leaves the cluster, MySQL Router stops redirecting read-only connections to the instance.
