

MySQL 8.0 Reference Manual

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 8.0 through 8.0.15. It may include documentation of features of MySQL versions that have not yet been released. For information about which versions have been released, see the [MySQL 8.0 Release Notes](#).

MySQL Cluster is currently not supported in MySQL 8.0. For information about MySQL Cluster, please see [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).

MySQL 8.0 features. This manual describes features that are not included in every edition of MySQL 8.0; such features may not be included in the edition of MySQL 8.0 licensed to you. If you have any questions about the features included in your edition of MySQL 8.0, refer to your MySQL 8.0 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the [MySQL 8.0 Release Notes](#).

For legal information, including licensing information, see the [Preface and Legal Notices](#).

For help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#), where you can discuss your issues with other MySQL users.

Table of Contents

Preface and Legal Notices	xxvii
1 General Information	1
1.1 About This Manual	2
1.2 Typographical and Syntax Conventions	3
1.3 Overview of the MySQL Database Management System	4
1.3.1 What is MySQL?	4
1.3.2 The Main Features of MySQL	6
1.3.3 History of MySQL	9
1.4 What Is New in MySQL 8.0	9
1.5 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0	28
1.6 MySQL Information Sources	37
1.6.1 MySQL Websites	37
1.6.2 MySQL Mailing Lists	37
1.6.3 MySQL Community Support at the MySQL Forums	40
1.6.4 MySQL Community Support on Internet Relay Chat (IRC)	40
1.6.5 MySQL Enterprise	40
1.7 How to Report Bugs or Problems	41
1.8 MySQL Standards Compliance	45
1.8.1 MySQL Extensions to Standard SQL	46
1.8.2 MySQL Differences from Standard SQL	49
1.8.3 How MySQL Deals with Constraints	51
1.9 Credits	54
1.9.1 Contributors to MySQL	54
1.9.2 Documenters and translators	59
1.9.3 Packages that support MySQL	60
1.9.4 Tools that were used to create MySQL	61
1.9.5 Supporters of MySQL	61
2 Installing and Upgrading MySQL	63
2.1 General Installation Guidance	65
2.1.1 Which MySQL Version and Distribution to Install	65
2.1.2 How to Get MySQL	67
2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG	67
2.1.4 Installation Layouts	81
2.1.5 Compiler-Specific Build Characteristics	81
2.2 Installing MySQL on Unix/Linux Using Generic Binaries	81
2.3 Installing MySQL on Microsoft Windows	84
2.3.1 MySQL Installation Layout on Microsoft Windows	87
2.3.2 Choosing an Installation Package	87
2.3.3 MySQL Installer for Windows	88
2.3.4 MySQL Notifier	111
2.3.5 Installing MySQL on Microsoft Windows Using a <code>noinstall</code> ZIP Archive	123
2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation	131
2.3.7 Windows Postinstallation Procedures	133
2.3.8 Upgrading MySQL on Windows	135
2.4 Installing MySQL on macOS	137
2.4.1 General Notes on Installing MySQL on macOS	137
2.4.2 Installing MySQL on macOS Using Native Packages	138
2.4.3 Installing and Using the MySQL Launch Daemon	142
2.4.4 Installing and Using the MySQL Preference Pane	145
2.5 Installing MySQL on Linux	149
2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository	150

2.5.2	Installing MySQL on Linux Using the MySQL APT Repository	154
2.5.3	Installing MySQL on Linux Using the MySQL SLES Repository	155
2.5.4	Installing MySQL on Linux Using RPM Packages from Oracle	155
2.5.5	Installing MySQL on Linux Using Debian Packages from Oracle	160
2.5.6	Deploying MySQL on Linux with Docker	162
2.5.7	Installing MySQL on Linux from the Native Software Repositories	174
2.5.8	Installing MySQL on Linux with Juju	177
2.5.9	Managing MySQL Server with systemd	177
2.6	Installing MySQL Using Unbreakable Linux Network (ULN)	182
2.7	Installing MySQL on Solaris	183
2.7.1	Installing MySQL on Solaris Using a Solaris PKG	184
2.8	Installing MySQL on FreeBSD	185
2.9	Installing MySQL from Source	186
2.9.1	MySQL Layout for Source Installation	188
2.9.2	Installing MySQL Using a Standard Source Distribution	188
2.9.3	Installing MySQL Using a Development Source Tree	193
2.9.4	MySQL Source-Configuration Options	195
2.9.5	Dealing with Problems Compiling MySQL	217
2.9.6	MySQL Configuration and Third-Party Tools	219
2.9.7	Generating MySQL Doxygen Documentation Content	219
2.10	Postinstallation Setup and Testing	220
2.10.1	Initializing the Data Directory	221
2.10.2	Starting the Server	226
2.10.3	Testing the Server	229
2.10.4	Securing the Initial MySQL Account	231
2.10.5	Starting and Stopping MySQL Automatically	233
2.11	Upgrading or Downgrading MySQL	234
2.11.1	Upgrading MySQL	234
2.11.2	Downgrading MySQL	252
2.11.3	Rebuilding or Repairing Tables or Indexes	252
2.11.4	Copying MySQL Databases to Another Machine	254
2.12	Perl Installation Notes	255
2.12.1	Installing Perl on Unix	255
2.12.2	Installing ActiveState Perl on Windows	256
2.12.3	Problems Using the Perl DBI/DBD Interface	256
3	Tutorial	259
3.1	Connecting to and Disconnecting from the Server	259
3.2	Entering Queries	260
3.3	Creating and Using a Database	263
3.3.1	Creating and Selecting a Database	265
3.3.2	Creating a Table	265
3.3.3	Loading Data into a Table	267
3.3.4	Retrieving Information from a Table	268
3.4	Getting Information About Databases and Tables	282
3.5	Using mysql in Batch Mode	283
3.6	Examples of Common Queries	284
3.6.1	The Maximum Value for a Column	285
3.6.2	The Row Holding the Maximum of a Certain Column	285
3.6.3	Maximum of Column per Group	286
3.6.4	The Rows Holding the Group-wise Maximum of a Certain Column	286
3.6.5	Using User-Defined Variables	287
3.6.6	Using Foreign Keys	287
3.6.7	Searching on Two Keys	289
3.6.8	Calculating Visits Per Day	289

3.6.9 Using AUTO_INCREMENT	290
3.7 Using MySQL with Apache	292
4 MySQL Programs	295
4.1 Overview of MySQL Programs	296
4.2 Using MySQL Programs	300
4.2.1 Invoking MySQL Programs	300
4.2.2 Connecting to the MySQL Server	301
4.2.3 Connecting Using a Path	304
4.2.4 Specifying Program Options	309
4.2.5 Using Options on the Command Line	309
4.2.6 Program Option Modifiers	311
4.2.7 Using Option Files	312
4.2.8 Command-Line Options that Affect Option-File Handling	317
4.2.9 Using Options to Set Program Variables	318
4.2.10 Option Defaults, Options Expecting Values, and the = Sign	319
4.2.11 Setting Environment Variables	323
4.3 MySQL Server and Server-Startup Programs	324
4.3.1 <code>mysqld</code> — The MySQL Server	324
4.3.2 <code>mysqld_safe</code> — MySQL Server Startup Script	324
4.3.3 <code>mysql.server</code> — MySQL Server Startup Script	330
4.3.4 <code>mysqld_multi</code> — Manage Multiple MySQL Servers	333
4.4 MySQL Installation-Related Programs	337
4.4.1 <code>comp_err</code> — Compile MySQL Error Message File	337
4.4.2 <code>mysql_secure_installation</code> — Improve MySQL Installation Security	338
4.4.3 <code>mysql_ssl_rsa_setup</code> — Create SSL/RSA Files	341
4.4.4 <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables	344
4.4.5 <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables	344
4.5 MySQL Client Programs	352
4.5.1 <code>mysql</code> — The MySQL Command-Line Tool	352
4.5.2 <code>mysqladmin</code> — Client for Administering a MySQL Server	380
4.5.3 <code>mysqlcheck</code> — A Table Maintenance Program	389
4.5.4 <code>mysqldump</code> — A Database Backup Program	398
4.5.5 <code>mysqlimport</code> — A Data Import Program	421
4.5.6 <code>mysqlpump</code> — A Database Backup Program	428
4.5.7 <code>mysqlshow</code> — Display Database, Table, and Column Information	444
4.5.8 <code>mysqlslap</code> — Load Emulation Client	450
4.6 MySQL Administrative and Utility Programs	460
4.6.1 <code>ibd2sdi</code> — InnoDB Tablespace SDI Extraction Utility	460
4.6.2 <code>innochecksum</code> — Offline InnoDB File Checksum Utility	463
4.6.3 <code>myisam_ftdump</code> — Display Full-Text Index information	469
4.6.4 <code>myisamchk</code> — MyISAM Table-Maintenance Utility	470
4.6.5 <code>myisamlog</code> — Display MyISAM Log File Contents	487
4.6.6 <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables	488
4.6.7 <code>mysql_config_editor</code> — MySQL Configuration Utility	494
4.6.8 <code>mysqlbinlog</code> — Utility for Processing Binary Log Files	501
4.6.9 <code>mysqldumpslow</code> — Summarize Slow Query Log Files	523
4.7 MySQL Program Development Utilities	525
4.7.1 <code>mysql_config</code> — Display Options for Compiling Clients	525
4.7.2 <code>my_print_defaults</code> — Display Options from Option Files	527
4.7.3 <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols	528
4.8 Miscellaneous Programs	528
4.8.1 <code>lz4_decompress</code> — Decompress mysqlpump LZ4-Compressed Output	528
4.8.2 <code>perror</code> — Explain Error Codes	529
4.8.3 <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa	530

4.8.4 <code>zlib_decompress</code> — Decompress mysqlpump ZLIB-Compressed Output	530
4.9 MySQL Program Environment Variables	530
5 MySQL Server Administration	533
5.1 The MySQL Server	534
5.1.1 Configuring the Server	534
5.1.2 Server Configuration Defaults	535
5.1.3 Server Option, System Variable, and Status Variable Reference	536
5.1.4 Server System Variable Reference	580
5.1.5 Server Status Variable Reference	605
5.1.6 Server Command Options	619
5.1.7 Server System Variables	659
5.1.8 Using System Variables	800
5.1.9 Server Status Variables	827
5.1.10 Server SQL Modes	848
5.1.11 IPv6 Support	860
5.1.12 MySQL Server Time Zone Support	864
5.1.13 Server Tracking of Client Session State Changes	869
5.1.14 Server-Side Help	872
5.1.15 Server Response to Signals	872
5.1.16 The Server Shutdown Process	873
5.2 The MySQL Data Directory	875
5.3 The <code>mysql</code> System Database	875
5.4 MySQL Server Logs	881
5.4.1 Selecting General Query and Slow Query Log Output Destinations	881
5.4.2 The Error Log	884
5.4.3 The General Query Log	898
5.4.4 The Binary Log	900
5.4.5 The Slow Query Log	912
5.4.6 The DDL Log	914
5.4.7 Server Log Maintenance	914
5.5 MySQL Server Components	916
5.5.1 Installing and Uninstalling Components	916
5.5.2 Obtaining Server Component Information	917
5.5.3 Error Log Components	917
5.6 MySQL Server Plugins	919
5.6.1 Installing and Uninstalling Plugins	920
5.6.2 Obtaining Server Plugin Information	924
5.6.3 MySQL Enterprise Thread Pool	925
5.6.4 The Rewriter Query Rewrite Plugin	933
5.6.5 Version Tokens	942
5.7 MySQL Server User-Defined Functions	954
5.7.1 Installing and Uninstalling User-Defined Functions	955
5.7.2 Obtaining User-Defined Function Information	955
5.8 Running Multiple MySQL Instances on One Machine	955
5.8.1 Setting Up Multiple Data Directories	957
5.8.2 Running Multiple MySQL Instances on Windows	958
5.8.3 Running Multiple MySQL Instances on Unix	961
5.8.4 Using Client Programs in a Multiple-Server Environment	962
6 Security	965
6.1 General Security Issues	966
6.1.1 Security Guidelines	966
6.1.2 Keeping Passwords Secure	968
6.1.3 Making MySQL Secure Against Attackers	971
6.1.4 Security-Related <code>mysqld</code> Options and Variables	973

6.1.5	How to Run MySQL as a Normal User	973
6.1.6	Security Issues with LOAD DATA LOCAL	974
6.1.7	Client Programming Security Guidelines	976
6.2	The MySQL Access Privilege System	977
6.2.1	Privileges Provided by MySQL	978
6.2.2	Static Versus Dynamic Privileges	989
6.2.3	Grant Tables	991
6.2.4	Specifying Account Names	999
6.2.5	Specifying Role Names	1001
6.2.6	Access Control, Stage 1: Connection Verification	1001
6.2.7	Access Control, Stage 2: Request Verification	1004
6.2.8	When Privilege Changes Take Effect	1006
6.2.9	Troubleshooting Problems Connecting to MySQL	1007
6.3	MySQL User Account Management	1011
6.3.1	User Names and Passwords	1012
6.3.2	Adding User Accounts	1013
6.3.3	Removing User Accounts	1015
6.3.4	Using Roles	1015
6.3.5	Reserved User Accounts	1022
6.3.6	Setting Account Resource Limits	1023
6.3.7	Assigning Account Passwords	1025
6.3.8	Password Management	1026
6.3.9	Server Handling of Expired Passwords	1033
6.3.10	Pluggable Authentication	1035
6.3.11	Proxy Users	1038
6.3.12	User Account Locking	1045
6.3.13	SQL-Based MySQL Account Activity Auditing	1045
6.4	Using Encrypted Connections	1047
6.4.1	Configuring MySQL to Use Encrypted Connections	1048
6.4.2	Command Options for Encrypted Connections	1051
6.4.3	Creating SSL and RSA Certificates and Keys	1055
6.4.4	OpenSSL Versus wolfSSL	1064
6.4.5	Building MySQL with Support for Encrypted Connections	1065
6.4.6	Encrypted Connection Protocols and Ciphers	1066
6.4.7	Connecting to MySQL Remotely from Windows with SSH	1069
6.5	Security Components and Plugins	1070
6.5.1	Authentication Plugins	1070
6.5.2	The Connection-Control Plugins	1130
6.5.3	The Password Validation Component	1136
6.5.4	The MySQL Keyring	1147
6.5.5	MySQL Enterprise Audit	1181
6.5.6	MySQL Enterprise Firewall	1247
6.6	FIPS Support	1260
7	Backup and Recovery	1263
7.1	Backup and Recovery Types	1264
7.2	Database Backup Methods	1267
7.3	Example Backup and Recovery Strategy	1269
7.3.1	Establishing a Backup Policy	1270
7.3.2	Using Backups for Recovery	1272
7.3.3	Backup Strategy Summary	1272
7.4	Using mysqldump for Backups	1273
7.4.1	Dumping Data in SQL Format with mysqldump	1273
7.4.2	Reloading SQL-Format Backups	1274
7.4.3	Dumping Data in Delimited-Text Format with mysqldump	1275

7.4.4 Reloading Delimited-Text Format Backups	1276
7.4.5 mysqldump Tips	1277
7.5 Point-in-Time (Incremental) Recovery Using the Binary Log	1279
7.5.1 Point-in-Time Recovery Using Event Times	1281
7.5.2 Point-in-Time Recovery Using Event Positions	1281
7.6 MyISAM Table Maintenance and Crash Recovery	1282
7.6.1 Using myisamchk for Crash Recovery	1282
7.6.2 How to Check MyISAM Tables for Errors	1283
7.6.3 How to Repair MyISAM Tables	1284
7.6.4 MyISAM Table Optimization	1286
7.6.5 Setting Up a MyISAM Table Maintenance Schedule	1287
8 Optimization	1289
8.1 Optimization Overview	1290
8.2 Optimizing SQL Statements	1292
8.2.1 Optimizing SELECT Statements	1292
8.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions	1339
8.2.3 Optimizing INFORMATION_SCHEMA Queries	1351
8.2.4 Optimizing Performance Schema Queries	1354
8.2.5 Optimizing Data Change Statements	1356
8.2.6 Optimizing Database Privileges	1357
8.2.7 Other Optimization Tips	1357
8.3 Optimization and Indexes	1358
8.3.1 How MySQL Uses Indexes	1358
8.3.2 Primary Key Optimization	1359
8.3.3 SPATIAL Index Optimization	1360
8.3.4 Foreign Key Optimization	1360
8.3.5 Column Indexes	1361
8.3.6 Multiple-Column Indexes	1362
8.3.7 Verifying Index Usage	1364
8.3.8 InnoDB and MyISAM Index Statistics Collection	1364
8.3.9 Comparison of B-Tree and Hash Indexes	1365
8.3.10 Use of Index Extensions	1367
8.3.11 Optimizer Use of Generated Column Indexes	1369
8.3.12 Invisible Indexes	1371
8.3.13 Descending Indexes	1372
8.4 Optimizing Database Structure	1373
8.4.1 Optimizing Data Size	1374
8.4.2 Optimizing MySQL Data Types	1376
8.4.3 Optimizing for Many Tables	1377
8.4.4 Internal Temporary Table Use in MySQL	1379
8.5 Optimizing for InnoDB Tables	1381
8.5.1 Optimizing Storage Layout for InnoDB Tables	1382
8.5.2 Optimizing InnoDB Transaction Management	1382
8.5.3 Optimizing InnoDB Read-Only Transactions	1383
8.5.4 Optimizing InnoDB Redo Logging	1384
8.5.5 Bulk Data Loading for InnoDB Tables	1385
8.5.6 Optimizing InnoDB Queries	1387
8.5.7 Optimizing InnoDB DDL Operations	1387
8.5.8 Optimizing InnoDB Disk I/O	1387
8.5.9 Optimizing InnoDB Configuration Variables	1391
8.5.10 Optimizing InnoDB for Systems with Many Tables	1392
8.6 Optimizing for MyISAM Tables	1392
8.6.1 Optimizing MyISAM Queries	1392

8.6.2 Bulk Data Loading for MyISAM Tables	1393
8.6.3 Optimizing REPAIR TABLE Statements	1395
8.7 Optimizing for MEMORY Tables	1396
8.8 Understanding the Query Execution Plan	1397
8.8.1 Optimizing Queries with EXPLAIN	1397
8.8.2 EXPLAIN Output Format	1398
8.8.3 Extended EXPLAIN Output Format	1411
8.8.4 Obtaining Execution Plan Information for a Named Connection	1413
8.8.5 Estimating Query Performance	1414
8.9 Controlling the Query Optimizer	1414
8.9.1 Controlling Query Plan Evaluation	1415
8.9.2 Optimizer Hints	1415
8.9.3 Switchable Optimizations	1429
8.9.4 Index Hints	1434
8.9.5 The Optimizer Cost Model	1436
8.9.6 Optimizer Statistics	1440
8.10 Buffering and Caching	1443
8.10.1 InnoDB Buffer Pool Optimization	1443
8.10.2 The MyISAM Key Cache	1443
8.10.3 Caching of Prepared Statements and Stored Programs	1448
8.11 Optimizing Locking Operations	1449
8.11.1 Internal Locking Methods	1449
8.11.2 Table Locking Issues	1452
8.11.3 Concurrent Inserts	1453
8.11.4 Metadata Locking	1454
8.11.5 External Locking	1455
8.12 Optimizing the MySQL Server	1456
8.12.1 Optimizing Disk I/O	1456
8.12.2 Using Symbolic Links	1458
8.12.3 Optimizing Memory Use	1460
8.12.4 Optimizing Network Use	1466
8.12.5 Resource Groups	1469
8.13 Measuring Performance (Benchmarking)	1473
8.13.1 Measuring the Speed of Expressions and Functions	1474
8.13.2 Using Your Own Benchmarks	1474
8.13.3 Measuring Performance with performance_schema	1474
8.14 Examining Thread Information	1475
8.14.1 Thread Command Values	1476
8.14.2 General Thread States	1478
8.14.3 Replication Master Thread States	1484
8.14.4 Replication Slave I/O Thread States	1485
8.14.5 Replication Slave SQL Thread States	1486
8.14.6 Replication Slave Connection Thread States	1487
8.14.7 Event Scheduler Thread States	1487
9 Language Structure	1489
9.1 Literal Values	1489
9.1.1 String Literals	1489
9.1.2 Numeric Literals	1492
9.1.3 Date and Time Literals	1492
9.1.4 Hexadecimal Literals	1495
9.1.5 Bit-Value Literals	1497
9.1.6 Boolean Literals	1499
9.1.7 NULL Values	1499
9.2 Schema Object Names	1499

9.2.1 Identifier Qualifiers	1501
9.2.2 Identifier Case Sensitivity	1503
9.2.3 Mapping of Identifiers to File Names	1505
9.2.4 Function Name Parsing and Resolution	1506
9.3 Keywords and Reserved Words	1510
9.4 User-Defined Variables	1538
9.5 Expression Syntax	1541
9.6 Comment Syntax	1543
10 Character Sets, Collations, Unicode	1545
10.1 Character Sets and Collations in General	1546
10.2 Character Sets and Collations in MySQL	1547
10.2.1 Character Set Repertoire	1549
10.2.2 UTF-8 for Metadata	1551
10.3 Specifying Character Sets and Collations	1552
10.3.1 Collation Naming Conventions	1553
10.3.2 Server Character Set and Collation	1554
10.3.3 Database Character Set and Collation	1555
10.3.4 Table Character Set and Collation	1556
10.3.5 Column Character Set and Collation	1557
10.3.6 Character String Literal Character Set and Collation	1558
10.3.7 The National Character Set	1560
10.3.8 Character Set Introducers	1560
10.3.9 Examples of Character Set and Collation Assignment	1562
10.3.10 Compatibility with Other DBMSs	1563
10.4 Connection Character Sets and Collations	1563
10.5 Configuring Application Character Set and Collation	1570
10.6 Error Message Character Set	1572
10.7 Column Character Set Conversion	1573
10.8 Collation Issues	1574
10.8.1 Using COLLATE in SQL Statements	1574
10.8.2 COLLATE Clause Precedence	1575
10.8.3 Character Set and Collation Compatibility	1575
10.8.4 Collation Coercibility in Expressions	1575
10.8.5 The binary Collation Compared to _bin Collations	1577
10.8.6 Examples of the Effect of Collation	1579
10.8.7 Using Collation in INFORMATION_SCHEMA Searches	1580
10.9 Unicode Support	1582
10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)	1584
10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)	1585
10.9.3 The utf8 Character Set (Alias for utf8mb3)	1586
10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)	1586
10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)	1586
10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)	1587
10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)	1587
10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets	1587
10.10 Supported Character Sets and Collations	1590
10.10.1 Unicode Character Sets	1591
10.10.2 West European Character Sets	1597
10.10.3 Central European Character Sets	1598
10.10.4 South European and Middle East Character Sets	1599
10.10.5 Baltic Character Sets	1600
10.10.6 Cyrillic Character Sets	1600
10.10.7 Asian Character Sets	1601
10.10.8 The Binary Character Set	1605

10.11	Setting the Error Message Language	1606
10.12	Adding a Character Set	1607
10.12.1	Character Definition Arrays	1609
10.12.2	String Collating Support for Complex Character Sets	1610
10.12.3	Multi-Byte Character Support for Complex Character Sets	1610
10.13	Adding a Collation to a Character Set	1610
10.13.1	Collation Implementation Types	1611
10.13.2	Choosing a Collation ID	1614
10.13.3	Adding a Simple Collation to an 8-Bit Character Set	1615
10.13.4	Adding a UCA Collation to a Unicode Character Set	1616
10.14	Character Set Configuration	1624
10.15	MySQL Server Locale Support	1625
11	Data Types	1629
11.1	Data Type Overview	1630
11.1.1	Numeric Type Overview	1630
11.1.2	Date and Time Type Overview	1633
11.1.3	String Type Overview	1635
11.2	Numeric Types	1639
11.2.1	Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT	1639
11.2.2	Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC	1640
11.2.3	Floating-Point Types (Approximate Value) - FLOAT, DOUBLE	1640
11.2.4	Bit-Value Type - BIT	1641
11.2.5	Numeric Type Attributes	1641
11.2.6	Out-of-Range and Overflow Handling	1642
11.3	Date and Time Types	1644
11.3.1	The DATE, DATETIME, and TIMESTAMP Types	1645
11.3.2	The TIME Type	1646
11.3.3	The YEAR Type	1647
11.3.4	Migrating YEAR(2) Columns to YEAR(4)	1647
11.3.5	Automatic Initialization and Updating for TIMESTAMP and DATETIME	1649
11.3.6	Fractional Seconds in Time Values	1653
11.3.7	Conversion Between Date and Time Types	1653
11.3.8	Two-Digit Years in Dates	1654
11.4	String Types	1655
11.4.1	The CHAR and VARCHAR Types	1655
11.4.2	The BINARY and VARBINARY Types	1657
11.4.3	The BLOB and TEXT Types	1658
11.4.4	The ENUM Type	1660
11.4.5	The SET Type	1663
11.5	Spatial Data Types	1665
11.5.1	Spatial Data Types	1667
11.5.2	The OpenGIS Geometry Model	1668
11.5.3	Supported Spatial Data Formats	1674
11.5.4	Geometry Well-Formedness and Validity	1677
11.5.5	Spatial Reference System Support	1678
11.5.6	Creating Spatial Columns	1679
11.5.7	Populating Spatial Columns	1679
11.5.8	Fetching Spatial Data	1680
11.5.9	Optimizing Spatial Analysis	1681
11.5.10	Creating Spatial Indexes	1681
11.5.11	Using Spatial Indexes	1682
11.6	The JSON Data Type	1684
11.7	Data Type Default Values	1700

11.8 Data Type Storage Requirements	1703
11.9 Choosing the Right Type for a Column	1707
11.10 Using Data Types from Other Database Engines	1707
12 Functions and Operators	1709
12.1 Function and Operator Reference	1711
12.2 Type Conversion in Expression Evaluation	1723
12.3 Operators	1726
12.3.1 Operator Precedence	1727
12.3.2 Comparison Functions and Operators	1728
12.3.3 Logical Operators	1735
12.3.4 Assignment Operators	1737
12.4 Control Flow Functions	1738
12.5 String Functions	1741
12.5.1 String Comparison Functions	1757
12.5.2 Regular Expressions	1760
12.5.3 Character Set and Collation of Function Results	1770
12.6 Numeric Functions and Operators	1771
12.6.1 Arithmetic Operators	1772
12.6.2 Mathematical Functions	1774
12.7 Date and Time Functions	1783
12.8 What Calendar Is Used By MySQL?	1807
12.9 Full-Text Search Functions	1807
12.9.1 Natural Language Full-Text Searches	1808
12.9.2 Boolean Full-Text Searches	1812
12.9.3 Full-Text Searches with Query Expansion	1817
12.9.4 Full-Text Stopwords	1818
12.9.5 Full-Text Restrictions	1823
12.9.6 Fine-Tuning MySQL Full-Text Search	1824
12.9.7 Adding a Collation for Full-Text Indexing	1827
12.9.8 ngram Full-Text Parser	1828
12.9.9 MeCab Full-Text Parser Plugin	1831
12.10 Cast Functions and Operators	1835
12.11 XML Functions	1841
12.12 Bit Functions and Operators	1853
12.13 Encryption and Compression Functions	1865
12.14 Information Functions	1872
12.15 Spatial Analysis Functions	1883
12.15.1 Spatial Function Reference	1883
12.15.2 Argument Handling by Spatial Functions	1886
12.15.3 Functions That Create Geometry Values from WKT Values	1886
12.15.4 Functions That Create Geometry Values from WKB Values	1889
12.15.5 MySQL-Specific Functions That Create Geometry Values	1890
12.15.6 Geometry Format Conversion Functions	1892
12.15.7 Geometry Property Functions	1894
12.15.8 Spatial Operator Functions	1906
12.15.9 Functions That Test Spatial Relations Between Geometry Objects	1910
12.15.10 Spatial Geohash Functions	1916
12.15.11 Spatial GeoJSON Functions	1918
12.15.12 Spatial Convenience Functions	1920
12.16 JSON Functions	1924
12.16.1 JSON Function Reference	1924
12.16.2 Functions That Create JSON Values	1925
12.16.3 Functions That Search JSON Values	1926
12.16.4 Functions That Modify JSON Values	1936

12.16.5 Functions That Return JSON Value Attributes	1945
12.16.6 JSON Table Functions	1948
12.16.7 JSON Utility Functions	1952
12.16.8 JSON Path Syntax	1958
12.17 Functions Used with Global Transaction Identifiers (GTIDs)	1959
12.18 MySQL Enterprise Encryption Functions	1962
12.18.1 MySQL Enterprise Encryption Installation	1962
12.18.2 MySQL Enterprise Encryption Usage and Examples	1963
12.18.3 MySQL Enterprise Encryption Function Reference	1965
12.18.4 MySQL Enterprise Encryption Function Descriptions	1965
12.19 Aggregate (GROUP BY) Functions	1969
12.19.1 Aggregate (GROUP BY) Function Descriptions	1969
12.19.2 GROUP BY Modifiers	1978
12.19.3 MySQL Handling of GROUP BY	1985
12.19.4 Detection of Functional Dependence	1988
12.20 Window Functions	1991
12.20.1 Window Function Descriptions	1991
12.20.2 Window Function Concepts and Syntax	1997
12.20.3 Window Function Frame Specification	2001
12.20.4 Named Windows	2005
12.20.5 Window Function Restrictions	2006
12.21 Internal Functions	2006
12.22 Miscellaneous Functions	2008
12.23 Precision Math	2025
12.23.1 Types of Numeric Values	2026
12.23.2 DECIMAL Data Type Characteristics	2026
12.23.3 Expression Handling	2027
12.23.4 Rounding Behavior	2029
12.23.5 Precision Math Examples	2030
13 SQL Statement Syntax	2035
13.1 Data Definition Statements	2036
13.1.1 Atomic Data Definition Statement Support	2036
13.1.2 ALTER DATABASE Syntax	2042
13.1.3 ALTER EVENT Syntax	2043
13.1.4 ALTER FUNCTION Syntax	2044
13.1.5 ALTER INSTANCE Syntax	2045
13.1.6 ALTER PROCEDURE Syntax	2045
13.1.7 ALTER SERVER Syntax	2045
13.1.8 ALTER TABLE Syntax	2046
13.1.9 ALTER TABLESPACE Syntax	2066
13.1.10 ALTER VIEW Syntax	2067
13.1.11 CREATE DATABASE Syntax	2067
13.1.12 CREATE EVENT Syntax	2068
13.1.13 CREATE FUNCTION Syntax	2073
13.1.14 CREATE INDEX Syntax	2073
13.1.15 CREATE PROCEDURE and CREATE FUNCTION Syntax	2082
13.1.16 CREATE SERVER Syntax	2087
13.1.17 CREATE SPATIAL REFERENCE SYSTEM Syntax	2088
13.1.18 CREATE TABLE Syntax	2090
13.1.19 CREATE TABLESPACE Syntax	2129
13.1.20 CREATE TRIGGER Syntax	2131
13.1.21 CREATE VIEW Syntax	2134
13.1.22 DROP DATABASE Syntax	2138
13.1.23 DROP EVENT Syntax	2139

13.1.24 DROP FUNCTION Syntax	2139
13.1.25 DROP INDEX Syntax	2140
13.1.26 DROP PROCEDURE and DROP FUNCTION Syntax	2140
13.1.27 DROP SERVER Syntax	2140
13.1.28 DROP SPATIAL REFERENCE SYSTEM Syntax	2140
13.1.29 DROP TABLE Syntax	2141
13.1.30 DROP TABLESPACE Syntax	2142
13.1.31 DROP TRIGGER Syntax	2143
13.1.32 DROP VIEW Syntax	2143
13.1.33 RENAME TABLE Syntax	2144
13.1.34 TRUNCATE TABLE Syntax	2145
13.2 Data Manipulation Statements	2146
13.2.1 CALL Syntax	2146
13.2.2 DELETE Syntax	2148
13.2.3 DO Syntax	2152
13.2.4 HANDLER Syntax	2152
13.2.5 IMPORT TABLE Syntax	2154
13.2.6 INSERT Syntax	2157
13.2.7 LOAD DATA INFILE Syntax	2164
13.2.8 LOAD XML Syntax	2174
13.2.9 REPLACE Syntax	2182
13.2.10 SELECT Syntax	2185
13.2.11 Subquery Syntax	2202
13.2.12 UPDATE Syntax	2215
13.2.13 WITH Syntax (Common Table Expressions)	2218
13.3 Transactional and Locking Statements	2230
13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax	2230
13.3.2 Statements That Cannot Be Rolled Back	2233
13.3.3 Statements That Cause an Implicit Commit	2233
13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax ...	2234
13.3.5 LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE Syntax	2235
13.3.6 LOCK TABLES and UNLOCK TABLES Syntax	2235
13.3.7 SET TRANSACTION Syntax	2241
13.3.8 XA Transactions	2243
13.4 Replication Statements	2247
13.4.1 SQL Statements for Controlling Master Servers	2247
13.4.2 SQL Statements for Controlling Slave Servers	2250
13.4.3 SQL Statements for Controlling Group Replication	2266
13.5 Prepared SQL Statement Syntax	2268
13.5.1 PREPARE Syntax	2271
13.5.2 EXECUTE Syntax	2272
13.5.3 DEALLOCATE PREPARE Syntax	2272
13.6 Compound-Statement Syntax	2273
13.6.1 BEGIN ... END Compound-Statement Syntax	2273
13.6.2 Statement Label Syntax	2273
13.6.3 DECLARE Syntax	2274
13.6.4 Variables in Stored Programs	2275
13.6.5 Flow Control Statements	2276
13.6.6 Cursors	2281
13.6.7 Condition Handling	2283
13.7 Database Administration Statements	2311
13.7.1 Account Management Statements	2311
13.7.2 Resource Group Management Statements	2348
13.7.3 Table Maintenance Statements	2352

13.7.4 Component, Plugin, and User-Defined Function Statements	2364
13.7.5 SET Syntax	2368
13.7.6 SHOW Syntax	2374
13.7.7 Other Administrative Statements	2428
13.8 Utility Statements	2440
13.8.1 DESCRIBE Syntax	2440
13.8.2 EXPLAIN Syntax	2440
13.8.3 HELP Syntax	2442
13.8.4 USE Syntax	2444
14 MySQL Data Dictionary	2447
14.1 Data Dictionary Schema	2447
14.2 Removal of File-based Metadata Storage	2449
14.3 Transactional Storage of Dictionary Data	2449
14.4 Dictionary Object Cache	2449
14.5 INFORMATION_SCHEMA and Data Dictionary Integration	2450
14.6 Serialized Dictionary Information (SDI)	2452
14.7 Data Dictionary Usage Differences	2453
14.8 Data Dictionary Limitations	2454
15 The InnoDB Storage Engine	2455
15.1 Introduction to InnoDB	2457
15.1.1 Benefits of Using InnoDB Tables	2458
15.1.2 Best Practices for InnoDB Tables	2459
15.1.3 Verifying that InnoDB is the Default Storage Engine	2460
15.1.4 Testing and Benchmarking with InnoDB	2460
15.2 InnoDB and the ACID Model	2461
15.3 InnoDB Multi-Versioning	2462
15.4 InnoDB Architecture	2463
15.4.1 Buffer Pool	2463
15.4.2 Change Buffer	2464
15.4.3 Adaptive Hash Index	2466
15.4.4 Redo Log Buffer	2466
15.4.5 System Tablespace	2467
15.4.6 Doublewrite Buffer	2467
15.4.7 Undo Logs	2467
15.4.8 File-Per-Table Tablespaces	2468
15.4.9 General Tablespaces	2468
15.4.10 Undo Tablespace	2468
15.4.11 Temporary Tablespace	2468
15.4.12 Redo Log	2470
15.5 InnoDB Locking and Transaction Model	2470
15.5.1 InnoDB Locking	2471
15.5.2 InnoDB Transaction Model	2475
15.5.3 Locks Set by Different SQL Statements in InnoDB	2485
15.5.4 Phantom Rows	2488
15.5.5 Deadlocks in InnoDB	2489
15.6 InnoDB Configuration	2492
15.6.1 InnoDB Startup Configuration	2492
15.6.2 Configuring InnoDB for Read-Only Operation	2498
15.6.3 InnoDB Buffer Pool Configuration	2500
15.6.4 Configuring InnoDB Change Buffering	2520
15.6.5 Configuring Thread Concurrency for InnoDB	2521
15.6.6 Configuring the Number of Background InnoDB I/O Threads	2522
15.6.7 Using Asynchronous I/O on Linux	2523
15.6.8 Configuring the InnoDB Master Thread I/O Rate	2523

15.6.9 Configuring Spin Lock Polling	2524
15.6.10 Configuring InnoDB Purge Scheduling	2524
15.6.11 Configuring Optimizer Statistics for InnoDB	2525
15.6.12 Configuring the Merge Threshold for Index Pages	2536
15.6.13 Enabling Automatic Configuration for a Dedicated MySQL Server	2539
15.7 InnoDB Tablespaces	2540
15.7.1 Resizing the InnoDB System Tablespace	2540
15.7.2 Changing the Number or Size of InnoDB Redo Log Files	2542
15.7.3 Using Raw Disk Partitions for the System Tablespace	2542
15.7.4 InnoDB File-Per-Table Tablespaces	2543
15.7.5 Creating a Tablespace Outside of the Data Directory	2546
15.7.6 Copying File-Per-Table Tablespaces to Another Instance	2547
15.7.7 Moving Tablespace Files While the Server is Offline	2555
15.7.8 Configuring Undo Tablespaces	2557
15.7.9 Truncating Undo Tablespaces	2558
15.7.10 InnoDB General Tablespaces	2560
15.7.11 InnoDB Tablespace Encryption	2566
15.8 InnoDB Tables and Indexes	2573
15.8.1 InnoDB Tables	2573
15.8.2 InnoDB Indexes	2598
15.9 InnoDB Table and Page Compression	2605
15.9.1 InnoDB Table Compression	2606
15.9.2 InnoDB Page Compression	2620
15.10 InnoDB Row Storage and Row Formats	2623
15.10.1 Overview of InnoDB Row Storage	2624
15.10.2 Specifying the Row Format for a Table	2624
15.10.3 DYNAMIC and COMPRESSED Row Formats	2626
15.10.4 COMPACT and REDUNDANT Row Formats	2627
15.11 InnoDB Disk I/O and File Space Management	2627
15.11.1 InnoDB Disk I/O	2628
15.11.2 File Space Management	2628
15.11.3 InnoDB Checkpoints	2630
15.11.4 Defragmenting a Table	2630
15.11.5 Reclaiming Disk Space with TRUNCATE TABLE	2631
15.12 InnoDB and Online DDL	2631
15.12.1 Online DDL Operations	2632
15.12.2 Online DDL Performance and Concurrency	2646
15.12.3 Online DDL Space Requirements	2650
15.12.4 Simplifying DDL Statements with Online DDL	2651
15.12.5 Online DDL Failure Conditions	2651
15.12.6 Online DDL Limitations	2652
15.13 InnoDB Startup Options and System Variables	2653
15.14 InnoDB INFORMATION_SCHEMA Tables	2747
15.14.1 InnoDB INFORMATION_SCHEMA Tables about Compression	2747
15.14.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information	2749
15.14.3 InnoDB INFORMATION_SCHEMA Schema Object Tables	2756
15.14.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables	2761
15.14.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables	2765
15.14.6 InnoDB INFORMATION_SCHEMA Metrics Table	2769
15.14.7 InnoDB INFORMATION_SCHEMA Temporary Table Info Table	2778
15.14.8 Retrieving InnoDB Tablespace Metadata from INFORMATION_SCHEMA.FILES ..	2779
15.15 InnoDB Integration with MySQL Performance Schema	2781
15.15.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema	2783

15.15.2 Monitoring InnoDB Mutex Waits Using Performance Schema	2785
15.16 InnoDB Monitors	2789
15.16.1 InnoDB Monitor Types	2789
15.16.2 Enabling InnoDB Monitors	2789
15.16.3 InnoDB Standard Monitor and Lock Monitor Output	2791
15.17 InnoDB Backup and Recovery	2795
15.17.1 InnoDB Backup	2796
15.17.2 InnoDB Recovery	2797
15.18 InnoDB and MySQL Replication	2800
15.19 InnoDB memcached Plugin	2802
15.19.1 Benefits of the InnoDB memcached Plugin	2802
15.19.2 InnoDB memcached Architecture	2803
15.19.3 Setting Up the InnoDB memcached Plugin	2807
15.19.4 InnoDB memcached Multiple get and Range Query Support	2813
15.19.5 Security Considerations for the InnoDB memcached Plugin	2815
15.19.6 Writing Applications for the InnoDB memcached Plugin	2817
15.19.7 The InnoDB memcached Plugin and Replication	2830
15.19.8 InnoDB memcached Plugin Internals	2834
15.19.9 Troubleshooting the InnoDB memcached Plugin	2839
15.20 InnoDB Troubleshooting	2841
15.20.1 Troubleshooting InnoDB I/O Problems	2841
15.20.2 Forcing InnoDB Recovery	2842
15.20.3 Troubleshooting InnoDB Data Dictionary Operations	2843
15.20.4 InnoDB Error Handling	2845
16 Alternative Storage Engines	2847
16.1 Setting the Storage Engine	2851
16.2 The MyISAM Storage Engine	2852
16.2.1 MyISAM Startup Options	2854
16.2.2 Space Needed for Keys	2856
16.2.3 MyISAM Table Storage Formats	2856
16.2.4 MyISAM Table Problems	2859
16.3 The MEMORY Storage Engine	2860
16.4 The CSV Storage Engine	2865
16.4.1 Repairing and Checking CSV Tables	2866
16.4.2 CSV Limitations	2867
16.5 The ARCHIVE Storage Engine	2867
16.6 The BLACKHOLE Storage Engine	2869
16.7 The MERGE Storage Engine	2871
16.7.1 MERGE Table Advantages and Disadvantages	2874
16.7.2 MERGE Table Problems	2875
16.8 The FEDERATED Storage Engine	2877
16.8.1 FEDERATED Storage Engine Overview	2877
16.8.2 How to Create FEDERATED Tables	2878
16.8.3 FEDERATED Storage Engine Notes and Tips	2881
16.8.4 FEDERATED Storage Engine Resources	2882
16.9 The EXAMPLE Storage Engine	2882
16.10 Other Storage Engines	2883
16.11 Overview of MySQL Storage Engine Architecture	2883
16.11.1 Pluggable Storage Engine Architecture	2883
16.11.2 The Common Database Server Layer	2884
17 Replication	2887
17.1 Configuring Replication	2889
17.1.1 Binary Log File Position Based Replication Configuration Overview	2889
17.1.2 Setting Up Binary Log File Position Based Replication	2890

17.1.3	Replication with Global Transaction Identifiers	2900
17.1.4	MySQL Multi-Source Replication	2919
17.1.5	Changing Replication Modes on Online Servers	2923
17.1.6	Replication and Binary Logging Options and Variables	2929
17.1.7	Common Replication Administration Tasks	3025
17.2	Replication Implementation	3028
17.2.1	Replication Formats	3029
17.2.2	Replication Implementation Details	3036
17.2.3	Replication Channels	3038
17.2.4	Replication Relay and Status Logs	3041
17.2.5	How Servers Evaluate Replication Filtering Rules	3047
17.3	Replication Solutions	3054
17.3.1	Using Replication for Backups	3055
17.3.2	Handling an Unexpected Halt of a Replication Slave	3058
17.3.3	Monitoring Row-based Replication	3061
17.3.4	Using Replication with Different Master and Slave Storage Engines	3061
17.3.5	Using Replication for Scale-Out	3063
17.3.6	Replicating Different Databases to Different Slaves	3064
17.3.7	Improving Replication Performance	3065
17.3.8	Switching Masters During Failover	3066
17.3.9	Setting Up Replication to Use Encrypted Connections	3068
17.3.10	Semisynchronous Replication	3071
17.3.11	Delayed Replication	3077
17.4	Replication Notes and Tips	3079
17.4.1	Replication Features and Issues	3079
17.4.2	Replication Compatibility Between MySQL Versions	3107
17.4.3	Upgrading a Replication Setup	3108
17.4.4	Troubleshooting Replication	3110
17.4.5	How to Report Replication Bugs or Problems	3111
18	Group Replication	3113
18.1	Group Replication Background	3114
18.1.1	Replication Technologies	3115
18.1.2	Group Replication Use Cases	3117
18.1.3	Group Replication Details	3117
18.2	Getting Started	3119
18.2.1	Deploying Group Replication in Single-Primary Mode	3119
18.3	Monitoring Group Replication	3130
18.3.1	Replication_group_member_stats	3130
18.3.2	Replication_group_members	3131
18.3.3	Replication_connection_status	3132
18.3.4	Replication_applier_status	3132
18.3.5	Group Replication Server States	3133
18.4	Group Replication Operations	3134
18.4.1	Deploying in Multi-Primary or Single-Primary Mode	3134
18.4.2	Tuning Recovery	3136
18.4.3	Network Partitioning	3137
18.4.4	Using MySQL Enterprise Backup with Group Replication	3143
18.5	Group Replication Security	3145
18.5.1	IP Address Whitelisting	3145
18.5.2	Secure Socket Layer Support (SSL)	3146
18.5.3	Virtual Private Networks (VPN)	3150
18.6	Group Replication System Variables	3150
18.7	Requirements and Limitations	3170
18.7.1	Group Replication Requirements	3170

18.7.2 Group Replication Limitations	3171
18.8 Frequently Asked Questions	3173
18.9 Group Replication Technical Details	3176
18.9.1 Group Replication Plugin Architecture	3176
18.9.2 The Group	3178
18.9.3 Data Manipulation Statements	3178
18.9.4 Data Definition Statements	3178
18.9.5 Distributed Recovery	3179
18.9.6 Observability	3185
18.9.7 Group Replication Performance	3186
19 MySQL Shell	3191
20 Using MySQL as a Document Store	3193
20.1 Key Concepts	3194
20.2 Setting Up MySQL as a Document Store	3195
20.2.1 Installing MySQL Shell	3195
20.2.2 Starting MySQL Shell	3198
20.3 Quick-Start Guide: MySQL Shell for JavaScript	3198
20.3.1 Introduction	3198
20.3.2 Import Database Sample	3199
20.3.3 MySQL Shell	3200
20.3.4 Documents and Collections	3202
20.3.5 Relational Tables	3212
20.3.6 Documents in Tables	3218
20.4 Quick-Start Guide: MySQL Shell for Python	3219
20.4.1 Introduction	3220
20.4.2 Import Database Sample	3221
20.4.3 MySQL Shell	3221
20.4.4 Documents and Collections	3223
20.4.5 Relational Tables	3234
20.4.6 Documents in Tables	3240
20.5 X Plugin	3241
20.5.1 Checking X Plugin Installation	3241
20.5.2 Disabling X Plugin	3241
20.5.3 Using Secure Connections with X Plugin	3241
20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin	3242
20.5.5 X Plugin Options and Variables	3242
20.5.6 Monitoring X Plugin	3259
21 InnoDB Cluster	3265
21.1 Introducing InnoDB Cluster	3265
21.2 Creating an InnoDB Cluster	3268
21.2.1 Deployment Scenarios	3268
21.2.2 InnoDB Cluster Requirements	3268
21.2.3 Methods of Installing	3269
21.2.4 Production Deployment of InnoDB Cluster	3269
21.2.5 Sandbox Deployment of InnoDB Cluster	3279
21.2.6 Adopting a Group Replication Deployment	3281
21.3 Using MySQL Router with InnoDB Cluster	3282
21.4 Working with InnoDB Cluster	3285
21.5 Known Limitations	3298
22 Partitioning	3301
22.1 Overview of Partitioning in MySQL	3302
22.2 Partitioning Types	3305
22.2.1 RANGE Partitioning	3307
22.2.2 LIST Partitioning	3311

22.2.3 COLUMNS Partitioning	3313
22.2.4 HASH Partitioning	3321
22.2.5 KEY Partitioning	3325
22.2.6 Subpartitioning	3326
22.2.7 How MySQL Partitioning Handles NULL	3328
22.3 Partition Management	3332
22.3.1 Management of RANGE and LIST Partitions	3333
22.3.2 Management of HASH and KEY Partitions	3340
22.3.3 Exchanging Partitions and Subpartitions with Tables	3341
22.3.4 Maintenance of Partitions	3349
22.3.5 Obtaining Information About Partitions	3350
22.4 Partition Pruning	3352
22.5 Partition Selection	3355
22.6 Restrictions and Limitations on Partitioning	3361
22.6.1 Partitioning Keys, Primary Keys, and Unique Keys	3366
22.6.2 Partitioning Limitations Relating to Storage Engines	3370
22.6.3 Partitioning Limitations Relating to Functions	3371
23 Stored Programs and Views	3373
23.1 Defining Stored Programs	3374
23.2 Using Stored Routines (Procedures and Functions)	3375
23.2.1 Stored Routine Syntax	3376
23.2.2 Stored Routines and MySQL Privileges	3376
23.2.3 Stored Routine Metadata	3377
23.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()	3377
23.3 Using Triggers	3377
23.3.1 Trigger Syntax and Examples	3378
23.3.2 Trigger Metadata	3382
23.4 Using the Event Scheduler	3382
23.4.1 Event Scheduler Overview	3383
23.4.2 Event Scheduler Configuration	3384
23.4.3 Event Syntax	3386
23.4.4 Event Metadata	3386
23.4.5 Event Scheduler Status	3387
23.4.6 The Event Scheduler and MySQL Privileges	3387
23.5 Using Views	3390
23.5.1 View Syntax	3391
23.5.2 View Processing Algorithms	3391
23.5.3 Updatable and Insertable Views	3392
23.5.4 The View WITH CHECK OPTION Clause	3395
23.5.5 View Metadata	3396
23.6 Access Control for Stored Programs and Views	3396
23.7 Binary Logging of Stored Programs	3398
24 INFORMATION_SCHEMA Tables	3405
24.1 Introduction	3406
24.2 The INFORMATION_SCHEMA CHARACTER_SETS Table	3409
24.3 The INFORMATION_SCHEMA COLLATIONS Table	3410
24.4 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table	3411
24.5 The INFORMATION_SCHEMA COLUMNS Table	3411
24.6 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table	3414
24.7 The INFORMATION_SCHEMA COLUMN_STATISTICS Table	3415
24.8 The INFORMATION_SCHEMA ENGINES Table	3415
24.9 The INFORMATION_SCHEMA EVENTS Table	3416
24.10 The INFORMATION_SCHEMA FILES Table	3420
24.11 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table	3423

24.12 The INFORMATION_SCHEMA KEYWORDS Table	3425
24.13 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table	3425
24.14 The INFORMATION_SCHEMA PARAMETERS Table	3426
24.15 The INFORMATION_SCHEMA PARTITIONS Table	3427
24.16 The INFORMATION_SCHEMA PLUGINS Table	3430
24.17 The INFORMATION_SCHEMA PROCESSLIST Table	3432
24.18 The INFORMATION_SCHEMA PROFILING Table	3433
24.19 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table	3434
24.20 The INFORMATION_SCHEMA RESOURCE_GROUPS Table	3435
24.21 The INFORMATION_SCHEMA ROUTINES Table	3436
24.22 The INFORMATION_SCHEMA SCHEMATA Table	3438
24.23 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table	3439
24.24 The INFORMATION_SCHEMA STATISTICS Table	3440
24.25 The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table	3442
24.26 The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table	3443
24.27 The INFORMATION_SCHEMA TABLES Table	3445
24.28 The INFORMATION_SCHEMA TABLESPACES Table	3448
24.29 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table	3449
24.30 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table	3450
24.31 The INFORMATION_SCHEMA TRIGGERS Table	3450
24.32 The INFORMATION_SCHEMA USER_PRIVILEGES Table	3452
24.33 The INFORMATION_SCHEMA VIEWS Table	3453
24.34 The INFORMATION_SCHEMA VIEW_ROUTINE_USAGE Table	3455
24.35 The INFORMATION_SCHEMA VIEW_TABLE_USAGE Table	3455
24.36 INFORMATION_SCHEMA InnoDB Tables	3456
24.36.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table	3456
24.36.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table	3460
24.36.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table	3463
24.36.4 The INFORMATION_SCHEMA INNODB_CACHED_INDEXES Table	3467
24.36.5 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables	3468
24.36.6 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables	3469
24.36.7 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables	3471
24.36.8 The INFORMATION_SCHEMA INNODB_COLUMNS Table	3472
24.36.9 The INFORMATION_SCHEMA INNODB_DATAFILES Table	3474
24.36.10 The INFORMATION_SCHEMA INNODB_FIELDS Table	3474
24.36.11 The INFORMATION_SCHEMA INNODB_FOREIGN Table	3475
24.36.12 The INFORMATION_SCHEMA INNODB_FOREIGN_COLS Table	3476
24.36.13 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table	3477
24.36.14 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table	3477
24.36.15 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table	3478
24.36.16 The INFORMATION_SCHEMA INNODB_FT_DELETED Table	3479
24.36.17 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table	3480
24.36.18 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table	3482
24.36.19 The INFORMATION_SCHEMA INNODB_INDEXES Table	3483
24.36.20 The INFORMATION_SCHEMA INNODB_LOCKS Table	3485
24.36.21 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table	3486
24.36.22 The INFORMATION_SCHEMA INNODB_METRICS Table	3486
24.36.23 The INFORMATION_SCHEMA INNODB_SESSION_TEMP_TABLESPACES Table	3488
24.36.24 The INFORMATION_SCHEMA INNODB_TABLES Table	3489
24.36.25 The INFORMATION_SCHEMA INNODB_TABLESPACES Table	3491

24.36.26 The INFORMATION_SCHEMA INNODB_TABLESPACES_BRIEF Table	3492
24.36.27 The INFORMATION_SCHEMA INNODB_TABLESTATS View	3493
24.36.28 The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table	3495
24.36.29 The INFORMATION_SCHEMA INNODB_TRX Table	3496
24.36.30 The INFORMATION_SCHEMA INNODB_VIRTUAL Table	3498
24.37 INFORMATION_SCHEMA Thread Pool Tables	3500
24.37.1 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table	3500
24.37.2 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table	3501
24.37.3 The INFORMATION_SCHEMA TP_THREAD_STATE Table	3501
24.38 INFORMATION_SCHEMA Connection-Control Tables	3502
24.38.1 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table	3502
24.39 Extensions to SHOW Statements	3502
25 MySQL Performance Schema	3505
25.1 Performance Schema Quick Start	3507
25.2 Performance Schema Build Configuration	3513
25.3 Performance Schema Startup Configuration	3514
25.4 Performance Schema Runtime Configuration	3516
25.4.1 Performance Schema Event Timing	3517
25.4.2 Performance Schema Event Filtering	3519
25.4.3 Event Pre-Filtering	3521
25.4.4 Pre-Filtering by Instrument	3522
25.4.5 Pre-Filtering by Object	3523
25.4.6 Pre-Filtering by Thread	3525
25.4.7 Pre-Filtering by Consumer	3527
25.4.8 Example Consumer Configurations	3530
25.4.9 Naming Instruments or Consumers for Filtering Operations	3535
25.4.10 Determining What Is Instrumented	3536
25.5 Performance Schema Queries	3537
25.6 Performance Schema Instrument Naming Conventions	3537
25.7 Performance Schema Status Monitoring	3541
25.8 Performance Schema Atom and Molecule Events	3544
25.9 Performance Schema Statement Digests and Sampling	3545
25.10 Performance Schema General Table Characteristics	3549
25.11 Performance Schema Table Descriptions	3550
25.11.1 Performance Schema Table Index	3551
25.11.2 Performance Schema Setup Tables	3554
25.11.3 Performance Schema Instance Tables	3562
25.11.4 Performance Schema Wait Event Tables	3568
25.11.5 Performance Schema Stage Event Tables	3573
25.11.6 Performance Schema Statement Event Tables	3579
25.11.7 Performance Schema Transaction Tables	3589
25.11.8 Performance Schema Connection Tables	3596
25.11.9 Performance Schema Connection Attribute Tables	3600
25.11.10 Performance Schema User-Defined Variable Tables	3603
25.11.11 Performance Schema Replication Tables	3604
25.11.12 Performance Schema Lock Tables	3621
25.11.13 Performance Schema System Variable Tables	3630
25.11.14 Performance Schema Status Variable Tables	3634
25.11.15 Performance Schema Thread Pool Tables	3636
25.11.16 Performance Schema Summary Tables	3641
25.11.17 Performance Schema Miscellaneous Tables	3670
25.12 Performance Schema Option and Variable Reference	3681
25.13 Performance Schema Command Options	3684

25.14 Performance Schema System Variables	3685
25.15 Performance Schema Status Variables	3704
25.16 The Performance Schema Memory-Allocation Model	3707
25.17 Performance Schema and Plugins	3708
25.18 Using the Performance Schema to Diagnose Problems	3709
25.18.1 Query Profiling Using Performance Schema	3710
25.18.2 Obtaining Parent Event Information	3712
26 MySQL sys Schema	3715
26.1 Prerequisites for Using the sys Schema	3715
26.2 Using the sys Schema	3716
26.3 sys Schema Progress Reporting	3717
26.4 sys Schema Object Reference	3718
26.4.1 sys Schema Object Index	3718
26.4.2 sys Schema Tables and Triggers	3722
26.4.3 sys Schema Views	3725
26.4.4 sys Schema Stored Procedures	3767
26.4.5 sys Schema Stored Functions	3787
27 Connectors and APIs	3801
27.1 MySQL Connector/C	3804
27.2 MySQL Connector/C++	3804
27.3 MySQL Connector/J	3804
27.4 MySQL Connector/NET	3804
27.5 MySQL Connector/ODBC	3805
27.6 MySQL Connector/Python	3805
27.7 MySQL C API	3805
27.7.1 MySQL C API Implementations	3806
27.7.2 Simultaneous MySQL Server and Connector/C Installations	3806
27.7.3 Example C API Client Programs	3807
27.7.4 Building and Running C API Client Programs	3807
27.7.5 C API Data Structures	3813
27.7.6 C API Function Overview	3819
27.7.7 C API Function Descriptions	3824
27.7.8 C API Prepared Statements	3891
27.7.9 C API Prepared Statement Data Structures	3891
27.7.10 C API Prepared Statement Function Overview	3898
27.7.11 C API Prepared Statement Function Descriptions	3900
27.7.12 C API Threaded Function Descriptions	3925
27.7.13 C API Client Plugin Functions	3926
27.7.14 C API Binary Log Interface	3929
27.7.15 C API Binary Log Data Structures	3929
27.7.16 C API Binary Log Function Overview	3931
27.7.17 C API Binary Log Function Descriptions	3931
27.7.18 C API Encrypted Connection Support	3934
27.7.19 C API Multiple Statement Execution Support	3935
27.7.20 C API Prepared Statement Handling of Date and Time Values	3938
27.7.21 C API Prepared CALL Statement Support	3939
27.7.22 C API Prepared Statement Problems	3943
27.7.23 C API Optional Result Set Metadata	3943
27.7.24 C API Automatic Reconnection Control	3944
27.7.25 C API Common Issues	3945
27.8 MySQL PHP API	3947

MySQL Glossary	5405

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 8.0, through release 8.0.15. Differences between minor versions of MySQL 8.0 are noted in the present text with reference to release numbers (8.0.x). For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.7 Reference Manual](#) covers the 5.7 series of MySQL software releases.

Licensing information—MySQL 8.0. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL 8.0, see the [MySQL 8.0 Commercial Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL 8.0, see the [MySQL 8.0 Community Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Legal Notices

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD,

Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Chapter 1 General Information

Table of Contents

1.1 About This Manual	2
1.2 Typographical and Syntax Conventions	3
1.3 Overview of the MySQL Database Management System	4
1.3.1 What is MySQL?	4
1.3.2 The Main Features of MySQL	6
1.3.3 History of MySQL	9
1.4 What Is New in MySQL 8.0	9
1.5 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0	28
1.6 MySQL Information Sources	37
1.6.1 MySQL Websites	37
1.6.2 MySQL Mailing Lists	37

The MySQL™ software delivers a very fast, multithreaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see [Section 1.3.2, “The Main Features of MySQL”](#).
- For an overview of new MySQL features, see [Section 1.4, “What Is New in MySQL 8.0”](#). For information about the changes in each version, see the [Release Notes](#).
- For installation instructions, see [Chapter 2, *Installing and Upgrading MySQL*](#). For information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#).

- For a tutorial introduction to the MySQL Database Server, see [Chapter 3, *Tutorial*](#).
- For information about configuring and administering MySQL Server, see [Chapter 5, *MySQL Server Administration*](#).
- For information about security in MySQL, see [Chapter 6, *Security*](#).
- For information about setting up replication servers, see [Chapter 17, *Replication*](#).
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see [Chapter 29, *MySQL Enterprise Edition*](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix A, *MySQL 8.0 Frequently Asked Questions*](#).
- For a history of new features and bug fixes, see the [Release Notes](#).

**Important**

To report problems or bugs, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 8.0, through release 8.0.15. Differences between minor versions of MySQL 8.0 are noted in the present text with reference to release numbers (8.0.x). For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.7 Reference Manual](#) covers the 5.7 series of MySQL software releases.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <https://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

The source code for MySQL itself contains internal documentation written using Doxygen. The generated Doxygen content is available at <https://dev.mysql.com/doc/dev/mysql-server/latest/>. It is also possible to generate this content locally from a MySQL source distribution using the instructions at [Section 2.9.7, “Generating MySQL Doxygen Documentation Content”](#).

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See [Section 1.6.2, “MySQL Mailing Lists”](#), and [Section 1.6.3, “MySQL Community Support at the MySQL Forums”](#). If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Chris Cole, Paul DuBois, Margaret Fisher, Edward Gilmore, Stefan Hinz, David Moss, Philip Olson, Daniel Price, Daniel So, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- *Text in this style* is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example:* “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the `%` character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db_name*, *tbl_name*, and *col_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case-sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“[” and “]”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“|”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *reset_option* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

1.3 Overview of the MySQL Database Management System

1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL website (<http://www.mysql.com/>) provides the latest information about MySQL software.

- **MySQL is a database management system.**

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

The MySQL Database Software is a client/server system that consists of a multithreaded SQL server that supports different back ends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multithreaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 8.0: [Section 1.4, “What Is New in MySQL 8.0”](#)
- MySQL 5.7: [What Is New in MySQL 5.7](#)
- MySQL 5.6: [What Is New in MySQL 5.6](#)
- MySQL 5.5: [What Is New in MySQL 5.5](#)

Internals and Portability

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See <https://www.mysql.com/support/supportedplatforms/database.html>.
- For portability, uses [CMake](#) in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multithreaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables ([MyISAM](#)) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.

- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, [FLOAT](#), [DOUBLE](#), [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [TEXT](#), [BLOB](#), [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), [YEAR](#), [SET](#), [ENUM](#), and OpenGIS spatial types. See [Chapter 11, Data Types](#).
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the [SELECT](#) list and [WHERE](#) clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL [GROUP BY](#) and [ORDER BY](#) clauses. Support for group functions ([COUNT\(\)](#), [AVG\(\)](#), [STD\(\)](#), [SUM\(\)](#), [MAX\(\)](#), [MIN\(\)](#), and [GROUP_CONCAT\(\)](#)).
- Support for [LEFT OUTER JOIN](#) and [RIGHT OUTER JOIN](#) with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific [SHOW](#) statements that retrieve information about databases, storage engines, tables, and indexes. Support for the [INFORMATION_SCHEMA](#) database, implemented according to standard SQL.
- An [EXPLAIN](#) statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, [ABS](#) is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See [Section 9.3, "Keywords and Reserved Words"](#).
- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for `InnoDB` tables is either 767 bytes or 3072 bytes. See [Section 15.8.1.7, “Limits on InnoDB Tables”](#). The maximum index width for `MyISAM` tables is 1000 bytes. See [Section 16.2, “The MyISAM Storage Engine”](#). An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
 - Clients can connect using TCP/IP sockets on any platform.
 - On Windows systems, clients can connect using named pipes if the server is started with the `--enable-named-pipe` option. Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
 - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 27, Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [MySQL Connector/ODBC Developer Guide](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [MySQL Connector/J 5.1 Developer Guide](#).
- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See [MySQL Connector/NET Developer Guide](#).

Localization

- The server can provide error messages to clients in many languages. See [Section 10.11, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, several Unicode character sets, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the default character set and collation. It is possible to change this when the MySQL server is started (see [Section 10.3.2, “Server Character Set and](#)

[Collation](#)"). To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See [Section 5.1.12, “MySQL Server Time Zone Support”](#).

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as [mysqldump](#) and [mysqladmin](#), and graphical programs such as [MySQL Workbench](#).
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the [mysqlcheck](#) client. MySQL also includes [myisamchk](#), a very fast command-line utility for performing these operations on [MyISAM](#) tables. See [Chapter 4, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the [mSQL](#) database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that [mSQL](#) was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as [mSQL](#). This API was designed to enable third-party code that was written for use with [mSQL](#) to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 What Is New in MySQL 8.0

This section summarizes what has been added to, deprecated in, and removed from MySQL 8.0. A companion section lists MySQL server options and variables that have been added, deprecated, or removed in MySQL 8.0. See [Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”](#).

- [Features Added in MySQL 8.0](#)
- [Features Deprecated in MySQL 8.0](#)
- [Features Removed in MySQL 8.0](#)

Features Added in MySQL 8.0

The following features have been added to MySQL 8.0:

- **Data dictionary.** MySQL now incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files and nontransactional tables. For more information, see [Chapter 14, MySQL Data Dictionary](#).
- **Atomic Data Definition Statements (Atomic DDL).** An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation

into a single, atomic transaction. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

- **Security and account management.** These enhancements were added to improve security and enable greater DBA flexibility in account management:
 - The grant tables in the `mysql` system database are now `InnoDB` (transactional) tables. Previously, these were `MyISAM` (nontransactional) tables. The change of grant table storage engine underlies an accompanying change to the behavior of account-management statements. Previously, an account-management statement (such as `CREATE USER` or `DROP USER`) that named multiple users could succeed for some users and fail for others. Now, each statement is transactional and either succeeds for all named users or rolls back and has no effect if any error occurs. The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).
 - A new `caching_sha2_password` authentication plugin is available. Like the `sha256_password` plugin, `caching_sha2_password` implements SHA-256 password hashing, but uses caching to address latency issues at connect time. It also supports more connection protocols and does not require linking against OpenSSL for RSA key pair-based password-exchange capabilities. See [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

The `caching_sha2_password` and `sha256_password` authentication plugins provide more secure password encryption than the `mysql_native_password` plugin, and `caching_sha2_password` provides better performance than `sha256_password`. Due to these superior security and performance characteristics of `caching_sha2_password`, it is now the preferred authentication plugin, and is also the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change of default plugin for server operation and compatibility of the server with clients and connectors, see [caching_sha2_password as the Preferred Authentication Plugin](#).

- MySQL now supports roles, which are named collections of privileges. Roles can be created and dropped. Roles can have privileges granted to and revoked from them. Roles can be granted to and revoked from user accounts. The active applicable roles for an account can be selected from among those granted to the account, and can be changed during sessions for that account. For more information, see [Section 6.3.4, “Using Roles”](#).
- MySQL now maintains information about password history, enabling restrictions on reuse of previous passwords. DBAs can require that new passwords not be selected from previous passwords for some number of password changes or period of time. It is possible to establish password-reuse policy globally as well as on a per-account basis.

It is also possible to require that attempts to change account passwords be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing password without proving that they know the current password. It is possible to establish password-verification policy globally as well as on a per-account basis.

These new capabilities provide DBAs more complete control over password management. For more information, see [Section 6.3.8, “Password Management”](#).

- MySQL now supports FIPS mode, if compiled using OpenSSL, and an OpenSSL library and FIPS Object Module are available at runtime. FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. See [Section 6.6, “FIPS Support”](#).
- **Resource management.** MySQL now supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute

according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads. Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups. For more information, see [Section 8.12.5, “Resource Groups”](#).

- **InnoDB enhancements.** These [InnoDB](#) enhancements were added:
 - The current maximum auto-increment counter value is written to the redo log each time the value changes, and saved to an engine-private system table on each checkpoint. These changes make the current maximum auto-increment counter value persistent across server restarts. Additionally:
 - A server restart no longer cancels the effect of the `AUTO_INCREMENT = N` table option. If you initialize the auto-increment counter to a specific value, or if you alter the auto-increment counter value to a larger value, the new value is persisted across server restarts.
 - A server restart immediately following a `ROLLBACK` operation no longer results in the reuse of auto-increment values that were allocated to the rolled-back transaction.
 - If you modify an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value (in an `UPDATE` operation, for example), the new value is persisted, and subsequent `INSERT` operations allocate auto-increment values starting from the new, larger value.

For more information, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#), and [InnoDB AUTO_INCREMENT Counter Initialization](#).

- When encountering index tree corruption, [InnoDB](#) writes a corruption flag to the redo log, which makes the corruption flag crash safe. [InnoDB](#) also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, [InnoDB](#) reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.
- The [InnoDB memcached](#) plugin supports multiple `get` operations (fetching multiple key/value pairs in a single `memcached` query) and range queries. See [Section 15.19.4, “InnoDB memcached Multiple get and Range Query Support”](#).
- A new dynamic configuration option, `innodb_deadlock_detect`, may be used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.
- The new `INFORMATION_SCHEMA.INNODB_CACHED_INDEXES` table reports the number of index pages cached in the [InnoDB](#) buffer pool for each index.
- [InnoDB](#) temporary tables are now created in the shared temporary tablespace, `ibtmp1`.
- The [InnoDB tablespace encryption feature](#) supports encryption of redo log and undo log data. See [Redo Log Data Encryption](#), and [Undo Log Data Encryption](#).
- [InnoDB](#) supports `NOWAIT` and `SKIP LOCKED` options with `SELECT ... FOR SHARE` and `SELECT ... FOR UPDATE` locking read statements. `NOWAIT` causes the statement to return immediately if a requested row is locked by another transaction. `SKIP LOCKED` removes locked rows from the result set. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

`SELECT ... FOR SHARE` replaces `SELECT ... LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility. The statements are equivalent. However, `FOR UPDATE` and `FOR SHARE` support `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. See [Section 13.2.10, “SELECT Syntax”](#).

`OF tbl_name` applies locking queries to named tables.

- `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, and `REBUILD PARTITION ALTER TABLE` options are supported by native partitioning in-place APIs and may be used with `ALGORITHM={COPY|INPLACE}` and `LOCK` clauses.

`DROP PARTITION` with `ALGORITHM=INPLACE` deletes data stored in the partition and drops the partition. However, `DROP PARTITION` with `ALGORITHM=COPY` or `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted.

- The `InnoDB` storage engine now uses the MySQL data dictionary rather than its own storage engine-specific data dictionary. For information about the data dictionary, see [Chapter 14, MySQL Data Dictionary](#).
- `mysql` system tables and data dictionary tables are now created in a single `InnoDB` tablespace file named `mysql.ibd` in the MySQL data directory. Previously, these tables were created in individual `InnoDB` tablespace files in the `mysql` database directory.
- The following undo tablespace changes are introduced in MySQL 8.0:
 - The number of undo tablespaces can now be modified at runtime, or when the server is restarted, using the `innodb_undo_tablespaces` configuration option. This change permits the addition of undo tablespaces and rollback segments as the database grows.
 - `innodb_undo_log_truncate` is enabled by default. See [Section 15.7.9, “Truncating Undo Tablespaces”](#).
 - The `innodb_undo_tablespaces` default value was changed from 0 to 2, which means that rollback segments are created in two separate undo tablespaces instead of the `InnoDB` system tablespace by default. A minimum of two undo tablespaces is required to permit truncation of undo logs.

The minimum `innodb_undo_tablespaces` value is 2, and setting `innodb_undo_tablespaces` to 0 is no longer permitted. A minimum value of 2 ensures that rollback segments are always created in undo tablespaces instead of the system tablespace. For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

- The naming convention used for undo tablespace files is changed from `undoNNN` to `undo_ANN`, where `NNN` is the undo space number.
- The `innodb_rollback_segments` configuration option defines the number of rollback segments per undo tablespace. Previously, `innodb_rollback_segments` was a global setting that specified the total number of rollback segments for the MySQL instance. This change increases the number of rollback segments available for concurrent transactions. More rollback segments increases the likelihood that concurrent transactions use separate rollback segments for undo logs, resulting in less resource contention.

- The `innodb_undo_logs` configuration option is removed. The `innodb_rollback_segments` configuration option performs the same function and should be used instead.
- The `InnoDB_available_undo_logs` status variable is removed. The number of available rollback segments per tablespace may be retrieved using `SHOW VARIABLES LIKE 'innodb_rollback_segments';`
- Default values for configuration options that affect buffer pool preflushing and flushing behavior were modified:
 - The `innodb_max_dirty_pages_pct_lwm` default value is now 10. The previous default value of 0 disables buffer pool preflushing. A value of 10 enables preflushing when the percentage of dirty pages in the buffer pool exceeds 10%. Enabling preflushing improves performance consistency.
 - The `innodb_max_dirty_pages_pct` default value was increased from 75 to 90. `InnoDB` attempts to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. The increased default value permits a greater percentage of dirty pages in the buffer pool.
- The default `innodb_autoinc_lock_mode` setting is now 2 (interleaved). Interleaved lock mode permits the execution of multi-row inserts in parallel, which improves concurrency and scalability. The new `innodb_autoinc_lock_mode` default setting reflects the change from statement-based replication to row based replication as the default replication type in MySQL 5.7. Statement-based replication requires the consecutive auto-increment lock mode (the previous default) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements. For more information, see [InnoDB AUTO_INCREMENT Lock Modes](#).

For systems that use statement-based replication, the new `innodb_autoinc_lock_mode` default setting may break applications that depend on sequential auto-increment values. To restore the previous default, set `innodb_autoinc_lock_mode` to 1.

- Renaming a general tablespace is supported by `ALTER TABLESPACE ... RENAME TO` syntax.
- The new `innodb_dedicated_server` configuration option, which is disabled by default, can be used to have `InnoDB` automatically configure the following options according to the amount of memory detected on the server:
 - `innodb_buffer_pool_size`
 - `innodb_log_file_size`
 - `innodb_flush_method`

This option is intended for MySQL server instances that run on a dedicated server. For more information, see [Section 15.6.13, “Enabling Automatic Configuration for a Dedicated MySQL Server”](#).

- The new `INFORMATION_SCHEMA.INNODB_TABLESPACES_BRIEF` view provides space, name, path, flag, and space type data for `InnoDB` tablespaces.
- The `zlib` library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11. MySQL implements compression with the help of the `zlib` library.

If you use `InnoDB` compressed tables, see [Section 2.11.1.3, “Changes in MySQL 8.0”](#) for related upgrade implications.

- Serialized Dictionary Information (SDI) is present in all [InnoDB](#) tablespace files except for global temporary tablespace and undo tablespace files. SDI is serialized metadata for table and tablespace objects. The presence of SDI data provides metadata redundancy. For example, dictionary object metadata may be extracted from tablespace files if the data dictionary becomes unavailable. SDI extraction is performed using the `ibd2sdi` tool. SDI data is stored in [JSON](#) format.

The inclusion of SDI data in tablespace files increases tablespace file size. An SDI record requires a single index page, which is 16KB in size by default. However, SDI data is compressed when it is stored to reduce the storage footprint.

- The [InnoDB](#) storage engine now supports atomic DDL, which ensures that DDL operations are either fully committed or rolled back, even if the server halts during the operation. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).
- Tablespace files can be moved or restored to a new location while the server is offline using the `innodb_directories` option. For more information, see [Section 15.7.7, “Moving Tablespace Files While the Server is Offline”](#).
- The following redo logging optimizations were implemented:
 - User threads can now write concurrently to the log buffer without synchronizing writes.
 - User threads can now add dirty pages to the flush list in a relaxed order.
 - A dedicated log thread is now responsible for writing the log buffer to the system buffers, flushing system buffers to disk, notifying user threads about written and flushed redo, maintaining the lag required for the relaxed flush list order, and write checkpoints.
 - System variables were added for configuring the use of spin delay by user threads waiting for flushed redo:
 - `innodb_log_wait_for_flush_spin_hwm`: Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo.
 - `innodb_log_spin_cpu_abs_lwm`: Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo.
 - `innodb_log_spin_cpu_pct_hwm`: Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo.
 - The `innodb_log_buffer_size` configuration option is now dynamic, which permits resizing of the log buffer while the server is running.

For more information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- As of MySQL 8.0.12, undo logging is supported for small updates to large object (LOB) data, which improves performance of LOB updates that are 100 bytes in size or less. Previously, LOB updates were a minimum of one LOB page in size, which is less than optimal for updates that might only modify a few bytes. This enhancement builds upon support added in MySQL 8.0.4 for partial update of LOB data.
- As of MySQL 8.0.12, `ALGORITHM=INSTANT` is supported for the following `ALTER TABLE` operations:
 - Adding a column. This feature is also referred to as “Instant `ADD COLUMN`”. Limitations apply. See [Section 15.12.1, “Online DDL Operations”](#).

- Adding or dropping a virtual column.
- Adding or dropping a column default value.
- Modifying the definition of an `ENUM` or `SET` column.
- Changing the index type.
- Renaming a table.

Operations that support `ALGORITHM=INSTANT` only modify metadata in the data dictionary. No metadata locks are taken on the table, and table data is unaffected, making the operations instantaneous. If not specified explicitly, `ALGORITHM=INSTANT` is used by default by operations that support it. If `ALGORITHM=INSTANT` is specified but not supported, the operation fails immediately with an error.

For more information about operations that support `ALGORITHM=INSTANT`, see [Section 15.12.1, “Online DDL Operations”](#).

- As of MySQL 8.0.13, the `TempTable` storage engine supports storage of binary large object (BLOB) type columns. This enhancement improves performance for queries that use temporary tables containing BLOB data. Previously, temporary tables that contained BLOB data were stored in the on-disk storage engine defined by `internal_tmp_disk_storage_engine`. For more information, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).
- As of MySQL 8.0.13, the `InnoDB` tablespace encryption feature supports general tablespaces. Previously, only file-per-table tablespaces could be encrypted. To support encryption of general tablespaces, `CREATE TABLESPACE` and `ALTER TABLESPACE` syntax was extended to include an `ENCRYPTION` clause.

The `INFORMATION_SCHEMA.INNODB_TABLESPACES` table now includes an `ENCRYPTION` column that indicates whether or not a tablespace is encrypted.

The `stage/innodb/alter tablespace (encryption)` Performance Schema stage instrument was added to permit monitoring of general tablespace encryption operations.

- To reduce the size of core files, the `innodb_buffer_pool_in_core_file` variable can be disabled to prevent `InnoDB` buffer pool pages from being written to core files.
- As of MySQL 8.0.13, user-created temporary tables and internal temporary tables created by the optimizer are stored in session temporary tablespaces that are allocated to a session from a pool of temporary tablespaces. When a session disconnects, its temporary tablespaces are truncated and released back to the pool. In previous releases, temporary tables were created in the global temporary tablespace (`ibtmp1`), which did not return disk space to the operating system after temporary tables were dropped.

The `innodb_temp_tablespaces_dir` variable defines the location where session temporary tablespaces are created. The default location is the `#innodb_temp` directory in the data directory.

The `INNODB_SESSION_TEMP_TABLESPACES` table provides metadata about session temporary tablespaces.

The global temporary tablespace (`ibtmp1`) now stores rollback segments for changes made to user-created temporary tables.

- **Character set support.** The default character set has changed from `latin1` to `utf8mb4`. The `utf8mb4` character set has several new collations, including `utf8mb4_ja_0900_as_cs`, the first Japanese language-specific collation available for Unicode in MySQL. For more information, see [Section 10.10.1, “Unicode Character Sets”](#).
- **JSON enhancements.** The following enhancements or additions were made to MySQL's JSON functionality:
 - Added the `->>` (inline path) operator, which is equivalent to calling `JSON_UNQUOTE()` on the result of `JSON_EXTRACT()`.

This is a refinement of the column path operator `->` introduced in MySQL 5.7; `col->>"$.path"` is equivalent to `JSON_UNQUOTE(col->"$.path")`. The inline path operator can be used wherever you can use `JSON_UNQUOTE(JSON_EXTRACT())`, such as `SELECT` column lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses. For more information, see the description of the operator, as well as [Section 12.16.8, “JSON Path Syntax”](#).
 - Added two JSON aggregation functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`. `JSON_ARRAYAGG()` takes a column or expression as its argument, and aggregates the result as a single JSON array. The expression can evaluate to any MySQL data type; this does not have to be a JSON value. `JSON_OBJECTAGG()` takes two columns or expressions which it interprets as a key and a value; it returns the result as a single JSON object. For more information and examples, see [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#).
 - Added the JSON utility function `JSON_PRETTY()`, which outputs an existing JSON value in an easy-to-read format; each JSON object member or array value is printed on a separate line, and a child object or array is indented 2 spaces with respect to its parent.

This function also works with a string that can be parsed as a JSON value.

For more detailed information and examples, see [Section 12.16.7, “JSON Utility Functions”](#).

- When sorting JSON values in a query using `ORDER BY`, each value is now represented by a variable-length part of the sort key, rather than a part of a fixed 1K in size. In many cases this can reduce excessive usage; for example, a scalar `INT` or even `BIGINT` value actually requires very few bytes, so that the remainder of this space (up to 90% or more) was taken up by padding. This change has the following benefits for performance:
 - Sort buffer space is now used more effectively, so that filesorts need not flush to disk as early or often as with fixed-length sort keys. This means that more data can be sorted in memory, avoiding unnecessary disk access.
 - Shorter keys can be compared more quickly than longer ones, providing a noticeable improvement in performance. This is true for sorts performed entirely in memory as well as for sorts that require writing to and reading from disk.
- Added support in MySQL 8.0.2 for partial, in-place updates of JSON column values, which is more efficient than completely removing an existing JSON value and writing a new one in its place, as was done previously when updating any JSON column. For this optimization to be applied, the update must be applied using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. New elements cannot be added to the JSON document being updated; values within the document cannot take more space than they did before the update. See [Partial Updates of JSON Values](#), for a detailed discussion of the requirements.

Partial updates of JSON documents can be written to the binary log, taking up less space than logging complete JSON documents. Partial updates are always logged as such when

statement-based replication is in use. For this to work with row-based replication, you must first set `binlog_row_value_options=PARTIAL_JSON`; see this variable's description for more information.

- Added the JSON utility functions `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()`. `JSON_STORAGE_SIZE()` returns the storage space in bytes used for the binary representation of a JSON document prior to any partial update (see previous item). `JSON_STORAGE_FREE()` shows the amount of space remaining in a table column of type `JSON` after it has been partially updated using `JSON_SET()` or `JSON_REPLACE()`; this is greater than zero if the binary representation of the new value is less than that of the previous value.

Each of these functions also accepts a valid string representation of a JSON document. For such a value, `JSON_STORAGE_SIZE()` returns the space used by its binary representation following its conversion to a JSON document. For a variable containing the string representation of a JSON document, `JSON_STORAGE_FREE()` returns zero. Either function produces an error if its (non-null) argument cannot be parsed as a valid JSON document, and `NULL` if the argument is `NULL`.

For more information and examples, see [Section 12.16.7, “JSON Utility Functions”](#).

`JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()` were implemented in MySQL 8.0.2.

- Added support in MySQL 8.0.2 for ranges such as `[$[1 to 5]` in XPath expressions. Also added support in this version for the `last` keyword and relative addressing, such that `[$[last]` always selects the last (highest-numbered) element in the array and `[$[last-1]` the next to last element. `last` and expressions using it can also be included in range definitions; for example, `[$[last-2 to last-1]` returns the last two elements but one from an array. See [Searching and Modifying JSON Values](#), for additional information and examples.
- Added a JSON merge function intended to conform to [RFC 7396](#). `JSON_MERGE_PATCH()`, when used on 2 JSON objects, merges them into a single JSON object that has as members a union of the following sets:
 - Each member of the first object for which there is no member with the same key in the second object.
 - Each member of the second object for which there is no member having the same key in the first object, and whose value is not the JSON `null` literal.
 - Each member having a key that exists in both objects, and whose value in the second object is not the JSON `null` literal.

As part of this work, the `JSON_MERGE()` function has been renamed `JSON_MERGE_PRESERVE()`. `JSON_MERGE()` continues to be recognized as an alias for `JSON_MERGE_PRESERVE()` in MySQL 8.0, but is now deprecated and is subject to removal in a future version of MySQL.

For more information and examples, see [Section 12.16.4, “Functions That Modify JSON Values”](#).

- Implemented “last duplicate key wins” normalization of duplicate keys, consistent with [RFC 7159](#) and most JavaScript parsers. An example of this behavior is shown here, where only the rightmost member having the key `x` is preserved:

```
mysql> SELECT JSON_OBJECT('x', '32', 'y', '[true, false]',
+>                                'x', 'abc', 'x', '100') AS Result;
+-----+
| Result |
+-----+
| {"x": "100", "y": "[true, false]"} |
```

```
+-----+
1 row in set (0.00 sec)
```

Values inserted into MySQL `JSON` columns are also normalized in this way, as shown in this example:

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES ('{"x": 17, "x": "red", "x": [3, 5, 7]}');

mysql> SELECT c1 FROM t1;
+-----+
| c1      |
+-----+
| {"x": [3, 5, 7]} |
+-----+
```

This is an incompatible change from previous versions of MySQL, where a “first duplicate key wins” algorithm was used in such cases.

See [Normalization, Merging, and Autowrapping of JSON Values](#), for more information and examples.

- Added the `JSON_TABLE()` function in MySQL 8.0.4. This function accepts JSON data and returns it as a relational table having the specified columns.

This function has the syntax `JSON_TABLE(expr, path COLUMNS column_list) [AS] alias`, where `expr` is an expression that returns JSON data, `path` is a JSON path applied to the source, and `column_list` is a list of column definitions. An example is shown here:

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"a":3,"b":"0"}, {"a":"3","b":"1"}, {"a":2,"b":1}, {"a":0}, {"b":[1,2]} ]',
->     "$[*]" COLUMNS(
->       rowid FOR ORDINALITY,
->
->       xa INT EXISTS PATH "$.a",
->       xb INT EXISTS PATH "$.b",
->
->       sa VARCHAR(100) PATH "$.a",
->       sb VARCHAR(100) PATH "$.b",
->
->       ja JSON PATH "$.a",
->       jb JSON PATH "$.b"
->     )
-> ) AS jt1;
```

rowid	xa	xb	sa	sb	ja	jb
1	1	1	3	0	3	"0"
2	1	1	3	1	"3"	"1"
3	1	1	2	1	2	1
4	1	0	0	NULL	0	NULL
5	0	1	NULL	NULL	NULL	[1, 2]

The JSON source expression can be any expression that yields a valid JSON document, including a JSON literal, a table column, or a function call that returns JSON such as `JSON_EXTRACT(t1, data, '$.post.comments')`. For more information, see [Section 12.16.6, “JSON Table Functions”](#).

- Data type support.** MySQL now supports use of expressions as default values in data type specifications. This includes the use of expressions as default values for the `BLOB`, `TEXT`, `GEOMETRY`,

and `JSON` data types, which previously could not be assigned default values at all. For details, see [Section 11.7, “Data Type Default Values”](#).

- **Optimizer.** These optimizer enhancements were added:
 - MySQL now supports invisible indexes. An invisible index is not used by the optimizer at all, but is otherwise maintained normally. Indexes are visible by default. Invisible indexes make it possible to test the effect of removing an index on query performance, without making a destructive change that must be undone should the index turn out to be required. See [Section 8.3.12, “Invisible Indexes”](#).
 - MySQL now supports descending indexes: `DESC` in an index definition is no longer ignored but causes storage of key values in descending order. Previously, indexes could be scanned in reverse order but at a performance penalty. A descending index can be scanned in forward order, which is more efficient. Descending indexes also make it possible for the optimizer to use multiple-column indexes when the most efficient scan order mixes ascending order for some columns and descending order for others. See [Section 8.3.13, “Descending Indexes”](#).
 - MySQL now supports creation of functional index key parts that index expression values rather than column values. Functional key parts enable indexing of values that cannot be indexed otherwise, such as `JSON` values. For details, see [Section 13.1.14, “CREATE INDEX Syntax”](#).
- **Common table expressions.** MySQL now supports common table expressions, both nonrecursive and recursive. Common table expressions enable use of named temporary result sets, implemented by permitting a `WITH` clause preceding `SELECT` statements and certain other statements. For more information, see [Section 13.2.13, “WITH Syntax \(Common Table Expressions\)”](#).
- **Window functions.** MySQL now supports window functions that, for each row from a query, perform a calculation using rows related to that row. These include functions such as `RANK()`, `LAG()`, and `NTILE()`. In addition, several existing aggregate functions now can be used as window functions; for example, `SUM()` and `AVG()`. For more information, see [Section 12.20, “Window Functions”](#).
- **Regular expression support.** Previously, MySQL used the Henry Spencer regular expression library to support regular expression operators (`REGEXP`, `RLIKE`). Regular expression support has been reimplemented using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe. The `REGEXP_LIKE()` function performs regular expression matching in the manner of the `REGEXP` and `RLIKE` operators, which now are synonyms for that function. In addition, the `REGEXP_INSTR()`, `REGEXP_REPLACE()`, and `REGEXP_SUBSTR()` functions are available to find match positions and perform substring substitution and extraction, respectively. The `regexp_stack_limit` and `regexp_time_limit` system variables provide control over resource consumption by the match engine. For more information, see [Section 12.5.2, “Regular Expressions”](#). For information about ways in which applications that use regular expressions may be affected by the implementation change, see [Regular Expression Compatibility Considerations](#).
- **Internal temporary tables.** The `TempTable` storage engine replaces the `MEMORY` storage engine as the default engine for in-memory internal temporary tables. The `TempTable` storage engine provides efficient storage for `VARCHAR` and `VARBINARY` columns. The `internal_tmp_mem_storage_engine` session variable defines the storage engine for in-memory internal temporary tables. Permitted values are `TempTable` (the default) and `MEMORY`. The `temptable_max_ram` configuration option defines the maximum amount of memory that the `TempTable` storage engine can use before data is stored to disk.
- **Logging.** Error logging was rewritten to use the MySQL component architecture. Traditional error logging is implemented using built-in components, and logging using the system log is implemented as a loadable component. In addition, a loadable JSON log writer is available. To control which log components to enable, use the `log_error_services` system variable. For more information, see [Section 5.4.2, “The Error Log”](#).

- **Backup lock.** A new type of backup lock permits DML during an online backup while preventing operations that could result in an inconsistent snapshot. The new backup lock is supported by `LOCK INSTANCE FOR BACKUP` and `UNLOCK INSTANCE` syntax. The `BACKUP_ADMIN` privilege is required to use these statements.
- **Replication.** The following enhancements have been made to MySQL Replication:
 - MySQL Replication now supports binary logging of partial updates to JSON documents using a compact binary format, saving space in the log over logging complete JSON documents. Such compact logging is done automatically when statement-based logging is in use, and can be enabled by setting the new `binlog_row_value_options` system variable to `PARTIAL_JSON`. For more information, see [Partial Updates of JSON Values](#), as well as the description of `binlog_row_value_options`.

Features Deprecated in MySQL 8.0

The following features are deprecated in MySQL 8.0 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.

For applications that use features deprecated in MySQL 8.0 that have been removed in a higher MySQL series, statements may fail when replicated from a MySQL 8.0 master to a higher-series slave, or may have different effects on master and slave. To avoid such problems, applications that use features deprecated in 8.0 should be revised to avoid them and use alternatives when possible.

- The `utf8mb3` character set is deprecated. Please use `utf8mb4` instead.
- The `validate_password` plugin has been reimplemented to use the server component infrastructure. The plugin form of `validate_password` is still available but is deprecated and will be removed in a future version of MySQL. MySQL installations that use the plugin should make the transition to using the component instead. See [Section 6.5.3.3, “Transitioning to the Password Validation Component”](#).
- The `ALTER TABLESPACE` and `DROP TABLESPACE ENGINE` clause is deprecated.
- The `PAD_CHAR_TO_FULL_LENGTH` SQL mode is deprecated.
- The `JSON_MERGE()` function is deprecated. Use `JSON_MERGE_PRESERVE()` instead.
- Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13.

Features Removed in MySQL 8.0

The following items are obsolete and have been removed in MySQL 8.0. Where alternatives are shown, applications should be updated to use them.

For MySQL 5.7 applications that use features removed in MySQL 8.0, statements may fail when replicated from a MySQL 5.7 master to a MySQL 8.0 slave, or may have different effects on master and slave. To avoid such problems, applications that use features removed in MySQL 8.0 should be revised to avoid them and use alternatives when possible.

- The `information_schema_stats` configuration option, introduced in MySQL 8.0.0, was removed and replaced by `information_schema_stats_expiry` in MySQL 8.0.3.

`information_schema_stats_expiry` defines an expiration setting for cached `INFORMATION_SCHEMA` table statistics. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

- Code related to obsolete `InnoDB` system tables was removed in MySQL 8.0.3. `INFORMATION_SCHEMA` views based on `InnoDB` system tables were replaced by internal system views on data dictionary tables. Affected `InnoDB INFORMATION_SCHEMA` views were renamed:

Table 1.1 Renamed InnoDB Information Schema Views

Old Name	New Name
<code>INNODB_SYS_COLUMNS</code>	<code>INNODB_COLUMNS</code>
<code>INNODB_SYS_DATAFILES</code>	<code>INNODB_DATAFILES</code>
<code>INNODB_SYS_FIELDS</code>	<code>INNODB_FIELDS</code>
<code>INNODB_SYS_FOREIGN</code>	<code>INNODB_FOREIGN</code>
<code>INNODB_SYS_FOREIGN_COLS</code>	<code>INNODB_FOREIGN_COLS</code>
<code>INNODB_SYS_INDEXES</code>	<code>INNODB_INDEXES</code>
<code>INNODB_SYS_TABLES</code>	<code>INNODB_TABLES</code>
<code>INNODB_SYS_TABLESPACES</code>	<code>INNODB_TABLESPACES</code>
<code>INNODB_SYS_TABLESTATS</code>	<code>INNODB_TABLESTATS</code>
<code>INNODB_SYS_VIRTUAL</code>	<code>INNODB_VIRTUAL</code>

After upgrading to MySQL 8.0.3 or later, update any scripts that reference previous `InnoDB INFORMATION_SCHEMA` view names.

- The following features related to account management have been removed:
 - Using `GRANT` to create users. Instead, use `CREATE USER`. Following this practice makes the `NO_AUTO_CREATE_USER` SQL mode immaterial for `GRANT` statements, so it too is removed.
 - Using `GRANT` to modify account properties other than privilege assignments. This includes authentication, SSL, and resource-limit properties. Instead, establish such properties at account-creation time with `CREATE USER` or modify them afterward with `ALTER USER`.
 - `IDENTIFIED BY PASSWORD 'hash_string'` syntax for `CREATE USER` and `GRANT`. Instead, use `IDENTIFIED WITH auth_plugin AS 'hash_string'` for `CREATE USER` and `ALTER USER`, where the `'hash_string'` value is in a format compatible with the named plugin.

Additionally, because `IDENTIFIED BY PASSWORD` syntax has been removed, the `log_built_in_as_identified_by_password` system variable is superfluous and has been removed.

- The `PASSWORD()` function. Additionally, `PASSWORD()` removal means that `SET PASSWORD ... = PASSWORD('auth_string')` syntax is no longer available.
- The `old_passwords` system variable.
- The query cache has been removed. Removal includes these items:
 - The `FLUSH QUERY CACHE` and `RESET QUERY CACHE` statements.
 - These system variables: `query_cache_limit`, `query_cache_min_res_unit`, `query_cache_size`, `query_cache_type`, `query_cache_wlock_invalidate`.

- These status variables: `Qcache_free_blocks`, `Qcache_free_memory`, `Qcache_hits`, `Qcache_inserts`, `Qcache_lowmem_prunes`, `Qcache_not_cached`, `Qcache_queries_in_cache`, `Qcache_total_blocks`.
- These thread states: `checking privileges on cached query`, `checking query cache for query`, `invalidating query cache entries`, `sending cached result to client`, `storing result in query cache`, `Waiting for query cache lock`.
- The `SQL_CACHE SELECT` modifier.

These deprecated query cache items remain deprecated, but have no effect, and will be removed in a future MySQL release:

- `SQL_NO_CACHE SELECT` modifier.
- The `ndb_cache_check_time` system variable.

The `have_query_cache` system variable remains deprecated, always has a value of `NO`, and will be removed in a future MySQL release.

- The data dictionary provides information about database objects, so the server no longer checks directory names in the data directory to find databases. Consequently, the `--ignore-db-dir` option and `ignore_db_dirs` system variables are extraneous and have been removed.
- The `tx_isolation` and `tx_read_only` system variables have been removed. Use `transaction_isolation` and `transaction_read_only` instead.
- The `sync_frm` system variable has been removed because `.frm` files have become obsolete.
- The `secure_auth` system variable and `--secure-auth` client option have been removed. The `MYSQL_SECURE_AUTH` option for the `mysql_options()` C API function was removed.
- The `multi_range_count` system variable has been removed.
- The `log_warnings` system variable and `--log-warnings` server option have been removed. Use the `log_error_verbosity` system variable instead.
- The global scope for the `sql_log_bin` system variable has been removed. `sql_log_bin` has session scope only, and applications that rely on accessing `@@global.sql_log_bin` should be adjusted.
- The `metadata_locks_cache_size` and `metadata_locks_hash_instances` system variables have been removed.
- The unused `date_format`, `datetime_format`, `time_format`, and `max_tmp_tables` system variables have been removed.
- These deprecated compatibility SQL modes have been removed: `DB2`, `MAXDB`, `MSSQL`, `MYSQL323`, `MYSQL40`, `ORACLE`, `POSTGRESQL`, `NO_FIELD_OPTIONS`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`. They can no longer be assigned to the `sql_mode` system variable or used as permitted values for the `mysqldump --compatible` option.

Removal of `MAXDB` means that the `TIMESTAMP` data type for `CREATE TABLE` or `ALTER TABLE` is treated as `TIMESTAMP`, and is no longer treated as `DATETIME`.

- The deprecated `ASC` or `DESC` qualifiers for `GROUP BY` clauses have been removed. Queries that previously relied on `GROUP BY` sorting may produce results that differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

- The `EXTENDED` and `PARTITIONS` keywords for the `EXPLAIN` statement have been removed. These keywords are unnecessary because their effect is always enabled.
- These encryption-related items have been removed:
 - The `ENCODE()` and `DECODE()` functions.
 - The `ENCRYPT()` function.
 - The `DES_ENCRYPT()`, and `DES_DECRYPT()` functions, the `--des-key-file` option, the `have_crypt` system variable, the `DES_KEY_FILE` option for the `FLUSH` statement, and the `HAVE_CRYPT CMake` option.

In place of the removed encryption functions: For `ENCRYPT()`, consider using `SHA2()` instead for one-way hashing. For the others, consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- In MySQL 5.7, several spatial functions available under multiple names were deprecated to move in the direction of making the spatial function namespace more consistent, the goal being that each spatial function name begin with `ST_` if it performs an exact operation, or with `MBR` if it performs an operation based on minimum bounding rectangles. In MySQL 8.0, the deprecated functions are removed to leave only the corresponding `ST_` and `MBR` functions:
 - These functions are removed in favor of the `MBR` names: `Contains()`, `Disjoint()`, `Equals()`, `Intersects()`, `Overlaps()`, `Within()`.
 - These functions are removed in favor of the `ST_` names: `Area()`, `AsBinary()`, `AsText()`, `AsWKB()`, `AsWKT()`, `Buffer()`, `Centroid()`, `ConvexHull()`, `Crosses()`, `Dimension()`, `Distance()`, `EndPoint()`, `Envelope()`, `ExteriorRing()`, `GeomCollFromText()`, `GeomCollFromWKB()`, `GeomFromText()`, `GeomFromWKB()`, `GeometryCollectionFromText()`, `GeometryCollectionFromWKB()`, `GeometryFromText()`, `GeometryFromWKB()`, `GeometryN()`, `GeometryType()`, `InteriorRingN()`, `IsClosed()`, `IsEmpty()`, `IsSimple()`, `LineFromText()`, `LineFromWKB()`, `LineStringFromText()`, `LineStringFromWKB()`, `MLineFromText()`, `MLineFromWKB()`, `MPointFromText()`, `MPointFromWKB()`, `MPolyFromText()`, `MPolyFromWKB()`, `MultiLineStringFromText()`, `MultiLineStringFromWKB()`, `MultiPointFromText()`, `MultiPointFromWKB()`, `MultiPolygonFromText()`, `MultiPolygonFromWKB()`, `NumGeometries()`, `NumInteriorRings()`, `NumPoints()`, `PointFromText()`, `PointFromWKB()`, `PointN()`, `PolyFromText()`, `PolyFromWKB()`, `PolygonFromText()`, `PolygonFromWKB()`, `SRID()`, `StartPoint()`, `Touches()`, `X()`, `Y()`.
 - `GLength()` is removed in favor of `ST_Length()`.
- The functions described in [Section 12.15.4, “Functions That Create Geometry Values from WKB Values”](#) previously accepted either WKB strings or geometry arguments. Geometry arguments are no longer permitted and produce an error. See that section for guidelines for migrating queries away from using geometry arguments.
- The parser no longer treats `\N` as a synonym for `NULL` in SQL statements. Use `NULL` instead.

This change does not affect text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, for which `NULL` continues to be represented by `\N`. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).
- `PROCEDURE ANALYSE()` syntax is removed.
- The client-side `--ssl` and `--ssl-verify-server-cert` options have been removed. Use `--ssl-mode=REQUIRED` instead of `--ssl=1` or `--enable-ssl`. Use `--ssl-mode=DISABLED` instead of `--`

`ssl=0`, `--skip-ssl`, or `--disable-ssl`. Use `--ssl-mode=VERIFY_IDENTITY` instead of `--ssl-verify-server-cert` options. (The server-side `--ssl` option remains unchanged.)

For the C API, `MYSQL_OPT_SSL_ENFORCE` and `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` options for `mysql_options()` correspond to the client-side `--ssl` and `--ssl-verify-server-cert` options and have been removed. Use `MYSQL_OPT_SSL_MODE` with an option value of `SSL_MODE_REQUIRED` or `SSL_MODE_VERIFY_IDENTITY` instead.

- The `--temp-pool` server option has been removed.
- The `--ignore-builtin-innodb` server option and `ignore_builtin_innodb` system variable have been removed.
- The server no longer performs conversion of pre-MySQL 5.1 database names containing special characters to 5.1 format with the addition of a `#mysql50#` prefix. Because these conversions are no longer performed, the `--fix-db-names` and `--fix-table-names` options for `mysqlcheck`, the `UPGRADE DATA DIRECTORY NAME` clause for the `ALTER DATABASE` statement, and the `Com_alter_db_upgrade` status variable have been removed.

Upgrades are supported only from one major version to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

- The `mysql_install_db` program has been removed from MySQL distributions. Data directory initialization should be performed by invoking `mysqld` with the `--initialize` or `--initialize-insecure` option instead. In addition, the `--bootstrap` option for `mysqld` that was used by `mysql_install_db` has been removed, and the `INSTALL_SCRIPTDIR CMake` option that controlled the installation location for `mysql_install_db` has been removed.
- The generic partitioning handler has been removed from the MySQL server. In order to support partitioning of a given table, the storage engine used for the table must now provide its own (“native”) partitioning handler. The `--partition` and `--skip-partition` options have been removed from the MySQL Server, and partitioning-related entries are no longer shown in the output of `SHOW PLUGINS` or in the `INFORMATION_SCHEMA.PLUGINS` table.

Two MySQL storage engines currently provide native partitioning support—`InnoDB` and `NDB`; of these, only `InnoDB` is supported in MySQL 8.0. Any attempt to create partitioned tables in MySQL 8.0 using any other storage engine fails.

Ramifications for upgrades. The direct upgrade of a partitioned table using a storage engine other than `InnoDB` (such as `MyISAM`) from MySQL 5.7 (or earlier) to MySQL 8.0 is not supported. There are two options for handling such a table:

- Remove the table's partitioning, using `ALTER TABLE ... REMOVE PARTITIONING`.
- Change the storage engine used for the table to `InnoDB`, with `ALTER TABLE ... ENGINE=INNODB`.

At least one of the two operations just listed must be performed for each partitioned non-`InnoDB` table prior to upgrading the server to MySQL 8.0. Otherwise, such a table cannot be used following the upgrade.

Due to the fact that table creation statements that would result in a partitioned table using a storage engine without partitioning support now fail with an error (`ER_CHECK_NOT_IMPLEMENTED`), you must make sure that any statements in a dump file (such as that written by `mysqldump`) from an older version of MySQL that you wish to import into a MySQL 8.0 server that create partitioned tables do not also

specify a storage engine such as [MyISAM](#) that has no native partitioning handler. You can do this by performing either of the following:

- Remove any references to partitioning from `CREATE TABLE` statements that use a value for the `STORAGE ENGINE` option other than `InnoDB`.
- Specifying the storage engine as `InnoDB`, or allow `InnoDB` to be used as the table's storage engine by default.

For more information, see [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

- System and status variable information is no longer maintained in the `INFORMATION_SCHEMA`. These tables have been removed: `GLOBAL_VARIABLES`, `SESSION_VARIABLES`, `GLOBAL_STATUS`, `SESSION_STATUS`. Use the corresponding Performance Schema tables instead. See [Section 25.11.13, “Performance Schema System Variable Tables”](#), and [Section 25.11.14, “Performance Schema Status Variable Tables”](#). In addition, the `show_compatibility_56` system variable has been removed. It was used in the transition period during which system and status variable information in `INFORMATION_SCHEMA` tables was moved to Performance Schema tables, and is no longer needed. These status variables have been removed: `Slave_heartbeat_period`, `Slave_last_heartbeat`, `Slave_received_heartbeats`, `Slave_retried_transactions`, `Slave_running`. The information they provided is available in Performance Schema tables; see [Migrating to Performance Schema System and Status Variable Tables](#).
- The Performance Schema `setup_timers` table has been removed, as has the `TICK` row in the `performance_timers` table.
- The `libmysqld` embedded server library has been removed, along with:
 - The `mysql_options()` `MYSQL_OPT_GUESS_CONNECTION`, `MYSQL_OPT_USE_EMBEDDED_CONNECTION`, `MYSQL_OPT_USE_REMOTE_CONNECTION`, and `MYSQL_SET_CLIENT_IP` options
 - The `mysql_config --libmysqld-libs`, `--embedded-libs`, and `--embedded` options
 - The `CMake WITH_EMBEDDED_SERVER`, `WITH_EMBEDDED_SHARED_LIBRARY`, and `INSTALL_SECURE_FILE_PRIV_EMBEDDED` options
 - The (undocumented) `mysql --server-arg` option
 - The `mysqltest --embedded-server`, `--server-arg`, and `--server-file` options
 - The `mysqltest_embedded` and `mysql_client_test_embedded` test programs
- The `mysql_plugin` utility has been removed. Alternatives include loading plugins at server startup using the `--plugin-load` or `--plugin-load-add` option, or at runtime using the `INSTALL PLUGIN` statement.
- The following server error codes are not used and have been removed. Applications that test specifically for any of these errors should be updated.

- The deprecated [INFORMATION_SCHEMA.INNODB_LOCKS](#) and [INNODB_LOCK_WAITS](#) tables have been removed. Use the Performance Schema [data_locks](#) and [data_lock_waits](#) tables instead.

Note

In MySQL 5.7, the [LOCK_TABLE](#) column in the [INNODB_LOCKS](#) table and the [locked_table](#) column in the [sys](#) schema [innodb_lock_waits](#) and [x\\$innodb_lock_waits](#) views contain combined schema/table name values. In MySQL 8.0, the [data_locks](#) table and the [sys](#) schema views contain separate schema name and table name columns. See [Section 26.4.3.9, “The innodb_lock_waits and x\\$innodb_lock_waits Views”](#).

- [InnoDB](#) no longer supports compressed temporary tables. When [innodb_strict_mode](#) is enabled (the default), [CREATE TEMPORARY TABLE](#) returns an error if [ROW_FORMAT=COMPRESSED](#) or [KEY_BLOCK_SIZE](#) is specified. If [innodb_strict_mode](#) is disabled, warnings are issued and the temporary table is created using a non-compressed row format.
- [InnoDB](#) no longer creates [.isl](#) files ([InnoDB Symbolic Link files](#)) when creating tablespace data files outside of the MySQL data directory. The [innodb_directories](#) option now supports locating tablespace files created outside of the data directory.

With this change, moving a remote tablespace while the server is offline by manually modifying an [.isl](#) file is no longer supported. Moving remote tablespace files is now supported by the [innodb_directories](#) option. See [Section 15.7.7, “Moving Tablespace Files While the Server is Offline”](#).

- The following [InnoDB](#) file format configuration options were removed:
 - [innodb_file_format](#)
 - [innodb_file_format_check](#)
 - [innodb_file_format_max](#)
 - [innodb_large_prefix](#)

File format configuration options were necessary for creating tables compatible with earlier versions of [InnoDB](#) in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, these options are no longer required.

The `FILE_FORMAT` column was removed from the `INNODB_TABLES` and `INNODB_TABLESPACES` Information Schema tables.

- The `innodb_support_xa` system variable, which enables support for two-phase commit in XA transactions, was removed. InnoDB support for two-phase commit in XA transactions is always enabled.
- Support for DTrace has been removed.
- The `JSON_APPEND()` function has been removed. Use `JSON_ARRAY_APPEND()` instead.
- Support for placing table partitions in shared InnoDB tablespaces was removed in MySQL 8.0.13. Shared tablespaces include the InnoDB system tablespace and general tablespaces. For information about identifying partitions in shared tablespaces and moving them to file-per-table tablespaces, see [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#).
- Support for setting user variables in statements other than `SET` was deprecated in MySQL 8.0.13. This functionality is subject to removal in MySQL 9.0.

1.5 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0

This section lists server variables, status variables, and options that were added for the first time, have been deprecated, or have been removed in MySQL 8.0.

- [Options and Variables Introduced in MySQL 8.0](#)
- [Options and Variables Deprecated in MySQL 8.0](#)
- [Options and Variables Removed in MySQL 8.0](#)

Options and Variables Introduced in MySQL 8.0

The following system variables, status variables, and options are new in MySQL 8.0, and have not been included in any previous release series.

- `Acl_cache_items_count`: Added in MySQL 8.0.0.
- `Audit_log_current_size`: Added in MySQL 8.0.11.
- `Audit_log_event_max_drop_size`: Added in MySQL 8.0.11.
- `Audit_log_events`: Added in MySQL 8.0.11.
- `Audit_log_events_filtered`: Added in MySQL 8.0.11.
- `Audit_log_events_lost`: Added in MySQL 8.0.11.
- `Audit_log_events_written`: Added in MySQL 8.0.11.
- `Audit_log_total_size`: Added in MySQL 8.0.11.
- `Audit_log_write_waits`: Added in MySQL 8.0.11.
- `Caching_sha2_password_rsa_public_key`: Added in MySQL 8.0.4.
- `Com_alter_resource_group`: Added in MySQL 8.0.3.
- `Com_alter_user_default_role`: Added in MySQL 8.0.0.

- `Com_create_resource_group`: Added in MySQL 8.0.3.
- `Com_create_role`: Added in MySQL 8.0.0.
- `Com_drop_resource_group`: Added in MySQL 8.0.3.
- `Com_drop_role`: Added in MySQL 8.0.0.
- `Com_grant_roles`: Added in MySQL 8.0.0.
- `Com_install_component`: Added in MySQL 8.0.0.
- `Com_revoke_roles`: Added in MySQL 8.0.0.
- `Com_set_resource_group`: Added in MySQL 8.0.3.
- `Com_set_role`: Added in MySQL 8.0.0.
- `Com_uninstall_component`: Added in MySQL 8.0.0.
- `Connection_control_delay_generated`: Added in MySQL 8.0.1.
- `Firewall_access_denied`: Added in MySQL 8.0.11.
- `Firewall_access_granted`: Added in MySQL 8.0.11.
- `Firewall_cached_entries`: Added in MySQL 8.0.11.
- `Secondary_engine_execution_count`: Added in MySQL 8.0.13.
- `activate_all_roles_on_login`: Added in MySQL 8.0.2.
- `audit-log`: Added in MySQL 8.0.11.
- `audit_log_buffer_size`: Added in MySQL 8.0.11.
- `audit_log_compression`: Added in MySQL 8.0.11.
- `audit_log_connection_policy`: Added in MySQL 8.0.11.
- `audit_log_current_session`: Added in MySQL 8.0.11.
- `audit_log_encryption`: Added in MySQL 8.0.11.
- `audit_log_exclude_accounts`: Added in MySQL 8.0.11.
- `audit_log_file`: Added in MySQL 8.0.11.
- `audit_log_filter_id`: Added in MySQL 8.0.11.
- `audit_log_flush`: Added in MySQL 8.0.11.
- `audit_log_format`: Added in MySQL 8.0.11.
- `audit_log_include_accounts`: Added in MySQL 8.0.11.
- `audit_log_policy`: Added in MySQL 8.0.11.
- `audit_log_read_buffer_size`: Added in MySQL 8.0.11.
- `audit_log_rotate_on_size`: Added in MySQL 8.0.11.

- `audit_log_statement_policy`: Added in MySQL 8.0.11.
- `audit_log_strategy`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_auth_method_name`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_bind_base_dn`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_bind_root_dn`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_bind_root_pwd`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_ca_path`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_group_search_attr`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_group_search_filter`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_init_pool_size`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_log_status`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_max_pool_size`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_server_host`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_server_port`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_tls`: Added in MySQL 8.0.11.
- `authentication_ldap_sasl_user_search_attr`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_auth_method_name`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_bind_base_dn`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_bind_root_dn`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_bind_root_pwd`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_ca_path`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_group_search_attr`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_group_search_filter`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_init_pool_size`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_log_status`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_max_pool_size`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_server_host`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_server_port`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_tls`: Added in MySQL 8.0.11.
- `authentication_ldap_simple_user_search_attr`: Added in MySQL 8.0.11.
- `authentication_windows_log_level`: Added in MySQL 8.0.11.

- `authentication_windows_use_principal_name`: Added in MySQL 8.0.11.
- `binlog_expire_logs_seconds`: Added in MySQL 8.0.1.
- `binlog_row_metadata`: Added in MySQL 8.0.1.
- `binlog_row_value_options`: Added in MySQL 8.0.3.
- `binlog_transaction_dependency_history_size`: Added in MySQL 8.0.1.
- `binlog_transaction_dependency_tracking`: Added in MySQL 8.0.1.
- `caching_sha2_password_auto_generate_rsa_keys`: Added in MySQL 8.0.4.
- `caching_sha2_password_private_key_path`: Added in MySQL 8.0.3.
- `caching_sha2_password_public_key_path`: Added in MySQL 8.0.3.
- `connection_control_failed_connections_threshold`: Added in MySQL 8.0.1.
- `connection_control_max_connection_delay`: Added in MySQL 8.0.1.
- `connection_control_min_connection_delay`: Added in MySQL 8.0.1.
- `cte_max_recursion_depth`: Added in MySQL 8.0.3.
- `default_collation_for_utf8mb4`: Added in MySQL 8.0.11.
- `dragnet.Status`: Added in MySQL 8.0.12.
- `dragnet.log_error_filter_rules`: Added in MySQL 8.0.4.
- `early-plugin-load`: Added in MySQL 8.0.0.
- `group_replication_communication_debug_options`: Added in MySQL 8.0.3.
- `group_replication_flow_control_hold_percent`: Added in MySQL 8.0.2.
- `group_replication_flow_control_max_commit_quota`: Added in MySQL 8.0.2.
- `group_replication_flow_control_member_quota_percent`: Added in MySQL 8.0.2.
- `group_replication_flow_control_min_quota`: Added in MySQL 8.0.2.
- `group_replication_flow_control_min_recovery_quota`: Added in MySQL 8.0.2.
- `group_replication_flow_control_period`: Added in MySQL 8.0.2.
- `group_replication_flow_control_release_percent`: Added in MySQL 8.0.2.
- `group_replication_member_expel_timeout`: Added in MySQL 8.0.13.
- `group_replication_member_weight`: Added in MySQL 8.0.2.
- `group_replication_recovery_get_public_key`: Added in MySQL 8.0.4.
- `group_replication_recovery_public_key_path`: Added in MySQL 8.0.4.
- `group_replication_unreachable_majority_timeout`: Added in MySQL 8.0.2.
- `histogram_generation_max_mem_size`: Added in MySQL 8.0.2.

- `information_schema_stats_expiry`: Added in MySQL 8.0.3.
- `innodb_buffer_pool_debug`: Added in MySQL 8.0.0.
- `innodb_buffer_pool_in_core_file`: Added in MySQL 8.0.14.
- `innodb_checkpoint_disabled`: Added in MySQL 8.0.2.
- `innodb_ddl_log_crash_reset_debug`: Added in MySQL 8.0.3.
- `innodb_deadlock_detect`: Added in MySQL 8.0.0.
- `innodb_dedicated_server`: Added in MySQL 8.0.3.
- `innodb_directories`: Added in MySQL 8.0.4.
- `innodb_fsync_threshold`: Added in MySQL 8.0.13.
- `innodb_log_checkpoint_fuzzy_now`: Added in MySQL 8.0.13.
- `innodb_log_spin_cpu_abs_lwm`: Added in MySQL 8.0.11.
- `innodb_log_spin_cpu_pct_hwm`: Added in MySQL 8.0.11.
- `innodb_log_wait_for_flush_spin_hwm`: Added in MySQL 8.0.11.
- `innodb_parallel_read_threads`: Added in MySQL 8.0.14.
- `innodb_print_ddl_logs`: Added in MySQL 8.0.3.
- `innodb_redo_log_encrypt`: Added in MySQL 8.0.1.
- `innodb_scan_directories`: Added in MySQL 8.0.2.
- `innodb_stats_include_delete_marked`: Added in MySQL 8.0.1.
- `innodb_temp_tablespaces_dir`: Added in MySQL 8.0.13.
- `innodb_tmpdir`: Added in MySQL 8.0.0.
- `innodb_undo_log_encrypt`: Added in MySQL 8.0.1.
- `internal_tmp_mem_storage_engine`: Added in MySQL 8.0.2.
- `keyring-migration-destination`: Added in MySQL 8.0.4.
- `keyring-migration-host`: Added in MySQL 8.0.4.
- `keyring-migration-password`: Added in MySQL 8.0.4.
- `keyring-migration-port`: Added in MySQL 8.0.4.
- `keyring-migration-socket`: Added in MySQL 8.0.4.
- `keyring-migration-source`: Added in MySQL 8.0.4.
- `keyring-migration-user`: Added in MySQL 8.0.4.
- `keyring_aws_cmek_id`: Added in MySQL 8.0.11.
- `keyring_aws_conf_file`: Added in MySQL 8.0.11.

- `keyring_aws_data_file`: Added in MySQL 8.0.11.
- `keyring_aws_region`: Added in MySQL 8.0.11.
- `keyring_encrypted_file_data`: Added in MySQL 8.0.11.
- `keyring_encrypted_file_password`: Added in MySQL 8.0.11.
- `keyring_okv_conf_dir`: Added in MySQL 8.0.11.
- `keyring_operations`: Added in MySQL 8.0.4.
- `log_error_filter_rules`: Added in MySQL 8.0.2.
- `log_error_services`: Added in MySQL 8.0.2.
- `log_error_suppression_list`: Added in MySQL 8.0.13.
- `mandatory_roles`: Added in MySQL 8.0.2.
- `mysql_firewall_mode`: Added in MySQL 8.0.11.
- `mysql_firewall_trace`: Added in MySQL 8.0.11.
- `mysqlx`: Added in MySQL 8.0.11.
- `mysqlx-interactive-timeout`: Added in MySQL 8.0.4.
- `mysqlx-port-read-timeout`: Added in MySQL 8.0.4.
- `mysqlx-wait-timeout`: Added in MySQL 8.0.4.
- `mysqlx-write-timeout`: Added in MySQL 8.0.4.
- `mysqlx_interactive_timeout`: Added in MySQL 8.0.4.
- `mysqlx_read_timeout`: Added in MySQL 8.0.4.
- `mysqlx_wait_timeout`: Added in MySQL 8.0.4.
- `mysqlx_write_timeout`: Added in MySQL 8.0.4.
- `no-dd-upgrade`: Added in MySQL 8.0.4.
- `no-monitor`: Added in MySQL 8.0.12.
- `original_commit_timestamp`: Added in MySQL 8.0.1.
- `password_history`: Added in MySQL 8.0.3.
- `password_require_current`: Added in MySQL 8.0.13.
- `password_reuse_interval`: Added in MySQL 8.0.3.
- `performance_schema_max_digest_sample_age`: Added in MySQL 8.0.3.
- `persisted_globals_load`: Added in MySQL 8.0.0.
- `regex_stack_limit`: Added in MySQL 8.0.4.
- `regex_time_limit`: Added in MySQL 8.0.4.

- `resultset_metadata`: Added in MySQL 8.0.3.
- `rpl_read_size`: Added in MySQL 8.0.11.
- `show_create_table_verbosity`: Added in MySQL 8.0.11.
- `sql_require_primary_key`: Added in MySQL 8.0.13.
- `ssl_fips_mode`: Added in MySQL 8.0.11.
- `syseventlog.facility`: Added in MySQL 8.0.13.
- `syseventlog.include_pid`: Added in MySQL 8.0.13.
- `syseventlog.tag`: Added in MySQL 8.0.13.
- `temptable_max_ram`: Added in MySQL 8.0.2.
- `thread_pool_algorithm`: Added in MySQL 8.0.11.
- `thread_pool_high_priority_connection`: Added in MySQL 8.0.11.
- `thread_pool_max_unused_threads`: Added in MySQL 8.0.11.
- `thread_pool_prio_kickup_timer`: Added in MySQL 8.0.11.
- `thread_pool_size`: Added in MySQL 8.0.11.
- `thread_pool_stall_limit`: Added in MySQL 8.0.11.
- `use_secondary_engine`: Added in MySQL 8.0.13.
- `validate_password.check_user_name`: Added in MySQL 8.0.4.
- `validate_password.dictionary_file`: Added in MySQL 8.0.4.
- `validate_password.dictionary_file_last_parsed`: Added in MySQL 8.0.4.
- `validate_password.dictionary_file_words_count`: Added in MySQL 8.0.4.
- `validate_password.length`: Added in MySQL 8.0.4.
- `validate_password.mixed_case_count`: Added in MySQL 8.0.4.
- `validate_password.number_count`: Added in MySQL 8.0.4.
- `validate_password.policy`: Added in MySQL 8.0.4.
- `validate_password.special_char_count`: Added in MySQL 8.0.4.
- `version_compile_zlib`: Added in MySQL 8.0.11.
- `windowing_use_high_precision`: Added in MySQL 8.0.2.

Options and Variables Deprecated in MySQL 8.0

The following system variables, status variables, and options have been deprecated in MySQL 8.0.

- `expire_logs_days`: Purge binary logs after this many days. Deprecated as of MySQL 8.0.3.
- `innodb_undo_tablespace`: The number of tablespace files that rollback segments are divided between. Deprecated as of MySQL 8.0.4.

- [log_syslog](#): Whether to write error log to syslog. Deprecated as of MySQL 8.0.2.
- [symbolic-links](#): Permit symbolic links for MyISAM tables. Deprecated as of MySQL 8.0.2.

Options and Variables Removed in MySQL 8.0

The following system variables, status variables, and options have been removed in MySQL 8.0.

- [Com_alter_db_upgrade](#): Count of ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME statements. Removed in MySQL 8.0.0.
- [Innodb_available_undo_logs](#): Display the total number of InnoDB rollback segments; different from innodb_rollback_segments, which displays the number of active rollback segments. Removed in MySQL 8.0.2.
- [Qcache_free_blocks](#): Number of free memory blocks in the query cache. Removed in MySQL 8.0.3.
- [Qcache_free_memory](#): The amount of free memory for the query cache. Removed in MySQL 8.0.3.
- [Qcache_hits](#): Number of query cache hits. Removed in MySQL 8.0.3.
- [Qcache_inserts](#): Number of query cache inserts. Removed in MySQL 8.0.3.
- [Qcache_lowmem_prunes](#): Number of queries that were deleted from the query cache due to lack of free memory in the cache. Removed in MySQL 8.0.3.
- [Qcache_not_cached](#): Number of noncached queries (not cacheable, or not cached due to the query_cache_type setting). Removed in MySQL 8.0.3.
- [Qcache_queries_in_cache](#): Number of queries registered in the query cache. Removed in MySQL 8.0.3.
- [Qcache_total_blocks](#): The total number of blocks in the query cache. Removed in MySQL 8.0.3.
- [Slave_heartbeat_period](#): The slave's replication heartbeat interval, in seconds. Removed in MySQL 8.0.1.
- [Slave_last_heartbeat](#): Shows when the latest heartbeat signal was received, in TIMESTAMP format. Removed in MySQL 8.0.1.
- [Slave_received_heartbeats](#): Number of heartbeats received by a replication slave since previous reset. Removed in MySQL 8.0.1.
- [Slave_retried_transactions](#): The total number of times since startup that the replication slave SQL thread has retried transactions. Removed in MySQL 8.0.1.
- [Slave_running](#): The state of this server as a replication slave (slave I/O thread status). Removed in MySQL 8.0.1.
- [bootstrap](#): Used by mysql installation scripts. Removed in MySQL 8.0.0.
- [date_format](#): The DATE format (unused). Removed in MySQL 8.0.3.
- [datetime_format](#): The DATETIME/TIMESTAMP format (unused). Removed in MySQL 8.0.3.
- [des-key-file](#): Load keys for des_encrypt() and des_decrypt from given file. Removed in MySQL 8.0.3.
- [group_replication_allow_local_disjoint_gtids_join](#): Allow the current server to join the group even if it has transactions not present in the group. Removed in MySQL 8.0.4.

- `have_crypt`: Availability of the `crypt()` system call. Removed in MySQL 8.0.3.
- `ignore-builtin-innodb`: Ignore the built-in InnoDB. Removed in MySQL 8.0.3.
- `ignore-db-dir`: Treat directory as nondatabase directory. Removed in MySQL 8.0.0.
- `ignore_db_dirs`: Directories treated as nondatabase directories. Removed in MySQL 8.0.0.
- `innodb_checksums`: Enable InnoDB checksums validation. Removed in MySQL 8.0.0.
- `innodb_disable_resize_buffer_pool_debug`: Disables resizing of the InnoDB buffer pool. Removed in MySQL 8.0.0.
- `innodb_file_format`: The format for new InnoDB tables. Removed in MySQL 8.0.0.
- `innodb_file_format_check`: Whether InnoDB performs file format compatibility checking. Removed in MySQL 8.0.0.
- `innodb_file_format_max`: The file format tag in the shared tablespace. Removed in MySQL 8.0.0.
- `innodb_large_prefix`: Enables longer keys for column prefix indexes. Removed in MySQL 8.0.0.
- `innodb_locks_unsafe_for_binlog`: Force InnoDB not to use next-key locking. Instead use only row-level locking. Removed in MySQL 8.0.0.
- `innodb_stats_sample_pages`: Number of index pages to sample for index distribution statistics. Removed in MySQL 8.0.0.
- `innodb_support_xa`: Enable InnoDB support for the XA two-phase commit. Removed in MySQL 8.0.0.
- `innodb_undo_logs`: Defines the number of undo logs (rollback segments) used by InnoDB; an alias for `innodb_rollback_segments`. Removed in MySQL 8.0.2.
- `log-warnings`: Log some noncritical warnings to the log file. Removed in MySQL 8.0.3.
- `log_builtin_as_identified_by_password`: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion. Removed in MySQL 8.0.11.
- `log_error_filter_rules`: Filter rules for error logging. Removed in MySQL 8.0.4.
- `log_syslog`: Whether to write error log to syslog. Removed in MySQL 8.0.13.
- `log_syslog_facility`: Facility for syslog messages. Removed in MySQL 8.0.13.
- `log_syslog_include_pid`: Whether to include server PID in syslog messages. Removed in MySQL 8.0.13.
- `log_syslog_tag`: Tag for server identifier in syslog messages. Removed in MySQL 8.0.13.
- `max_tmp_tables`: Unused. Removed in MySQL 8.0.3.
- `metadata_locks_cache_size`: Size of the metadata locks cache. Removed in MySQL 8.0.13.
- `metadata_locks_hash_instances`: Number of metadata lock hashes. Removed in MySQL 8.0.13.
- `multi_range_count`: The maximum number of ranges to send to a table handler at once during range selects. Removed in MySQL 8.0.3.
- `old_passwords`: Selects password hashing method for PASSWORD(). Removed in MySQL 8.0.11.

- [partition](#): Enable (or disable) partitioning support. Removed in MySQL 8.0.0.
- [query_cache_limit](#): Do not cache results that are bigger than this. Removed in MySQL 8.0.3.
- [query_cache_min_res_unit](#): Minimal size of unit in which space for results is allocated (last unit will be trimmed after writing all result data). Removed in MySQL 8.0.3.
- [query_cache_size](#): The memory allocated to store results from old queries. Removed in MySQL 8.0.3.
- [query_cache_type](#): Query cache type. Removed in MySQL 8.0.3.
- [query_cache_wlock_invalidate](#): Invalidate queries in query cache on LOCK for write. Removed in MySQL 8.0.3.
- [secure-auth](#): Disallow authentication for accounts that have old (pre-4.1) passwords. Removed in MySQL 8.0.3.
- [show_compatibility_56](#): Compatibility for SHOW STATUS/VARIABLES. Removed in MySQL 8.0.1.
- [skip-partition](#): Do not enable user-defined partitioning. Removed in MySQL 8.0.0.
- [sync_frm](#): Sync .frm to disk on create. Enabled by default. Removed in MySQL 8.0.0.
- [temp-pool](#): Using this option will cause most temporary files created to use a small set of names, rather than a unique name for each new file. Removed in MySQL 8.0.1.
- [time_format](#): The TIME format (unused). Removed in MySQL 8.0.3.
- [tx_isolation](#): The default transaction isolation level. Removed in MySQL 8.0.3.
- [tx_read_only](#): Default transaction access mode. Removed in MySQL 8.0.3.

1.6 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as MySQL websites, mailing lists, user forums, and Internet Relay Chat.

1.6.1 MySQL Websites

The primary website for MySQL documentation is <https://dev.mysql.com/doc/>. Online and downloadable documentation formats are available for the MySQL Reference Manual, MySQL Connectors, and more.

The MySQL developers provide information about new and upcoming features as the [MySQL Server Blog](#).

1.6.2 MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from lists.mysql.com to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- [announce](#)

The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- [mysql](#)

The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- [bugs](#)

The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See [Section 1.7, “How to Report Bugs or Problems”](#).

- [internals](#)

The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- [mysqldoc](#)

The list for people who work on the MySQL documentation.

- [benchmarks](#)

The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- [packagers](#)

The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- [java](#)

The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- [win32](#)

The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- [myodbc](#)

The list for all topics concerning connecting to the MySQL server with ODBC.

- [gui-tools](#)

The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- [cluster](#)

The list for discussion of MySQL Cluster.

- [dotnet](#)

The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/NET.

- [plusplus](#)

The list for all topics concerning programming with the C++ API for MySQL.

- [perl](#)

The list for all topics concerning Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- [<mysql-france-subscribe@yahoogroups.com>](mailto:mysql-france-subscribe@yahoogroups.com)

A French mailing list.

- [<list@tinc.net>](mailto:list@tinc.net)

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- [<mysql-de-request@lists.4t2.com>](mailto:mysql-de-request@lists.4t2.com)

A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at <http://www.4t2.com/mysql/>.

- [<mysql-br-request@listas.linkway.com.br>](mailto:mysql-br-request@listas.linkway.com.br)

A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- [<mysql-alta@elistas.net>](mailto:mysql-alta@elistas.net)

A Spanish mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

1.6.2.1 Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your

answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.6.3 MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.6.4 MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

freenode (see <http://www.freenode.net/> for servers)

- [#mysql](#) is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.
- [#workbench](#) is primarily for MySQL Workbench related questions and thoughts, and it is also a good place to meet the MySQL Workbench developers.

1.6.5 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs

- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see [MySQL Enterprise](#).

1.7 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <https://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section B.5, “Problems and Common Errors”](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See [Section 1.6.2, “MySQL Mailing Lists”](#).
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL website.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

To discuss problems with other users, you can use one of the MySQL mailing lists. [Section 1.6.2, “MySQL Mailing Lists”](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the

bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [Section 28.5, “Debugging and Porting MySQL”](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See [How to Report Connector/ODBC Problems or Bugs](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows”

menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- The contents of the `docs/INFO_BIN` file from your MySQL installation. This file contains information about how MySQL was configured and compiled.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See [Section 28.5, “Debugging and Porting MySQL”](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
      <output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
      <output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
      <A short version of the output from SELECT,
      including the time taken to run the query>
mysql> SHOW STATUS;
      <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at <http://bugs.mysql.com/>, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.
- If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
 - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.
- For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, *MySQL Server Administration*](#).

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in [Section 9.2.2, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 5.4.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section B.5.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.1, “Which MySQL Version and Distribution to Install”](#).

1.8 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992. “SQL:1999”, “SQL:2003”, “SQL:2008”, and “SQL:2011” refer to the versions of the standard released in the corresponding years, with the last being the most recent version. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See [Section 13.2.4, “HANDLER Syntax”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the [NDBCLUSTER](#) storage engine. See [MySQL NDB Cluster 7.5](#) and [NDB Cluster 7.6](#).

We implement XML functionality which supports most of the W3C XPath standard. See [Section 12.11](#), “XML Functions”.

MySQL supports a native JSON data type as defined by RFC 7159, and based on the ECMAScript standard (ECMA-262). See [Section 11.6](#), “The JSON Data Type”. MySQL also implements a subset of the SQL/JSON functions specified by a pre-publication draft of the SQL:2016 standard; see [Section 12.16](#), “JSON Functions”, for more information.

Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the [sql_mode](#) system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see [Section 5.1.10](#), “Server SQL Modes”.

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the [sql_mode](#) system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
      -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'` because the `--ansi` option also sets the transaction isolation level.

See [Section 5.1.6](#), “Server Command Options”.

1.8.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably will not find in other SQL DBMSs. Be warned that if you use them, your code will not be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ coll FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. Consequently, database and table names are case-sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 9.2.2, “Identifier Case Sensitivity”](#).

- General language syntax

- By default, strings can be enclosed by `"` as well as `'`. If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by `'` and the server interprets strings enclosed by `"` as identifiers.
- `\` is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace.`

- SQL statement syntax

- The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
- The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 13.1.11, “CREATE DATABASE Syntax”](#), [Section 13.1.22, “DROP DATABASE Syntax”](#), and [Section 13.1.2, “ALTER DATABASE Syntax”](#).
- The `DO` statement.
- `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
- The `FLUSH` and `RESET` statements.
- The `SET` statement. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

- The `SHOW` statement. See [Section 13.7.6, “SHOW Syntax”](#). The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 24, `INFORMATION_SCHEMA` Tables](#).
- Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).
- Use of `RENAME TABLE`. See [Section 13.1.33, “RENAME TABLE Syntax”](#).
- Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 13.2.9, “REPLACE Syntax”](#).
- Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 13.1.8, “ALTER TABLE Syntax”](#).
- Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 13.1.18, “CREATE TABLE Syntax”](#).
- Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
- Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
- The capability of dropping multiple tables with a single `DROP TABLE` statement.
- The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
- `INSERT INTO tbl_name SET col_name = ...` syntax.
- The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 13.2.10, “SELECT Syntax”](#).
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#).
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
- The ability to set variables in a statement with the `:=` assignment operator. See [Section 9.4, “User-Defined Variables”](#).
- Data types
 - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
 - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
 - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.

- MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.
- Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
- String comparisons are case insensitive by default, with sort ordering determined by the collation of the current character set, which is `utf8mb4` by default. To perform case-sensitive comparisons instead, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
- The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
- The `=`, `<>`, `<=`, `<`, `>=`, `>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

- The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See [Section 12.14, “Information Functions”](#).
- `LIKE` is permitted on numeric values.
- The `REGEXP` and `NOT REGEXP` extended regular expression operators.
- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `MD5()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#).

1.8.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 13.7.1.8, “REVOKE Syntax”](#).
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See [Section 12.10, “Cast Functions and Operators”](#).

1.8.2.1 SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 13.2.6.1, “INSERT ... SELECT Syntax”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).

1.8.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.8.2.3 Foreign Key Differences

The MySQL implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, `InnoDB` acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of those parent rows.

`InnoDB` performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL but rather an `InnoDB` extension.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the same cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, `InnoDB` sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information about how the `InnoDB` storage engine handles foreign keys, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

1.8.2.4 '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in [Section 9.6, “Comment Syntax”](#).

Standard SQL uses “`--`” as a start-comment sequence. MySQL Server uses `#` as the start comment character. MySQL Server also supports a variant of the `--` comment style. That is, the `--` start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a valid expression in SQL, but `--` is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with `--` can have serious consequences.

Using our implementation requires a space following the `--` for it to be recognized as a start-comment sequence in MySQL Server. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with `--`.

1.8.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 5.1.10, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

1.8.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 13.2.6, “INSERT Syntax”](#), [Section 13.2.12, “UPDATE Syntax”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See [Section 27.7.7.36, “mysql_info\(\)”](#), and [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

Only `InnoDB` tables support foreign keys. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

1.8.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and [foreign key constraints](#) help keep this spread-out data consistent.

MySQL supports `ON UPDATE` and `ON DELETE` foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are `RESTRICT` (the default), `CASCADE`, `SET NULL`, and `NO ACTION`.

`SET DEFAULT` is also supported by the MySQL Server but is currently rejected as invalid by `InnoDB`. Since MySQL does not support deferred constraint checking, `NO ACTION` is treated as `RESTRICT`. For the exact syntax supported by MySQL for foreign keys, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#).

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
> FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
> WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

TABLE_SCHEMA	TABLE_NAME	COLUMN_NAME	CONSTRAINT_NAME
fk1	myuser	myuser_id	f
fk1	product_order	customer_id	f2
fk1	product_order	product_id	f1

```
3 rows in set (0.01 sec)
```

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

Only `InnoDB` tables support foreign keys. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#), for information specific to foreign key support in `InnoDB`.

1.8.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See [Section 5.1.10, “Server SQL Modes”](#).

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a `NULL` into a `NOT NULL` column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for `ENUM` and `SET` columns are handled as described in [Section 1.8.3.4, “ENUM and SET Constraints”](#).
- MySQL permits you to store certain incorrect date values into `DATE` and `DATETIME` columns (such as `'2000-02-31'` or `'2000-02-00'`). In this case, when an application has not enabled strict SQL mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value `'0000-00-00'` is stored in the column instead.
- If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ... SELECT` statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. Implicit default values are discussed in [Section 11.7, “Data Type Default Values”](#).
- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

You can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

1.8.3.4 ENUM and SET Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See [Section 11.4.4, “The ENUM Type”](#), and [Section 11.4.5, “The SET Type”](#).

With strict mode enabled (see [Section 5.1.10, “Server SQL Modes”](#)), the definition of a `ENUM` or `SET` column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a', 'b', 'c')`, values such as `'`, `'d'`, or `'ax'` are invalid and are rejected.
- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a', 'b', 'c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (0). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

1.9 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

1.9.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize those who have made contributions of one kind or another to the [MySQL distribution](#). Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwertg@mbbox.vol.it> or <qwertg@tin.it>

The initial port to Win32/NT.

- Per Eric Olsson

For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <irena@mail.yacc.it>

Win32 port with Borland compiler. [mysqlshutdown.exe](#) and [mysqlwatch.exe](#).

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with [mSQL](#), but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. [mysqladmin](#) and [mysql](#) client are programs that were largely influenced by their [mSQL](#) counterparts. We have put a lot of effort into making the MySQL syntax a superset of [mSQL](#). Many of the API's ideas are borrowed from [mSQL](#) to make it easy to port free [mSQL](#) programs to the MySQL API. The MySQL software doesn't contain any code from [mSQL](#). Two files in the distribution ([client/insert_test.c](#) and [client/select_test.c](#)) are based on the corresponding (noncopyrighted) files in the [mSQL](#) distribution, but are modified as examples showing the changes necessary to convert code from [mSQL](#) to MySQL Server. ([mSQL](#) is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>

[mysqldump](#) (previously [msqldump](#), but ported and enhanced by Monty).

- Yuri Dario

For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

Author of [mysqlhotcopy](#).

- Zarko Mocnik <zarko.mocnik@dem.si>

Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>

The [_MB](#) character set macros and the [ujis](#) and [sjis](#) character sets.

- Joshua Chamas <joshua@chamas.com>

Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>

`mysqlaccess`, a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)

For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>

Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>

For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>

For `xmysql`, a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>

For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>

For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>

For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>

For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>

Ideas for secure checking of DNS host names.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>

Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>

A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>

Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>

`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>

Ported (and extended) the benchmark suite to `DBI/DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.

- Alexis Mikhailov <root@medinf.chuvashia.su>
User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
- Andreas F. Bobak <bobak@relog.ch>
The `AGGREGATE` extension to user-defined functions.
- Ross Wakelin <R.Wakelin@march.co.uk>
Help to set up InstallShield for MySQL-Win32.
- Jethro Wright III <jetman@li.net>
The `libmysql.dll` library.
- James Pereria <jpereira@iafrica.com>
Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
- Curt Sampson <cjs@portal.ca>
Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
- Martin Ramsch <m.ramsch@computer.org>
Examples in the MySQL Tutorial.
- Steve Harvey
For making `mysqlaccess` more secure.
- Konark IA-64 Centre of Persistent Systems Private Limited
Help with the Win64 port of the MySQL server.
- Albert Chin-A-Young.
Configure updates for Tru64, large file support and better TCP wrappers support.
- John Birrell
Emulation of `pthread_mutex()` for OS/2.
- Benjamin Pflugmann
Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.
- Jocelyn Fournier
Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).
- Marc Liyanage
Maintaining the OS X packages and providing invaluable feedback on how to create OS X packages.
- Robert Rutherford
Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>

Irix setup.

- Luuk de Boer <luuk@wxs.nl>

Benchmark questions.

- Tim Sailer <tps@users.buoy.com>

DBD: :mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>

SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>

xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>

Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>

General questions.

- Jonathan J Smith <jsmith@wtp.net>

Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>

Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>

Is flexible and can handle Linux and perhaps HP-UX.

- John Lyon <jllyon@imag.net>

Questions about installing MySQL on Linux systems, using either `.rpm` files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

`DBD`, Linux, some SQL syntax questions.

1.9.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

- Jay Flaherty <fty@mediapulse.com>

Big parts of the Perl `DBI/DBD` section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

French error messages.

- Petr Snajdr, <snajdr@pvt.net>
Czech error messages.
- Jaroslaw Lewandowski <jotel@itnet.com.pl>
Polish error messages.
- Miguel Angel Fernandez Roiz
Spanish error messages.
- Roy-Magne Mo <rmo@www.hivolda.no>
Norwegian error messages and testing of MySQL 3.21.xx.
- Timur I. Bakeyev <root@timur.tatarstan.ru>
Russian error messages.
- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>
Italian error messages.
- Dirk Munzinger <dirk@trinity.saar.de>
German error messages.
- Billik Stefan <billik@sun.uniag.sk>
Slovak error messages.
- Stefan Saroiu <tzoompy@cs.washington.edu>
Romanian error messages.
- Peter Feher
Hungarian error messages.
- Roberto M. Serqueira
Portuguese error messages.
- Carsten H. Pedersen
Danish error messages.
- Arjen Lentz
Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

1.9.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes
For the `DBD` (Perl) interface.
- Andreas Koenig <a.koenig@mind.de>
For the Perl interface for MySQL Server.
- Jochen Wiedmann <wiedmann@neckar-alb.de>
For maintaining the Perl `DBD::mysql` module.
- Eugene Chan <eugene@acenet.com.sg>
For porting PHP for MySQL Server.
- Georg Richter
MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.
- Giovanni Maruzzelli <maruzz@matrice.it>
For porting iODBC (Unix ODBC).
- Xavier Leroy <Xavier.Leroy@inria.fr>
The author of LinuxThreads (used by the MySQL Server on Linux).

1.9.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation
From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb`) and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).
- Free Software Foundation & The XEmacs development team
For a really great editor/environment.
- Julian Seward
Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.
- Dorothea Lütkehaus and Andreas Zeller
For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`.

1.9.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL website in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSOft

Development on the embedded `mysqld` version.

- FutureQuest

The `--skip-show-database` option.

Chapter 2 Installing and Upgrading MySQL

Table of Contents

2.1 General Installation Guidance	65
2.1.1 Which MySQL Version and Distribution to Install	65
2.1.2 How to Get MySQL	67
2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG	67
2.1.4 Installation Layouts	81
2.1.5 Compiler-Specific Build Characteristics	81
2.2 Installing MySQL on Unix/Linux Using Generic Binaries	81
2.3 Installing MySQL on Microsoft Windows	84
2.3.1 MySQL Installation Layout on Microsoft Windows	87
2.3.2 Choosing an Installation Package	87
2.3.3 MySQL Installer for Windows	88
2.3.4 MySQL Notifier	111
2.3.5 Installing MySQL on Microsoft Windows Using a <code>noinstall</code> ZIP Archive	123
2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation	131
2.3.7 Windows Postinstallation Procedures	133
2.3.8 Upgrading MySQL on Windows	135
2.4 Installing MySQL on macOS	137
2.4.1 General Notes on Installing MySQL on macOS	137
2.4.2 Installing MySQL on macOS Using Native Packages	138
2.4.3 Installing and Using the MySQL Launch Daemon	142
2.4.4 Installing and Using the MySQL Preference Pane	145
2.5 Installing MySQL on Linux	149
2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository	150
2.5.2 Installing MySQL on Linux Using the MySQL APT Repository	154
2.5.3 Installing MySQL on Linux Using the MySQL SLES Repository	155
2.5.4 Installing MySQL on Linux Using RPM Packages from Oracle	155
2.5.5 Installing MySQL on Linux Using Debian Packages from Oracle	160
2.5.6 Deploying MySQL on Linux with Docker	162
2.5.7 Installing MySQL on Linux from the Native Software Repositories	174
2.5.8 Installing MySQL on Linux with Juju	177
2.5.9 Managing MySQL Server with systemd	177
2.6 Installing MySQL Using Unbreakable Linux Network (ULN)	182
2.7 Installing MySQL on Solaris	183
2.7.1 Installing MySQL on Solaris Using a Solaris PKG	184
2.8 Installing MySQL on FreeBSD	185
2.9 Installing MySQL from Source	186
2.9.1 MySQL Layout for Source Installation	188
2.9.2 Installing MySQL Using a Standard Source Distribution	188
2.9.3 Installing MySQL Using a Development Source Tree	193
2.9.4 MySQL Source-Configuration Options	195
2.9.5 Dealing with Problems Compiling MySQL	217
2.9.6 MySQL Configuration and Third-Party Tools	219
2.9.7 Generating MySQL Doxygen Documentation Content	219
2.10 Postinstallation Setup and Testing	220
2.10.1 Initializing the Data Directory	221
2.10.2 Starting the Server	226
2.10.3 Testing the Server	229

2.10.4 Securing the Initial MySQL Account	231
2.10.5 Starting and Stopping MySQL Automatically	233
2.11 Upgrading or Downgrading MySQL	234
2.11.1 Upgrading MySQL	234
2.11.2 Downgrading MySQL	252
2.11.3 Rebuilding or Repairing Tables or Indexes	252
2.11.4 Copying MySQL Databases to Another Machine	254
2.12 Perl Installation Notes	255
2.12.1 Installing Perl on Unix	255
2.12.2 Installing ActiveState Perl on Windows	256
2.12.3 Problems Using the Perl DBI/DBD Interface	256

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Section 2.11.1, “Upgrading MySQL”](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see [Section A.8, “MySQL 8.0 FAQ: Migration”](#), which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

- 1. Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see <https://www.mysql.com/support/supportedplatforms/database.html> on the MySQL website.

- 2. Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see [Section 2.1.1, “Which MySQL Version and Distribution to Install”](#).

- 3. Download the distribution that you want to install.**

For instructions, see [Section 2.1.2, “How to Get MySQL”](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.3, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

- 4. Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

- 5. Perform any necessary postinstallation setup.**

After installing MySQL, see [Section 2.10, “Postinstallation Setup and Testing”](#) for information about making sure the MySQL server is working properly. Also refer to the information provided in [Section 2.10.4, “Securing the Initial MySQL Account”](#). This section describes how to secure the initial

MySQL `root` user account, *which has no password* until you assign one. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.12, “Perl Installation Notes”](#).

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.9, “Installing MySQL from Source”](#)

For specific platform help on installation, configuration, and building from source see the corresponding platform section:

- Linux, including notes on distribution specific methods, see [Section 2.5, “Installing MySQL on Linux”](#).
- IBM AIX, see [Section 2.7, “Installing MySQL on Solaris”](#).
- FreeBSD, see [Section 2.8, “Installing MySQL on FreeBSD”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either the MySQL Installer or Zipped binary, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

For information about managing MySQL instances, see [Section 2.3.4, “MySQL Notifier”](#).

For details and instructions on building MySQL from source code using Microsoft Visual Studio, see [Section 2.9, “Installing MySQL from Source”](#).

- **OS X**

For installation on OS X, including using both the binary package and native PKG formats, see [Section 2.4, “Installing MySQL on macOS”](#).

For information on making use of an OS X Launch Daemon to automatically start and stop MySQL, see [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#).

For information on the MySQL Preference Pane, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#) or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

2.1.1 Which MySQL Version and Distribution to Install

MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see <https://www.mysql.com/support/supportedplatforms/database.html> on the MySQL website.

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install a development release or a General Availability (GA) release. Development releases have the newest features, but are not recommended for production use. GA releases, also called production or stable releases, are meant for production use. We recommend using the most recent GA release.

The naming scheme in MySQL 8.0 uses release names that consist of three numbers and an optional suffix; for example, **mysql-8.0.1-dmr**. The numbers within the release name are interpreted as follows:

- The first number (**8**) is the major version number.
- The second number (**0**) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.
- The third number (**1**) is the version number within the release series. This is incremented for each new bugfix release. In most cases, the most recent version within a series is the best choice.

Release names can also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **dmr** indicates a development milestone release (DMR). MySQL development uses a milestone model, in which each milestone introduces a small subset of thoroughly tested features. From one milestone to the next, feature interfaces may change or features may even be removed, based on feedback provided by community members who try these early releases. Features within milestone releases may be considered to be of pre-production quality.
- **rc** indicates a Release Candidate (RC). Release candidates are believed to be stable, having passed all of MySQL's internal testing. New features may still be introduced in RC releases, but the focus shifts to fixing bugs to stabilize features introduced earlier within the series.
- Absence of a suffix indicates a General Availability (GA) or Production release. GA releases are stable, having successfully passed through the earlier release stages, and are believed to be reliable, free of serious bugs, and suitable for use in production systems.

Development within a series begins with DMR releases, followed by RC releases, and finally reaches GA status releases.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for OS X. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files. On Windows, you can use [the MySQL Installer](#) to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` with features that might not be included in the standard binary distributions. Here is a list of the most common extra options used to ensure feature availability:
 - `-DWITH_LIBWRAP=1` for TCP wrappers support.

- `-DWITH_ZLIB={system|bundled}` for features that depend on compression
- `-DWITH_DEBUG=1` for debugging support

For additional information, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- You want to configure `mysqld` without some features that are included in the standard binary distributions.
- You want to read or modify the C and C++ code that makes up MySQL. For this purpose, obtain a source distribution.
- Source distributions contain more tests and examples than binary distributions.

2.1.2 How to Get MySQL

Check our downloads page at <https://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see <https://dev.mysql.com/downloads/mirrors.html>. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the [MySQL Yum Repository](#). See [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details.

For Debian-based Linux platforms, MySQL can be installed using the [MySQL APT Repository](#). See [Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository”](#) for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the [MySQL SLES Repository](#). See [Section 2.5.3, “Installing MySQL on Linux Using the MySQL SLES Repository”](#) for details.

To obtain the latest development source, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using [GnuPG](#), the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.3.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from <http://www.gnu.org/software/textutils/>. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from <http://www.fourmilab.ch/md5/>. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-8.0.15-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-8.0.15-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-8.0.15.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-8.0.15.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

2.1.3.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using **MD5 checksums**, but requires more work.

We sign MySQL downloadable packages with **GnuPG** (GNU Privacy Guard). **GnuPG** is an Open Source alternative to the well-known Pretty Good Privacy (**PGP**) by Phil Zimmermann. Most Linux distributions ship with **GnuPG** installed by default. Otherwise, see <http://www.gnupg.org/> for more information about **GnuPG** and how to obtain and install it.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://pgp.mit.edu/>. The key that you want to obtain is named `mysql-build@oss.oracle.com`. Alternatively, you can copy and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.5 (GNU/Linux)

-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg:             imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:             new user IDs: 1
gpg:             new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see [Section 2.1.3.4, "Signature Checking Using RPM"](#).

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

Table 2.1 MySQL Package and Signature Files for Source files

File Type	File Name
Distribution file	<code>mysql-standard-8.0.15-linux-i686.tar.gz</code>
Signature file	<code>mysql-standard-8.0.15-linux-i686.tar.gz.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

If the downloaded package is valid, you will see a "Good signature" similar to:

```
shell> gpg --verify mysql-standard-8.0.15-linux-i686.tar.gz.asc
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The [Good signature](#) message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
shell> gpg --verify mysql-standard-8.0.15-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.
- *WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

2.1.3.3 Signature Checking Using Gpg4win for Windows

The [Section 2.1.3.2, "Signature Checking Using GnuPG"](#) section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like [Gpg4win](#). You may use a different tool but our examples are based on Gpg4win, and utilize its bundled [Kleopatra](#) GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

Figure 2.1 Kleopatra: Initial Screen

Next, add the MySQL Release Engineering certificate. Do this by clicking **File, Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

Figure 2.2 Kleopatra: Lookup Certificates on Server Wizard: Finding a Certificate

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog will be displayed, choose **Okay**, and this certificate will now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates, Change Owner Trust...** We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** to enable "full trust" and then press **OK**.

Figure 2.3 Kleopatra: Change Trust level for MySQL Release Engineering

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows

File Type	File Name
Distribution file	<code>mysql-installer-community-8.0.15.msi</code>
Signature file	<code>mysql-installer-community-8.0.15.msi.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (`.asc`) file into Kleopatra, or load the dialog from **File, Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.

Figure 2.4 Kleopatra: The Decrypt and Verify Files Dialog

Click **Decrypt/Verify** to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

Figure 2.5 Kleopatra: the Decrypt and Verify Results Dialog: All operations completed

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.

Figure 2.6 Kleopatra: the Decrypt and Verify Results Dialog: Bad

The [Section 2.1.3.2, “Signature Checking Using GnuPG”](#) section explains why you probably don't see a green `Good signature` result.

2.1.3.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-8.0.15-0.linux_glibc2.5.i386.rpm
MySQL-server-8.0.15-0.linux_glibc2.5.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
shell> rpm --import https://dev.mysql.com/doc/refman/8.0/en/checking-gpg-signature.html
```

If you need to obtain the MySQL public key, see [Section 2.1.3.2, “Signature Checking Using GnuPG”](#).

2.1.4 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#)
- [Section 2.9.1, “MySQL Layout for Source Installation”](#)
- [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)
- [Table 2.11, “MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone”](#)
- [Table 2.6, “MySQL Installation Layout on macOS”](#)

2.1.5 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

`icc` (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed `tar` files (files with a `.tar.xz` extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution on Unix/Linux platforms. For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#). See [Section 2.1.2, “How to Get MySQL”](#) on how to obtain MySQL in different distribution formats.

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.xz`, where `VERSION` is a number (for example, `8.0.15`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

Warnings

- If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience

problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related [APT guide](#) or [Yum guide](#).

- MySQL has a dependency on the `libaio` library. Data directory initialization and subsequent server startup steps will fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```
shell> yum search libaio # search for info
shell> yum install libaio # install library
```

Or, on APT-based systems:

```
shell> apt-cache search libaio # search for info
shell> apt-get install libaio1 # install library
```

To install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package

Directory	Contents of Directory
<code>bin</code>	<code>mysqld</code> server, client and utility programs
<code>docs</code>	MySQL manual in Info format
<code>man</code>	Unix manual pages
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>share</code>	Error messages, dictionary, and SQL for database installation
<code>support-files</code>	Miscellaneous support files

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See [Section 2.9, “Installing MySQL from Source”](#).

To install and use a MySQL binary distribution, the command sequence looks like this:

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
shell> cd /usr/local
shell> tar xvf /path/to/mysql-VERSION-OS.tar.xz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> mkdir mysql-files
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
shell> bin/mysqld --initialize --user=mysql
```

```
shell> bin/mysql_ssl_rsa_setup
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

**Note**

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (Solaris) command.

The `mysql-files` directory provides a convenient location to use as the value for the `secure_file_priv` system variable, which limits import and export operations to a specific directory. See [Section 5.1.7, “Server System Variables”](#).

A more detailed version of the preceding description for installing a binary distribution follows.

Create a mysql User and Group

If your system does not already have a user and group to use for running `mysqld`, you may need to create them. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix/Linux, or they may have different names such as `adduser` and `addgroup`.

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
```

**Note**

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` and `-s /bin/false` options to create a user that does not have login permissions to your server host. Omit these options if your `useradd` does not support them.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
shell> cd /usr/local
```

Obtain a distribution file using the instructions in [Section 2.1.2, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar xvf /path/to/mysql-VERSION-OS.tar.xz
```

The `tar` command creates a directory named `mysql-VERSION-OS`.

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `xz Utils` to uncompress the distribution and a reasonable `tar` to unpack it.

**Note**

The compression algorithm changed from Gzip to XZ in MySQL Server 8.0.12; and the generic binary's file extension changed from .tar.gz to .tar.xz.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

If your `tar` does not support the `xz` format then use the `xz` command to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> xz -dc /path/to/mysql-VERSION-OS.tar.xz | tar x
```

Next, create a symbolic link to the installation directory created by `tar`:

```
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `ln` command makes a symbolic link to the installation directory. This enables you to refer more easily to it as `/usr/local/mysql`. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the `/usr/local/mysql/bin` directory to your `PATH` variable:

```
shell> export PATH=$PATH:/usr/local/mysql/bin
```

Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

2.3 Installing MySQL on Microsoft Windows

**Important**

MySQL 8.0 Server requires the Microsoft Visual C++ 2015 Redistributable Package to run on Windows platforms. Users should make sure the package has been installed on the system before installing the server. The package is available at the [Microsoft Download Center](#). Additionally, MySQL debug binaries require Visual Studio 2015 to be installed.

MySQL is available for Microsoft Windows 64-bit operating systems only. For supported Windows platform information, see <https://www.mysql.com/support/supportedplatforms/database.html>.

There are different methods to install MySQL on Microsoft Windows.

MySQL Installer Method

The simplest and recommended method is to download MySQL Installer (for Windows) and let it install and configure all of the MySQL products on your system. Here is how:

1. Download MySQL Installer from <https://dev.mysql.com/downloads/installer/> and execute it.

**Note**

Unlike the standard MySQL Installer, the smaller "web-community" version does not bundle any MySQL applications but it will download the MySQL products you choose to install.

2. Choose the appropriate **Setup Type** for your system. Typically you will choose **Developer Default** to install MySQL server and other MySQL tools related to MySQL development, helpful tools like MySQL Workbench. Or, choose the **Custom** setup type to manually select your desired MySQL products.

**Note**

Multiple versions of MySQL server can exist on a single system. You can choose one or multiple versions.

3. Complete the installation process by following the instructions. This will install several MySQL products and start the MySQL server.

MySQL is now installed. If you configured MySQL as a service, then Windows will automatically start MySQL server every time you restart your system.

**Note**

You probably also installed other helpful MySQL products like MySQL Workbench and MySQL Notifier on your system. Consider loading [Chapter 30, MySQL Workbench](#) to check your new MySQL server connection, and [Section 2.3.4, "MySQL Notifier"](#) to view the connection's status. By default, these two programs automatically start after installing MySQL.

This process also installs the MySQL Installer application on your system, and later you can use MySQL Installer to upgrade or reconfigure your MySQL products.

Additional Installation Information

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see [Section 2.3.5.8, "Starting MySQL as a Windows Service"](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the [Service Control Manager](#). When installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see [Section C.10.5, "Windows Platform Limitations"](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see [MySQL Connector/ODBC Developer Guide](#).

**Note**

MySQL Installer will install and configure Connector/ODBC for you.

- To use MySQL server with .NET applications, you must have the Connector/NET driver. For more information, including installation and configuration instructions, see [MySQL Connector/NET Developer Guide](#).

**Note**

MySQL Installer will install and configure MySQL Connector/NET for you.

MySQL distributions for Windows can be downloaded from <https://dev.mysql.com/downloads/>. See [Section 2.1.2, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the compressed file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see [Section 2.3.2, “Choosing an Installation Package”](#).

- A MySQL Installer distribution includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL Notifier, and MySQL for Excel. MySQL Installer can also be used to upgrade these products in the future.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, “MySQL Installer for Windows”](#).

- The standard binary distribution (packaged as a compressed file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the compressed file, see [Section 2.3.5, “Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive”](#).

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see [Section 2.9, “Installing MySQL from Source”](#).

MySQL on Windows Considerations

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 13.1.18, “CREATE TABLE Syntax”](#).

- **MySQL and Virus Checking Software**

Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see [Section 2.3.5.2, “Creating an Option File”](#).

2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 8.0 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.0` for installations performed with MySQL Installer. If you use the ZIP archive method to install MySQL, you may prefer to install in `C:\mysql`. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

Table 2.4 Default MySQL Installation Layout for Microsoft Windows

Directory	Contents of Directory	Notes
<code>bin</code>	<code>mysqld</code> server, client and utility programs	
<code>%PROGRAMDATA%\MySQL\MySQL Server 8.0\</code>	Log files, databases	The Windows system variable <code>%PROGRAMDATA%</code> defaults to <code>C:\ProgramData</code> .
<code>docs</code>	Release documentation	With MySQL Installer, use the <code>Modify</code> operation to select this optional folder.
<code>include</code>	Include (header) files	
<code>lib</code>	Libraries	
<code>share</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation	

2.3.2 Choosing an Installation Package

For MySQL 8.0, there are multiple installation package formats to choose from when installing MySQL on Windows. The package formats described in this section are:

- [MySQL Installer](#)
- [MySQL noinstall ZIP Archives](#)
- [MySQL Docker Images](#)

Program Database (PDB) files (with file name extension `pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.

MySQL Installer

This package has a file name similar to `mysql-installer-community-8.0.15.0.msi` or `mysql-installer-commercial-8.0.15.0.msi`, and utilizes MSIs to automatically install MySQL server and other products. MySQL Installer will download and apply updates to itself, and for each of the installed

products. It also configures the installed MySQL server (including a sandbox InnoDB cluster test setup) and MySQL Router. MySQL Installer is recommended for most users.

MySQL Installer can install and manage (add, modify, upgrade, and remove) many other MySQL products, including:

- Applications – MySQL Workbench, MySQL for Visual Studio, MySQL Notifier, MySQL for Excel, MySQL Utilities, MySQL Shell, MySQL Router
- Connectors – MySQL Connector/C, MySQL Connector/C++, MySQL Connector/NET, Connector/ODBC, MySQL Connector/Python, MySQL Connector/J, MySQL Connector/Node.js
- Documentation – MySQL Manual (PDF format), samples and examples

MySQL Installer operates on all MySQL supported versions of Windows (see <https://www.mysql.com/support/supportedplatforms/database.html>).

Note

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it will not work on minimal installation options like the Server Core version of Windows Server.

For instructions on how to install MySQL using MySQL Installer, see [Section 2.3.3, “MySQL Installer for Windows”](#).

MySQL noinstall ZIP Archives

These packages contain the files found in the complete installation package, with the exception of the GUI. This format does not include an automated installer, and must be manually installed and configured.

The `noinstall` ZIP archives are split into two separate compressed files. The main package is named `mysql-VERSION-winx64.zip`. This contains the components needed to use MySQL on your system. The optional MySQL test suite, MySQL benchmark suite, and debugging binaries/information components (including PDB files) are in a separate compressed file named `mysql-VERSION-winx64-debug-test.zip`.

If you choose to install a `noinstall` ZIP archive, see [Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”](#).

MySQL Docker Images

For information on using the MySQL Docker images provided by Oracle on Windows platform, see [Section 2.5.6.3, “Deploying MySQL on Windows and Other Non-Linux Platforms with Docker”](#).

Warning

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk.

2.3.3 MySQL Installer for Windows

MySQL Installer is a standalone application designed to ease the complexity of installing and managing MySQL products that run on Microsoft Windows. It supports the following MySQL products:

- MySQL Servers

MySQL Installer can install and manage multiple, separate MySQL server instances on the same host at the same time. For example, MySQL Installer can install, configure, and upgrade a separate instance of MySQL 5.6, MySQL 5.7, and MySQL 8.0 on the same host. MySQL Installer does not permit server upgrades between major and minor version numbers, but does permit upgrades within a release series (such as 5.7.18 to 5.7.19).

A host *cannot* have both Community and Commercial (Enterprise) Editions of MySQL server installed.

- MySQL Applications

MySQL Workbench, MySQL Shell, MySQL Router, MySQL for Visual Studio, MySQL for Excel, MySQL Notifier, and MySQL Utilities.

- MySQL Connectors

MySQL Connector/NET, MySQL Connector/Python, MySQL Connector/ODBC, MySQL Connector/J, MySQL Connector/C, and MySQL Connector/C++.

**Note**

To install MySQL Connector/Node.js, see <https://dev.mysql.com/downloads/connector/nodejs/>. Connector/Node.js does not provide an `.msi` file for use with MySQL Installer.

- Documentation and Samples

MySQL Reference Manuals (by version) in PDF format and MySQL database samples (by version).

Installation Requirements

MySQL Installer requires Microsoft .NET Framework 4.5.2 or later. If this version is not installed on the host computer, you can download it by visiting the [Microsoft website](#).

MySQL Installer Community Edition

Download this edition from <https://dev.mysql.com/downloads/installer/> to install the Community Edition of all MySQL products for Windows. Select one of the following MySQL Installer package options:

- *Web*: Contains MySQL Installer and configuration files only. The web package downloads only the MySQL products you select to install, but it requires an internet connection for each download. The size of this file is approximately 2 MB; the name of the file has the form `mysql-installer-community-web-VERSION.N.msi` where `VERSION` is the MySQL server version number such as 8.0 and `N` is the package number, which begins at 0.
- *Full*: Bundles all of the MySQL products for Windows (including the MySQL server). The file size is over 300 MB, and its name has the form `mysql-installer-community-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 8.0 and `N` is the package number, which begins at 0.

MySQL Installer Commercial Edition

Download this edition from <https://edelivery.oracle.com/> to install the Commercial (Enterprise) Edition of MySQL products for Windows. The Commercial Edition includes all of the current and previous GA versions in the Community Edition (excludes development-milestone versions) and also includes the following products:

- Workbench SE/EE

- MySQL Enterprise Backup
- MySQL Enterprise Firewall

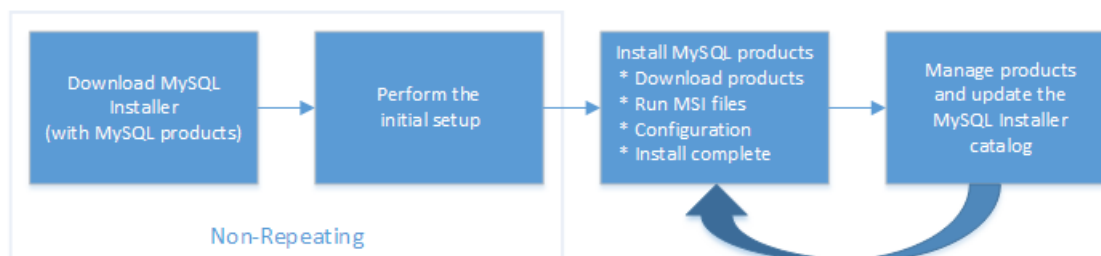

This edition integrates with your My Oracle Support (MOS) account. For knowledge-base content and patches, see [My Oracle Support](#).

2.3.3.1 MySQL Installer Initial Setup

- [MySQL Installer Licensing and Support Authentication](#)
- [Choosing a Setup Type](#)
- [Path Conflicts](#)
- [Check Requirements](#)
- [MySQL Installer Configuration Files](#)

When you download MySQL Installer for the first time, a setup wizard guides you through the initial installation of MySQL products. As the following figure shows, the initial setup is a one-time activity in the overall process. MySQL Installer detects existing MySQL products installed on the host during its initial setup and adds them to the list of products to be managed.

Figure 2.7 MySQL Installer Process Overview

MySQL Installer extracts configuration files (described later) to the hard drive of the host during the initial setup. Although MySQL Installer is a 32-bit application, it can install both 32-bit and 64-bit binaries.

The initial setup adds a link to the Start menu under the **MySQL** group. Click **Start, All Programs, MySQL, MySQL Installer** to open MySQL Installer.

MySQL Installer Licensing and Support Authentication

MySQL Installer requires you to accept the license agreement before it will install new MySQL packages. After you accept the terms of the agreement, you can add, update, reconfigure, and remove all of the products and features provided by the MySQL Installer edition you downloaded.

For the Commercial Edition, entering your My Oracle Support (MOS) credentials is optional when installing bundled MySQL products, but your credentials are required when choosing unbundled MySQL products that MySQL Installer must download. An unbundled product is any `.msi` file that you download using MySQL Installer after the initial setup. Your credentials must match the user name and password that you have registered with Oracle for access to the support site.

Choosing a Setup Type

During the initial setup, you are prompted to select the MySQL products to be installed on the host. One alternative is to use a predetermined setup type that matches your setup requirements. By default, both GA and pre-release products are included in the download and installation with the **Developer Default**,

Client only, and **Full** setup types. Select the **Only install GA products** option to restrict the product set to include GA products only when using these setup types.

Choosing one of the following setup types determines the initial installation only and does not limit your ability to install or update MySQL products for Windows later:

- **Developer Default:** Install the following products that compliment application development with MySQL:
 - [MySQL Server](#) (Installs the version that you selected when you downloaded MySQL Installer.)
 - [MySQL Shell](#)
 - [MySQL Router](#)
 - [MySQL Workbench](#)
 - [MySQL for Visual Studio](#)
 - [MySQL for Excel](#)
 - [MySQL Notifier](#)
 - [MySQL Connectors](#) (.NET / Python / ODBC / Java / C / C++)
 - MySQL Utilities
 - MySQL Documentation
 - MySQL Samples and Examples
- **Server only:** Only install the MySQL server. This setup type installs the general availability (GA) or development release server that you selected when you downloaded MySQL Installer. It uses the default installation and data paths.
- **Client only:** Only install the most recent MySQL applications and MySQL connectors. This setup type is similar to the [Developer Default](#) type, except that it does not include MySQL server or the client programs typically bundled with the server, such as `mysql` or `mysqladmin`.
- **Full:** Install all available MySQL products.
- **Custom** The custom setup type enables you to filter and select individual MySQL products from the [MySQL Installer catalog](#).

Use the [Custom](#) setup type to install:

- A product or product version that is not available from the usual download locations. The catalog contains all product releases, including the other releases between pre-release (or development) and GA.
- An instance of MySQL server using an alternative installation path, data path, or both. For instructions on how to adjust the paths, see [Setting Alternative Server Paths with MySQL Installer](#).
- Two or more MySQL server versions on the same host at the same time (for example, 5.6, 5.7, and 8.0).
- A specific combination of products and features not offered as a predetermine setup type. For example, you can install a single product, such as MySQL Workbench, instead of installing all client applications for Windows.

Path Conflicts

When the default installation or data folder (required by MySQL server) for a product to be installed already exists on the host, the wizard displays the **Path Conflict** step to identify each conflict and enable you to take action to avoid having files in the existing folder overwritten by the new installation. You see this step in the initial setup only when MySQL Installer detects a conflict.

To resolve the path conflict, do one of the following:

- Select a product from the list to display the conflict options. A warning symbol indicates which path is in conflict. Use the browse button to choose a new path and then click **Next**.
- Click **Back** to choose a different setup type or product version, if applicable. The **Custom** setup type enables you to select individual product versions.
- Click **Next** to ignore the conflict and overwrite files in the existing folder.
- Delete the existing product. Click **Cancel** to stop the initial setup and close MySQL Installer. Open MySQL Installer again from the Start menu and delete the installed product from the host using the Delete operation from the **dashboard**.

Check Requirements

MySQL Installer uses entries in the `package-rules.xml` file to determine whether the prerequisite software for each product is installed on the host. When the requirements check fails, MySQL Installer displays the **Check Requirements** step to help you update the host. The following figure identifies and describes the key areas of this step.

Figure 2.8 Check Requirements

Description of Check Requirements Elements

- Shows the current step in the initial setup. Steps in this list may change slightly depending on the products already installed on the host, the availability of prerequisite software, and the products to be installed on the host.
- Lists all pending installation requirements by product and indicates the status as follows:
 - A blank space in the **Status** column means that MySQL Installer can attempt to download and install the required software for you.
 - The word *Manual* in the **Status** column means that you must satisfy the requirement manually. Select each product in the list to see its requirement details.
- Describes the requirement in detail to assist you with each manual resolution. When possible, a download URL is provided. After you download and install the required software, click **Check** to verify that the requirement has been met.
- Provides the following set operations to proceed:
 - Back** – Return to the previous step. This action enables you to select a different the setup type.
 - Execute** – Have MySQL Installer attempt to download and install the required software for all items without a manual status. Manual requirements are resolved by you and verified by clicking **Check**.
 - Next** – Do not execute the request to apply the requirements automatically and proceed to the installation without including the products that fail the check requirements step.
 - Cancel** – Stop the installation of MySQL products. Because MySQL Installer is already installed, the initial setup begins again when you open MySQL Installer from the Start menu and click **Add** from the dashboard. For a description of the available management operations, see [Product Catalog](#).

MySQL Installer Configuration Files

All MySQL Installer files are located within the `C:\Program Files (x86)` and `C:\ProgramData` folders. The following table describes the files and folders that define MySQL Installer as a standalone application.

Note

Installed MySQL products are neither altered nor removed when you update or uninstall MySQL Installer.

Table 2.5 MySQL Installer Configuration Files

File or Folder	Description	Folder Hierarchy
MySQL Installer for Windows	This folder contains all of the files needed to run MySQL Installer and MySQLInstallerConsole.exe , a command-line program with similar functionality.	<code>C:\Program Files (x86)</code>
Templates	The Templates folder has one file for each version of MySQL server. Template files contain keys and formulas to calculate some values dynamically.	<code>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</code>

File or Folder	Description	Folder Hierarchy
<code>package-rules.xml</code>	This file contains the prerequisites for every product to be installed.	<code>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</code>
<code>products.xml</code>	The <code>products</code> file (or product catalog) contains a list of all products available for download.	<code>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</code>
Product Cache	The <code>Product Cache</code> folder contains all standalone <code>.msi</code> files bundled with the full package or downloaded afterward.	<code>C:\ProgramData\MySQL\MySQL Installer for Windows</code>

2.3.3.2 Installation Workflow with MySQL Installer

MySQL Installer provides a wizard-like tool to install and configure new MySQL products for Windows. Unlike the initial setup, which runs only once, MySQL Installer invokes the wizard each time you download or install a new product. For first-time installations, the steps of the initial setup proceed directly into the steps of the installation.

Note

Full permissions are granted to the user executing MySQL Installer to all generated files, such as `my.ini`. This does not apply to files and directories for specific products, such as the MySQL server data directory in `%ProgramData%` that is owned by `SYSTEM`.

Products installed and configured on a host follow a general pattern that might require your input during the various steps. MySQL Installer loads all selected products together using the following workflow:

- **Product download.** If you installed the full (not web) MySQL Installer package, all `.msi` files were loaded to the `Product Cache` folder during the initial setup and are not downloaded again. Otherwise, click **Execute** to begin the download. The status of each product changes from `Downloading` to `Downloaded`.
- **Product installation.** The status of each product in the list changes from `Ready to Install`, to `Installing`, and lastly to `Complete`. During the process, click **Show Details** to view the installation actions.

If you cancel the installation at this point, the products are installed, but the server (if installed) is not yet configured. To restart the server configuration, open MySQL Installer from the Start menu and click the **Reconfigure** link next to the appropriate server in the dashboard.

- **Product configuration.** This step applies to MySQL Server, MySQL Router, and samples only. The status for each item in the list should indicate `Ready to Configure`.

Click **Next** to start the configuration wizard for all items in the list. The configuration options presented during this step are specific to the version of database or router that you selected to install.

Click **Execute** to begin applying the configuration options or click **Back** (repeatedly) to return to each configuration page. Click **Finish** to open the [MySQL Installer dashboard](#).

- **Installation complete.** This step finalizes the installation for products that do not require configuration. It enables you to copy the log to a clipboard and to start certain applications, such as MySQL Workbench and MySQL Shell. Click **Finish** to open the [MySQL Installer dashboard](#).

Group Replication

You have two options to implement a high-availability solution when you install MySQL 5.7.17 or higher (64-bit) using MySQL Installer:

- Standalone MySQL Server / Classic MySQL Replication (default)

Select this option to begin the initial configuration of a standalone MySQL server. You can configure multiple servers with classic MySQL Replication manually or use MySQL Shell to configure a production InnoDB cluster.

Click **Next** to proceed to the remaining configuration steps. For a description of the configuration options that apply to a standalone MySQL server on Windows, see [Server Configuration with MySQL Installer](#).

- Sandbox InnoDB Cluster Setup (for testing only)

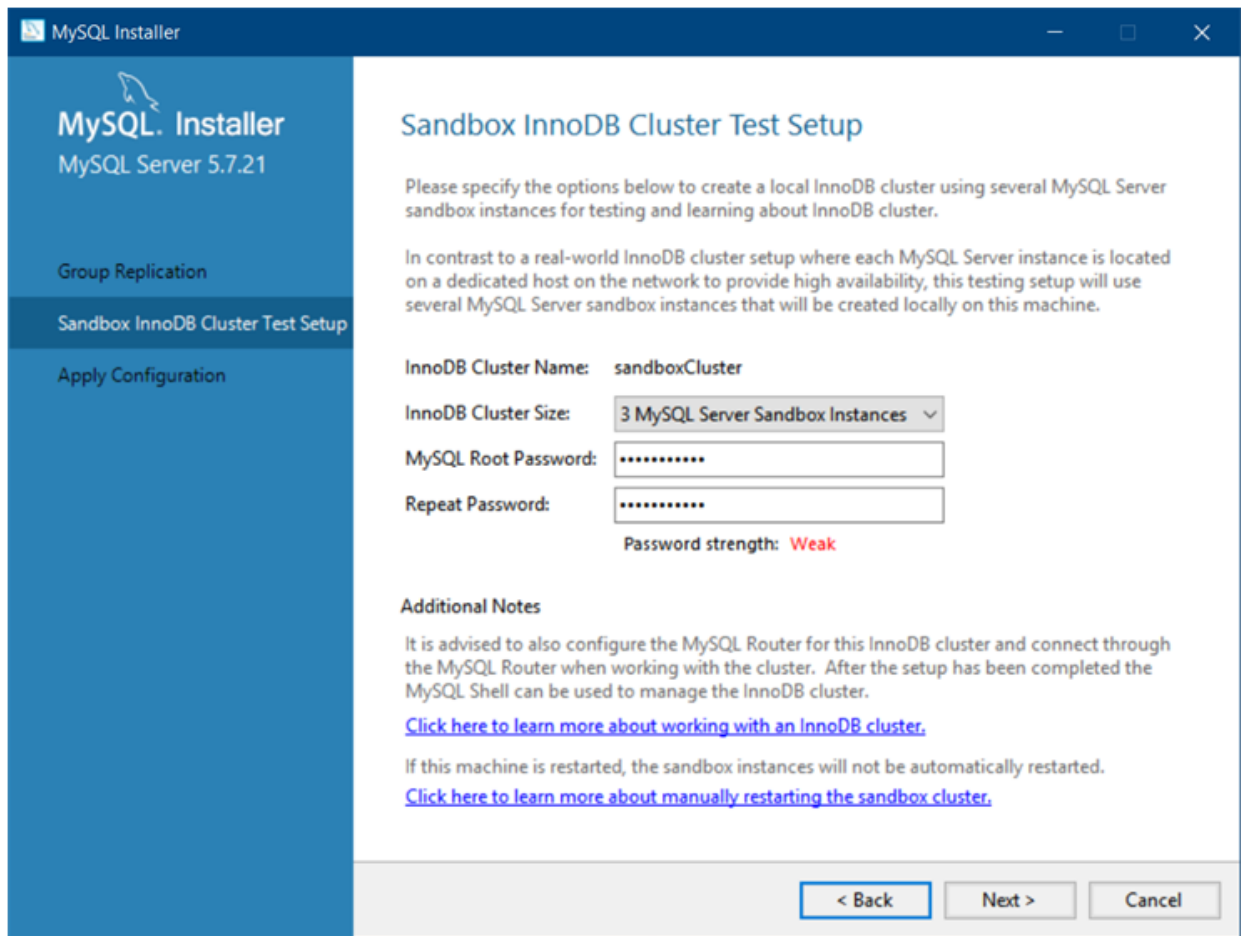

Select this option to create and configure sandbox InnoDB cluster instances locally for testing. You can configure a sandbox InnoDB cluster to have three, five, seven, or nine MySQL server instances. Use the **Reconfigure** quick action in the MySQL Installer dashboard to adjust the number of instances in the InnoDB cluster after the configuration has finished.

Note

Existing instance ports (3310 to 3390), which may have been set for a sandbox InnoDB cluster manually using MySQL Shell, will be deleted by MySQL Installer if you run the sandbox InnoDB cluster test setup.

As the following figure shows, this step requires that you enter a password for the MySQL `root` account. The password strength is evaluated when you retype it.

Figure 2.9 Sandbox InnoDB cluster Test Setup

The sandbox InnoDB cluster, named `sandboxCluster` by default, is available on selected ports. After the configuration executes, click the **Summary** tab to view the specific ports that apply to your cluster. Sandbox InnoDB cluster configuration entries are stored in the `installer_config.xml` file.

You can use MySQL Installer to install MySQL Shell, if it is not installed. MySQL Shell enables you to manage the sandbox instances. To connect with the MySQL Shell on port 3310, execute the following command:

```
mysqlsh root@localhost:3310
```

MySQL Installer also provides a wizard for configuring MySQL Router to connect to the test InnoDB cluster that was created in this step. For configuration details, see [MySQL Router Configuration](#). To learn more about MySQL Router operations, see [Routing for MySQL InnoDB cluster](#).

Server Configuration with MySQL Installer

MySQL Installer handles the initial configuration of the MySQL server. For example:

- It creates the configuration file (`my.ini`) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process. Some definitions are host dependent. For example, `query_cache` is enabled if the host has fewer than three cores.

**Note**

Query cache was deprecated in MySQL 5.7 and removed in MySQL 8.0 (and later).

- By default, a Windows service for the MySQL server is added.
- Provides default installation and data paths for MySQL server. For instructions on how to change the default paths, see [Setting Alternative Server Paths with MySQL Installer](#).
- It can optionally create MySQL server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named `Mysq1Sys` with limited privileges, which would then run the MySQL Server.

User accounts may also be added and configured in MySQL Workbench.

- Checking **Show Advanced Options** enables additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

During the configuration process, click **Next** to proceed to the next step or **Back** to return to the previous step. Click **Execute** at the final step to apply the server configuration.

The sections that follow describe the server configuration options that apply to MySQL server on Windows. The server version you installed will determine which steps and options you can configure. Configuring MySQL server may include some or all of the following steps:

- [Type and Networking](#)
- [Authentication Method](#)
- [Accounts and Roles](#)
- [Windows Service](#)
- [Plugins and Extensions](#)
- [Logging Options](#)
- [Advanced Options](#)
- [Apply Server Configuration](#)

Type and Networking

- Server Configuration Type

Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) that will be assigned to your MySQL server instance.

- **Development:** A machine that will host many other applications, and typically this is your personal workstation. This option configures MySQL to use the least amount of memory.
- **Server:** Several other applications will be running on this machine, such as a web server. This option configures MySQL to use a medium amount of memory.
- **Dedicated:** A machine that is dedicated to running the MySQL server. Because no other major applications will run on this server, such as a web server, this option configures MySQL to use the majority of available memory.

- Connectivity

Connectivity options control how the connection to MySQL is made. Options include:

- **TCP/IP:** You may enable TCP/IP Networking here as otherwise only local host connections are permitted. Also define the **Port** (for classic MySQL), **X Protocol Port** (for MySQL as a document store), and whether to open the firewall port for network access.

Important

For MySQL 5.7.12 to MySQL 8.0.4 server configurations, the X Protocol port is set separately in the [Plugins and Extensions step](#).

If the port number is in use already, you will see the information icon () next to the default value and **Next** is disabled until you provide a new port number.

- **Named Pipe:** Enable and define the pipe name, similar to using the `--enable-named-pipe` option.
- **Shared Memory:** Enable and then define the memory name, similar to using the `--shared-memory` option.
- Advanced Configuration

Check **Show Advanced Options** to set custom logging and advanced options in later steps. The Logging Options step enables you to define custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log. The Advanced Options step enables you to set the unique server ID required when binary logging is enabled in a replication topology.

- MySQL Enterprise Firewall (Commercial Edition only)

The **Enable Enterprise Firewall** check box is selected by default. For post-installation instructions, see [Section 6.5.6, “MySQL Enterprise Firewall”](#).

Authentication Method

The **Authentication Method** step is visible only during the installation or upgrade of MySQL 8.0.4 or higher. It introduces a choice between two server-side authentication options. The MySQL user accounts that you create in the next step will use the authentication method that you select in this step.

MySQL 8.0 connectors and community drivers that use `libmysqlclient` 8.0 now support the `mysql_native_password` default authentication plugin. However, if you are unable to update your clients and applications to support this new authentication method, you can configure the MySQL server to use `mysql_native_password` for legacy authentication. For more information about the implications of this change, see [caching_sha2_password as the Preferred Authentication Plugin](#).

If you are installing or upgrading to MySQL 8.0.4 or higher, select one of the following authentication methods:

- Use Strong Password Encryption for Authentication (RECOMMENDED)

MySQL 8.0 supports a new authentication based on improved, stronger SHA256-based password methods. It is recommended that all new MySQL server installations use this method going forward.

**Important**

The `caching_sha2_password` authentication plugin on the server requires new versions of connectors and clients, which add support for the new MySQL 8.0 default authentication.

- Use Legacy Authentication Method (Retain MySQL 5.x Compatibility)

Using the old MySQL 5.x legacy authentication method should be considered only in the following cases:

- Applications cannot be updated to use MySQL 8.0 connectors and drivers.
- Recompilation of an existing application is not feasible.
- An updated, language-specific connector or driver is not available yet.

Accounts and Roles

- Root Account Password

Assigning a root password is required and you will be asked for it when performing other MySQL Installer operations. Password strength is evaluated when you repeat the password in the box provided. For descriptive information regarding password requirements or status, move your mouse pointer over

the information icon () when it appears.

- MySQL User Accounts

Optionally, you can create additional MySQL user accounts with predefined user roles. Each predefined role, such as DB Admin, are configured with their own set of privileges. For example, the DB Admin role has more privileges than the DB Designer role. Click the **Role** drop-down list for a description of each role.

**Note**

If the MySQL server is installed, then you must also enter the current root password.

Windows Service

On the Windows platform, MySQL server can run as a named service managed by the operating system and be configured to start up automatically when Windows starts. Alternatively, you can configure MySQL server to run as an executable program that requires manual configuration.

- **Configure MySQL server as a Windows service** (Selected by default.)

When the default configuration option is selected, you can also select the following:

- **Start the MySQL Server at System Startup**

When selected (default), the service startup type is set to Automatic; otherwise, the startup type is set to Manual.

- **Run Windows Service as**

When **Standard System Account** is selected (default), the service logs on as Network Service.

The **Custom User** option must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

A custom user is configured in Windows by searching for "local security policy" in the Start menu. In the Local Security Policy window, select **Local Policies, User Rights Assignment**, and then **Log On As A Service** to open the property dialog. Click **Add User or Group** to add the custom user and then click **OK** in each dialog to save the changes.

- Deselect the Windows Service option

Plugins and Extensions

The **Plugins and Extensions** step is visible during a new installation of MySQL 5.7.12 to MySQL 8.0.4 only. It supports the X Plugin, which must be installed and activated to use MySQL as a document store.

Important

As of MySQL 8.0.11, the X Plugin now is activated by default. To specify X Protocol and Firewall ports to enable MySQL 8.0.11 (or higher) as a document store, see the connectivity options in the [Types and Networking](#) step.

If you are upgrading from a previous MySQL version, then you need to open MySQL Installer again and select the **Reconfigure** MySQL server option. The options include:

- **Enable X Protocol / MySQL as a Document Store** (Selected by default.)

When the X Protocol option is selected, MySQL Installer loads and starts the X Plugin. Without the X Plugin running, X Protocol clients cannot connect to the server.

- **Port Number:** [33060](#)

Requires an unused port. The default port number is 33060.

- **Open Firewall port for network access**

Open by default when the X Protocol is selected.

For more information about using MySQL as a document store and the X Plugin, see [Section 20.1, "Key Concepts"](#) and [Section 20.5, "X Plugin"](#).

Logging Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

Advanced configuration options are related to the following MySQL log files:

- [Error Log](#)
- [General Log](#)
- [Slow Query Log](#)
- [Bin Log](#)

**Note**

The binary log is enabled by default for MySQL 5.7 and higher.

Advanced Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

The advanced-configuration options include:

- **Server ID**

Set the unique identifier used in a replication topology. If binary logging is enabled, you must specify a server ID. The default ID value depends on the server version. For more information, see the description of the `--server-id` option.

- **Table Names Case**

You can set the following options during the initial and subsequent configuration the server. For the MySQL 8.0 release series, these options apply only to the initial configuration of the server.

- Lower Case

Sets the `lower_case_table_names` option value to 1 (default), in which table names are stored in lowercase on disk and comparisons are not case sensitive.

- Preserve Given Case

Sets the `lower_case_table_names` option value to 2, in which table names are stored as given but compared in lowercase.

Apply Server Configuration

All configuration settings are applied to the MySQL server when you click **Execute**. Use the **Configuration Steps** tab to follow the progress of each action; the icon for each toggles from white to green (with a check mark) on success. Otherwise, the process stops and displays an error message if an individual action times out. Click the **Log** tab to view the log.

When the installation is done and you click **Finish**, MySQL Installer and the installed MySQL products are added to the Microsoft Windows Start menu under the [MySQL](#) group. Opening MySQL Installer loads the [dashboard](#) where installed MySQL products are listed and other MySQL Installer operations are available.

Setting Alternative Server Paths with MySQL Installer

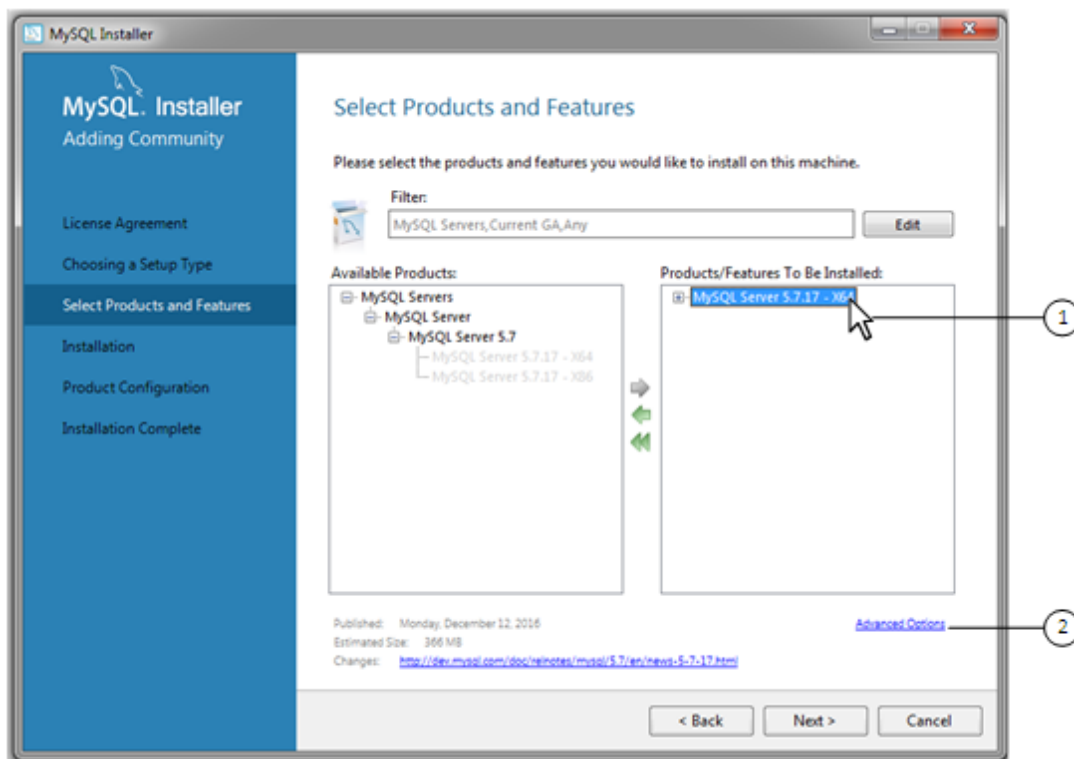

You can change the default installation path, the data path, or both when you install MySQL server. After you have installed the server, the paths cannot be altered without removing and reinstalling the server instance.

To change paths for MySQL server

1. Identify the MySQL server to change and display the **Advanced Options** link.
 - a. Navigate to the **Select Products and Features** step by doing one of the following:
 - i. If this is an [initial setup](#), select the [Custom](#) setup type and click **Next**.

- ii. If MySQL Installer is installed already, launch it from the Start menu and then click **Add** from the dashboard.
 - b. Click **Edit** to filter the list of products, locate the server instance to be installed in the **Available Products** list.
 - c. With the server instance selected, use the arrow to move the selected server to the **Products/Features To Be Installed** list.
 - d. Click the server to select it. When you select the server, the **Advanced Options** link appears. For details, see the figure that follows.
2. Click **Advanced Options** to open a dialog window with the path-setting options. After setting the path, click **Next** to continue with the configuration steps.

Figure 2.10 Change MySQL Server Path

MySQL Applications, Connectors, and Documentation

MySQL Installer downloads and installs a suite of tools for developing and managing business-critical applications on Windows. The suite consist of applications, connectors, documentation, and samples.

During the [initial setup](#), choose any predetermined setup type, except [Server only](#), to install the latest GA version of the tools. Use the [Custom](#) setup type to install an individual tool or specific version. If MySQL Installer is installed on the host already, use the **Add** operation to select and install tools from the MySQL Installer dashboard.

MySQL Router Configuration

MySQL Installer provides a configuration wizard that can bootstrap an installed instance of MySQL Router 2.1.3 or later to route traffic between MySQL applications and an InnoDB cluster. When configured,

MySQL Router runs as a local Windows service. For detailed information about using MySQL Router with an InnoDB cluster, see [Routing for MySQL InnoDB cluster](#).

To configure MySQL Router, do the following:

1. Set up InnoDB cluster. For instructions on how to configure a sandbox InnoDB cluster on the local host using MySQL Installer, see [Group Replication](#). InnoDB cluster requires MySQL Server 5.7.17 or higher.

For general InnoDB cluster information, see [Chapter 21, InnoDB Cluster](#).

2. Using MySQL Installer, download and install the MySQL Router application. After the installation finishes, the configuration wizard prompts you for information. Select the **Configure MySQL Router for InnoDB cluster** check box to begin the configuration and provide the following configuration values:

- **Hostname:** localhost by default.
- **Port:** The port number of the primary server in the InnoDB cluster. The default is 3310.
- **Management User:** An administrative user with root-level privileges.
- **Password:** The password for the management user.
- **Classic MySQL protocol connections to InnoDB cluster**

Read/Write: Set the first base port number to one that is unused (between 80 and 65532) and the wizard will select the remaining ports for you.

The figure that follows shows an example of the MySQL Router configuration page, with the first base port number specified as 6446 and the remaining ports set by the wizard as 6447, 6448, and 6449.

Figure 2.11 MySQL Router Configuration

MySQL Installer

MySQL Router 2.1.3

MySQL Router Configuration

Apply Configuration

MySQL Router Configuration

☒ Configure MySQL Router for InnoDB cluster.

This wizard can bootstrap the MySQL Router to route traffic between MySQL applications and a MySQL InnoDB cluster. Applications that connect to the router will be automatically directed to an available R/W or R/O member of the cluster.

Please provide a connection to the InnoDB cluster below. In order to register the MySQL Router for monitoring, use the current Read/Write instance of the cluster.

Hostname:

Port:

Management User:

Password:

MySQL Router requires specification of a base port (between 80 and 65532). This port is used for classic read/write connections. The other ports must come sequentially after the base port. If any port below is indicated as being unavailable, please change the base port.

Classic MySQL protocol connections to InnoDB cluster:

Read/Write:

Read Only:

MySQL X Protocol connections to InnoDB cluster:

Read/Write:

Read Only:

Next > Cancel

3. Click **Next** and then **Execute** to apply the configuration. Click **Finish** to close MySQL Installer or return to the MySQL Installer dashboard.

2.3.3.3 MySQL Installer Product Catalog and Dashboard

- [Product Catalog](#)
- [MySQL Installer Dashboard](#)
- [Locating Products to Install](#)

This section describes the MySQL Installer product catalog and the dashboard.

Product Catalog

The product catalog stores the complete list of released MySQL products for Microsoft Windows that are available to download from [MySQL Downloads](#). By default, and when an Internet connection is present, MySQL Installer updates the catalog daily. You can also update the catalog manually from the dashboard (described later).

An up-to-date catalog performs the following actions:

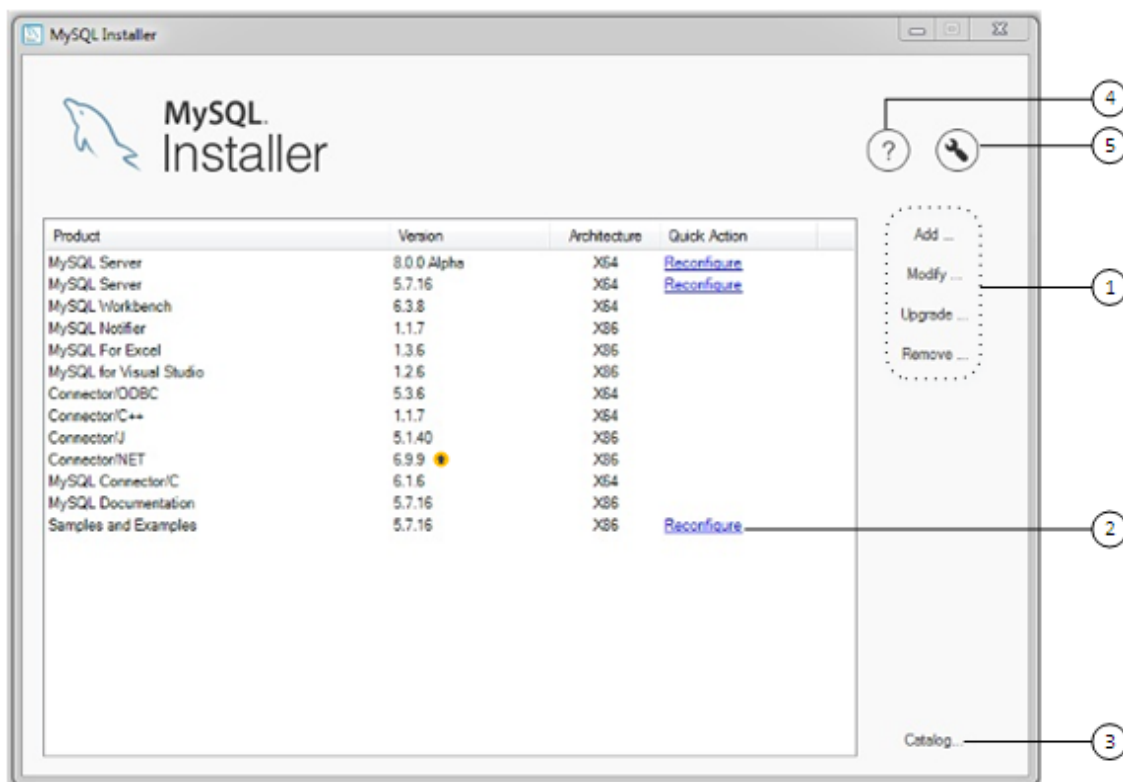

- Populates the **Available Products** pane of the Select Products and Features step. This step appears when you select:
 - The [Custom](#) setup type during the [initial setup](#).
 - The **Add** operation from the dashboard.
- Identifies when product updates are available for the installed products listed in the dashboard.

The catalog includes all development releases (Pre-Release), general releases (Current GA), and minor releases (Other Releases). Products in the catalog will vary somewhat, depending on the MySQL Installer edition that you download.

MySQL Installer Dashboard

The MySQL Installer dashboard is the default view that you see when you start MySQL Installer after the [initial setup](#) finishes. If you closed MySQL Installer before the setup was finished, MySQL Installer resumes the initial setup before it displays the dashboard.

Figure 2.12 MySQL Installer Dashboard Elements

Description of MySQL Installer Dashboard Elements

- MySQL Installer dashboard operations provide a variety of actions that apply to installed products or products listed in the catalog. To initiate the following operations, first click the operation link and then select the product or products to manage:
 - Add:** This operation opens the Select Products and Features page. From there, you can filter the product in the product catalog, select one or more products to download (as needed), and begin the installation. For hints about using the filter, see [Locating Products to Install](#).
 - Modify:** Use this operation to add or remove the features associated with installed products. Features that you can modify vary in complexity by product. When the **Program Shortcut** check box is selected, the product appears in the Start menu under the [MySQL](#) group.
 - Upgrade:** This operation loads the Select Products to Upgrade page and populates it with all the upgrade candidates. An installed product can have more than one upgrade version and requires a current product catalog.

Important server upgrade conditions:

- MySQL Installer does not permit server upgrades between major release versions or minor release versions, but does permit upgrades within a release series, such as an upgrade from 5.7.18 to 5.7.19.
- Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server.

To choose a new product version:

- a. Click **Upgrade**. Confirm that the check box next to product name in the **Upgradeable Products** pane has a check mark. Deselect the products that you do not intend to upgrade at this time.

Note

For server milestone releases in the same release series, MySQL Installer deselects the server upgrade and displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform a logical upgrade manually. You can reselect server upgrade at your own risk. For instructions on how to perform a logical upgrade with a milestone release, see [Logical Upgrade](#).

- b. Click a product in the list to highlight it. This action populates the **Upgradeable Versions** pane with the details of each available version for the selected product: version number, published date, and a [Changes](#) link to open the release notes for that version.

MySQL Installer upgrades all of the selected products in one action. Click **Show Details** to view the actions performed by MySQL Installer.

- **Remove** This operation opens the Remove Products page and populates it with the MySQL products installed on the host. Select the MySQL products you want to remove (uninstall) and then click **Execute** to begin the removal process.

To select products to remove, do one of the following:

- Select the check box for one or more products.
 - Select the **Product** check box to select all products.
2. The **Reconfigure** link in the Quick Action column next to each installed server loads the current configuration values for the server and then cycles through all configuration steps enabling you to change the options and values. On completion, MySQL Installer stops the server, applies the configuration changes, and restarts the server for you. For a description of each configuration option, see [Server Configuration with MySQL Installer](#).

Installed [Samples and Examples](#) associated with a specific MySQL server version can be also be reconfigured to apply feature-configuration changes, if any. You must provide credentials with root privileges to reconfigure these items.

3. The **Catalog** link enables you to download the latest catalog of MySQL products manually and then to integrate those product changes with MySQL Installer. The catalog-download action does not perform an upgrade of the products already installed on the host. Instead, it returns to the dashboard and displays an arrow icon in the Version column for each installed product that has a newer version. Use the **Upgrade** operation to install the newer product version.

You can also use the **Catalog** link to display the current change history of each product without downloading the new catalog. Select the **Do not update at this time** check box to view the change history only.

4. The MySQL Installer About icon () shows the current version of MySQL Installer and general information about MySQL. The version number is located above the **Back** button.

Always include this version number when reporting a problem with MySQL Installer.

5. The MySQL Installer Options icon (🔧) includes the following tabs:
 - **Product Catalog:** Manages the daily automatic catalog updates. By default, catalog updates are scheduled at a fixed hour. When new products or product versions are available, MySQL Installer adds them to the catalog and then displays an arrow icon (📶) next to the version number of installed products listed in the dashboard.

Use this option to enable or disable automatic catalog updates and to reset the time of day when the MySQL Installer updates the catalog automatically. For specific settings, see the task named [ManifestUpdate](#) in the Windows Task Scheduler.
 - **Connectivity Settings:** Several operations performed by MySQL Installer require internet access. This option enables you to use a default value to validate the connection or to use a different URL, one selected from a list or added by you manually. With the **Manual** option selected, new URLs can be added and all URLs in the list can be moved or deleted. When the **Automatic** option is selected, MySQL Installer attempts to connect to each default URL in the list (in order) until a connection is made. If no connection can be made, it raises an error.

Locating Products to Install

MySQL products in the catalog are listed by category: MySQL Servers, Applications, MySQL Connectors, and Documentation. Only the latest GA versions appear in the **Available Products** pane by default. If you are looking for a pre-release or older version of a product, it may not be visible in the default list.

To change the default product list, click **Add** on the dashboard to open the Select Products and Features page, and then click **Edit** to open the filter dialog box (see the figure that follows). Modify the product values and then click **Filter**.

Figure 2.13 Filter Available Products

The screenshot shows a dialog box titled 'Filter Available Products'. It has the following controls:

- Text:** A text input field.
- Category:** A dropdown menu currently showing 'All Software'.
- Age:** A dropdown menu currently showing 'Current GA'.
- Already Downloaded:** A checkbox that is currently unchecked.
- Architecture:** Three radio buttons labeled 'Any' (selected), '32-bit', and '64-bit'.
- Filter:** A button at the bottom right.

Reset one or more of the following values to filter the list of available products:

- **Text:** Filter by text.
- **Category:** All Software (default), MySQL Servers, Applications, MySQL Connectors, or Documentation (for samples and documentation).
- **Age:** Pre-Release, Current GA (default), or Other Releases.

**Note**

The Commercial Edition of MySQL Installer does not display any MySQL products when you select the Pre-Release age filter. Products in development are available from the Community Edition of MySQL Installer only.

- Already Downloaded (the check box is deselected by default).
- Architecture: Any (default), 32-bit, or 64-bit.

2.3.3.4 MySQLInstallerConsole Reference

`MySQLInstallerConsole.exe` provides command-line functionality that is similar to MySQL Installer. It is installed when MySQL Installer is initially executed and then available within the `MySQL Installer` directory. Typically, that is in `C:\Program Files (x86)\MySQL\MySQL Installer\`, and the console must be executed with administrative privileges.

To use, invoke the command prompt with administrative privileges by choosing **Start, Accessories**, then right-click on **Command Prompt** and choose **Run as administrator**. And from the command line, optionally change the directory to where `MySQLInstallerConsole.exe` is located:

```
C:\> cd Program Files (x86)\MySQL\MySQL Installer for Windows
C:\Program Files (x86)\MySQL\MySQL Installer for Windows> MySQLInstallerConsole.exe help
===== Start Initialization =====
MySQL Installer is running in Community mode

Attempting to update manifest.
Initializing product requirements
Loading product catalog
Checking for product catalog snippets
Checking for product packages in the bundle
Categorizing product catalog
Finding all installed packages.
Your product catalog was last updated at 11/1/2016 4:10:38 PM
===== End Initialization =====

The following commands are available:

Configure - Configures one or more of your installed programs.
Help      - Provides list of available commands.
Install   - Install and configure one or more available MySQL programs.
List      - Provides an interactive way to list all products available.
Modify    - Modifies the features of installed products.
Remove    - Removes one or more products from your system.
Status    - Shows the status of all installed products.
Update    - Update the current product catalog.
Upgrade   - Upgrades one or more of your installed programs.
```

`MySQLInstallerConsole.exe` supports the following commands:

**Note**

Configuration block values that contain a colon (":") must be wrapped in double quotes. For example, `installdir="C:\MySQL\MySQL Server 8.0"`.

- `configure [product1]:[setting]=[value]; [product2]:[setting]=[value]; [...]`

Configure one or more MySQL products on your system. Multiple setting=value pairs can be configured for each product.

Switches include:

- `-showsettings` : Displays the available options for the selected product, by passing in the product name after `-showsettings`.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole configure -showsettings server
C:\> MySQLInstallerConsole configure server:port=3307
```

- `help [command]`

Displays a help message with usage examples, and then exits. Pass in an additional command to receive help specific to that command.

```
C:\> MySQLInstallerConsole help
C:\> MySQLInstallerConsole help install
```

- `install [product]:[features]:[config block]:[config block]:[config block]; [...]`

Install one or more MySQL products on your system. If pre-release products are available, both GA and pre-release products are installed when the value of the `-type` switch is `Developer`, `Client`, or `Full`. Use the `-only_ga_products` switch to restrict the product set to GA products only when using these setup types.

Switches and syntax options include:

- `-only_ga_products` : Restricts the product set to include GA products only.
- `-type=[SetupType]` : Installs a predefined set of software. The "SetupType" can be one of the following:

Note

Non-custom setup types can only be chosen if no other MySQL products are installed.

- **Developer**: Installs a complete development environment.
- **Server**: Installs a single MySQL server
- **Client**: Installs client programs and libraries
- **Full**: Installs everything
- **Custom**: Installs user selected products. This is the default option.
- `-showsettings` : Displays the available options for the selected product, by passing in the product name after `-showsettings`.
- `-silent` : Disable confirmation prompts.
- `[config block]`: One or more configuration blocks can be specified. Each configuration block is a semicolon separated list of key value pairs. A block can include either a "config" or "user" type key, where "config" is the default type if one is not defined.

Configuration block values that contain a colon character (:) must be wrapped in double quotes. For example, `installdir="C:\MySQL\MySQL Server 8.0"`.

Only one "config" type block can be defined per product. A "user" block should be defined for each user that should be created during the product's installation.

Note

Adding users is not supported when a product is being reconfigured.

- `[feature]`: The feature block is a semicolon separated list of features, or an asterisk character (*) to select all features.

```
C:\> MySQLInstallerConsole install server;5.6.25:*:port=3307;serverid=2:type=user;username=foo;password=bar;
C:\> MySQLInstallerConsole install server;5.6.25;x64 -silent
```

An example that passes in additional configuration blocks, separated by ^ to fit:

```
C:\> MySQLInstallerConsole install server;5.6.25;x64:*:type=config;openfirewall=true; ^
      generallog=true;binlog=true;serverid=3306;enable_tcpip=true;port=3306;rootpasswd=pass; ^
      installdir="C:\MySQL\MySQL Server 5.6":type=user;datadir="C:\MySQL\data";username=foo;password=bar
```

- `list`

Lists an interactive console where all of the available MySQL products can be searched. Execute `MySQLInstallerConsole list` to launch the console, and enter in a substring to search.

```
C:\> MySQLInstallerConsole list
```

- `modify [product1:-removelist/+addlist] [product2:-removelist/+addlist] [...]`

Modifies or displays features of a previously installed MySQL product.

- `-silent`: Disable confirmation prompts.

```
C:\> MySQLInstallerConsole modify server
C:\> MySQLInstallerConsole modify server:+documentation
C:\> MySQLInstallerConsole modify server:-debug
```

- `remove [product1] [product2] [...]`

Removes one or more products from your system.

- `*`: Pass in * to remove all of the MySQL products.
- `-continue`: Continue the operation even if an error occurs.
- `-silent`: Disable confirmation prompts.

```
C:\> MySQLInstallerConsole remove *
C:\> MySQLInstallerConsole remove server
```

- `status`

Provides a quick overview of the MySQL products that are installed on the system. Information includes product name and version, architecture, date installed, and install location.

```
C:\> MySQLInstallerConsole status
```

- `update`

Downloads the latest MySQL product catalog to your system. On success, the download catalog will be applied the next time either MySQLInstaller or MySQLInstallerConsole is executed.

```
C:\> MySQLInstallerConsole update
```

Note

The **Automatic Catalog Update** GUI option executes this command from the Windows Task Scheduler.

- `upgrade [product1:version] [product2:version] [...]`

Upgrades one or more products on your system. Syntax options include:

- `*` : Pass in `*` to upgrade all products to the latest version, or pass in specific products.
- `!` : Pass in `!` as a version number to upgrade the MySQL product to its latest version.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole upgrade *
C:\> MySQLInstallerConsole upgrade workbench:6.3.5
C:\> MySQLInstallerConsole upgrade workbench:!
C:\> MySQLInstallerConsole upgrade workbench:6.3.5 excel:1.3.2
```

2.3.4 MySQL Notifier

MySQL Notifier is a tool that enables you to monitor and adjust the status of your local and remote MySQL server instances through an indicator that resides in the Microsoft Windows taskbar. MySQL Notifier also gives quick access to MySQL Workbench through its context menu.

MySQL Notifier is installed by using MySQL Installer. It can be loaded automatically when Microsoft Windows is started.

To install, download and execute the [MySQL Installer](#). With MySQL Notifier selected from Applications, proceed with the installation. See the [MySQL Installer manual](#) for additional details.

For notes detailing the changes in each release of MySQL Notifier, see the [MySQL Notifier Release Notes](#).

Visit the [MySQL Notifier forum](#) for additional MySQL Notifier help and support.

Features include:

- Start, stop, and restart instances of the MySQL server.
- Automatically detects (and adds) new MySQL server services. These are listed under **Manage Monitored Items**, and may also be configured.

- The Tray icon changes, depending on the status. It is a right-pointing green triangle if all monitored MySQL server instances are running or a red square if at least one service is stopped. The **Update MySQL Notifier tray icon based on service status** option, which dictates this behavior, is enabled by default for each service.
- Links to other applications like MySQL Workbench, MySQL Installer, and the MySQL Utilities. For example, choosing **Manage Instance** will load the MySQL Workbench Server Administration window for that particular instance.
- If MySQL Workbench is also installed, then the **Manage Instance** and **SQL Editor** options are available for local (but not remote) MySQL instances.
- Monitors both local and remote MySQL instances.

2.3.4.1 MySQL Notifier Usage

MySQL Notifier provides visual status information for the MySQL servers that are monitored on both local or remote computers. The MySQL Notifier icon in the taskbar changes color to indicate the current status: Running or Stopped.

MySQL Notifier automatically adds discovered MySQL services on the local computer. By default, the **Automatically add new services whose name contains** option is enabled and set to `mysql`. Related notification options include being notified when new services are either discovered or experience status changes, and are also enabled by default. Uninstalling a service removes the service from MySQL Notifier.

Clicking the MySQL Notifier icon from the Windows taskbar reveals the MySQL Notifier main menu, which lists each MySQL server separately and displays its current status. You can start, stop, or restart each MySQL server from the menu as the following figure shows. When MySQL Workbench is installed locally, the **Manage Instance** and **SQL Editor** menu items start the application.

Figure 2.14 MySQL Notifier Service Instance Menu

The **Actions** menu includes the following items:

- **Manage Monitored Items**
- **Launch MySQL Installer** (Only when the product is installed.)
- **Check for Updates** (Only when MySQL Installer is installed.)
- **MySQL Utilities Shell** (Only when the product is installed.)
- **Refresh Status**

- **Options**
- **About**
- **Close MySQL Notifier**

The main menu does not show the **Actions** menu when there are no services being monitored by MySQL Notifier.

MySQL Notifier Options

The **Actions**, **Options** menu provides a set of options that configure MySQL Notifier operations. Options are grouped into the following categories: **General Options**, **Notification Options**, and **MySQL Server Connections Options**.

Click **Accept** to enable the selected options or **Cancel** to ignore all changes. Click **Reset to Defaults** and then **Accept** to apply default option values.

General Options. This group includes:

- **Use colorful status icons:** Enables a colorful style of icons for the tray of MySQL Notifier. Selected by default.
- **Run at Windows Startup:** Allows the application to be loaded when Microsoft Windows starts. Deselected by default.
- **Automatically Check For Updates Every # Weeks:** Checks for a new version of MySQL Notifier, and runs this check every # weeks. Selected by default with the updates every four weeks.
- **Automatically add new services whose name contains:** The text used to filter services and add them automatically to the monitored list of the local computer running MySQL Notifier and on remote computers already monitoring Windows services. Selected by default for names containing `mysql`.
- **Ping monitored MySQL Server instances every # seconds:** The interval (in seconds) to ping monitored MySQL Server instances for status changes. Longer intervals might be necessary if the list of monitored remote instances is large. 30 seconds by default.

Notification Options. This group includes:

- **Notify me when a service is automatically added:** Display a balloon notification from the taskbar when a newly discovered service is added to the monitored services list. Selected by default.
- **Notify me when a service changes status:** Displays a balloon notification from the taskbar when a monitored service changes its status. Selected by default.

MySQL Server Connections Options. This group includes:

- **Automatic connections migration delayed until:** When there are connections to migrate to MySQL Workbench (if installed), this option postpones the migration by one hour, one day, one week, one month, or indefinitely.

Managing Monitored Items

The **Actions**, **Manage Monitored Items** menu enables you to add, configure, and delete the services and MySQL instances you intend to monitor. The **Manage Items** window has two tabs: **Services** and **Instances**.

Services Tab. When MySQL is configured as a local service, MySQL Notifier adds the service to the **Services** tab automatically. With the **Services** tab open, you can select the following options that apply to all services being monitored:

- **Notify me when status changes**
- **Update MySQL Notifier tray icon based on service status**

The next figure shows the **Services** tab open and both options selected. This tab shows the service name, the computer where the service is hosted, and the current status of the service.

Figure 2.15 MySQL Notifier: Manage Services

To stop monitoring a service, select it from the list of monitored services and click **Delete**.

Click **Add** and then **Windows Service** to open the **Add Service** window. To add a new service, select a computer from the drop-down list, choose a service from the list, and then click **OK** to accept. Use the **Filter** field to reduce the set of services in the list or select **Only show services that match auto-add filter?** to reuse the general-options filter from the **Options** menu.

A variety of Windows services (including MySQL) may be selected as the following figure shows. In addition to the service name, the list shows the current status of each Windows services for the selected computer.

Figure 2.16 MySQL Notifier: Adding New Services

Instances Tab. When MySQL is configured as a MySQL instance, MySQL Notifier adds the instance to the **Instances** tab automatically. With the **Instances** tab open, you can select the following options that apply to each instance being monitored:

- **Notify me when status changes**
- **Update MySQL Notifier tray icon based on service status**
- **Monitor MySQL Instance status every [#] [seconds | minutes | hours | days]**

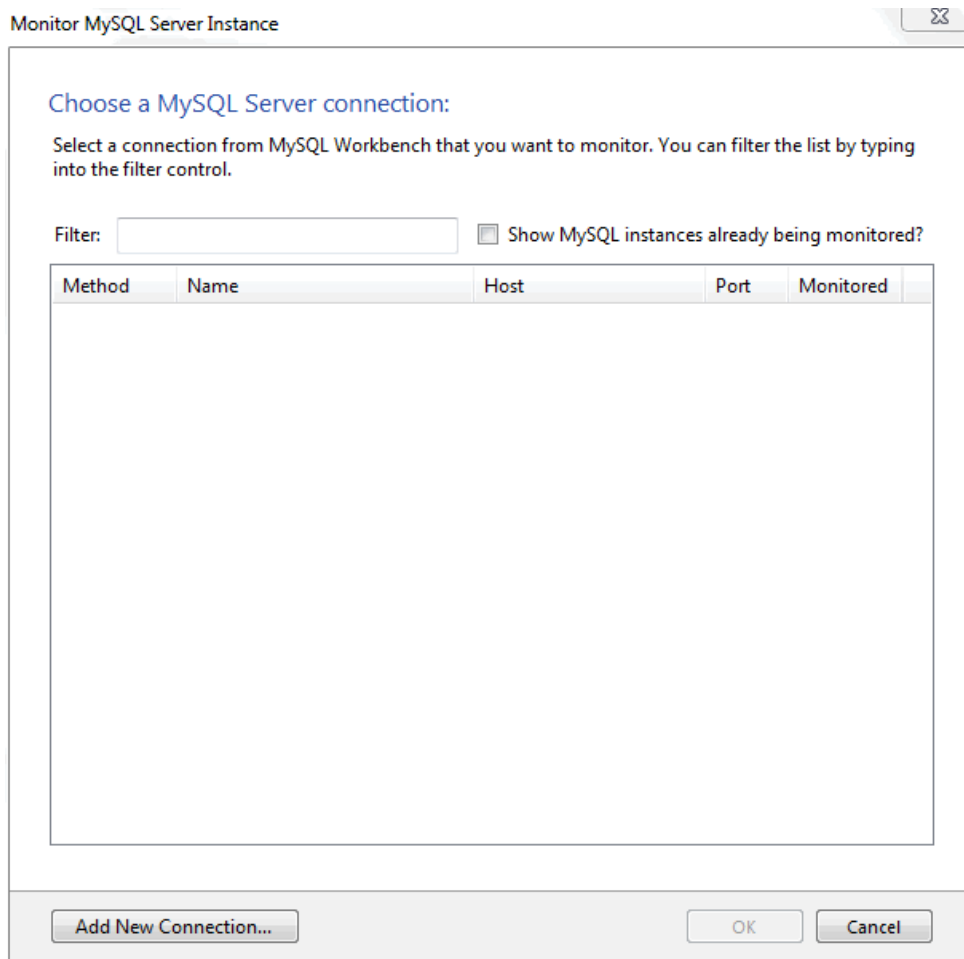

The next figure shows the **Instances** tab open and both options selected. Monitoring the instance status is set to every two minutes in this example. This tab shows the instance name, the database driver, and the current status of the instance.

Figure 2.17 MySQL Notifier: Manage MySQL Instances

To stop monitoring an instance, select it from the list of monitored MySQL instances and click **Delete**.

Click **Add** and then **MySQL Instances** to open the **Monitor MySQL Server Instance** window. Use the **Filter** field to reduce the set of instances in the list or select **Show MySQL instances already being monitored?** to show monitored items only.

Optionally, you can select a connection from MySQL Workbench to monitor. Click **Add New Connection**, shown in the next figure, to create a new connection.

Figure 2.18 MySQL Notifier: Adding New Instances

Troubleshooting

For issues that are not documented here, visit the [MySQL Notifier Support Forum](#) for MySQL Notifier help and support.

- *Problem:* attempting to start/stop/restart a MySQL service might generate an error similar to "The Service **MySQLVERSION** failed the most recent status change request with the message "The service **mysqlVERSION** was not found in the Windows Services".

Explanation: this is a case-sensitivity issue, in that the service name is **MySQLVERSION** compared to having **mysqlVERSION** in the configuration file.

Solution: either update your MySQL Notifier configuration file with the correct information, or stop MySQL Notifier and delete this configuration file. The MySQL Notifier configuration file is located at `%APPDATA%\Oracle\MySQL Notifier\settings.config` where `%APPDATA%` is a variable and depends on your system. A typical location is "C:\Users\YourUsername\AppData\Running\Oracle\MySQL Notifier\settings.config" where *YourUsername* is your system's user name. In this file, and within the `ServerList` section, change the `ServerName` values from lowercase to the actual service names. For example, change **mysqlVERSION** to **MySQLVERSION**, save, and then restart MySQL Notifier. Alternatively, stop MySQL Notifier, delete this file, then restart MySQL Notifier.

- **Problem:** when connecting to a remote computer for the purpose of monitoring a remote Windows service, the **Add Service** dialog does not always show all the services shown in the Windows Services console.

Explanation: this behavior is governed by the operating system and the outcome is expected when working with nondomain user accounts. For a complete description of the behavior, see the [User Account Control and WMI](#) article from Microsoft.

Solution: when the remote computer is in a compatible domain, it is recommended that domain user accounts are used to connect through WMI to a remote computer. For detailed setup instructions using WMI, see [Section 2.3.4.2, “Setting Up Remote Monitoring in MySQL Notifier”](#).

Alternatively, when domain user accounts are not available, Microsoft provides a less secure workaround that should only be implemented with caution. For more information, see the [Description of User Account Control and remote restrictions in Windows Vista](#) KB article from Microsoft.

2.3.4.2 Setting Up Remote Monitoring in MySQL Notifier

MySQL Notifier uses Windows Management Instrumentation (WMI) to manage and monitor services on remote computers. This section explains how it works and how to set up your system to monitor remote MySQL instances.

In order to configure WMI, it is important to understand that the underlying Distributed Component Object Model (DCOM) architecture is doing the WMI work. Specifically, MySQL Notifier is using asynchronous notification queries on remote Microsoft Windows hosts as .NET events. These events send an asynchronous callback to the computer running MySQL Notifier so it knows when a service status has changed on the remote computer. Asynchronous notifications offer the best performance compared to semisynchronous notifications or synchronous notifications that use timers.

As the following figure shows, asynchronous notification requires the remote computer to send a callback to the client computer (thus opening a reverse connection), so the Windows Firewall and DCOM settings must be properly configured for the communication to function properly. The client (Computer A), which includes an unsecured application (`unsecapp.exe` in this example), makes an asynchronous call to a remote computer (Computer B) and receives a call back with data.

Figure 2.19 MySQL Notifier Distributed Component Object Model (DCOM)

Most of the common errors thrown by asynchronous WMI notifications are related to Windows Firewall blocking the communication, or to DCOM / WMI settings not being set up properly. For a list of common errors with solutions, see [Common Errors](#).

The following steps are required to make WMI function. These steps are divided between two machines. A single host computer that runs MySQL Notifier (Computer A), and multiple remote machines that are being monitored (Computer B).

Computer running MySQL Notifier (Computer A)

1. Enable remote administration by either editing the **Group Policy Editor**, or using [NETSH](#):

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type [GPEDIT.MSC](#), and then click **OK**.
- b. Under the **Local Computer Policy** heading, expand **Computer Configuration**.
- c. Expand **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Double-click **Windows Firewall: Allow inbound remote administration exception** to open a configuration window.
- f. Check the **Enabled** option button and then click **OK**.

Using the [NETSH](#) command:

Note

The "netsh firewall" command is deprecated as of Microsoft Server 2008 and Vista, and replaced with "netsh advfirewall firewall".

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).
- b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

2. Open the DCOM port TCP 135:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).
- b. Execute the following command:

```
NETSH advfirewall firewall add rule name=DCOM_TCP135 protocol=TCP localport=135 dir=in action=allow
```

3. Add the client application that contains the sink for the callback ([MySQLNotifier.exe](#)) to the Windows Firewall Exceptions List (use either the Windows Firewall configuration or [NETSH](#)):

Using the Windows Firewall configuration:

- a. In the Control Panel, double-click **Windows Firewall**.
- b. In the Windows Firewall window, click **Allow a program or feature through Windows Firewall**.
- c. In the Allowed Programs window, click **Change Settings** and do one of the following:
 - If [MySQLNotifier.exe](#) is in the Allowed programs and features list, make sure it is checked for the type of networks the computer connects to (Private, Public or both).

- If `MySQLNotifier.exe` is not in the list, click **Allow another program**.
 - i. In the **Add a Program** window, select the `MySQLNotifier.exe` if it exists in the Programs list, otherwise click **Browse** and go to the directory where `MySQLNotifier.exe` was installed to select it, then click **Add**.
 - ii. Make sure `MySQLNotifier.exe` is checked for the type of networks the computer connects to (Private, Public or both).

Using the `NETSH` command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
- b. Execute the following command, where you change "`[YOUR_INSTALL_DIRECTORY]`":

```
NETSH advfirewall firewall add rule name=MySQLNotifier program=[YOUR_INSTALL_DIRECTORY]\MySQLNotifier.exe
```

4. If Computer B is either a member of `WORKGROUP` or is in a different domain that is untrusted by Computer A, then the callback connection (Connection 2) is created as an Anonymous connection. To grant Anonymous connections DCOM Remote Access permissions:
 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.

Monitored Remote Computer (Computer B)

If the user account that is logged on to the computer running the MySQL Notifier (Computer A) is a local administrator on the remote computer (Computer B), such that the same account is an administrator on Computer B, you can skip to the "Allow for remote administration" step.

Setting DCOM security to allow a non-administrator user to access a computer remotely:

1. Grant "DCOM remote launch" and activation permissions for a user or group:
 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Launch and Activation Permission, click **Edit Limits**.
 - e. In the **Launch and Activation Permission** dialog box, follow these steps if your name or your group does not appear in the Groups or user names list:

- i. In the **Launch and Activation Permission** dialog box, click **Add**.
- ii. In the Select Users or Groups dialog box, add your name and the group in the **Enter the object names to select** box, and then click **OK**.
- f. In the **Launch and Activation Permission** dialog box, select your user and group in the Group or user names box. In the Allow column under Permissions for User, select **Remote Launch**, select **Remote Activation**, and then click **OK**.

Grant DCOM remote access permissions:

- a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.
2. Allowing non-administrator users access to a specific WMI namespace:
 - a. In the Control Panel, double-click **Administrative Tools**.
 - b. In the Administrative Tools window, double-click **Computer Management**.
 - c. In the Computer Management window, expand the **Services and Applications** tree.
 - d. Right-click the WMI Control icon and select **Properties**.
 - e. In the WMI Control Properties window, click the **Security** tab.
 - f. In the Security tab, select the namespace and click **Security**. Root/CIMV2 is a commonly used namespace.
 - g. Locate the appropriate account and check **Remote Enable** in the Permissions list.
 3. Allow for remote administration by either editing the **Group Policy Editor** or using `NETSH`:

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type `GPEDIT.MSC`, and then click **OK**.
- b. Under the Local Computer Policy heading, double-click **Computer Configuration**.
- c. Double-click **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Click **Windows Firewall: Allow inbound remote administration exception**.

- f. On the Action menu either select **Edit**, or double-click the selection from the previous step.
- g. Check the **Enabled** radio button, and then click **OK**.

Using the [NETSH](#) command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
- b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

4. Confirm that the user account you are logging in with uses the [Name](#) value and not the [Full Name](#) value:
 - a. In the **Control Panel**, double-click **Administrative Tools**.
 - b. In the **Administrative Tools** window, double-click **Computer Management**.
 - c. In the **Computer Management** window, expand the **System Tools** then **Local Users and Groups**.
 - d. Click the **Users** node, and on the right side panel locate your user and make sure it uses the **Name** value to connect, and not the **Full Name** value.

Common Errors

- [0x80070005](#)
 - DCOM Security was not configured properly (see Computer B, the [Setting DCOM security...](#) step).
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- [0x8007000E](#)
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- [0x80041003](#)
 - Access to the remote WMI namespace was not configured properly (see Computer B, the [Allowing non-administrator users access to a specific WMI namespace](#) step).
- [0x800706BA](#)
 - The DCOM port is not open on the client computers (Computer A) firewall. See the [Open the DCOM port TCP 135](#) step for Computer A.
 - The remote computer (Computer B) is inaccessible because its network location is set to Public. Make sure you can access it through the Windows Explorer.

2.3.5 Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a ZIP Archive package is as follows:

1. Extract the main archive to the desired install directory
Optional: also extract the debug-test archive if you plan to execute the MySQL benchmark and test suite
2. Create an option file
3. Choose a MySQL server type
4. Initialize MySQL
5. Start the MySQL server
6. Secure the default user accounts

This process is described in the sections that follow.

2.3.5.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to [Section 2.3.8, “Upgrading MySQL on Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.5.2, “Creating an Option File”](#).

Note

The MySQL Installer installs MySQL under `C:\Program Files\MySQL`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.5.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 8.0` and `C:\Program Files\MySQL\MySQL Server 8.0\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see

Section 4.2.7, “Using Option Files”). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

Note

When using the MySQL Installer to install MySQL Server, it will create the `my.ini` at the default location, and the user executing MySQL Installer is granted full permissions to this new `my.ini` file.

In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see Section 5.1.2, “Server Configuration Defaults”.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in Section 4.2.7, “Using Option Files”.

The ZIP archive does not include a `data` directory. To initialize a MySQL installation by creating the data directory and populating the tables in the mysql system database, initialize MySQL using either `--initialize` or `--initialize-insecure`. For additional information, see Section 2.10.1.1, “Initializing the Data Directory Manually Using `mysqld`”.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 8.0\data`) to `E:\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.5.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 8.0.

Binary	Description
<code>mysqld</code>	Optimized binary with named-pipe support
<code>mysqld-debug</code>	Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 8.0 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

2.3.5.4 Initializing the Data Directory

If you installed MySQL using the `noinstall` package, no data directory is included. To initialize the data directory, use the instructions at [Section 2.10.1.1, “Initializing the Data Directory Manually Using `mysqld`”](#).

2.3.5.5 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

Note

The MySQL server will automatically start after using MySQL Installer, and [MySQL Notifier](#) can be used to start/stop/restart at any time.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 8.0`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see [Section 2.3.5.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

**Note**

The database must be initialized before MySQL can be started. For additional information about the initialization process, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --console
```

For a server that includes [InnoDB](#) support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '8.0.15' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 8.0\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` option.

**Note**

The initial `root` account in the MySQL grant tables has no password. After starting the server, you should set up a password for it using the instructions in [Section 2.10.4, “Securing the Initial MySQL Account”](#).

2.3.5.6 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

**Note**

[MySQL Notifier](#) can also be used to start/stop/restart the MySQL server.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin" -u root shutdown
```

**Note**

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

**Note**

Users in the MySQL grant system are wholly independent from any login users under Microsoft Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 8.0\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--log-error` option. Alternatively, you can try to start the server with the `--console` option; in this case, the server may display some useful information on the screen that will help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [Section 28.5.3, "The DEBUG Package"](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

2.3.5.7 Customizing the PATH for MySQL Tools

**Warning**

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 8.0\bin`)

**Note**

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. The new `PATH` value should now be available to any new command shell you open, allowing you to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

2.3.5.8 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

**Note**

`MySQL Notifier` can also be used to monitor the status of the MySQL service.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel. To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin"  
-u root shutdown
```

**Note**

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

**Note**

Users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 8.0\bin`), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.

- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
      --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

Note

On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. Otherwise, `mysqld.exe` will attempt to start the MySQL server.

You can also specify options as Start parameters in the Windows `Services` utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables `%TEMP%` and `%TMP%` (and also `%TMPDIR%`, if it has ever been set) for the system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is `LocalSystem`, and the default value for its `%TEMP%` and `%TMP%` is `C:\Windows\Temp`, a directory `LocalSystem` has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the `--tmpdir` option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

Starting the service

After a MySQL server instance has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using a `NET START MySQL` command. The `NET` command is not case-sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 8.0\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --install-manual
```

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.3.5.6, “Starting MySQL from the Windows Command Line”](#).

If you encounter difficulties during installation, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

For more information about stopping or removing a Windows service, see [Section 5.8.2.2, “Starting Multiple MySQL Instances as Windows Services”](#).

2.3.5.9 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See [Section 4.2.2, “Connecting to the MySQL Server”](#).

For more information about `mysqlshow`, see [Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the [error log](#). The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the [data directory](#) specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 8.0\data`, or `C:\ProgramData\Mysql` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 5.4.2, “The Error Log”](#).

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld`

as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, it displays these messages:

```
System error 1067 has occurred.
Fatal error: Can't open and lock privilege tables:
Table 'mysql.user' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 8.0` and `C:\Program Files\MySQL\MySQL Server 8.0\data`, respectively).

This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 8.0`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 8.0
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 4.2.7, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.3.5.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

2.3.7 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:

- **MySQL Installer:** Used to install and upgrade MySQL products.
- **MySQL Workbench:** Manages the MySQL server and edits SQL statements.
- **MySQL Notifier:** Starts, stops, or restarts the MySQL server, and monitors its status.
- **MySQL for Excel:** Edits MySQL data with Microsoft Excel.

If necessary, initialize the data directory and create the MySQL grant tables. Windows installation operations performed by MySQL Installer initialize the data directory automatically. For installation from a ZIP Archive package, you can initialize the data directory as described at [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned a password to the initial `root` account. (See [Section 2.3.3, “MySQL Installer for Windows”](#).) Otherwise, use the password-assignment procedure given in [Section 2.10.4, “Securing the Initial MySQL Account”](#).

Before assigning passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.3.5.5, “Starting the Server for the First Time”](#)). You can also set up a MySQL service that runs automatically when Windows starts (see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#)).

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using MySQL Installer (see [Section 2.3.3, “MySQL Installer for Windows”](#)), the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.0`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 8.0"
```

A common installation location for installation from a ZIP archive is `C:\mysql`:

```
C:\> cd C:\mysql
```

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 2.3.5.7, “Customizing the PATH for MySQL Tools”](#).

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
C:\> bin\mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql          |
| performance_schema |
| sys            |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed MySQL using MySQL Installer, the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You must use those options if you have already secured the initial MySQL accounts.) With `-p`, the client program prompts for the `root` password. For example:

```
C:\> bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----+
| Databases |
+-----+
| information_schema |
| mysql          |
| performance_schema |
| sys            |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> bin\mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| db           |
| engine_cost  |
| event        |
| func         |
| general_log  |
| gtid_executed |
| help_category |
| help_keyword |
| help_relation |
+-----+
```

```

| help_topic
| innodb_index_stats
| innodb_table_stats
| ndb_binlog_index
| plugin
| proc
| procs_priv
| proxies_priv
| server_cost
| servers
| slave_master_info
| slave_relay_log_info
| slave_worker_info
| slow_log
| tables_priv
| time_zone
| time_zone_leap_second
| time_zone_name
| time_zone_transition
| time_zone_transition_type
| user
+-----+

```

Use the `mysql` program to select information from a table in the `mysql` database:

```

C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+-----+-----+
| User | Host      | plugin                |
+-----+-----+-----+
| root | localhost | caching_sha2_password |
+-----+-----+-----+

```

For more information about `mysql` and `mysqlshow`, see [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.8 Upgrading MySQL on Windows

There are two approaches for upgrading MySQL on Windows:

- Using MySQL Installer
- Using the Windows ZIP archive distribution

The approach you select depends on how the existing installation was performed. Before proceeding, review [Section 2.11.1, “Upgrading MySQL”](#) for additional information on upgrading MySQL that is not specific to Windows.

Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server.

Upgrading MySQL with MySQL Installer

Performing an upgrade with MySQL Installer is the best approach when the current server installation was performed with it and the upgrade is within the current release series. MySQL Installer does not support upgrades between release series, such as from 5.7 to 8.0, and it does not provide an upgrade indicator to prompt you to upgrade. For instruction on upgrading between release series, see [Upgrading MySQL Using the Windows ZIP Distribution](#).

To perform an upgrade using MySQL Installer:

1. Start MySQL Installer.

2. From the dashboard, click **Catalog** to download the latest changes to the catalog. The installed server can be upgraded only if the dashboard displays an arrow next to the version number of the server.
3. Click **Upgrade**. All products that have newer versions will appear in a list.

Note

For server milestone releases in the same release series, MySQL Installer deselects the server upgrade and displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform an upgrade manually. You can reselect server upgrade and proceed at your own risk.

4. Deselect all but the MySQL server product, unless you intend to upgrade other products at this time, and click **Next**.
5. Click **Execute** to start the download. When the download finishes, click **Next** to apply the updates.
6. Configure the server.

Upgrading MySQL Using the Windows ZIP Distribution

To perform an upgrade using the Windows ZIP archive distribution:

1. Always back up your current MySQL installation before performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).
2. Download the latest Windows ZIP Archive distribution of MySQL from <https://dev.mysql.com/downloads/>.
3. Before upgrading MySQL, stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.7 to 8.0, use `mysqladmin` from MySQL 5.7 as follows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, invoke `mysqladmin` with the `-p` option and enter the password when prompted.

4. Extract the ZIP archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql8`. Overwriting the existing installation is recommended.
5. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).)
6. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
7. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

8. If you encounter errors, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

2.4 Installing MySQL on macOS

For a list of macOS versions that the MySQL server supports, see <https://www.mysql.com/support/supportedplatforms/database.html>.

MySQL for macOS is available in a number of different forms:

- **Native Package Installer**, which uses the native macOS installer (DMG) to walk you through the installation of MySQL. For more information, see [Section 2.4.2, “Installing MySQL on macOS Using Native Packages”](#). You can use the package installer with macOS. The user you use to perform the installation must have administrator privileges.
- **Compressed TAR archive**, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

In addition to the core installation, the Package Installer also includes [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#) and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#) to simplify the management of your installation.

For additional information on using MySQL on macOS, see [Section 2.4.1, “General Notes on Installing MySQL on macOS”](#).

2.4.1 General Notes on Installing MySQL on macOS

You should keep the following issues and notes in mind:

- **Other MySQL installations:** The installation procedure does not recognize MySQL installations by package managers such as Homebrew. The installation and upgrade process is for MySQL packages provided by us. If other installations are present, then consider stopping them before executing this installer to avoid port conflicts.

Homebrew: For example, if you installed MySQL Server using Homebrew to its default location then the MySQL installer installs to a different location and won't upgrade the version from Homebrew. In this scenario you would end up with multiple MySQL installations that, by default, attempt to use the same ports. Stop the other MySQL Server instances before running this installer, such as executing `brew services stop mysql` to stop the Homebrew's MySQL service.
- **Launchd:** A launchd daemon is installed that alters MySQL configuration options. Consider editing it if needed, see the documentation below for additional information. Also, macOS 10.10 removed startup item support in favor of launchd daemons. The optional MySQL preference pane under macOS **System Preferences** uses the launchd daemon.
- **Users:** You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the `Directory Utility`, and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.
- **Data:** Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will

need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory. By default, the MySQL directories are installed under `/usr/local/`.

- **Aliases:** You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 4.2.1, "Invoking MySQL Programs"](#).

- **Removing:** After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.
- **Legacy:** Prior to OS X 10.7, MySQL server was bundled with OS X Server.

2.4.2 Installing MySQL on macOS Using Native Packages

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

Note

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on macOS Server), the preference pane, or `mysqladmin shutdown` on the command line.

To install MySQL using the package installer:

1. Download the disk image (`.dmg`) file (the community version is available [here](#)) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

Double-click the MySQL installer package from the disk. It is named according to the version of MySQL you have downloaded. For example, for MySQL server 8.0.15 it might be named `mysql-8.0.15-osx-10.13-x86_64.pkg`.

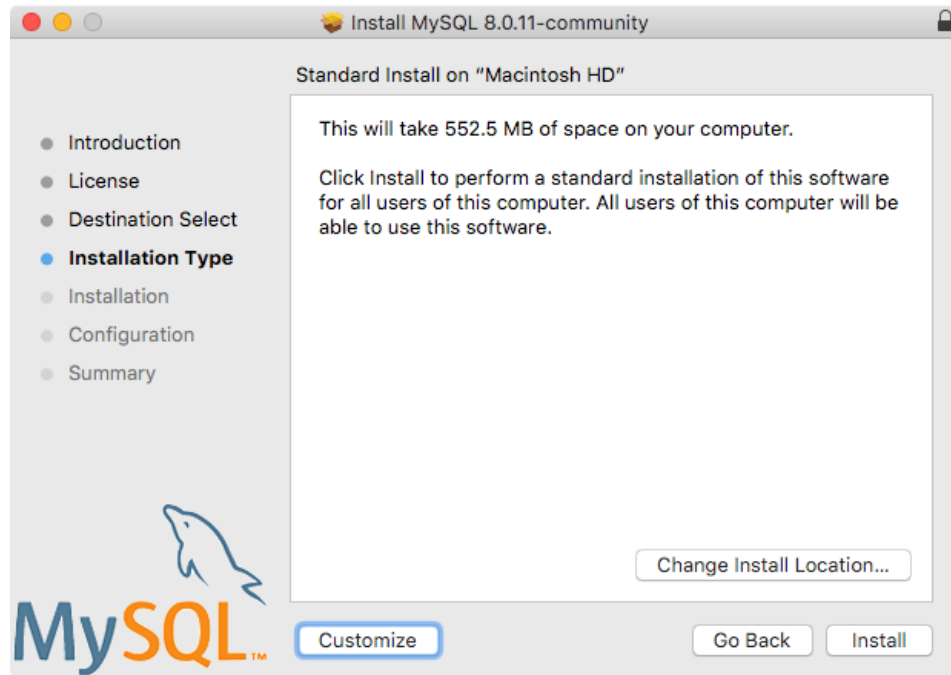

2. The initial wizard introduction screen references the MySQL server version to install. Click **Continue** to begin the installation.

The MySQL community edition shows a copy of the relevant GNU General Public License. Click **Continue** and then **Agree** to continue.

3. From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, MySQL Test, Preference Pane, Launchd Support -- all but MySQL Test are enabled by default).

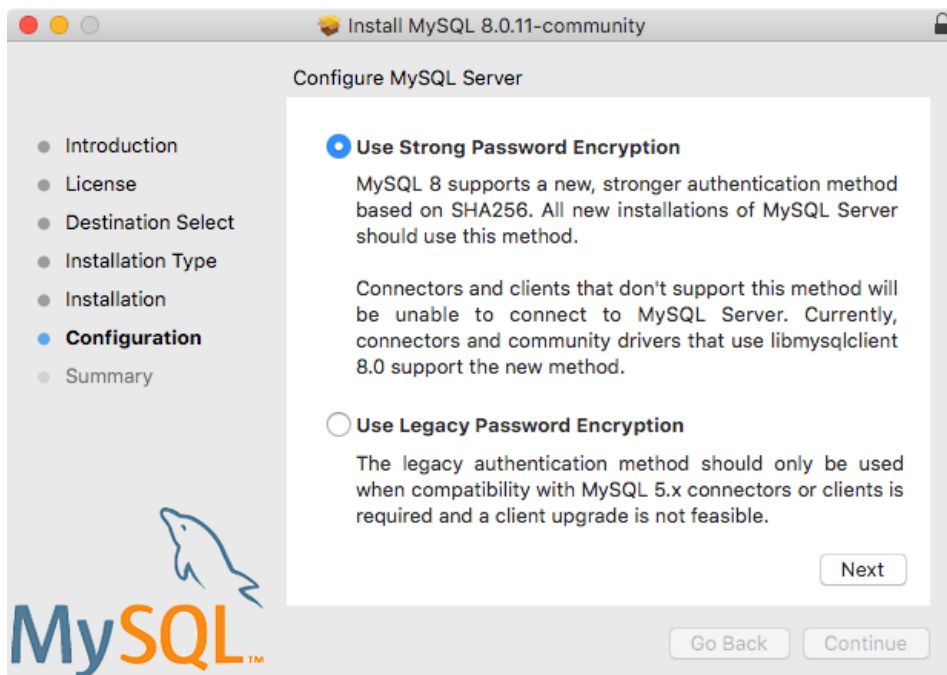

**Note**

Although the **Change Install Location** option is visible, the installation location cannot be changed.

Figure 2.20 MySQL Package Installer Wizard: Installation Type**Figure 2.21 MySQL Package Installer Wizard: Customize**

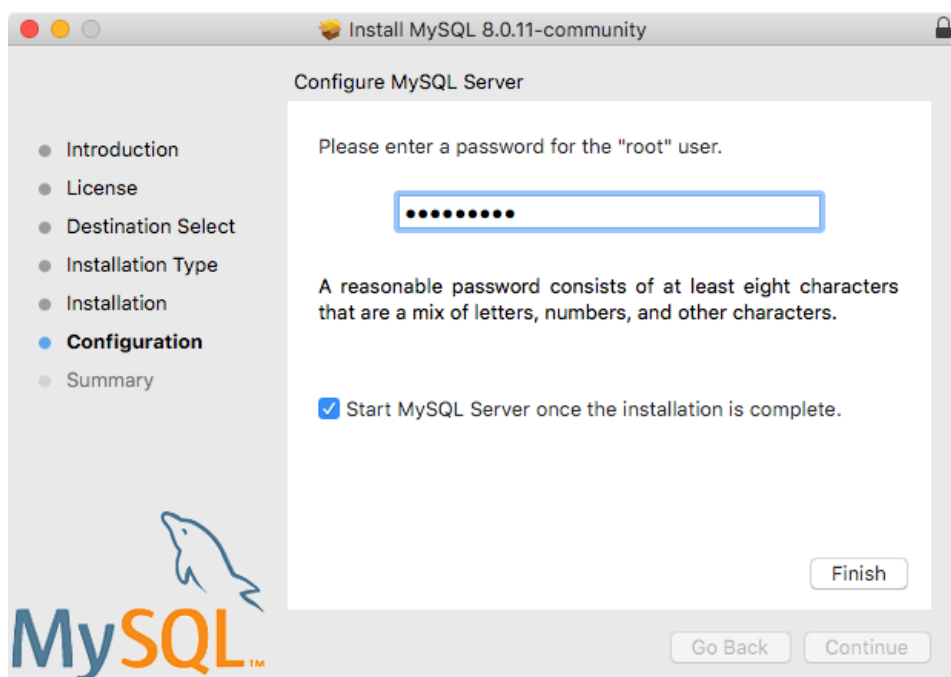

4. Click **Install** to install MySQL Server. The installation process ends here if upgrading a current MySQL Server installation, otherwise follow the wizard's additional configuration steps for your new MySQL Server installation.
5. After a successful new MySQL Server installation, complete the configuration steps by choosing the default encryption type for passwords, define the root password, and also enable (or disable) MySQL server at startup.
6. The default MySQL 8.0 password mechanism is `caching_sha2_password` (Strong), and this step allows you to change it to `mysql_native_password` (Legacy).

Figure 2.22 MySQL Package Installer Wizard: Choose a Password Encryption Type

Choosing the legacy password mechanism alters the generated `launchd` file to set `--default_authentication_plugin=mysql_native_password` under `ProgramArguments`. Choosing strong password encryption does not set `--default_authentication_plugin` because the default MySQL Server value is used, which is `caching_sha2_password`.

7. Define a password for the root user, and also toggle whether MySQL Server should start after the configuration step is complete.

Figure 2.23 MySQL Package Installer Wizard: Define Root Password

8. **Summary** is the final step and references a successful and complete MySQL Server installation. **Close** the wizard.

Figure 2.24 MySQL Package Installer Wizard: Summary

MySQL server is now installed. If you chose to not start MySQL, then use either `launchctl` from the command line or start MySQL by clicking "Start" using the MySQL preference pane. For additional information, see [Section 2.4.3, "Installing and Using the MySQL Launch Daemon"](#), and [Section 2.4.4,](#)

“Installing and Using the MySQL Preference Pane”. Use the MySQL Preference Pane or `launchd` to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-8.0.15-osx10.13-x86_64.dmg` installs MySQL into `/usr/local/mysql-8.0.15-osx10.13-x86_64/` with a symlink to `/usr/local/mysql`. The following table shows the layout of this MySQL installation directory.

Table 2.6 MySQL Installation Layout on macOS

Directory	Contents of Directory
<code>bin</code>	<code>mysqld</code> server, client and utility programs
<code>data</code>	Log files, databases, where <code>/usr/local/mysql/data/mysqld.local.err</code> is the default error log
<code>docs</code>	Helper documents, like the Release Notes and build information
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>man</code>	Unix manual pages
<code>mysql-test</code>	MySQL test suite ('MySQL Test' is disabled by default during the installation process when using the installer package (DMG))
<code>share</code>	Miscellaneous support files, including error messages, sample configuration files, SQL for database installation
<code>support-files</code>	Scripts and sample configuration files
<code>/tmp/mysql.sock</code>	Location of the MySQL Unix socket

2.4.3 Installing and Using the MySQL Launch Daemon

macOS uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

By default, the installation package (DMG) on macOS installs a `launchd` file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd"
<plist version="1.0">
<dict>
  <key>Label</key>          <string>com.oracle.oss.mysql.mysqld</string>
  <key>ProcessType</key>    <string>Interactive</string>
  <key>Disabled</key>       <false/>
  <key>RunAtLoad</key>      <true/>
  <key>KeepAlive</key>      <true/>
  <key>SessionCreate</key>  <true/>
  <key>LaunchOnlyOnce</key> <false/>
  <key>UserName</key>       <string>_mysql</string>
  <key>GroupName</key>     <string>_mysql</string>
  <key>ExitTimeOut</key>    <integer>600</integer>
  <key>Program</key>       <string>/usr/local/mysql/bin/mysqld</string>
  <key>ProgramArguments</key>
    <array>
      <string>/usr/local/mysql/bin/mysqld</string>
```

```

<string>--user=_mysql</string>
<string>--basedir=/usr/local/mysql</string>
<string>--datadir=/usr/local/mysql/data</string>
<string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
<string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
<string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
<string>--keyring-file-data=/usr/local/mysql/keyring/keyring</string>
<string>--early-plugin-load=keyring_file=keyring_file.so</string>
</array>
<key>WorkingDirectory</key> <string>/usr/local/mysql</string>
</dict>
</plist>

```

Note

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it's a copy-n-paste error. The md5 checksum of a file containing the above snippet is *d925f05f6d1b6ee5ce5451b596d6baed*.

To enable the launchd service, you can either:

- Open macOS system preferences and select the MySQL preference panel, and then execute **Start MySQL Server**.

Figure 2.25 MySQL Preference Pane: Location

The **Instances** page includes an option to start or stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.

Figure 2.26 MySQL Preference Pane: Instances

- Or, manually load the launchd file.

```
shell> cd /Library/LaunchDaemons
shell> sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
```

- To configure MySQL to automatically start at bootup, you can:

```
shell> sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
```

Note

When upgrading MySQL server, the launchd installation process will remove the old startup items that were installed with MySQL server 5.7.7 and below.

Also, upgrading will replace your existing launchd file named `com.oracle.oss.mysql.mysqld.plist`.

Additional launchd related information:

- The plist entries override `my.cnf` entries, because they are passed in as command line arguments. For additional information about passing in program options, see [Section 4.2.4, “Specifying Program Options”](#).
- The **ProgramArguments** section defines the command line options that are passed into the program, which is the `mysqld` binary in this case.
- The default plist definition is written with less sophisticated use cases in mind. For more complicated setups, you may want to remove some of the arguments and instead rely on a MySQL configuration file, such as `my.cnf`.
- If you edit the plist file, then uncheck the installer option when reinstalling or upgrading MySQL. Otherwise, your edited plist file will be overwritten, and all edits will be lost.

Because the default plist definition defines several **ProgramArguments**, you might remove most of these arguments and instead rely upon your `my.cnf` MySQL configuration file to define them. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.0.dtd">
<plist version="1.0">
<dict>
  <key>Label</key>          <string>com.oracle.oss.mysql.mysqld</string>
  <key>ProcessType</key>    <string>Interactive</string>
  <key>Disabled</key>       <false/>
  <key>RunAtLoad</key>      <true/>
  <key>KeepAlive</key>      <true/>
  <key>SessionCreate</key>  <true/>
  <key>LaunchOnlyOnce</key> <false/>
  <key>UserName</key>       <string>_mysql</string>
  <key>GroupName</key>     <string>_mysql</string>
  <key>ExitTimeOut</key>    <integer>600</integer>
  <key>Program</key>       <string>/usr/local/mysql/bin/mysqld</string>
  <key>ProgramArguments</key>
    <array>
      <string>/usr/local/mysql/bin/mysqld</string>
      <string>--user=_mysql</string>
      <string>--basedir=/usr/local/mysql</string>
      <string>--datadir=/usr/local/mysql/data</string>
      <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
      <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
      <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
      <string>--keyring-file-data=/usr/local/mysql/keyring/keyring</string>
      <string>--early-plugin-load=keyring_file=keyring_file.so</string>
    </array>
  <key>WorkingDirectory</key> <string>/usr/local/mysql</string>
</dict>
</plist>
```

In this case, the `basedir`, `datadir`, `plugin_dir`, `log_error`, `pid_file`, `keyring_file_data`, and `--early-plugin-load` options were removed from the default plist *ProgramArguments* definition, which you might have defined in `my.cnf` instead.

2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

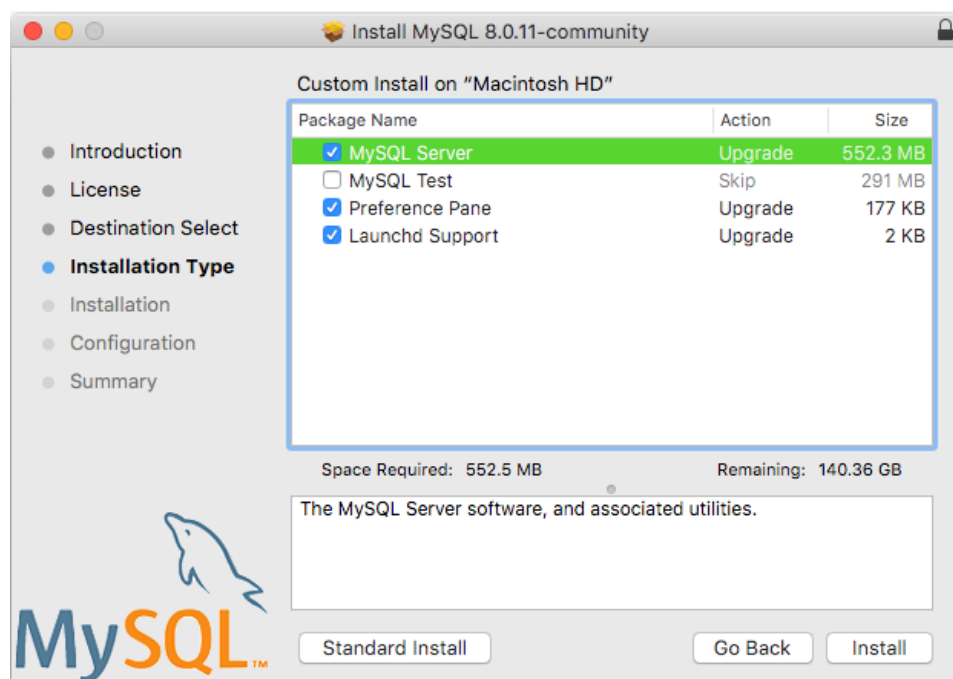

This preference pane is installed by default, and is listed under your system's *System Preferences* window.

Figure 2.27 MySQL Preference Pane: Location

The MySQL preference pane is installed with the same DMG file that installs MySQL Server. Typically it is installed with MySQL Server but it can be installed by itself too.

To install the MySQL preference pane:

1. Go through the process of installing the MySQL server, as described in the documentation at [Section 2.4.2, "Installing MySQL on macOS Using Native Packages"](#).
2. Click **Customize** at the **Installation Type** step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected. The other options, such as MySQL Server, can be selected or deselected.

Figure 2.28 MySQL Package Installer Wizard: Customize

3. Complete the installation process.

Note

The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using this preference pane.

The **Instances** page includes an option to start and stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the pain and launchd information.

The **Instances** page includes an option to start or stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.

Figure 2.29 MySQL Preference Pane: Instances

The **Configuration** page shows MySQL Server options including the path to the MySQL configuration file.

Figure 2.30 MySQL Preference Pane: Configuration

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

Table 2.7 Linux Installation Methods and Information

Type	Setup Method	Additional Information
Apt	Enable the MySQL Apt repository	Documentation
Yum	Enable the MySQL Yum repository	Documentation
Zypper	Enable the MySQL SLES repository	Documentation
RPM	Download a specific package	Documentation
DEB	Download a specific package	Documentation
Generic	Download a generic package	Documentation
Source	Compile from source	Documentation

Type	Setup Method	Additional Information
Docker	Use Docker Hub, Docker Store, or Oracle Container Registry	Documentation
Oracle Unbreakable Linux Network	Use ULN channels	Documentation

As an alternative, you can use the package manager on your system to automatically download and install MySQL with packages from the native software repositories of your Linux distribution. These native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. For more information on using the native package installers, see [Section 2.5.7, “Installing MySQL on Linux from the Native Software Repositories”](#).

Note

For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).

2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

The [MySQL Yum repository](#) for Oracle Linux, Red Hat Enterprise Linux, CentOS, and Fedora provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, MySQL Router, MySQL Shell, Connector/ODBC, Connector/Python and so on (not all packages are available for all the distributions; see [Installing Additional MySQL Products and Components with Yum](#) for details).

Before You Start

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system using a third-party-distributed RPM package; if that is not the case, follow the instructions given in [Section 2.11.1.6, “Upgrading MySQL with the MySQL Yum Repository”](#) or [Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository](#).

Steps for a Fresh Installation of MySQL

Follow the steps below to install the latest GA version of MySQL with the MySQL Yum repository:

Adding the MySQL Yum Repository

First, add the MySQL Yum repository to your system's repository list. This is a one-time operation, which can be performed by installing an RPM provided by MySQL. Follow these steps:

- Go to the Download MySQL Yum Repository page (<https://dev.mysql.com/downloads/repo/yum/>) in the MySQL Developer Zone.
- Select and download the release package for your platform.

- c. Install the downloaded release package with the following command, replacing *platform-and-version-specific-package-name* with the name of the downloaded RPM package:

```
shell> sudo yum localinstall platform-and-version-specific-package-name.rpm
```

For an EL6-based system, the command is in the form of:

```
shell> sudo yum localinstall mysql80-community-release-el6-{version-number}.noarch.rpm
```

For an EL7-based system:

```
shell> sudo yum localinstall mysql80-community-release-el7-{version-number}.noarch.rpm
```

For Fedora 28:

```
shell> sudo dnf localinstall mysql80-community-release-fc28-{version-number}.noarch.rpm
```

For Fedora 27:

```
shell> sudo dnf localinstall mysql80-community-release-fc27-{version-number}.noarch.rpm
```

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See [Section 2.1.3.2, “Signature Checking Using GnuPG”](#) for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep "mysql.*-community.*"
```

Note

Once the MySQL Yum repository is enabled on your system, any system-wide update by the `yum update` command (or `dnf upgrade` for dnf-enabled systems) will upgrade MySQL packages on your system and also replace any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see [Section 2.11.1.6, “Upgrading MySQL with the MySQL Yum Repository”](#) and, for a discussion on some possible effects of that on your system, see [Upgrading the Shared Client Libraries](#).

Selecting a Release Series

When using the MySQL Yum repository, the latest GA series (currently MySQL 8.0) is selected for installation by default. If this is what you want, you can skip to the next step, [Installing MySQL](#).

Within the MySQL Yum repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest GA series (currently MySQL 8.0) is enabled by default, and the subrepositories for all other series (for example, the MySQL 8.0 series) are disabled by default. Use this command to see all the subrepositories in the MySQL Yum repository, and see which of them are enabled or disabled (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist all | grep mysql
```

To install the latest release from the latest GA series, no configuration is needed. To install the latest release from a specific series other than the latest GA series, disable the subrepository for the latest GA series and enable the subrepository for the specific series before running the installation command. If your platform supports `yum-config-manager`, you can do that by issuing these commands, which disable the subrepository for the 5.7 series and enable the one for the 8.0 series:

```
shell> sudo yum-config-manager --disable mysql57-community
shell> sudo yum-config-manager --enable mysql80-community
```

For dnf-enabled platforms:

```
shell> sudo dnf config-manager --disable mysql57-community
shell> sudo dnf config-manager --enable mysql80-community
```

Besides using `yum-config-manager` or the `dnf config-manager` command, you can also select a release series by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is a typical entry for a release series' subrepository in the file:

```
[mysql57-community]
name=MySQL 5.7 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.7-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Find the entry for the subrepository you want to configure, and edit the `enabled` option. Specify `enabled=0` to disable a subrepository, or `enabled=1` to enable a subrepository. For example, to install MySQL 8.0, make sure you have `enabled=0` for the above subrepository entry for MySQL 5.7, and have `enabled=1` for the entry for the 8.0 series:

```
# Enable to use MySQL 8.0
[mysql80-community]
name=MySQL 8.0 Community Server
baseurl=http://repo.mysql.com/yum/mysql-8.0-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

You should only enable subrepository for one release series at any time. When subrepositories for more than one release series are enabled, the latest series will be used by Yum.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep mysql
```

Installing MySQL

Install MySQL by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

Starting the MySQL Server

Start the MySQL server with the following command:

```
shell> sudo service mysqld start
Starting mysqld: [ OK ]
```

You can check the status of the MySQL server with the following command:

```
shell> sudo service mysqld status
mysqld (pid 3066) is running.
```

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account '`root`'@'`localhost`' is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command:

```
shell> sudo grep 'temporary password' /var/log/mysqld.log
```

Change the root password as soon as possible by logging in with the generated, temporary password and set a custom password for the superuser account:

```
shell> mysql -uroot -p
```

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one upper case letter, one lower case letter, one digit, and one special character, and that the total password length is at least 8 characters.

For more information on the postinstallation procedures, see [Section 2.10, “Postinstallation Setup and Testing”](#).

Note

Compatibility Information for EL7-based platforms: The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once

you have installed MySQL using the MySQL Yum repository, you will not be able to install these packages (and vice versa).

- `akonadi-mysql`

Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum --disablerepo=* --enablerepo='mysql*-community*' list available
```

Install any packages of your choice with the following command, replacing `package-name` with name of the package (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install package-name
```

For example, to install MySQL Workbench on Fedora:

```
shell> sudo dnf install mysql-workbench-community
```

To install the shared client libraries (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-libs
```

Platform Specific Notes

ARM Support

ARM 64-bit (aarch64) is supported on Oracle Linux 7 and requires the Oracle Linux 7 Software Collections Repository (`ol7_software_collections`). For example, to install the server:

```
shell> yum-config-manager --enable ol7_software_collections
shell> yum install mysql-community-server
```

Note

ARM 64-bit (aarch64) is supported on Oracle Linux 7 as of MySQL 8.0.12.

Known Limitation

The 8.0.12 release requires you to adjust the `libstdc++7` path by executing `ln -s /opt/oracle/oracle-armtoolset-1/root/usr/lib64 /usr/lib64/gcc7` after executing the `yum install` step.

Updating MySQL with Yum

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See [Section 2.11.1.6, “Upgrading MySQL with the MySQL Yum Repository”](#) for details.

2.5.2 Installing MySQL on Linux Using the MySQL APT Repository

The MySQL APT repository provides [deb](#) packages for installing and managing the MySQL server, client, and other components on the following Linux platforms:

- Debian 9
- Ubuntu 16.04, 17.10, and 18.04

Instructions for using the MySQL APT Repository are available in [A Quick Guide to Using the MySQL APT Repository](#).

2.5.3 Installing MySQL on Linux Using the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Instructions for using the MySQL SLES repository are available in [A Quick Guide to Using the MySQL SLES Repository](#).

2.5.4 Installing MySQL on Linux Using RPM Packages from Oracle

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages provided by Oracle. There are two sources for obtaining them, for the Community Edition of MySQL:

- From the MySQL software repositories:
 - The MySQL Yum repository (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details).
 - The MySQL SLES repository (see [Section 2.5.3, “Installing MySQL on Linux Using the MySQL SLES Repository”](#) for details).
- From the [Download MySQL Community Server](#) page in the [MySQL Developer Zone](#).

Note

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the installation instructions in this manual do not necessarily apply to them. The vendor's instructions should be consulted instead.

MySQL RPM Packages

Table 2.8 RPM Packages for MySQL Community Edition

Package Name	Summary
mysql-community- client	MySQL client applications and tools
mysql-community- common	Common files for server and client libraries
mysql-community- devel	Development header files and libraries for MySQL database client applications
mysql-community- embedded-compat	MySQL server as an embedded library

Package Name	Summary
	with compatibility for applications using version 18 of the library
mysql-community-libs	Shared libraries for MySQL database client applications
mysql-community-libs-compat	Shared compatibility libraries for previous MySQL installations
mysql-community-minimal-debuginfo	Debug information for package mysql-community-server-minimal; useful when developing applications that use this package or when debugging this package
mysql-community-server	Database server and related tools
mysql-community-server-minimal	Minimal installation of the database server and related tools
mysql-community-test	Test suite for the MySQL server
mysql-community-	The source code RPM looks similar to mysql-community-8.0.15-1.el7.src.rpm, depending on selected OS

Table 2.9 RPM Packages for the MySQL Enterprise Edition

Package Name	Summary
mysql-commercial-backup	MySQL Enterprise Backup (added in 8.0.11)
mysql-commercial-client	MySQL client applications and tools
mysql-commercial-common	Common files for server and client libraries
mysql-commercial-devel	Development header files and libraries for MySQL database client applications
mysql-commercial-embedded-compat	MySQL server as an embedded library with compatibility for applications using version 18 of the library

Package Name	Summary
mysql-commercial- libs	Shared libraries for MySQL database client applications
mysql-commercial- libs-compat	Shared compatibility libraries for previous MySQL installations; the version of the libraries matches the version of the libraries installed by default by the distribution you are using
mysql-commercial- minimal-debuginfo	Debug information for package mysql-commercial-server-minimal; useful when developing applications that use this package or when debugging this package
mysql-commercial- server	Database server and related tools
mysql-commercial- server-minimal	Minimal installation of the database server and related tools (added in 8.0.0)
mysql-commercial- test	Test suite for the MySQL server

The full names for the RPMs have the following syntax:

```
packagename-version-distribution-arch.rpm
```

The [distribution](#) and [arch](#) values indicate the Linux distribution and the processor type for which the package was built. See the table below for lists of the distribution identifiers:

Table 2.10 MySQL Linux RPM Package Distribution Identifiers

distribution Value	Intended Use
el6 , el7	Red Hat Enterprise Linux/Oracle Linux/CentOS 6 or 7
fc27 , fc28	Fedora 27 and 28
sles12	SUSE Linux Enterprise Server 12

To see all files in an RPM package (for example, [mysql-community-server](#)), use the following command:

```
shell> rpm -qpl mysql-community-server-version-distribution-arch.rpm
```

The discussion in the rest of this section applies only to an installation process using the RPM packages directly downloaded from Oracle, instead of through a MySQL repository.

Dependency relationships exist among some of the packages. If you plan to install many of the packages, you may wish to download the RPM bundle `tar` file instead, which contains all the RPM packages listed above, so that you need not download them separately.

In most cases, you need to install the `mysql-community-server`, `mysql-community-client`, `mysql-community-libs`, `mysql-community-common`, and `mysql-community-libs-compat` packages to get a functional, standard MySQL installation. To perform such a standard, basic installation, go to the folder that contains all those packages (and, preferably, no other RPM packages with similar names), and issue the following command:

```
shell> sudo yum install mysql-community-{server,client,common,libs}-* --exclude='*minimal*'
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

While it is much preferable to use a high-level package management tool like `yum` to install the packages, users who prefer direct `rpm` commands can replace the `yum install` command with the `rpm -Uvh` command; however, using `rpm -Uvh` instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

To install only the client programs, you can skip `mysql-community-server` in your list of packages to install; issue the following command:

```
shell> sudo yum install mysql-community-{client,common,libs}-*
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

A standard installation of MySQL using the RPM packages result in files and resources created under the system directories, shown in the following table.

Table 2.11 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone

Files or Resources	Location
Client programs and scripts	<code>/usr/bin</code>
<code>mysqld</code> server	<code>/usr/sbin</code>
Configuration file	<code>/etc/my.cnf</code>
Data directory	<code>/var/lib/mysql</code>
Error log file	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>/var/log/mysqld.log</code> For SLES: <code>/var/log/mysql/mysqld.log</code>
Value of <code>secure_file_priv</code>	<code>/var/lib/mysql-files</code>
System V init script	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>/etc/init.d/mysqld</code> For SLES: <code>/etc/init.d/mysql</code>
Systemd service	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>mysqld</code> For SLES: <code>mysql</code>
Pid file	<code>/var/run/mysql/mysqld.pid</code>
Socket	<code>/var/lib/mysql/mysql.sock</code>

Files or Resources	Location
Keyring directory	<code>/var/lib/mysql-keyring</code>
Unix manual pages	<code>/usr/share/man</code>
Include (header) files	<code>/usr/include/mysql</code>
Libraries	<code>/usr/lib/mysql</code>
Miscellaneous support files (for example, error messages, and character set files)	<code>/usr/share/mysql</code>

The installation also creates a user named `mysql` and a group named `mysql` on the system.

Note

Installation of previous versions of MySQL using older packages might have created a configuration file named `/usr/my.cnf`. It is highly recommended that you examine the contents of the file and migrate the desired settings inside to the file `/etc/my.cnf` file, then remove `/usr/my.cnf`.

MySQL is NOT automatically started at the end of the installation process. For Red Hat Enterprise Linux, Oracle Linux, CentOS, and Fedora systems, use the following command to start MySQL:

```
shell> sudo service mysqld start
```

For SLES systems, the command is the same, but the service name is different:

```
shell> sudo service mysql start
```

If the operating system is systemd enabled, standard `service` commands such as `stop`, `start`, `status` and `restart` should be used to manage the MySQL server service. The `mysqld` service is enabled by default, and it starts at system reboot. Notice that certain things might work differently on systemd platforms: for example, changing the location of the data directory might cause issues. See [Section 2.5.9, “Managing MySQL Server with systemd”](#) for additional information.

During an upgrade installation using RPM packages, if the MySQL server is running when the upgrade occurs then the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. One exception: if the edition also changes during an upgrade (such as community to commercial, or vice-versa), then MySQL server is not restarted.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- An SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account `'root'@'localhost'` is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command for RHEL, Oracle Linux, CentOS, and Fedora systems:

```
shell> sudo grep 'temporary password' /var/log/mysqld.log
```

Use the following command for SLES systems:

```
shell> sudo grep 'temporary password' /var/log/mysql/mysqld.log
```

The next step is to log in with the generated, temporary password and set a custom password for the superuser account:

```
shell> mysql -uroot -p
```

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one upper case letter, one lower case letter, one digit, and one special character, and that the total password length is at least 8 characters.

If something goes wrong during installation, you might find debug information in the error log file `/var/log/mysqld.log`.

For some Linux distributions, it might be necessary to increase the limit on number of file descriptors available to `mysqld`. See [Section B.5.2.17, “File Not Found and Similar Errors”](#)

Installing Client Libraries from Multiple MySQL Versions. It is possible to install multiple client library versions, such as for the case that you want to maintain compatibility with older applications linked against previous libraries. To install an older client library, use the `--oldpackage` option with `rpm`. For example, to install `mysql-community-libs-5.5` on an EL6 system that has `libmysqlclient.21` from MySQL 8.0, use a command like this:

```
shell> rpm --oldpackage -ivh mysql-community-libs-5.5.50-2.el6.x86_64.rpm
```

Debug Package. A special variant of MySQL Server compiled with the [debug package](#) has been included in the server RPM packages. It performs debugging and memory allocation checks and produces a trace file when the server is running. To use that debug version, start MySQL with `/usr/sbin/mysqld-debug`, instead of starting it as a service or with `/usr/sbin/mysqld`. See [Section 28.5.3, “The DBUG Package”](#) for the debug options you can use.

Note

The default plugin directory for debug builds changed from `/usr/lib64/mysql/plugin` to `/usr/lib64/mysql/plugin/debug` in MySQL 8.0.4. Previously, it was necessary to change `plugin_dir` to `/usr/lib64/mysql/plugin/debug` for debug builds.

Rebuilding RPMs from source SRPMs. Source code SRPM packages for MySQL are available for download. They can be used as-is to rebuild the MySQL RPMs with the standard `rpmbuild` tool chain.

2.5.5 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The packages are available through two different channels:

- The [MySQL APT Repository](#). This is the preferred method for installing MySQL on Debian-like systems, as it provides a simple and convenient way to install and update MySQL products. For details, see [Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository”](#).

- The [MySQL Developer Zone's Download Area](#). For details, see [Section 2.1.2, “How to Get MySQL”](#). The following are some information on the Debian packages available there and the instructions for installing them:
- Various Debian packages are provided in the MySQL Developer Zone for installing different components of MySQL on different Debian or Ubuntu platforms (currently, Debian 9, and Ubuntu 16, 17, and 18 are supported). The preferred method is to use the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball bundles have names in the format of `mysql-server_MVER-DVER_CPU.deb-bundle.tar`. *MVER* is the MySQL version and *DVER* is the Linux distribution version. The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table:

Table 2.12 MySQL Debian and Ubuntu Installation Packages CPU Identifiers

<i>CPU</i> Value	Intended Processor Type or Family
i386	Pentium processor or better, 32 bit
amd64	64-bit x86 processor

- After downloading the tarball, unpack it with the following command:

```
shell> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar
```

- You may need to install the `libaio` library if it is not already present on your system:

```
shell> sudo apt-get install libaio1
```

- Preconfigure the MySQL server package with the following command:

```
shell> sudo dpkg-preconfigure mysql-community-server_*.deb
```

You will be asked to provide a password for the root user for your MySQL installation. You might also be asked other questions regarding the installation.

Important

Make sure you remember the root password you set. Users who want to set a password later can leave the **password** field blank in the dialogue box and just press **OK**; in that case, root access to the server is authenticated using the [MySQL Socket Peer-Credential Authentication Plugin](#) for connections using a Unix socket file. You can set the root password later using `mysql_secure_installation`.

- For a basic installation of the MySQL server, install the database common files package, the client package, the client metapackage, the server package, and the server metapackage (in that order); you can do that with a single command:

```
shell> sudo dpkg -i mysql-{common,community-client,client,community-server,server}_*.deb
```

There are also packages with `server-core` and `client-core` in the package names. These contain binaries only and are installed automatically by the standard packages. Installing them by themselves will not result in a functioning MySQL setup.

If you are being warned of unmet dependencies by `dpkg`, you can fix them using `apt-get`:

```
sudo apt-get -f install
```

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is under `/var/lib/mysql`

Note

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

2.5.6 Deploying MySQL on Linux with Docker

The Docker deployment framework supports easy installation and configuration of MySQL Server. This section explains how to use a MySQL Server Docker image.

You need to have Docker installed on your system before you can use a MySQL Server Docker image. See [Install Docker](#) for instructions.

Important

You need to either run `docker` commands with `sudo`, or create a `docker` usergroup, and then add to it any users who want to run `docker` commands. See details [here](#). Because Docker containers are always run with root privileges, you should understand the [Docker daemon attack surface](#) and properly mitigate the related risks.

2.5.6.1 Basic Steps for MySQL Server Deployment with Docker

Warning

The MySQL Docker images maintained by the MySQL team are built specifically for Linux platforms. Other platforms are not supported, and users using these MySQL Docker images on them are doing so at their own risk. See [the discussion here](#) for some known limitations for running these containers on non-Linux operating systems.

Accepting the License Agreement and Logging in with the Docker Client (for MySQL Enterprise Edition)

A subscription is required to use the Docker images for MySQL Enterprise Edition. Subscriptions work by a Bring Your Own License model; see [How to Buy MySQL Products and Services](#) for details. You also need to accept the license agreement and log in to the container repository before downloading the MySQL Enterprise Edition image.

For downloading from the Oracle Container Registry:

- Visit the Oracle Container Registry at <https://container-registry.oracle.com/> and choose **MySQL**.
- Under the list of MySQL repositories, choose `enterprise-server`.
- If you have not signed in to the Oracle Container Registry yet, click the **Sign in** button on the right of the page, and then enter your Oracle account credentials when prompted to.
- Follow the instructions on the right of the page to accept the license agreement.
- Log in to the Oracle Container Registry with your Docker client (the `docker` command). Use the `docker login` command for the purpose:

```
# docker login container-registry.oracle.com
Username: Oracle-Account-ID
Password: password
Login successful.
```

For downloading from the Docker Store:

- Visit the MySQL Server Enterprise Edition page at <https://store.docker.com/images/mysql-enterprise-server>.
- If you have not logged in to the Docker Store yet, do so using the **Log in** link and your Docker credentials.
- Click the **Proceed to Checkout** button that appears.
- Follow the instructions on the right of the page to accept the license agreement.
- Log in to the Docker Store with your Docker client (the `docker` command). Use the `docker login` command for the purpose:

```
# docker login
Username: Docker-ID
Password: password
Login successful.
```

Downloading a MySQL Server Docker Image

Downloading the server image in a separate step is not strictly necessary; however, performing this step before you create your Docker container ensures your local image is up to date. To download the MySQL Community Edition image, run this command:

```
docker pull mysql/mysql-server:tag
```

The `tag` is the label for the image version you want to pull (for example, `5.5`, `5.6`, `5.7`, `8.0`, or `latest`). If `:tag` is omitted, the `latest` label is used, and the image for the latest GA version of MySQL

Community Server is downloaded. Refer to the list of tags for available versions on the [mysql/mysql-server](#) page in the Docker Hub.

You can list downloaded Docker images with this command:

```
shell> docker images
```

REPOSITORY	TAG	IMAGE ID	CREATED	SIZE
mysql/mysql-server	latest	3157d7f55f8d	4 weeks ago	241MB

To download the MySQL Enterprise Edition image from the Docker Store, run this command:

```
docker pull store/oracle/mysql-enterprise-server:tag
```

To download the MySQL Enterprise Edition image from the Oracle Container Registry, run this command:

```
docker pull container-registry.oracle.com/mysql/enterprise-server:tag
```

There are different choices for *tag*, corresponding to the two versions of MySQL Enterprise Edition Docker images provided by the MySQL team at Oracle:

- 8.0, 8.0.x (x is the latest version number in the 8.0 series): MySQL Enterprise Edition 8.0, the latest GA
- 5.7, 5.7.y (y is the latest version number in the 5.7 series): MySQL Enterprise Edition 5.7

Starting a MySQL Server Instance

Start a new Docker container for the MySQL Community Server with this command:

```
docker run --name=mysql11 -d mysql/mysql-server:tag
```

Start a new Docker container for the MySQL Enterprise Server with this command, if the Docker image was downloaded from the Oracle Container Registry:

```
docker run --name=mysql11 -d container-registry.oracle.com/mysql/enterprise-server:tag
```

Start a new Docker container for the MySQL Enterprise Server with this command, if the Docker image was downloaded from the Docker Store:

```
docker run --name=mysql11 -d store/oracle/mysql-enterprise-server:tag
```

The `--name` option, for supplying a custom name for your server container (`mysql11` in the example), is optional; if no container name is supplied, a random one is generated. If the Docker image of the specified name and tag has not been downloaded by an earlier `docker pull` or `docker run` command, the image is now downloaded. After download completes, initialization for the container begins, and the container appears in the list of running containers when you run the `docker ps` command; for example:

```
shell> docker ps
```

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS
a24888f0d6f4	mysql/mysql-server	"/entrypoint.sh my..."	14 seconds ago	Up 13 seconds (health: starti

The container initialization might take some time. When the server is ready for use, the `STATUS` of the container in the output of the `docker ps` command changes from (`health: starting`) to (`healthy`).

The `-d` option used in the `docker run` command above makes the container run in the background. Use this command to monitor the output from the container:

```
docker logs mysql1
```

Once initialization is finished, the command's output is going to contain the random password generated for the root user; check the password with, for example, this command:

```
shell> docker logs mysql1 2>&1 | grep GENERATED
GENERATED ROOT PASSWORD: Axegh3kAJyDLaRuBemecis&EShOs
```

Connecting to MySQL Server from within the Container

Once the server is ready, you can run the `mysql` client within the MySQL Server container you just started, and connect it to the MySQL Server. Use the `docker exec -it` command to start a `mysql` client inside the Docker container you have started, like the following:

```
docker exec -it mysql1 mysql -uroot -p
```

When asked, enter the generated root password (see the last step in [Starting a MySQL Server Instance](#) above on how to find the password). Because the `MYSQLONE TIMEPASSWORD` option is true by default, after you have connected a `mysql` client to the server, you must reset the server root password by issuing this statement:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'password';
```

Substitute `password` with the password of your choice. Once the password is reset, the server is ready for use.

Container Shell Access

To have shell access to your MySQL Server container, use the `docker exec -it` command to start a bash shell inside the container:

```
shell> docker exec -it mysql1 bash
bash-4.2#
```

You can then run Linux commands inside the container. For example, to view contents in the server's data directory inside the container, use this command:

```
bash-4.2# ls /var/lib/mysql
auto.cnf      ca.pem        client-key.pem  ib_logfile0    ibdata1  mysql          mysql.sock.lock  private_key.p
ca-key.pem    client-cert.pem  ib_buffer_pool  ib_logfile1    ibtmp1   mysql.sock     performance_schema  public_
```

Stopping and Deleting a MySQL Container

To stop the MySQL Server container we have created, use this command:

```
docker stop mysql1
```

`docker stop` sends a SIGTERM signal to the `mysqld` process, so that the server is shut down gracefully.

Also notice that when the main process of a container (`mysqld` in the case of a MySQL Server container) is stopped, the Docker container stops automatically.

To start the MySQL Server container again:

```
docker start mysql1
```

To stop and start again the MySQL Server container with a single command:

```
docker restart mysql1
```

To delete the MySQL container, stop it first, and then use the `docker rm` command:

```
docker stop mysql1
```

```
docker rm mysql1
```

If you want the [Docker volume for the server's data directory](#) to be deleted at the same time, add the `-v` option to the `docker rm` command.

Upgrading a MySQL Server Container

Important

- Before performing any upgrade to MySQL, follow carefully the instructions in [Section 2.11.1, “Upgrading MySQL”](#). Among other instructions discussed there, it is especially important to back up your database before the upgrade.
- The instructions in this section require that the server's data and configuration have been persisted on the host. See [Persisting Data and Configuration Changes](#) for details.

Follow these steps to upgrade a Docker installation of MySQL 5.7 to 8.0:

- Stop the MySQL 5.7 server (container name is `mysql57` in this example):

```
docker stop mysql57
```

- Download the MySQL 8.0 Server Docker image. See instructions in [Downloading a MySQL Server Docker Image](#); make sure you use the right tag for MySQL 8.0.
- Start a new MySQL 8.0 Docker container (named `mysql80` in this example) with the old server data and configuration (with proper modifications if needed—see [Section 2.11.1, “Upgrading MySQL”](#)) that have been persisted on the host (by [bind-mounting](#) in this example). For the MySQL Community Server, run this command:

```
docker run --name=mysql80 \
  --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
  --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
  -d mysql/mysql-server:8.0
```

If needed, adjust `mysql/mysql-server` to the correct repository name—for example, replace it with `store/oracle/mysql-enterprise-server` for MySQL Enterprise Edition images from the Docker Store, or with `container-registry.oracle.com/mysql/enterprise-server` for the MySQL Enterprise Edition images from the Oracle Container Registry.

- Wait for the server to finish startup. You can check the status of the server using the `docker ps` command (see [Starting a MySQL Server Instance](#) for how to do that).
- Run the `mysql_upgrade` utility in the MySQL 8.0 Server container:

```
docker exec -it mysql80 mysql_upgrade -uroot -p
```

When prompted, enter the root password for your old MySQL 5.7 Server.

- Finish the upgrade by restarting the MySQL 8.0 Server container:

```
docker restart mysql80
```

More Topics on Deploying MySQL Server with Docker

For more topics on deploying MySQL Server with Docker like server configuration, persisting data and configuration, server error log, and container environment variables, see [Section 2.5.6.2, “More Topics on Deploying MySQL Server with Docker”](#).

2.5.6.2 More Topics on Deploying MySQL Server with Docker

Note

Most of the sample commands below have `mysql/mysql-server` as the Docker image repository when that has to be specified (like with the `docker pull` and `docker run` commands); change that if your image is from another repository—for example, replace it with `store/oracle/mysql-enterprise-server` for MySQL Enterprise Edition images from the Docker Store, or with `container-registry.oracle.com/mysql/enterprise-server` for MySQL Enterprise Edition images from the Oracle Container Registry.

- [Using MySQL Enterprise Backup with Docker](#)
- [Docker Environment Variables](#)

The Optimized MySQL Installation for Docker

Docker images for MySQL are optimized for code size, which means they only include crucial components that are expected to be relevant for the majority of users who run MySQL instances in Docker containers. A MySQL Docker installation is different from a common, non-Docker installation in the following aspects:

- Included binaries are limited to:
 - `/usr/bin/my_print_defaults`
 - `/usr/bin/mysql`
 - `/usr/bin/mysql_config`
 - `/usr/bin/mysql_install_db`
 - `/usr/bin/mysql_tzinfo_to_sql`
 - `/usr/bin/mysql_upgrade`
 - `/usr/bin/mysqladmin`
 - `/usr/bin/mysqlcheck`
 - `/usr/bin/mysqldump`

- `/usr/bin/mysqldump`
- `/usr/bin/mysqlbackup` (for MySQL Enterprise Edition 8.0 only)
- `/usr/sbin/mysqld`
- All binaries are stripped; they contain no debug information.

Configuring the MySQL Server

When you start the MySQL Docker container, you can pass configuration options to the server through the `docker run` command; for example:

```
docker run --name mysql1 -d mysql/mysql-server:tag --character-set-server=utf8mb4 --collation-server=utf8mb4_c
```

The command starts your MySQL Server with `utf8mb4` as the default character set and `utf8mb4_col` as the default collation for your databases.

Another way to configure the MySQL Server is to prepare a configuration file and mount it at the location of the server configuration file inside the container. See [Persisting Data and Configuration Changes](#) for details.

Persisting Data and Configuration Changes

Docker containers are in principle ephemeral, and any data or configuration are expected to be lost if the container is deleted or corrupted (see discussions [here](#)). [Docker volumes](#), however, provides a mechanism to persist data created inside a Docker container. At its initialization, the MySQL Server container creates a Docker volume for the server data directory. The JSON output for running the `docker inspect` command on the container has a `Mount` key, whose value provides information on the data directory volume:

```
shell> docker inspect mysql1
...
  "Mounts": [
    {
      "Type": "volume",
      "Name": "4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652",
      "Source": "/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data",
      "Destination": "/var/lib/mysql",
      "Driver": "local",
      "Mode": "",
      "RW": true,
      "Propagation": ""
    }
  ],
  ...
```

The output shows that the source folder `/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data`, in which data is persisted on the host, has been mounted at `/var/lib/mysql`, the server data directory inside the container.

Another way to preserve data is to [bind-mount](#) a host directory using the `--mount` option when creating the container. The same technique can be used to persist the configuration of the server. The following command creates a MySQL Server container and bind-mounts both the data directory and the server configuration file:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
--mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
-d mysql/mysql-server:tag
```

The command mounts `path-on-host-machine/my.cnf` at `/etc/my.cnf` (the server configuration file inside the container), and `path-on-host-machine/datadir` at `/var/lib/mysql` (the data directory inside the container). The following conditions must be met for the bind-mounting to work:

- The configuration file `path-on-host-machine/my.cnf` must already exist, and it must contain the specification for starting the server using the user `mysql`:

```
[mysqld]
user=mysql
```

You can also include other server configuration options in the file.

- The data directory `path-on-host-machine/datadir` must already exist. For server initialization to happen, the directory must be empty. You can also mount a directory prepopulated with data and start the server with it; however, you must make sure you start the Docker container with the same configuration as the server that created the data, and any host files or directories required are mounted when starting the container.

Running Additional Initialization Scripts

If there are any `.sh` or `.sql` scripts you want to run on the database immediately after it has been created, you can put them into a host directory and then mount the directory at `/docker-entrypoint-initdb.d/` inside the container. For example:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/scripts/,dst=/docker-entrypoint-initdb.d/ \
-d mysql/mysql-server:tag
```

Connect to MySQL from an Application in Another Docker Container

By setting up a Docker network, you can allow multiple Docker containers to communicate with each other, so that a client application in another Docker container can access the MySQL Server in the server container. First, create a Docker network:

```
docker network create my-custom-net
```

Then, when you are creating and starting the server and the client containers, use the `--network` option to put them on network you created. For example:

```
docker run --name=mysql1 --network=my-custom-net -d mysql/mysql-server
```

```
docker run --name=myapp1 --network=my-custom-net -d myapp
```

The `myapp1` container can then connect to the `mysql1` container with the `mysql1` hostname and vice versa, as Docker automatically sets up a DNS for the given container names. In the following example, we run the `mysql` client from inside the `myapp1` container to connect to host `mysql1` in its own container:

```
docker exec -it myapp1 mysql --host=mysql1 --user=myuser --password
```

For other networking techniques for containers, see the [Docker container networking](#) section in the Docker Documentation.

Server Error Log

When the MySQL Server is first started with your server container, a [server error log](#) is NOT generated if either of the following conditions is true:

- A server configuration file from the host has been mounted, but the file does not contain the system variable `log_error` (see [Persisting Data and Configuration Changes](#) on bind-mounting a server configuration file).

- A server configuration file from the host has not been mounted, but the Docker environment variable `MYSQL_LOG_CONSOLE` is `true` (which is the variable's default state for MySQL 8.0 server containers). The MySQL Server's error log is then redirected to `stderr`, so that the error log goes into the Docker container's log and is viewable using the `docker logs mysql-d-container` command.

To make MySQL Server generate an error log when either of the two conditions is true, use the `--log-error` option to [configure the server](#) to generate the error log at a specific location inside the container. To persist the error log, mount a host file at the location of the error log inside the container as explained in [Persisting Data and Configuration Changes](#). However, you must make sure your MySQL Server inside its container has write access to the mounted host file.

Using MySQL Enterprise Backup with Docker

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). MySQL Enterprise Backup is included in the Docker installation of MySQL Enterprise Edition.

In the following example, we assume that you already have a MySQL Server running in a Docker container (see [Section 2.5.6.1, “Basic Steps for MySQL Server Deployment with Docker”](#) on how to start a MySQL Server instance with Docker). For MySQL Enterprise Backup to back up the MySQL Server, it must have access to the server's data directory. This can be achieved by, for example, [bind-mounting a host directory on the data directory of the MySQL Server](#) when you start the server:

```
docker run --name=mysqlserver \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
-d store/oracle/mysql-enterprise-server:8.0
```

With this command, the MySQL Server is started with a Docker image of the MySQL Enterprise Edition, and the host directory `/path-on-host-machine/datadir/` has been mounted onto the server's data directory (`/var/lib/mysql`) inside the server container. We also assume that, after the server has been started, the required privileges have also been set up for MySQL Enterprise Backup to access the server (see [Grant MySQL Privileges to Backup Administrator](#) for details). Use the following steps then to backup and restore a MySQL Server instance.

To backup a MySQL Server instance running in a Docker container using MySQL Enterprise Backup with Docker.

1. On the same host where the MySQL Server container is running, start another container with an image of MySQL Enterprise Edition to perform a back up with the MySQL Enterprise Backup command `backup-to-image`. Provide access to the server's data directory using the bind mount we created in the last step. Also, mount a host directory (`/path-on-host-machine/backups/` in this example) onto the storage folder for backups in the container (`/data/backups` in the example) to persist the backups we are creating. Here is a sample command for this step:

```
shell> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm store/oracle/mysql-enterprise-server:8.0 \
mysqlbackup -umysqlbackup -ppassword --backup-dir=/tmp/backup-tmp --with-timestamp \
--backup-image=/data/backups/db.mbi backup-to-image

[Entrypoint] MySQL Docker Image 8.0.11-1.1.5
MySQL Enterprise Backup version 8.0.11 Linux-4.1.12-61.1.16.el7uek.x86_64-x86_64 [2018-04-08 07:06:45]
Copyright (c) 2003, 2018, Oracle and/or its affiliates. All Rights Reserved.

180921 17:27:25 MAIN      INFO: A thread created with Id '140594390935680'
180921 17:27:25 MAIN      INFO: Starting with following command line ...
...
```

```

Parameters Summary
-----
Start LSN          : 29615616
End LSN            : 29651854
-----

mysqlbackup completed OK!

```

It is important to check the end of the output by `mysqlbackup` to make sure the backup has been completed successfully.

2. The container exits once the backup job is finished and, with the `--rm` option used to start it, it is removed after it exits. An image backup has been created, and can be found in the host directory mounted in the last step for storing backups:

```

shell> ls /tmp/backups
db.mbi

```

To restore a MySQL Server instance in a Docker container using MySQL Enterprise Backup with Docker:

1. Stop the MySQL Server container, which also stops the MySQL Server running inside:

```
docker stop mysqlserver
```

2. On the host, delete all contents in the bind mount for the MySQL Server data directory:

```
rm -rf /path-on-host-machine/datadir/*
```

3. Start a container with an image of MySQL Enterprise Edition to perform the restore with the MySQL Enterprise Backup command `copy-back-and-apply-log`. Bind-mount the server's data directory and the storage folder for the backups, like what we did when we backed up the server:

```

shell> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm store/oracle/mysql-enterprise-server:8.0 \
mysqlbackup --backup-dir=/tmp/backup-tmp --with-timestamp \
--datadir=/var/lib/mysql --backup-image=/data/backups/db.mbi copy-back-and-apply-log

[Entrypoint] MySQL Docker Image 8.0.11-1.1.5
MySQL Enterprise Backup version 8.0.11 Linux-4.1.12-61.1.16.el7uek.x86_64-x86_64 [2018-04-08 07:06:45]
Copyright (c) 2003, 2018, Oracle and/or its affiliates. All Rights Reserved.

180921 22:06:52 MAIN      INFO: A thread created with Id '139768047519872'
180921 22:06:52 MAIN      INFO: Starting with following command line ...
...
180921 22:06:52 PCR1      INFO: We were able to parse ibbackup_logfile up to
lsn 29680612.
180921 22:06:52 PCR1      INFO: Last MySQL binlog file position 0 155, file name binlog.000003
180921 22:06:52 PCR1      INFO: The first data file is '/var/lib/mysql/ibdata1'
and the new created log files are at '/var/lib/mysql'
180921 22:06:52 MAIN      INFO: No Keyring file to process.
180921 22:06:52 MAIN      INFO: Apply-log operation completed successfully.
180921 22:06:52 MAIN      INFO: Full Backup has been restored successfully.

mysqlbackup completed OK! with 3 warnings

```

The container exits once the backup job is finished and, with the `--rm` option used when starting it, it is removed after it exits.

4. Restart the server container, which also restarts the restored server:

```
docker restart mysqlserver
```

Or, start a new MySQL Server on the restored data directory:

```
docker run --name=mysqlserver2 \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
-d store/oracle/mysql-enterprise-server:8.0
```

Log on to the server to check that the server is running with the restored data.

Docker Environment Variables

When you create a MySQL Server container, you can configure the MySQL instance by using the `--env` option (`-e` in short) and specifying one or more of the following environment variables.

Notes

- None of the variables below has any effect if the data directory you mount is not empty, as no server initialization is going to be attempted then (see [Persisting Data and Configuration Changes](#) for more details). Any pre-existing contents in the folder, including any old server settings, are not modified during the container startup.
- The boolean variables including `MYSQL_RANDOM_ROOT_PASSWORD`, `MYSQL_ONETIME_PASSWORD`, `MYSQL_ALLOW_EMPTY_PASSWORD`, and `MYSQL_LOG_CONSOLE` are made true by setting them with any strings of nonzero lengths. Therefore, setting them to, for example, “0”, “false”, or “no” does not make them false, but actually makes them true. This is a known issue of the MySQL Server containers.
- `MYSQL_RANDOM_ROOT_PASSWORD`: When this variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), a random password for the server's root user is generated when the Docker container is started. The password is printed to `stdout` of the container and can be found by looking at the container's log (see [Starting a MySQL Server Instance](#)).
- `MYSQL_ONETIME_PASSWORD`: When the variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), the root user's password is set as expired and must be changed before MySQL can be used normally.
- `MYSQL_DATABASE`: This variable allows you to specify the name of a database to be created on image startup. If a user name and a password are supplied with `MYSQL_USER` and `MYSQL_PASSWORD`, the user is created and granted superuser access to this database (corresponding to `GRANT ALL`). The specified database is created by a `CREATE DATABASE IF NOT EXIST` statement, so that the variable has no effect if the database already exists.
- `MYSQL_USER`, `MYSQL_PASSWORD`: These variables are used in conjunction to create a user and set that user's password, and the user is granted superuser permissions for the database specified by the `MYSQL_DATABASE` variable. Both `MYSQL_USER` and `MYSQL_PASSWORD` are required for a user to be created—if any of the two variables is not set, the other is ignored. If both variables are set but `MYSQL_DATABASE` is not, the user is created without any privileges.

Note

There is no need to use this mechanism to create the root superuser, which is created by default with the password set by either one of the mechanisms discussed in the descriptions for `MYSQL_ROOT_PASSWORD` and `MYSQL_RANDOM_ROOT_PASSWORD`, unless `MYSQL_ALLOW_EMPTY_PASSWORD` is true.

- **MYSQL_ROOT_HOST**: By default, MySQL creates the 'root'@'localhost' account. This account can only be connected to from inside the container as described in [Connecting to MySQL Server from within the Container](#). To allow root connections from other hosts, set this environment variable. For example, the value `172.17.0.1`, which is the default Docker gateway IP, allows connections from the host machine that runs the container. The option accepts only one entry, but wildcards are allowed (for example, `MYSQL_ROOT_HOST=172.*.*.*` or `MYSQL_ROOT_HOST=%`).
- **MYSQL_LOG_CONSOLE**: When the variable is true (which is its default state for MySQL 8.0 server containers), the MySQL Server's error log is redirected to `stderr`, so that the error log goes into the Docker container's log and is viewable using the `docker logs mysqld-container` command.

**Note**

The variable has no effect if a server configuration file from the host has been mounted (see [Persisting Data and Configuration Changes](#) on bind-mounting a configuration file).

- **MYSQL_ROOT_PASSWORD**: This variable specifies a password that is set for the MySQL root account.

**Warning**

Setting the MySQL root user password on the command line is insecure. As an alternative to specifying the password explicitly, you can set the variable with a container file path for a password file, and then mount a file from your host that contains the password at the container file path. This is still not very secure, as the location of the password file is still exposed. It is preferable to use the default settings of `MYSQL_RANDOM_ROOT_PASSWORD` and `MYSQL_ONETIME_PASSWORD` both being true.

- **MYSQL_ALLOW_EMPTY_PASSWORD**. Set it to true to allow the container to be started with a blank password for the root user.

**Warning**

Setting this variable to true is insecure, because it is going to leave your MySQL instance completely unprotected, allowing anyone to gain complete superuser access. It is preferable to use the default settings of `MYSQL_RANDOM_ROOT_PASSWORD` and `MYSQL_ONETIME_PASSWORD` both being true.

2.5.6.3 Deploying MySQL on Windows and Other Non-Linux Platforms with Docker

**Warning**

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk. This section discusses some known issues for the images when used on non-Linux platforms.

Known Issues for using the MySQL Server Docker images from Oracle on Windows include:

- If you are bind-mounting on the container's MySQL data directory (see [Persisting Data and Configuration Changes](#) for details), you have to set the location of the server socket file with the `--socket` option to somewhere outside of the MySQL data directory; otherwise, the server will fail to start. This is because the way Docker for Windows handles file mounting does not allow a host file from being bind-mounted on the socket file.

2.5.7 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard package management systems. This section provides basic instructions for installing MySQL using those package management systems.

Important

Native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in [Section 2.5, "Installing MySQL on Linux"](#).

Distribution specific instructions are shown below:

• Red Hat Linux, Fedora, CentOS

Note

For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See [Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository"](#) for details.

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit

Complete!

```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysqld`. To start the MySQL server use `service`:

```
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run [mysql_secure_installation](#) to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

Note

For Debian 8 and Ubuntu 14 and 16, MySQL can be installed using the [MySQL APT Repository](#) instead of the platform's native software repository. See [Section 2.5.2, "Installing MySQL on Linux Using the MySQL APT Repository"](#) for details.

On Debian and related distributions, there are two packages for MySQL in their software repositories, `mysql-client` and `mysql-server`, for the client and server components respectively. You should

specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

Note

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbshell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix

```

**Note**

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

2.5.8 Installing MySQL on Linux with Juju

The Juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see <https://jujucharms.com/mysql/>.

2.5.9 Managing MySQL Server with systemd

If you install MySQL using an RPM or Debian package on the following Linux platforms, server startup and shutdown is managed by systemd:

- RPM package platforms:
 - Red Hat Enterprise Linux 7; Oracle Linux 7; CentOS 7
 - SUSE Linux Enterprise Server 12
 - Fedora 27 and 28
- Debian package platforms:
 - Debian 8 or higher
 - Ubuntu 16 or higher

If you install MySQL from a generic binary distribution on a platform that uses systemd, you can manually configure systemd support for MySQL following the instructions provided in the post-installation setup section of the [MySQL 8.0 Secure Deployment Guide](#).

If you install MySQL from a source distribution on a platform that uses systemd, obtain systemd support for MySQL by configuring the distribution using the `-DWITH_SYSTEMD=1` CMake option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

The following discussion covers these topics:

- [Overview of systemd](#)
- [Configuring systemd for MySQL](#)

- [Configuring Multiple MySQL Instances Using systemd](#)
- [Migrating from mysqld_safe to systemd](#)

Note

On platforms for which systemd support for MySQL is installed, scripts such as `mysqld_safe` and the System V initialization script are unnecessary and are not installed. For example, `mysqld_safe` can handle server restarts, but systemd provides the same capability, and does so in a manner consistent with management of other services rather than by using an application-specific program.

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support for MySQL is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

Overview of systemd

systemd provides automatic MySQL server startup and shutdown. It also enables manual server management using the `systemctl` command. For example:

```
systemctl {start|stop|restart|status} mysqld
```

Alternatively, use the `service` command (with the arguments reversed), which is compatible with System V systems:

```
service mysqld {start|stop|restart|status}
```

Note

For the `systemctl` or `service` commands, if the MySQL service name is not `mysqld`, use the appropriate name. For example, use `mysql` rather than `mysqld` on Debian-based and SLES systems.

Support for systemd includes these files:

- `mysqld.service` (RPM platforms), `mysql.service` (Debian platforms): systemd service unit configuration file, with details about the MySQL service.
- `mysqld@.service` (RPM platforms), `mysql@.service` (Debian platforms): Like `mysqld.service` or `mysql.service`, but used for managing multiple MySQL instances.
- `mysqld.tmpfiles.d`: File containing information to support the `tmpfiles` feature. This file is installed under the name `mysql.conf`.
- `mysqld_pre_systemd` (RPM platforms), `mysql-system-start` (Debian platforms): Support script for the unit file. This script assists in creating the error log file only if the log location matches a pattern (`/var/log/mysql/*.log` for RPM platforms, `/var/log/mysql/*.log` for Debian platforms). In other cases, the error log directory must be writable or the error log must be present and writable for the user running the `mysqld` process.

Configuring systemd for MySQL

To add or change systemd options for MySQL, these methods are available:

- Use a localized systemd configuration file.

- Arrange for systemd to set environment variables for the MySQL server process.
- Set the `MYSQLD_OPTS` systemd variable.

To use a localized systemd configuration file, create the `/etc/systemd/system/mysqld.service.d` directory if it does not exist. In that directory, create a file that contains a `[Service]` section listing the desired settings. For example:

```
[Service]
LimitNOFILE=max_open_files
PIDFile=/path/to/pid/file
Nice=nice_level
LimitCore=core_file_limit
Environment="LD_PRELOAD=/path/to/malloc/library"
Environment="TZ=time_zone_setting"
```

The discussion here uses `override.conf` as the name of this file. Newer versions of systemd support the following command, which opens an editor and permits you to edit the file:

```
systemctl edit mysqld # RPM platforms
systemctl edit mysql  # Debian platforms
```

Whenever you create or change `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

With systemd, the `override.conf` configuration method must be used for certain parameters, rather than settings in a `[mysqld]` or `[mysqld_safe]` group in a MySQL option file:

- For some parameters, `override.conf` must be used because systemd itself must know their values and it cannot read MySQL option files to get them.
- Parameters that specify values otherwise settable only using options known to `mysqld_safe` must be specified using systemd because there is no corresponding `mysqld` parameter.

For additional information about using systemd rather than `mysqld_safe`, see [Migrating from `mysqld_safe` to systemd](#).

You can set the following parameters in `override.conf`:

- To specify the process ID file, use `override.conf` and change both `PIDFile` and `ExecStart` to name the PID file path name. Any setting of the process ID file in MySQL option files is ignored. To modify `ExecStart`, it must first be cleared. For example:

```
[Service]
PIDFile=/var/run/mysqld/mysqld-custom.pid
ExecStart=
ExecStart=/usr/sbin/mysqld --daemonize --pid-file=/var/run/mysqld/mysqld-custom.pid $MYSQLD_OPTS
```

- To set the number of file descriptors available to the MySQL server, use `LimitNOFILE` in `override.conf` rather than the `--open-files-limit` option for `mysqld` or `mysqld_safe`.
- To set the maximum core file size, use `LimitCore` in `override.conf` rather than the `--core-file-size` option for `mysqld_safe`.

- To set the scheduling priority for the MySQL server, use `Nice` in `override.conf` rather than the `--nice` option for `mysqld_safe`.

Some MySQL parameters are configured using environment variables:

- `LD_PRELOAD`: Set this variable if the MySQL server should use a specific memory-allocation library.
- `NOTIFY_SOCKET`: This environment variable specifies the socket that `mysqld` uses to communicate notification of startup completion and service status change with `systemd`. It is set by `systemd` when the `mysqld` service is started. The `mysqld` service reads the variable setting and writes to the defined location. If the variable is not set, `mysqld` writes nothing.
- `TZ`: Set this variable to specify the default time zone for the server.

There are multiple ways to specify environment variable values for use by the MySQL server process managed by `systemd`:

- Use `Environment` lines in the `override.conf` file. For the syntax, see the example in the preceding discussion that describes how to use this file.
- Specify the values in the `/etc/sysconfig/mysql` file (create the file if it does not exist). Assign values using the following syntax:

```
LD_PRELOAD=/path/to/malloc/library
TZ=time_zone_setting
```

After modifying `/etc/sysconfig/mysql`, restart the server to make the changes effective:

```
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

To specify options for `mysqld` without modifying `systemd` configuration files directly, set or unset the `MYSQLD_OPTS` `systemd` variable. For example:

```
systemctl set-environment MYQSLD_OPTS="--general_log=1"
systemctl unset-environment MYQSLD_OPTS
```

`MYSQLD_OPTS` can also be set in the `/etc/sysconfig/mysql` file.

After modifying the `systemd` environment, restart the server to make the changes effective:

```
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

For platforms that use `systemd`, the data directory is initialized if empty at server startup. This might be a problem if the data directory is a remote mount that has temporarily disappeared: The mount point would appear to be an empty data directory, which then would be initialized as a new data directory. To suppress this automatic initialization behavior, specify the following line in the `/etc/sysconfig/mysql` file (create the file if it does not exist):

```
NO_INIT=true
```

Configuring Multiple MySQL Instances Using `systemd`

This section describes how to configure `systemd` for multiple instances of MySQL.

**Note**

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

To use multiple-instance capability, modify the `my.cnf` option file to include configuration of key options for each instance. These file locations are typical:

- `/etc/my.cnf` or `/etc/mysql/my.cnf` (RPM platforms)
- `/etc/mysql/mysql.conf.d/mysqld.cnf` (Debian platforms)

For example, to manage two instances named `replica01` and `replica02`, add something like this to the option file:

RPM platforms:

```
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysqld-replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysqld-replica02.log
```

Debian platforms:

```
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysql/replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysql/replica02.log
```

The replica names shown here use `@` as the delimiter because that is the only delimiter supported by systemd.

Instances then are managed by normal systemd commands, such as:

```
systemctl start mysqld@replica01
systemctl start mysqld@replica02
```

To enable instances to run at boot time, do this:

```
systemctl enable mysqld@replica01
systemctl enable mysqld@replica02
```

Use of wildcards is also supported. For example, this command displays the status of all replica instances:

```
systemctl status 'mysqld@replica*'
```

For management of multiple MySQL instances on the same machine, systemd automatically uses a different unit file:

- `mysqld@.service` rather than `mysqld.service` (RPM platforms)
- `mysql@.service` rather than `mysql.service` (Debian platforms)

In the unit file, `%I` and `%i` reference the parameter passed in after the `@` marker and are used to manage the specific instance. For a command such as this:

```
systemctl start mysqld@replica01
```

systemd starts the server using a command such as this:

```
mysqld --defaults-group-suffix=%I ...
```

The result is that the `[server]`, `[mysqld]`, and `[mysqld@replica01]` option groups are read and used for that instance of the service.

Note

On Debian platforms, AppArmor prevents the server from reading or writing `/var/lib/mysql-replica*`, or anything other than the default locations. To address this, you must customize or disable the profile in `/etc/apparmor.d/usr.sbin.mysqld`.

Note

On Debian platforms, the packaging scripts for MySQL uninstallation cannot currently handle `mysqld@` instances. Before removing or upgrading the package, you must stop any extra instances manually first.

Migrating from `mysqld_safe` to `systemd`

Because `mysqld_safe` is not installed on platforms that use systemd to manage MySQL, options previously specified for that program (for example, in an `[mysqld_safe]` option group) must be specified another way:

- Some `mysqld_safe` options are also understood by `mysqld` and can be moved from the `[mysqld_safe]` option group to the `[mysqld]` group. This does *not* include `--pid-file`, `--open-files-limit`, or `--nice`. To specify those options, use the `override.conf` systemd file, described previously.
- For some `mysqld_safe` options, there are alternative `mysqld` procedures. For example, the `mysqld_safe` option for enabling `syslog` logging is `--syslog`, which is deprecated. To write error log output to the system log, use the instructions at [Section 5.4.2.3, “Error Logging to the System Log”](#).
- `mysqld_safe` options not understood by `mysqld` can be specified in `override.conf` or environment variables. For example, with `mysqld_safe`, if the server should use a specific memory allocation library, this is specified using the `--malloc-lib` option. For installations that manage the server with systemd, arrange to set the `LD_PRELOAD` environment variable instead, as described previously.

2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in [Section 2.5, “Installing MySQL on Linux”](#). One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under <http://linux.oracle.com/>.

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the [ULN FAQ](#). The page also describes how to install and update packages. The MySQL packages are in the “MySQL for Oracle Linux 6” and “MySQL for Oracle Linux 7” channels for your system architecture on ULN.

Note

At the time of this writing, ULN provides MySQL 8.0 for Oracle Linux 6 and Oracle Linux 7.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in [this section](#), particularly under [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 8.0), make sure to read the section on upgrading MySQL, [Section 2.11.1, “Upgrading MySQL”](#).

2.7 Installing MySQL on Solaris

Note

MySQL 8.0 supports Solaris 11.4 and higher

MySQL on Solaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see [Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

Important

The installation packages have a dependency on the Oracle Developer Studio 12.6 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio [here](#). The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in [Installing Only the Runtime Libraries on Oracle Solaris 11](#).

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <https://dev.mysql.com/downloads/mysql/8.0.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql -s /bin/false mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, because the Solaris `tar` cannot handle long file names, use GNU `tar` (`gtar`) to unpack the distribution. If you do not have GNU `tar` on your system, install it with the following command:

```
pkg install archiver/gnu-tar
```

- You should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris using a binary package of the native Solaris PKG format instead of the binary tarball distribution.

Important

The installation package has a dependency on the Oracle Developer Studio 12.6 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio [here](#). The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in [Installing Only the Runtime Libraries on Oracle Solaris 11](#).

To use this package, download the corresponding `mysql-VERSION-solaris11-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
shell> gunzip mysql-8.0.15-solaris11-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-8.0.15-solaris11-x86_64.pkg

The following packages are available:
  1  mysql      MySQL Community Server (GPL)
                        (i86pc) 8.0.15

Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-8.0.15-solaris11-x86_64.pkg
shell> mysqld_safe &
shell> mysql_upgrade
```

You should check the notes in [Section 2.11, “Upgrading or Downgrading MySQL”](#) before performing any upgrade.

2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql80-server
# make
...
# cd /usr/ports/databases/mysql80-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql80-server
# make deinstall
...
# cd /usr/ports/databases/mysql80-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See [Section 4.9, “MySQL Program Environment Variables”](#).

2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see <https://www.mysql.com/support/supportedplatforms/database.html>.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

Warning

Building MySQL with nonstandard options may lead to reduced functionality, performance, or security.

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at <https://dev.mysql.com/doc/dev/mysql-server/latest/>. It is also possible to generate this content locally from a MySQL source distribution using the instructions at [Section 2.9.7, “Generating MySQL Doxygen Documentation Content”](#).

Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see [Section 2.1.2, “How to Get MySQL”](#). For instructions on building from a standard distribution, see [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#).

Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `8.0.15`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name

indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. For information on building from one of the development trees, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- [CMake](#), which is used as the build framework on all platforms. [CMake](#) can be downloaded from <http://www.cmake.org>.
- A good [make](#) program. Although some platforms come with their own [make](#) implementations, it is highly recommended that you use GNU [make](#) 3.75 or higher. It may already be available on your system as [gmake](#). GNU [make](#) is available from <http://www.gnu.org/software/make/>.
- MySQL 8.0 source code permits use of C++11 features. To enable a good level of C++11 support across all supported platforms, the following minimum compiler versions apply:
 - GCC: 4.8 or higher
 - Clang: 3.4 or higher (Xcode 7 on macOS)
 - Solaris Studio: 12.4 or higher (Solaris client build only)
 - Visual Studio: 2015
 - CMake: On Windows, the required Visual Studio version results in a required CMake version of 3.2.3 or higher
- The MySQL C API requires a C++ or C99 compiler to compile.
- The Boost C++ libraries are required to build MySQL (but not to use it). MySQL compilation requires a particular Boost version. Typically, that is the current Boost version, but if a specific MySQL source distribution requires a different version, the configuration process will stop with a message indicating the Boost version that it requires. To obtain Boost and its installation instructions, visit [the official site](#). After Boost is installed, tell the build system where the Boost files are located by defining the `WITH_BOOST` option when you invoke [CMake](#). For example:

```
shell> cmake . -DWITH_BOOST=/usr/local/boost_version_number
```

Adjust the path as necessary to match your installation.

- The [ncurses](#) library.
- Sufficient free memory. If you encounter problems such as “internal compiler error” when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a `.tar.gz` compressed `tar` file: GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

- For a `.zip` Zip archive: `WinZip` or another tool that can read `.zip` files.
- For an `.rpm` RPM package: The `rpmbuild` program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. The [GitHub Help](#) provides instructions for downloading and installing Git on different platforms. MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](#)
- `bison` 2.1 or higher, available from <http://www.gnu.org/software/bison/>. (Version 1 is no longer supported.) Use the latest version of `bison` where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.

`bison` is available from <http://www.gnu.org/software/bison/>. `bison` for Windows can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for `bison` is the `C:\Program Files\GnuWin32` directory. Some utilities may fail to find `bison` because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example `C:\GnuWin32`.

- On Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from <http://www.gnu.org/software/m4/>.

Note

If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See [Section 4.2.11, “Setting Environment Variables”](#).

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

2.9.1 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#), and [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#). To configure installation locations different from the defaults, use the options described at [Section 2.9.4, “MySQL Source-Configuration Options”](#).

2.9.2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#).
2. Obtain a distribution file using the instructions in [Section 2.1.2, “How to Get MySQL”](#).
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

In MySQL 8.0, `CMake` is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see [How to Build MySQL Server with CMake](#).

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#)), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> mkdir bld
shell> cd bld
shell> cmake ..
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> mkdir mysql-files
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
shell> bin/mysqld --initialize --user=mysql
shell> bin/mysql_ssl_rsa_setup
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

A more detailed version of the source-build specific instructions is shown following.

Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10, “Postinstallation Setup and Testing”](#), for postinstallation setup and testing.

- [Perform Preconfiguration Setup](#)

- [Obtain and Unpack the Distribution](#)
- [Configure the Distribution](#)
- [Build the Distribution](#)
- [Install the Distribution](#)
- [Perform Postinstallation Setup](#)

Perform Preconfiguration Setup

On Unix, set up the `mysql` user and group that will be used to run and execute the MySQL server and own the database directory. For details, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Then perform the following steps as the `mysql` user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.2, “How to Get MySQL”](#).

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf mysql-VERSION.tar.gz
```

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

```
shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, `CMake` can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use `WinZip` or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Build outside of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level. Create the directory and go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ../mysql-src
```

The build directory needs not be outside the source tree. For example, you can build in a directory named `bld` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `bld` and then go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake .. -G "Visual Studio 12 2013"
shell> cmake .. -G "Visual Studio 12 2013 Win64"
```

On macOS, to use the Xcode IDE:

```
shell> cmake .. -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

To list the configuration options, use one of the following commands:

```
shell> cmake .. -L      # overview
shell> cmake .. -LH     # overview with help text
shell> cmake .. -LAH    # all params with help text
shell> ccmake ..        # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build directory on Unix before re-running `CMake`:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the `CMakeFiles` directory for useful information about the failure. To file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#), for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
shell> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1`, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See [Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”](#).

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

2.9.3 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on [GitHub](#). To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On [GitHub](#), MySQL Server and other MySQL projects are found on the [MySQL](#) page. The MySQL Server project is a single repository that contains branches for several MySQL series.

MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](#)

- [Prerequisites for Installing from Development Source](#)
- [Setting Up a MySQL Git Repository](#)

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements outlined in [Section 2.9, “Installing MySQL from Source”](#).

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine, use this procedure:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named `mysql-server`. The initial download will take some time to complete, depending on the speed of your connection.

```
~$ git clone https://github.com/mysql/mysql-server.git
Cloning into 'mysql-server'...
remote: Counting objects: 1198513, done.
remote: Total 1198513 (delta 0), reused 0 (delta 0), pack-reused 1198513
Receiving objects: 100% (1198513/1198513), 1.01 GiB | 7.44 MiB/s, done.
Resolving deltas: 100% (993200/993200), done.
Checking connectivity... done.
Checking out files: 100% (25510/25510), done.
```

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```
~$ cd mysql-server
~/mysql-server$ ls
BUILD                                cmd-line-utils                    libservices                       sql
CMakeLists.txt                     config.h.cmake                   man                               sql-common
COPYING                             configure.cmake                  mysql-test                       storage
Docs                                debug                             mysys                            strings
Doxyfile-perfschema                extra                             msysssl                         support-files
INSTALL                             include                          packaging                        testclients
README                              libbinlogevents                 plugin                           unittest
VERSION                             libbinlogstandalone             rapid                            vio
client                             libevent                        regex                            win
cmake                               libmysql                        scripts                          zlib
```

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL repository.

```
~/mysql-server$ git branch -r
origin/5.5
origin/5.6
origin/5.7
origin/8.0
origin/HEAD -> origin/5.7
origin/cluster-7.2
origin/cluster-7.3
origin/cluster-7.4
origin/cluster-7.5
```

4. To view the branches that are checked out in your local repository, issue the `git branch` command. When you cloned the MySQL Git repository, the MySQL 5.7 branch was checked out automatically. The asterisk identifies the 5.7 branch as the active branch.

```
~/mysql-server$ git branch
* 5.7
```

5. To check out a different MySQL branch, run the `git checkout` command, specifying the branch name. For example, to check out the MySQL 8.0 branch:

```
~/mysql-server$ git checkout 8.0
Checking out files: 100% (9600/9600), done.
Branch 8.0 set up to track remote branch 8.0 from origin.
Switched to a new branch '8.0'
```

6. Run `git branch` to verify that the MySQL 8.0 branch is present. MySQL 8.0, which is the last branch you checked out, is marked by an asterisk indicating that it is the active branch.

```
~/mysql-server$ git branch
5.7
* 8.0
```

7. Use the `git checkout` command to switch between branches. For example:

```
~/mysql-server$ git checkout 5.7
```

8. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the `git pull` command:

```
~/mysql-server$ git checkout 8.0
~/mysql-server$ git pull
```

To examine the commit history, use the `git log` option:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub [MySQL](#) site.

If you see changes or code that you have a question about, send an email to the MySQL [internals](#) mailing list. See [Section 1.6.2, “MySQL Mailing Lists”](#). For information about contributing a patch, see [Contributing to MySQL Server](#).

9. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#), except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `CMake` with values for the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See [Section 28.1.2, “The MySQL Test Suite”](#).

2.9.4 MySQL Source-Configuration Options

The `CMake` program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `CMake` command line. For information about options supported by `CMake`, run either of these commands in the top-level source directory:

```
cmake . -LH
ccmake .
```

You can also affect `CMake` using certain environment variables. See [Section 4.9, “MySQL Program Environment Variables”](#).

For boolean options, the value may be specified as 1 or `ON` to enable the option, or as 0 or `OFF` to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server

startup with the `--basedir`, `--port`, and `--socket` options for `mysqld`. Where applicable, configuration option descriptions indicate the corresponding `mysqld` startup option.

The following sections provide more information about CMake options.

- [CMake Option Reference](#)
- [General Options](#)

CMake Option Reference

The following table shows the available CMake options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

Table 2.13 MySQL Source-Configuration Option Reference (CMake)

Formats	Description	Default	Introduced	Removed
<code>BUILD_CONFIG</code>	Use same build options as official releases			
<code>BUNDLE_RUNTIME_LIBRARIES</code>	Bundle runtime libraries with server MSI and Zip packages for Windows	<code>OFF</code>	8.0.11	
<code>CMAKE_BUILD_TYPE</code>	Type of build to produce	<code>RelWithDebInfo</code>		
<code>CMAKE_CXX_FLAGS</code>	Flags for C++ Compiler			
<code>CMAKE_C_FLAGS</code>	Flags for C Compiler			
<code>CMAKE_INSTALL_PREFIX</code>	Installation base directory	<code>/usr/local/mysql</code>		
<code>COMPILATION_COMMENT</code>	Comment about compilation environment			
<code>CPACK_MONOLITHIC_INSTALL</code>	Whether package build produces single file	<code>OFF</code>		
<code>DEFAULT_CHARSET</code>	The default server character set	<code>utf8mb4</code>		
<code>DEFAULT_COLLATION</code>	The default server collation	<code>utf8mb4_0900_ai_ci</code>		
<code>DISABLE_DATA_LOCK</code>	Exclude the performance schema data lock instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_COND</code>	Exclude Performance Schema condition instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_ERROR</code>	Exclude the performance schema server error instrumentation	<code>OFF</code>		

Formats	Description	Default	Introduced	Removed
<code>DISABLE_PSI_FILE</code>	Exclude Performance Schema file instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_IDLE</code>	Exclude Performance Schema idle instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_MEMORY</code>	Exclude Performance Schema memory instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_METADATA</code>	Exclude Performance Schema metadata instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_MUTEX</code>	Exclude Performance Schema mutex instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_PS</code>	Exclude the performance schema prepared statements	<code>OFF</code>		
<code>DISABLE_PSI_RWLOCK</code>	Exclude Performance Schema rwlock instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_SOCKET</code>	Exclude Performance Schema socket instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_SP</code>	Exclude Performance Schema stored program instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_STAGE</code>	Exclude Performance Schema stage instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_STATEMENT</code>	Exclude Performance Schema statement instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_STATEMENT_DIGEST</code>	Exclude Performance Schema statements_digest instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_TABLE</code>	Exclude Performance Schema table instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_THREAD</code>	Exclude the performance schema thread instrumentation	<code>OFF</code>		
<code>DISABLE_PSI_TRANSACTION</code>	Exclude the performance schema transaction instrumentation	<code>OFF</code>		
<code>DISABLE_SHARED</code>	Do not build shared libraries, compile position-dependent code	<code>OFF</code>		
<code>DOWNLOAD_BOOST</code>	Whether to download the Boost library	<code>OFF</code>		
<code>DOWNLOAD_BOOST_TIMEOUT</code>	Timeout in seconds for downloading the Boost library	<code>600</code>		
<code>ENABLED_LOCAL_INFILE</code>	Whether to enable LOCAL for LOAD DATA INFILE	<code>OFF</code>		
<code>ENABLED_PROFILING</code>	Whether to enable query profiling code	<code>ON</code>		

Formats	Description	Default	Introduced	Removed
ENABLE_DEBUG_SYNC	Whether to enable Debug Sync support	ON		8.0.1
ENABLE_DOWNLOADS	Whether to download optional files	OFF		
ENABLE_DTRACE	Whether to include DTrace support			8.0.1
ENABLE_EXPERIMENTAL_SYSTEM_VARIABLES	Whether to enable experimental InnoDB system variables	OFF	8.0.11	
ENABLE_GCOV	Whether to include gcov support			
ENABLE_GPROF	Enable gprof (optimized Linux builds only)	OFF		
FORCE_INSOURCE_BUILD	Whether to force an in-source build	OFF	8.0.14	
FORCE_UNSUPPORTED_COMPILER	Whether to permit unsupported compiler	OFF		
IGNORE_AIO_CHECK	With -DBUILD_CONFIG=mysql_release, ignore libaio check	OFF		
INSTALL_BINDIR	User executables directory	PREFIX/bin		
INSTALL_DOCDIR	Documentation directory	PREFIX/docs		
INSTALL_DOCREADMEDIR	README file directory	PREFIX		
INSTALL_INCLUDEDIR	Header file directory	PREFIX/include		
INSTALL_INFODIR	Info file directory	PREFIX/docs		
INSTALL_LAYOUT	Select predefined installation layout	STANDALONE		
INSTALL_LIBDIR	Library file directory	PREFIX/lib		
INSTALL_MANDIR	Manual page directory	PREFIX/man		
INSTALL_MYSQLKEYRINGDIR	Directory for keyring_file plugin data file	platform specific		
INSTALL_MYSQLSHAREDIR	Shared data directory	PREFIX/share		
INSTALL_MYSQLTESTDIR	mysql-test directory	PREFIX/mysql-test		
INSTALL_PKGCONFIGDIR	Directory for mysqlclient.pc pkg-config file	INSTALL_LIBDIR/pkgconfig		
INSTALL_PLUGINDIR	Plugin directory	PREFIX/lib/plugin		
INSTALL_SBINDIR	Server executable directory	PREFIX/bin		
INSTALL_SECURE_FILE_PRIV	secure_file_priv default value	platform specific		
INSTALL_SHAREDIR	aclocal/mysql.m4 installation directory	PREFIX/share		

Formats	Description	Default	Introduced	Removed
<code>INSTALL_STATIC_LIBRARIES</code>	Whether to install static libraries	<code>ON</code>		
<code>INSTALL_SUPPORTFILES_DIR</code>	Extra support files directory	<code>PREFIX/support-files</code>		
<code>LINK_RANDOMIZE</code>	Whether to randomize order of symbols in <code>mysqld</code> binary	<code>OFF</code>	8.0.1	
<code>LINK_RANDOMIZE_SEED</code>	Seed value for <code>LINK_RANDOMIZE</code> option	<code>mysql</code>	8.0.1	
<code>MAX_INDEXES</code>	Maximum indexes per table	<code>64</code>		
<code>MUTEX_TYPE</code>	InnoDB mutex type	<code>event</code>		
<code>MYSQLX_TCP_PORT</code>	TCP/IP port number used by X Plugin	<code>33060</code>		
<code>MYSQLX_UNIX_ADDR</code>	Unix socket file used by X Plugin	<code>/tmp/mysqlx.sock</code>		
<code>MYSQL_DATADIR</code>	Data directory			
<code>MYSQL_MAINTAINER_MODE</code>	Whether to enable MySQL maintainer-specific development environment	<code>OFF</code>		
<code>MYSQL_PROJECT_NAME</code>	Windows/OS X project name	<code>MySQL</code>		
<code>MYSQL_TCP_PORT</code>	TCP/IP port number	<code>3306</code>		
<code>MYSQL_UNIX_ADDR</code>	Unix socket file	<code>/tmp/mysql.sock</code>		
<code>ODBC_INCLUDES</code>	ODBC includes directory			
<code>ODBC_LIB_DIR</code>	ODBC library directory			
<code>OPTIMIZER_TRACE</code>	Whether to support optimizer tracing			
<code>REPRODUCIBLE_BUILD</code>	Take extra care to create a build result independent of build location and time		8.0.11	
<code>SYSCONFDIR</code>	Option file directory			
<code>SYSTEMD_PID_DIR</code>	Directory for PID file under <code>systemd</code>	<code>/var/run/mysqld</code>		
<code>SYSTEMD_SERVICE_NAME</code>	Name of MySQL service under <code>systemd</code>	<code>mysqld</code>		
<code>TMPDIR</code>	<code>tmpdir</code> default value			
<code>USE_LD_GOLD</code>	Whether to use GNU gold loader	<code>ON</code>	8.0.0	
<code>WIN_DEBUG_NO_INLINE</code>	Whether to disable function inlining	<code>OFF</code>		
<code>WITHOUT_XXX_STORAGE_ENGINE</code>	Exclude storage engine <code>xxx</code> from build			
<code>WITH_ANT</code>	Path to Ant for building GCS Java wrapper		8.0.11	

Formats	Description	Default	Introduced	Removed
<code>WITH_ASAN</code>	Enable AddressSanitizer	<code>OFF</code>		
<code>WITH_ASAN_SCOPE</code>	Enable AddressSanitizer - fsanitize-address-use-after-scope Clang flag	<code>OFF</code>	8.0.4	
<code>WITH_AUTHENTICATION_LDAP</code>	Whether to report error if LDAP authentication plugins cannot be built	<code>OFF</code>	8.0.2	
<code>WITH_AUTHENTICATION_PAM</code>	Build PAM authentication plugin	<code>OFF</code>		
<code>WITH_AWS_SDK</code>	Location of Amazon Web Services software development kit		8.0.2	
<code>WITH_BOOST</code>	The location of the Boost library sources			
<code>WITH_CLIENT_PROTOCOL_TRACING</code>	Build client-side protocol tracing framework	<code>ON</code>		
<code>WITH_CURL</code>	Location of curl library		8.0.2	
<code>WITH_DEBUG</code>	Whether to include debugging support	<code>OFF</code>		
<code>WITH_DEFAULT_COMPILER_OPTIONS</code>	Whether to use default compiler options	<code>ON</code>		
<code>WITH_DEFAULT_FEATURE_SET</code>	Whether to use default feature set	<code>ON</code>		
<code>WITH_EDITLINE</code>	Which libedit/editline library to use	<code>bundled</code>		
<code>WITH_GMOCK</code>	Path to googlemock distribution			
<code>WITH_ICU</code>	Type of ICU support	<code>bundled</code>	8.0.4	
<code>WITH_INNOODB_EXTRA_DEBUG</code>	Whether to include extra debugging support for InnoDB.	<code>OFF</code>		
<code>WITH_INNOODB_MEMCACHED</code>	Whether to generate memcached shared libraries.	<code>OFF</code>		
<code>WITH_KEYRING_TEST</code>	Build the keyring test program	<code>OFF</code>		
<code>WITH_LIBEVENT</code>	Which libevent library to use	<code>bundled</code>		
<code>WITH_LIBWRAP</code>	Whether to include libwrap (TCP wrappers) support	<code>OFF</code>		
<code>WITH_LTO</code>	Enable link-time optimizer	<code>OFF</code>	8.0.13	
<code>WITH_LZ4</code>	Type of LZ4 library support	<code>bundled</code>		
<code>WITH_LZMA</code>	Type of LZMA library support	<code>bundled</code>	8.0.4	
<code>WITH_MECAB</code>	Compiles MeCab			
<code>WITH_MSAN</code>	Enable MemorySanitizer	<code>OFF</code>		
<code>WITH_MSVCRT_DEBUG</code>	Enable Visual Studio CRT memory leak tracing	<code>OFF</code>		

Formats	Description	Default	Introduced	Removed
<code>WITH_MYSQLX</code>	Whether to disable X Protocol	<code>ON</code>	8.0.11	
<code>WITH_NUMA</code>	Set NUMA memory allocation policy			
<code>WITH_PROTOBUF</code>	Which Protocol Buffers package to use	<code>bundled</code>		
<code>WITH_RAPID</code>	Whether to build rapid development cycle plugins	<code>ON</code>		
<code>WITH_RAPIDJSON</code>	Type of RapidJSON support	<code>bundled</code>	8.0.13	
<code>WITH_RE2</code>	Type of RE2 library support	<code>bundled</code>	8.0.4	
<code>WITH_SSL</code>	Type of SSL support	<code>system</code>		
<code>WITH_SYSTEMD</code>	Enable installation of systemd support files	<code>OFF</code>		
<code>WITH_SYSTEM_LIBS</code>	Set system value of library options not set explicitly	<code>OFF</code>	8.0.11	
<code>WITH_TEST_TRACE_PLUGIN</code>	Build test protocol trace plugin	<code>OFF</code>		
<code>WITH_TSAN</code>	Enable ThreadSanitizer	<code>OFF</code>		
<code>WITH_UBSAN</code>	Enable Undefined Behavior Sanitizer	<code>OFF</code>		
<code>WITH_UNIT_TESTS</code>	Compile MySQL with unit tests	<code>ON</code>		
<code>WITH_UNIXODBC</code>	Enable unixODBC support	<code>OFF</code>		
<code>WITH_VALGRIND</code>	Whether to compile in Valgrind header files	<code>OFF</code>		
<code>WITH_ZLIB</code>	Type of zlib support	<code>bundled</code>		
<code>WITH_xxx_STORAGE_ENGINE</code>	Compile storage engine xxx statically into server			

General Options

- `-DBUILD_CONFIG=mysql_release`

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DBUNDLE_RUNTIME_LIBRARIES=bool`

Whether to bundle runtime libraries with server MSI and Zip packages for Windows.

- `-DCMAKE_BUILD_TYPE=type`

The type of build to produce:

- `RelWithDebInfo`: Enable optimizations and generate debugging information. This is the default MySQL build type.
- `Release`: Enable optimizations but omit debugging information to reduce the build size. This build type was added in MySQL 8.0.13.

- **Debug**: Disable optimizations and generate debugging information. This build type is also used if the `WITH_DEBUG` option is enabled. That is, `-DWITH_DEBUG=1` has the same effect as `-DCMAKE_BUILD_TYPE=Debug`.
- `-DCPACK_MONOLITHIC_INSTALL=bool`

This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

- `-DFORCE_INSOURCE_BUILD=bool`

Defines whether to force an in-source build. Out-of-source builds are recommended, as they permit multiple builds from the same source, and cleanup can be performed quickly by removing the build directory. To force an in-source build, invoke `CMake` with `-DFORCE_INSOURCE_BUILD=ON`.

Installation Layout Options

The `CMAKE_INSTALL_PREFIX` option indicates the base installation directory. Other options with names of the form `INSTALL_XXX` that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- `-DCMAKE_INSTALL_PREFIX=dir_name`

The installation base directory.

This value can be set at server startup with the `--basedir` option.

- `-DINSTALL_BINDIR=dir_name`

Where to install user programs.

- `-DINSTALL_DOCDIR=dir_name`

Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- **STANDALONE**: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.
- **RPM**: Layout similar to RPM packages.
- **SVR4**: Solaris package layout.

- [DEB](#): DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

The `INSTALL_LAYOUT` value determines the default value of the `secure_file_priv`, `keyring_encrypted_file_data`, and `keyring_file_data` system variables. See the descriptions of those variables in [Section 5.1.7, “Server System Variables”](#), and [Section 6.5.4.11, “Keyring System Variables”](#).

- `-DINSTALL_LIBDIR=dir_name`

Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

Where to install manual pages.

- `-DINSTALL_MYSQLKEYRINGDIR=dir_path`

The default directory to use as the location of the `keyring_file` plugin data file. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `keyring_file_data` system variable in [Section 5.1.7, “Server System Variables”](#).

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

Where to install the `mysql-test` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- `-DINSTALL_PKGCONFIGDIR=dir_name`

The directory in which to install the `mysqlclient.pc` file for use by `pkg-config`. The default value is `INSTALL_LIBDIR/pkgconfig`, unless `INSTALL_LIBDIR` ends with `/mysql`, in which case that is removed first.

- `-DINSTALL_PLUGINDIR=dir_name`

The location of the plugin directory.

This value can be set at server startup with the `--plugin_dir` option.

- `-DINSTALL_SBINDIR=dir_name`

Where to install the `mysqld` server.

- `-DINSTALL_SECURE_FILE_PRIVDIR=dir_name`

The default value for the `secure_file_priv` system variable. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `secure_file_priv` system variable in [Section 5.1.7, “Server System Variables”](#).

- `-DINSTALL_SHAREDIR=dir_name`

Where to install `aclocal/mysql.m4`.

- `-DINSTALL_STATIC_LIBRARIES=bool`

Whether to install static libraries. The default is `ON`. If set to `OFF`, these libraries are not installed: `libmysqlclient.a`, `libmysqldservices.a`.

- `-DINSTALL_SUPPORTFILES_DIR=dir_name`

Where to install extra support files.

- `-DLINK_RANDOMIZE=bool`

Whether to randomize the order of symbols in the `mysqld` binary. The default is `OFF`. This option should be enabled only for debugging purposes.

- `-DLINK_RANDOMIZE_SEED=val`

Seed value for the `LINK_RANDOMIZE` option. The value is a string. The default is `mysql`, an arbitrary choice.

- `-DMYSQL_DATADIR=dir_name`

The location of the MySQL data directory.

This value can be set at server startup with the `--datadir` option.

- `-DODBC_INCLUDES=dir_name`

The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=dir_name`

The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- `-DSYSCONFDIR=dir_name`

The default `my.cnf` option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.

- `-DSYSTEMD_PID_DIR=dir_name`

The name of the directory in which to create the PID file when MySQL is managed by systemd. The default is `/var/run/mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DSYSTEMD_SERVICE_NAME=name`

The name of the MySQL service to use when MySQL is managed by systemd. The default is `mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DTMPDIR=dir_name`

The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The `InnoDB`, `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible *engine* values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, and `FEDERATED`. Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
```

Note

It is not possible to compile without Performance Schema support. If it is desired to compile without particular types of instrumentation, that can be done with the following `CMake` options:

```
DISABLE_PSI_COND
DISABLE_PSI_DATA_LOCK
DISABLE_PSI_ERROR
DISABLE_PSI_FILE
DISABLE_PSI_IDLE
DISABLE_PSI_MEMORY
DISABLE_PSI_METADATA
DISABLE_PSI_MUTEX
DISABLE_PSI_PS
DISABLE_PSI_RWLOCK
DISABLE_PSI_SOCKET
DISABLE_PSI_SP
DISABLE_PSI_STAGE
DISABLE_PSI_STATEMENT
DISABLE_PSI_STATEMENT_DIGEST
DISABLE_PSI_TABLE
DISABLE_PSI_THREAD
DISABLE_PSI_TRANSACTION
```

For example, to compile without mutex instrumentation, configure MySQL using the `-DDISABLE_PSI_MUTEX=1` option.

To exclude a storage engine from the build, use `-DWITH_engine_STORAGE_ENGINE=0`. Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=0
-DWITH_EXAMPLE_STORAGE_ENGINE=0
-DWITH_FEDERATED_STORAGE_ENGINE=0
```

It is also possible to exclude a storage engine from the build using `-DWITHOUT_engine_STORAGE_ENGINE=1` (but `-DWITH_engine_STORAGE_ENGINE=0` is preferred). Examples:

```
-DWITHOUT_ARCHIVE_STORAGE_ENGINE=1
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- `-DCOMPILATION_COMMENT=string`

A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`

The server character set. By default, MySQL uses the `utf8mb4` character set.

`charset_name` may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb4`, `utf16`, `utf16le`, `utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

This value can be set at server startup with the `--character_set_server` option.

- `-DDEFAULT_COLLATION=collation_name`

The server collation. By default, MySQL uses `utf8mb4_0900_ai_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

This value can be set at server startup with the `--collation_server` option.

- `-DDISABLE_PSI_COND=bool`

Whether to exclude the Performance Schema condition instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_FILE=bool`

Whether to exclude the Performance Schema file instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_IDLE=bool`

Whether to exclude the Performance Schema idle instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_MEMORY=bool`

Whether to exclude the Performance Schema memory instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_METADATA=bool`

Whether to exclude the Performance Schema metadata instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_MUTEX=bool`

Whether to exclude the Performance Schema mutex instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_RWLOCK=bool`

Whether to exclude the Performance Schema rwlock instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_SOCKET=bool`

Whether to exclude the Performance Schema socket instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_SP=bool`

Whether to exclude the Performance Schema stored program instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STAGE=bool`

Whether to exclude the Performance Schema stage instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STATEMENT=bool`

Whether to exclude the Performance Schema statement instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STATEMENT_DIGEST=bool`

Whether to exclude the Performance Schema statement_digest instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_TABLE=bool`

Whether to exclude the Performance Schema table instrumentation. The default is `OFF` (include).

- `-DDISABLE_SHARED=bool`

Whether to disable building build shared libraries and compile position-dependent code. The default is `OFF` (compile position-independent code).

Enabling this option disables `-fPIC`, with the consequence that shared libraries are not built, including plugins and components. Invoking `CMake` produces this warning: `Dynamic plugins are disabled.`

- `-DDISABLE_PSI_PS=bool`

Exclude the performance schema prepared statements instances instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_THREAD=bool`

Exclude the performance schema thread instrumentation. The default is `OFF` (include).

Only disable threads when building without any instrumentation, because other instrumentations have a dependency on threads.

- `-DDISABLE_PSI_TRANSACTION=bool`

Exclude the performance schema transaction instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_DATA_LOCK=bool`

Exclude the performance schema data lock instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_ERROR=bool`

Exclude the performance schema server error instrumentation. The default is `OFF` (include).

- `-DDOWNLOAD_BOOST=bool`

Whether to download the Boost library. The default is `OFF`.

See the `WITH_BOOST` option for additional discussion about using Boost.

- `-DDOWNLOAD_BOOST_TIMEOUT=seconds`

The timeout in seconds for downloading the Boost library. The default is 600 seconds.

See the `WITH_BOOST` option for additional discussion about using Boost.

- `-DENABLE_DEBUG_SYNC=bool`

As of MySQL 8.0.1, `ENABLE_DEBUG_SYNC` is removed and enabling `WITH_DEBUG` enables Debug Sync.

- `-DENABLE_DOWNLOADS=bool`

Whether to download optional files. For example, with this option enabled, `CMake` downloads the Google Test distribution that is used by the test suite to run unit tests, or Ant and JUnit required for building GCS Java wrapper.

- `-DENABLE_DTRACE=bool`

Whether to include support for DTrace probes.

This option was removed in MySQL 8.0.1.

- `-DENABLE_EXPERIMENTAL_SYSVARS=bool`

Whether to enable experimental `InnoDB` system variables. Experimental system variables are intended for those engaged in MySQL development, should only be used in a development or test environment, and may be removed without notice in a future MySQL release. For information about experimental system variables, refer to `/storage/innobase/handler/ha_innodb.cc` in the MySQL source tree. Experimental system variables can be identified by searching for “`PLUGIN_VAR_EXPERIMENTAL`”.

- `-DENABLE_GCOV=bool`

Whether to include gcov support (Linux only).

- `-DENABLE_GPROF=bool`

Whether to enable `gprof` (optimized Linux builds only).

- `-DISABLED_LOCAL_INFILE=bool`

This option controls the compiled-in default `LOCAL` capability for the MySQL client library. Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.

By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` disabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled, respectively.

`ENABLED_LOCAL_INFILE` controls the default for client-side `LOCAL` capability. For the server, the `local_infile` system variable controls server-side `LOCAL` capability. To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries

are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled, respectively. `local_infile` can also be set at runtime. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DFORCE_UNSUPPORTED_COMPILER=bool`

By default, `CMake` checks for minimum versions of supported compilers: Visual Studio 2015 (Windows); GCC 4.8 or Clang 3.4 (Linux); Developer Studio 12.5 (Solaris server); Developer Studio 12.4 or GCC 4.8 (Solaris client library); Clang 3.6 (macOS), Clang 3.4 (FreeBSD). To disable this check, use `-DFORCE_UNSUPPORTED_COMPILER=ON`.

- `-DIGNORE_AIO_CHECK=bool`

If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`.

- `-DMAX_INDEXES=num`

The maximum number of indexes per table. The default is 64. The maximum is 255. Values smaller than 64 are ignored and the default of 64 is used.

- `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `-DMUTEX_TYPE=type`

The mutex type used by `InnoDB`. Options include:

- `event`: Use event mutexes. This is the default value and the original `InnoDB` mutex implementation.
- `sys`: Use POSIX mutexes on UNIX systems. Use `CRITICAL_SECTION` objects on Windows, if available.
- `futex`: Use Linux `futex`s instead of condition variables to schedule waiting threads.

- `-DMYSQLX_TCP_PORT=port_num`

The port number on which X Plugin listens for TCP/IP connections. The default is 33060.

This value can be set at server startup with the `--mysqlx-port` option.

- `-DMYSQLX_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for X Plugin socket connections. This must be an absolute path name. The default is `/tmp/mysqlx.sock`.

This value can be set at server startup with the `--mysqlx-socket` option.

- `-DMYSQL_PROJECT_NAME=name`

For Windows or macOS, the project name to incorporate into the project file name.

- `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` option.

- `-DOPTIMIZER_TRACE=bool`

Whether to support optimizer tracing. See [MySQL Internals: Tracing the Optimizer](#).

- `-DREPRODUCIBLE_BUILD=bool`

For builds on Linux systems, this option controls whether to take extra care to create a build result independent of build location and time.

This option was added in MySQL 8.0.11. As of MySQL 8.0.12, it defaults to `ON` for `RelWithDebInfo` builds.

- `-DUSE_LD_GOLD=bool`

`CMake` causes the build process to link with the GNU `gold` linker if it is available. To suppress use of this linker, specify the `-DUSE_LD_GOLD=0` option.

- `-DWIN_DEBUG_NO_INLINE=bool`

Whether to disable function inlining on Windows. The default is off (inlining enabled).

- `-DWITH_ANT=path_name`

Set the path to Ant, required when building GCS Java wrapper. Works in a similar way to the existing `WITH_BOOST` `CMake` option. Set `WITH_ANT` to the path of a directory where the Ant tarball, or an already unpacked archive, is saved. When `WITH_ANT` is not set, or is set with the special value `system`, the build assumes a binary `ant` exists in `$PATH`.

- `-DWITH_ASAN=bool`

Whether to enable the AddressSanitizer, for compilers that support it. The default is off.

- `-DWITH_ASAN_SCOPE=bool`

Whether to enable the AddressSanitizer `-fsanitize-address-use-after-scope` Clang flag for use-after-scope detection. The default is off. To use this option, `-DWITH_ASAN` must also be enabled.

- `-DWITH_AUTHENTICATION_LDAP=bool`

Whether to report an error if the LDAP authentication plugins cannot be built:

- If this option is disabled (the default), the LDAP plugins are built if the required header files and libraries are found. If they are not, `CMake` displays a note about it.
- If this option is enabled, a failure to find the required header file and libraries causes `CMake` to produce an error, preventing the server from being built.

- `-DWITH_AUTHENTICATION_PAM=bool`

Whether to build the PAM authentication plugin, for source trees that include this plugin. (See [Section 6.5.1.5, “PAM Pluggable Authentication”](#).) If this option is specified and the plugin cannot be compiled, the build fails.

- `-DWITH_AWS_SDK=path_name`

The location of the Amazon Web Services software development kit.

- `-DWITH_BOOST=path_name`

The Boost library is required to build MySQL. These [CMake](#) options enable control over the library source location, and whether to download it automatically:

- `-DWITH_BOOST=path_name` specifies the Boost library directory location. It is also possible to specify the Boost location by setting the `BOOST_ROOT` or `WITH_BOOST` environment variable.

`-DWITH_BOOST=system` is also permitted and indicates that the correct version of Boost is installed on the compilation host in the standard location. In this case, the installed version of Boost is used rather than any version included with a MySQL source distribution.

- `-DDOWNLOAD_BOOST=bool` specifies whether to download the Boost source if it is not present in the specified location. The default is `OFF`.
- `-DDOWNLOAD_BOOST_TIMEOUT=seconds` the timeout in seconds for downloading the Boost library. The default is 600 seconds.

For example, if you normally build MySQL placing the object output in the `bld` subdirectory of your MySQL source tree, you can build with Boost like this:

```
mkdir bld
cd bld
cmake .. -DDOWNLOAD_BOOST=ON -DWITH_BOOST=$HOME/my_boost
```

This causes Boost to be downloaded into the `my_boost` directory under your home directory. If the required Boost version is already there, no download is done. If the required Boost version changes, the newer version is downloaded.

If Boost is already installed locally and your compiler finds the Boost header files on its own, it may not be necessary to specify the preceding [CMake](#) options. However, if the version of Boost required by MySQL changes and the locally installed version has not been upgraded, you may have build problems. Using the [CMake](#) options should give you a successful build.

With the above settings that allow Boost download into a specified location, when the required Boost version changes, you need to remove the `bld` folder, recreate it, and perform the `cmake` step again. Otherwise, the new Boost version might not get downloaded, and compilation might fail.

- `-DWITH_CLIENT_PROTOCOL_TRACING=bool`

Whether to build the client-side protocol tracing framework into the client library. By default, this option is enabled.

For information about writing protocol trace client plugins, see [Section 28.2.4.11, “Writing Protocol Trace Plugins”](#).

See also the `WITH_TEST_TRACE_PLUGIN` option.

- `-DWITH_CURL=curl_type`

The location of the `curl` library. `curl_type` can be `system` (use the system `curl` library) or a path name to the `curl` library.

- `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

Sync debug checking for the `InnoDB` storage engine is defined under `UNIV_DEBUG` and is available when debugging support is compiled in using the `WITH_DEBUG` option. When debugging support is compiled in, the `innodb_sync_debug` configuration option can be used to enable or disable `InnoDB` sync debug checking.

Enabling `WITH_DEBUG` also enables Debug Sync. This facility is used for testing and debugging. When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where *N* is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) *N* becomes the default timeout for individual synchronization points.

Sync debug checking for the `InnoDB` storage engine is available when debugging support is compiled in using the `WITH_DEBUG` option.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DWITH_DEFAULT_FEATURE_SET=bool`

Whether to use the flags from `cmake/build_configurations/feature_set.cmake`.

- `-DWITH_EDITLINE=value`

Which `libedit/editline` library to use. The permitted values are `bundled` (the default) and `system`.

- `-DWITH_LTO=bool`

Whether to enable the link-time optimizer, if the compiler supports it. The default is `OFF`.

This option was added in MySQL 8.0.13.

- `-DWITH_ICU={icu_type|path_name}`

MySQL uses International Components for Unicode (ICU) to support regular expression operations. The `WITH_ICU` option indicates the type of ICU support to include or the path name to the ICU installation to use.

- `icu_type` can be one of the following values:

- `bundled`: Use the ICU library bundled with the distribution. This is the default, and is the only supported option for Windows.
- `system`: Use the system ICU library.

- `path_name` is the path name to the ICU installation to use. This can be preferable to using the `icu_type` value of `system` because it can prevent CMake from detecting and using an older or incorrect ICU version installed on the system. (Another permitted way to do the same thing is to set `WITH_ICU` to `system` and set the `CMAKE_PREFIX_PATH` option to `path_name`.)

- `-DWITH_INNODB_EXTRA_DEBUG=bool`

Whether to include extra InnoDB debugging support.

Enabling `WITH_INNODB_EXTRA_DEBUG` turns on extra InnoDB debug checks. This option can only be enabled when `WITH_DEBUG` is enabled.

- `-DWITH_GMOCK=path_name`

The path to the googletest distribution, for use with Google Test-based unit tests. The option value is the path to the distribution Zip file. Alternatively, set the `WITH_GMOCK` environment variable to the path name. It is also possible to use `-DENABLE_DOWNLOADS=1` and CMake will download the distribution from GitHub.

If you build MySQL without the Google Test-based unit tests (by configuring without `WITH_GMOCK`), CMake displays a message indicating how to download it.

- `-DWITH_INNODB_MEMCACHED=bool`

Whether to generate memcached shared libraries (`libmemcached.so` and `innodb_engine.so`).

- `-DWITH_KEYRING_TEST=bool`

Whether to build the test program that accompanies the `keyring_file` plugin. The default is `OFF`. Test file source code is located in the `plugin/keyring/keyring-test` directory.

- `-DWITH_LIBEVENT=string`

Which `libevent` library to use. Permitted values are `bundled` (default), `system`, and `yes`. If you specify `system` or `yes`, the system `libevent` library is used if present. If the system library is not found, the bundled `libevent` library is used. The `libevent` library is required by InnoDB memcached.

- `-DWITH_LIBWRAP=bool`

Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_LZ4=lz4_type`

The `WITH_LZ4` indicates the source of `zlib` support:

- `bundled`: Use the `lz4` library bundled with the distribution. This is the default.
- `system`: Use the system `lz4` library. If `WITH_LZ4` is set to this value, the `lz4_decompress` utility is not built. In this case, the system `lz4` command can be used instead.

- `-DWITH_MSAN=bool`

Whether to enable MemorySanitizer, for compilers that support it. The default is off.

For this option to have an effect if enabled, all libraries linked to MySQL must also have been compiled with the option enabled.

- `-DWITH_MECAB={disabled|system|path_name}`

Use this option to compile the MeCab parser. If you have installed MeCab to its default installation directory, set `-DWITH_MECAB=system`. The `system` option applies to MeCab installations performed from source or from binaries using a native package management utility. If you installed MeCab to a custom installation directory, specify the path to the MeCab installation. For example, `-DWITH_MECAB=/opt/mecab`. If the `system` option does not work, specifying the MeCab installation path should work in all cases.

For related information, see [Section 12.9.9, “MeCab Full-Text Parser Plugin”](#).

- `-DWITH_MSVCRT_DEBUG=bool`

Whether to enable Visual Studio CRT memory leak tracing. The default is `OFF`.

- `-DWITH_MYSQLX=bool`

Whether to build with support for X Plugin. Default `ON`. See [Chapter 20, Using MySQL as a Document Store](#).

- `-DWITH_NUMA=bool`

Explicitly set the NUMA memory allocation policy. `CMake` sets the default `WITH_NUMA` value based on whether the current platform has NUMA support. For platforms without NUMA support, `CMake` behaves as follows:

- With no NUMA option (the normal case), `CMake` continues normally, producing only this warning: NUMA library missing or required version not available
- With `-DWITH_NUMA=ON`, `CMake` aborts with this error: NUMA library missing or required version not available
- `-DWITH_PROTOBUF=protobuf_type`

Which Protocol Buffers package to use. `protobuf_type` can be one of the following values:

- `bundled`: Use the package bundled with the distribution. This is the default.
- `system`: Use the package installed on the system.

Other values are ignored, with a fallback to `bundled`.

- `-DWITH_RAPID=bool`

Whether to build the rapid development cycle plugins. When enabled, a `rapid` directory is created in the build tree containing these plugins. When disabled, no `rapid` directory is created in the build tree. The default is `ON`, unless the `rapid` directory is removed from the source tree, in which case the default becomes `OFF`.

- `-DWITH_RAPIDJSON=rapidjson_type`

The type of RapidJSON library support to include. `rapidjson_type` can be one of the following values:

- `bundled`: Use the RapidJSON library bundled with the distribution. This is the default.
- `system`: Use the system RapidJSON library. Version 1.1.0 or higher is required.

This option was added in MySQL 8.0.13.

- `-DWITH_LZMA=lzma_type`

The type of LZMA library support to include. `lzma_type` can be one of the following values:

- `bundled`: Use the LZMA library bundled with the distribution. This is the default.
- `system`: Use the system LZMA library.
- `-DWITH_RE2=re2_type`

The type of RE2 library support to include. `re2_type` can be one of the following values:

- `bundled`: Use the RE2 library bundled with the distribution. This is the default.
- `system`: Use the system RE2 library.
- `-DWITH_SSL={ssl_type|path_name}`

The type of SSL support to include or the path name to the OpenSSL installation to use.

- `ssl_type` can be one of the following values:

- `system`: Use the system OpenSSL library. This is the default.

On macOS and Windows, using `system` builds as if CMake was invoked with `path_name` and points to the installed OpenSSL library. This is because they do not have system SSL libraries. On macOS, `brew install openssl` installs to `/usr/local/opt/openssl` and `system` will find it. On Windows, it checks `%ProgramFiles%/OpenSSL`, `%ProgramFiles%/OpenSSL-Win32`, `%ProgramFiles%/OpenSSL-Win64`, `C:/OpenSSL`, `C:/OpenSSL-Win32`, and `C:/OpenSSL-Win64`.

- `yes`: This is a synonym for `system`.
- `wolfssl`: Use the wolfSSL library. To use this option value, you must follow the instructions in the `extra/README-wolfssl.txt` file.
- `path_name` is the path name to the OpenSSL installation to use. This can be preferable to using the `ssl_type` value of `system` because it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set `WITH_SSL` to `system` and set the `CMAKE_PREFIX_PATH` option to `path_name`.)

For information about using SSL support, see [Section 6.4, “Using Encrypted Connections”](#).

- `-DWITH_SYSTEMD=bool`

Whether to enable installation of systemd support files. By default, this option is disabled. When enabled, systemd support files are installed, and scripts such as `mysqld_safe` and the System V initialization script are not installed. On platforms where systemd is not available, enabling `WITH_SYSTEMD` results in an error from CMake.

For more information about using systemd, see [Section 2.5.9, “Managing MySQL Server with systemd”](#). That section also includes information about specifying options previously specified in `[mysqld_safe]` option groups. Because `mysqld_safe` is not installed when systemd is used, such options must be specified another way.

- `-DWITH_SYSTEM_LIBS=bool`

This option serves as an “umbrella” option to set the `system` value of any of the following CMake options that are not set explicitly: `WITH_CURL`, `WITH_EDITLINE`, `WITH_ICU`, `WITH_LIBEVENT`, `WITH_LZ4`, `WITH_LZMA`, `WITH_PROTOBUF`, `WITH_RE2`, `WITH_SSL`, `WITH_ZLIB`.

- `-DWITH_TEST_TRACE_PLUGIN=bool`

Whether to build the test protocol trace client plugin (see [Using the Test Protocol Trace Plugin](#)). By default, this option is disabled. Enabling this option has no effect unless the `WITH_CLIENT_PROTOCOL_TRACING` option is enabled. If MySQL is configured with both options enabled, the `libmysqlclient` client library is built with the test protocol trace plugin built in, and all the standard MySQL clients load the plugin. However, even when the test plugin is enabled, it has no effect by default. Control over the plugin is afforded using environment variables; see [Using the Test Protocol Trace Plugin](#).

**Note**

Do *not* enable the `WITH_TEST_TRACE_PLUGIN` option if you want to use your own protocol trace plugins because only one such plugin can be loaded at a time and an error occurs for attempts to load a second one. If you have already built MySQL with the test protocol trace plugin enabled to see how it works, you must rebuild MySQL without it before you can use your own plugins.

For information about writing trace plugins, see [Section 28.2.4.11, “Writing Protocol Trace Plugins”](#).

- `-DWITH_TSAN=bool`

Whether to enable the ThreadSanitizer, for compilers that support it. The default is off.

- `-DWITH_UBSAN=bool`

Whether to enable the Undefined Behavior Sanitizer, for compilers that support it. The default is off.

- `-DWITH_UNIT_TESTS={ON|OFF}`

If enabled, compile MySQL with unit tests. The default is ON unless the server is not being compiled.

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See [Building Debug Configurations](#).

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` indicates the source of `zlib` support:

- `bundled`: Use the `zlib` library bundled with the distribution. This is the default.
- `system`: Use the system `zlib` library. If `WITH_ZLIB` is set to this value, the `zlib_decompress` utility is not built. In this case, the system `openssl zlib` command can be used instead.

Compiler Flags

- `-DCMAKE_C_FLAGS="flags"`

Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

Flags for the C++ Compiler.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`

Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`.

Note

All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```
mkdir bld
cd bld
cmake .. -DCMAKE_C_FLAGS=-m32 \
  -DCMAKE_CXX_FLAGS=-m32 \
  -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-Onumber`), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \
  -DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

2.9.5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running `CMake`:

On Unix:

```
shell> make clean
```

```
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running `CMake`. For instructions on building outside of the source tree, see [How to Build MySQL Server with CMake](#).

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the `CC` and `CXX` environment variables. For example:

```
shell> CC=gcc
shell> CXX=g++
shell> export CC CXX
```

To specify your own C and C++ compiler flags, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options. See [Compiler Flags](#).

To see what flags you might need to specify, invoke `mysql_config` with the `--cflags` and `--cxxflags` options.

- To see what commands are executed during the compile stage, after using `CMake` to configure MySQL, run `make VERBOSE=1` rather than just `make`.
- If compilation fails, check whether the `MYSQL_MAINTAINER_MODE` option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in [Section 2.9, “Installing MySQL from Source”](#).

2.9.6 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 8.0.4-rc, the file looks like this:

```
MYSQL_VERSION_MAJOR=8
MYSQL_VERSION_MINOR=0
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-rc
```

If the source is not for a General Availability (GA) release, the `MYSQL_VERSION_EXTRA` value will be nonempty. For the example, the value corresponds to Release Candidate.

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

2.9.7 Generating MySQL Doxygen Documentation Content

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at <https://dev.mysql.com/doc/dev/mysql-server/latest/>. It is also possible to generate this content locally from a MySQL source distribution using the following procedure:

1. Install `doxygen` 1.8.11 or higher. Distributions are available here:

```
http://www.stack.nl/~dimitri/doxygen/download.html
```

After installing `doxygen`, verify the version number:

```
shell> doxygen --version
1.8.11
```

2. Install PlantUML. Distributions are available here:

```
http://plantuml.com/download.html
```

When you install PlantUML on Windows (tested on Windows 10), you must run it at least once as administrator so it creates the registry keys. Open an administrator console and run this command:

```
java -jar path-to-plantuml.jar
```

The command should open a GUI window and return no errors on the console.

3. Install the Graphviz `dot` command. Distributions are available here:

```
http://www.graphviz.org/
```

After installing Graphviz, verify `dot` availability. For example:

```
shell> which dot
/usr/bin/dot
shell> dot -v
dot - graphviz version 2.28.0 (20130928.0220)
```

4. Set the `PLANTUML_JAR_PATH` environment to the location where you installed PlantUML. For example:

```
export PLANTUML_JAR_PATH=path-to-plantuml.jar
```

5. To invoke `doxygen`, change location to the top-level directory of your MySQL source distribution and execute these commands:

```
mkdir -p generated/doxygen
doxygen
```

Inspect the error log. It is available in the `doxyerror.log` file in the top-level directory. Assuming that the build executed successfully, view the generated output using a browser. For example:

```
firefox generated/doxygen/html/index.html
```

You can use a different browser, and even bookmark the page.

2.10 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:
 - Windows installation operations performed by MySQL Installer.
 - Installation on Linux using a server RPM or Debian distribution from Oracle.
 - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.
 - Installation on macOS using a DMG distribution.

For other platforms and installation types, including installation from generic binary and source distributions, you must initialize the data directory yourself. For instructions, see [Section 2.10.1, “Initializing the Data Directory”](#).

- Start the server and make sure that it can be accessed. For instructions, see [Section 2.10.2, “Starting the Server”](#), and [Section 2.10.3, “Testing the Server”](#).

- Assign passwords to the initial `root` account in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. For instructions, see [Section 2.10.4, “Securing the Initial MySQL Account”](#).
- Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).
- Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).

2.10.1 Initializing the Data Directory

After installing MySQL, the data directory, including the tables in the `mysql` system database, must be initialized. For some MySQL installation methods, data directory initialization can be done automatically, as described in [Section 2.10, “Postinstallation Setup and Testing”](#). For other installation methods, including installation from generic binary and source distributions, you must initialize the data directory yourself.

This section describes how to initialize the data directory on Unix and Unix-like systems. (For Windows, see [Section 2.3.7, “Windows Postinstallation Procedures”](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 2.10.3, “Testing the Server”](#).

In the examples shown here, the server is going to run under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server. For information about creating the account, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

1. Change location into the top-level directory of your MySQL installation directory, which is typically `/usr/local/mysql`:

```
shell> cd /usr/local/mysql
```

You will find several files and subdirectories inside the folder, including the `bin` subdirectory, which contains the server as well as the client and utility programs.

2. Create a directory whose location can be provided to the `secure_file_priv` system variable, which limits import/export operations to that specific directory:

```
shell> mkdir mysql-files
```

Grant ownership of the directory to the `mysql` user and group ownership to the `mysql` group, and set the right permissions for the directory:

```
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
```

3. Initialize the data directory, including the `mysql` database containing the initial MySQL grant tables that determine how users are permitted to connect to the server.

Typically, data directory initialization need be done only after you first installed MySQL. If you are upgrading an existing installation, you should run `mysql_upgrade` instead (see [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)). However, the command that initializes

the data directory does not overwrite any existing privilege tables, so it should be safe to run in any circumstances. Use the server to initialize the data directory; for example:

```
shell> bin/mysqld --initialize --user=mysql
```

See [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#) for some important information on the command, especially on the command options you might use.

Note

Initialization of the data directory might fail because some required software libraries are missing from your system. For example:

```
shell> bin/mysqld --initialize --user=mysql
bin/mysqld: error while loading shared libraries: libnuma.so.1: cannot
open shared object file: No such file or directory
```

When this happens, you have to install the missing libraries manually or with your system's package manager before retrying the data directory initialization.

4. If you want the server to be able to deploy with automatic support for secure connections, use the `mysql_ssl_rsa_setup` utility to create default SSL and RSA files:

```
shell> bin/mysql_ssl_rsa_setup
```

For more information, see [Section 4.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

5. If the plugin directory (the directory named by the `plugin_dir` system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making the plugin directory read only to the server or by setting the `secure_file_priv` system variable at server startup to a directory where `SELECT` writes can be performed safely. (For example, set it to the `mysql-files` directory created earlier.)
6. To specify options that the MySQL server should use at startup, put them in a `/etc/my.cnf` or `/etc/mysql/my.cnf` file. You can use such a file to set, for example, the `secure_file_priv` system variable. See [Section 5.1.2, “Server Configuration Defaults”](#). If you do not do this, the server starts with its default settings.
7. If you want MySQL to start automatically when you boot your machine, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).

Data directory initialization creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in [Section 5.1.12, “MySQL Server Time Zone Support”](#).

2.10.1.1 Initializing the Data Directory Manually Using mysqld

This section describes how to initialize the data directory using `mysqld`, the MySQL server.

Note

In MySQL 8.0, the default authentication plugin has changed from `mysql_native_password` to `caching_sha2_password`, and the `'root'@'localhost'` administrative account uses `caching_sha2_password` by default. If you prefer that the `root` account use the previous default authentication plugin (`mysql_native_password`), see [caching_sha2_password and the root Administrative Account](#).

The following instructions assume that your current location is the MySQL installation directory, represented here by `BASEDIR`:

```
shell> cd BASEDIR
```

To initialize the data directory, invoke `mysqld` with the `--initialize` or `--initialize-insecure` option, depending on whether you want the server to generate a random initial password for the `'root'@'localhost'` account.

On Windows, use one of these commands:

```
C:\> bin\mysqld --initialize --console
C:\> bin\mysqld --initialize-insecure --console
```

On Unix and Unix-like systems, it is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, start `mysqld` from the system `root` account and include the `--user` option as shown here:

```
shell> bin/mysqld --initialize --user=mysql
shell> bin/mysqld --initialize-insecure --user=mysql
```

Otherwise, execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

Regardless of platform, use `--initialize` for “secure by default” installation (that is, including generation of a random initial `root` password). In this case, the password is marked as expired and you will need to choose a new one. With the `--initialize-insecure` option, no `root` password is generated; it is assumed that you will assign a password to the account in timely fashion before putting the server into production use.

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysqld` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on one line):

```
shell> bin/mysqld --initialize --user=mysql
--basedir=/opt/mysql/mysql
--datadir=/opt/mysql/mysql/data
```

Alternatively, put the relevant option settings in an option file and pass the name of that file to `mysqld`. For Unix and Unix-like systems, suppose that the option file name is `/opt/mysql/mysql/etc/my.cnf`. Put these lines in the file:

```
[mysqld]
basedir=/opt/mysql/mysql
datadir=/opt/mysql/mysql/data
```

Then invoke `mysqld` as follows (enter the command on a single line with the `--defaults-file` option first):

```
shell> bin/mysqld --defaults-file=/opt/mysql/mysql/etc/my.cnf
--initialize --user=mysql
```

On Windows, suppose that `C:\my.ini` contains these lines:

```
[mysqld]
basedir=C:\\Program Files\\MySQL\\MySQL Server 8.0
datadir=D:\\MySQLdata
```

Then invoke `mysqld` as follows (the `--defaults-file` option must be first):

```
C:\> bin\mysqld --defaults-file=C:\my.ini --initialize --console
```

When invoked with the `--initialize` or `--initialize-insecure` option, `mysqld` performs the following initialization sequence.

Note

The server writes any messages to its standard error output. This may be redirected to the error log, so look there if you do not see the messages on your screen. For information about the error log, including where it is located, see [Section 5.4.2, “The Error Log”](#).

On Windows, use the `--console` option to direct messages to the console.

1. The server checks for the existence of the data directory as follows:

- If no data directory exists, the server creates it.
- If a data directory exists but is not empty (that is, it contains files or subdirectories), the server exits after producing an error message:

```
[ERROR] --initialize specified but the data directory exists. Aborting.
```

In this case, remove or rename the data directory and try again.

An existing data directory is permitted to be nonempty if every entry has a name that begins with a period (.).

2. Within the data directory, the server creates the `mysql` system database and its tables, including the grant tables, server-side help tables, and time zone tables. For a complete listing and description of the grant tables, see [Section 6.2, “The MySQL Access Privilege System”](#).
3. The server initializes the `system tablespace` and related data structures needed to manage `InnoDB` tables.

Note

After `mysqld` sets up the `InnoDB system tablespace`, changes to some tablespace characteristics require setting up a whole new `instance`. This includes the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the `innodb_data_file_path` and `innodb_log_file_size` configuration parameters are in place in the MySQL [configuration file](#) before running `mysqld`. Also make sure to specify as necessary other parameters that affect the creation and location of `InnoDB` files, such as `innodb_data_home_dir` and `innodb_log_group_home_dir`.

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the `--defaults-extra-file` option when you run `mysqld`.

4. The server creates a `'root'@'localhost'` superuser account and other reserved accounts (see [Section 6.3.5, “Reserved User Accounts”](#)). Some reserved accounts are locked and cannot be used by clients, but `'root'@'localhost'` is intended for administrative use and you should assign it a password.

The server's action with respect to a password for the `'root'@'localhost'` account depends on how you invoke it:

- With `--initialize` but not `--initialize-insecure`, the server generates a random password, marks it as expired, and writes a message displaying the password:

```
[Warning] A temporary password is generated for root@localhost:
iTag*AfrH5ej
```

- With `--initialize-insecure`, (either with or without `--initialize` because `--initialize-insecure` implies `--initialize`), the server does not generate a password or mark it expired, and writes a warning message:

```
Warning] root@localhost is created with an empty password ! Please
consider switching off the --initialize-insecure option.
```

See later in this section for instructions on assigning a new `'root'@'localhost'` password.

5. The server populates the server-side help tables if content is available (in the `fill_help_tables.sql` file). The server does not populate the time zone tables; to do so, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).
6. If the `--init-file` option was given to name a file of SQL statements, the server executes the statements in the file. This option enables you to perform custom bootstrapping sequences.

When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers.

7. The server exits.

After you initialize the data directory by starting the server with `--initialize` or `--initialize-insecure`, start the server normally (that is, without either of those options) and assign the `'root'@'localhost'` account a new password:

1. Start the server. For instructions, see [Section 2.10.2, “Starting the Server”](#).
2. Connect to the server:
 - If you used `--initialize` but not `--initialize-insecure` to initialize the data directory, connect to the server as `root` using the random password that the server generated during the initialization sequence:

```
shell> mysql -u root -p
Enter password: (enter the random root password here)
```

Look in the server error log if you do not know this password.

- If you used `--initialize-insecure` to initialize the data directory, connect to the server as `root` without a password:

```
shell> mysql -u root --skip-password
```

3. After connecting, assign a new `root` password:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'new_password';
```

Note

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=:1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':1' IDENTIFIED BY 'root-password';
```

It is possible to put those statements in a file to be executed by the `--init-file` option discussed previously.

Note

The data directory initialization sequence performed by the server does not substitute for the actions performed by `mysql_secure_installation` or `mysql_ssl_rsa_setup`. See [Section 4.4.2, “mysql_secure_installation — Improve MySQL Installation Security”](#), and [Section 4.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

2.10.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see [Section 2.3.5.5, “Starting the Server for the First Time”](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 2.10.3, “Testing the Server”](#).

Start the MySQL server like this if your installation includes `mysqld_safe`:

```
shell> bin/mysqld_safe --user=mysql &
```

Note

For Linux systems on which MySQL is installed using RPM packages, server startup and shutdown is managed using `systemd` rather than `mysqld_safe`, and `mysqld_safe` is not installed. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

Start the server like this if your installation includes `systemd` support:

```
shell> systemctl start mysqld
```

Substitute the appropriate service name if it differs from `mysqld`; for example, `mysql` on SLES systems.

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, run `mysqld_safe` as `root` and include the `--user` option as shown. Otherwise, you should execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` database, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the `data` directory and run the command with the `--user` option.

If you have other problems starting the server, see [Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”](#). For more information about `mysqld_safe`, see [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#). For more information about systemd support, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

2.10.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the [error log](#) to see why the server does not start. Log files are located in the [data directory](#) (typically `C:\Program Files\MySQL\MySQL Server 8.0\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `NDB`), be sure that you have them configured the way you want before starting the server. If you are using `InnoDB` tables, see [Section 15.6, “InnoDB Configuration”](#) for guidelines and [Section 15.13, “InnoDB Startup Options and System Variables”](#) for option syntax.

Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the [data directory](#). The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server will not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the `data` directory there.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the [data directory](#). The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
```

```
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1      localhost
```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug` option. See [Section 28.5.3, “The DBUG Package”](#).

2.10.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 4.2.11, “Setting Environment Variables”](#).

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `-u root` option to connect as `root`. If you have assigned a password for the `root` account already, you'll also need to specify `-p` on the command line and enter the password when prompted. For example:

```
shell> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
```

```
mysqladmin Ver 14.12 Distrib 8.0.15, for pc-linux-gnu on i686
...

Server version      8.0.15
Protocol version    10
Connection          Localhost via UNIX socket
UNIX socket         /var/lib/mysql/mysql.sock
Uptime:             14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the `root` account has a password already):

```
shell> bin/mysqladmin -u root shutdown
```

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see [Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”](#).

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
shell> bin/mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql           |
| performance_schema |
| sys             |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
shell> bin/mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| db           |
| engine_cost  |
| event        |
| func         |
| general_log  |
| gtid_executed |
| help_category |
+-----+
```

```
| help_keyword
| help_relation
| help_topic
| innodb_index_stats
| innodb_table_stats
| ndb_binlog_index
| plugin
| proc
| procs_priv
| proxies_priv
| server_cost
| servers
| slave_master_info
| slave_relay_log_info
| slave_worker_info
| slow_log
| tables_priv
| time_zone
| time_zone_leap_second
| time_zone_name
| time_zone_transition
| time_zone_transition_type
| user
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
shell> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+
| User | Host      | plugin                |
+-----+
| root | localhost | caching_sha2_password |
+-----+
```

At this point, your server is running and you can access it. To tighten security if you have not yet assigned a password to the initial account, follow the instructions in [Section 2.10.4, “Securing the Initial MySQL Account”](#).

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.10.4 Securing the Initial MySQL Account

The MySQL installation process involves initializing the data directory, including the `mysql` database containing the grant tables that define MySQL accounts. For details, see [Section 2.10, “Postinstallation Setup and Testing”](#).

This section describes how to assign a password to the initial `root` account created during the MySQL installation procedure, if you have not already done so.

Note

On Windows, you can also perform the process described in this section during installation with MySQL Installer (see [Section 2.3.3, “MySQL Installer for Windows”](#)). On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation. MySQL Workbench is available on all platforms, and also offers the ability to manage user accounts (see [Chapter 30, MySQL Workbench](#)).

A password may already be assigned to the initial account under these circumstances:

- On Windows, installations performed using MySQL Installer give you the option of assigning a password.
- Installation using the macOS installer generates an initial random password, which the installer displays to the user in a dialog box.
- Installation using RPM packages generates an initial random password, which is written to the server error log.
- Installations using Debian packages give you the option of assigning a password.
- For data directory initialization performed manually using `mysqld --initialize`, `mysqld` generates an initial random password, marks it expired, and writes it to the server error log. For details, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using `mysqld`”](#).

The `mysql.user` grant table defines the initial MySQL user account and its access privileges. Installation of MySQL creates only a `'root'@'localhost'` superuser account that has all privileges and can do anything. If the `root` account has an empty password, your MySQL installation is unprotected: Anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.

The `'root'@'localhost'` account also has a row in the `mysql.proxies_priv` table that enables granting the `PROXY` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 6.3.11, “Proxy Users”](#).

To assign a password for the initial MySQL `root` account, use the following procedure. Replace `new_password` in the examples with the password that you want to use.

Start the server if it is not running. For instructions, see [Section 2.10.2, “Starting the Server”](#).

The initial `root` account may or may not have a password. Choose whichever of the following procedures applies:

- If the `root` account exists with an initial random password that has been expired, connect to the server as `root` using that password, then choose a new password. This is the case if the data directory was initialized using `mysqld --initialize`, either manually or using an installer that does not give you the option of specifying a password during the install operation. Because the password exists, you must use it to connect to the server. But because the password is expired, you cannot use the account for any purpose other than to choose a new password, until you do choose one.

1. If you do not know the initial random password, look in the server error log.
2. Connect to the server as `root` using the password:

```
shell> mysql -u root -p
Enter password: (enter the random root password here)
```

3. Choose a new password to replace the random password:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'new_password';
```

- If the `root` account exists but has no password, connect to the server as `root` using no password, then assign a password. This is the case if you initialized the data directory using `mysqld --initialize-insecure`.

1. Connect to the server as `root` using no password:

```
shell> mysql -u root --skip-password
```

2. Assign a password:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'new_password';
```

After assigning the `root` account a password, you must supply that password whenever you connect to the server using the account. For example, to connect to the server using the `mysql` client, use this command:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```

To shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

Note

For additional information about setting passwords, see [Section 6.3.7, “Assigning Account Passwords”](#). If you forget your `root` password after setting it, see [Section B.5.3.2, “How to Reset the Root Password”](#).

To set up additional accounts, see [Section 6.3.2, “Adding User Accounts”](#).

2.10.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).
- On Unix and Unix-like systems, you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).
- On Linux systems that support `systemd`, you can use it to control the server. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).
- On systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).
- On macOS, install a `launchd` daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking `mysqld_safe`. For details, see [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#). A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

- On Solaris, use the service management framework (SMF) system to initiate and control MySQL startup.

systemd, the `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the macOS Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. systemd, `mysql.server`, and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

Table 2.14 MySQL Startup Scripts and Supported Server Option Groups

Script	Option Groups
<code>mysqld</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code>
<code>mysqld_safe</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>
<code>mysql.server</code>	<code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>

`[mysqld-major_version]` means that groups with names like `[mysqld-5.7]` and `[mysqld-8.0]` are read by servers having versions 5.7.x, 8.0.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. To be current, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead.

For more information on MySQL configuration files and their structure and contents, see [Section 4.2.7, “Using Option Files”](#).

2.11 Upgrading or Downgrading MySQL

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

Downgrading is less common. It is typically performed because of a compatibility or performance issue that occurs on a production system that was not uncovered during initial upgrade verification on test systems.

Note

Downgrade from MySQL 8.0 to MySQL 5.7 (or from a MySQL 8.0 release to a previous MySQL 8.0 release) is not supported. The only supported alternative is to restore a backup taken *before* upgrading. It is therefore imperative that you backup your data before starting the upgrade process.

2.11.1 Upgrading MySQL

This section describes how to upgrade to a new MySQL version.

Note

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

2.11.1.1 Before You Begin

Review the information in this section before upgrading. Perform any recommended actions.

- Protect your data by creating a backup. The backup should include the `mysql` system database, which contains the MySQL data dictionary tables and system tables. See [Section 7.2, “Database Backup Methods”](#).

Important

Downgrade from MySQL 8.0 to MySQL 5.7 (or from a MySQL 8.0 release to a previous MySQL 8.0 release) is not supported. The only supported alternative is to restore a backup taken *before* upgrading. It is therefore imperative that you backup your data before upgrading.

- Review [Section 2.11.1.2, “Upgrade Paths”](#) to ensure that your intended upgrade path is supported.
- Review [Section 2.11.1.3, “Changes in MySQL 8.0”](#) for changes that may require action before upgrading.
- Review [Section 1.4, “What Is New in MySQL 8.0”](#) for deprecated and removed features. An upgrade may require changes with respect to those features if you use any of them.
- Review [Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”](#). If you use deprecated or removed variables, an upgrade may require configuration changes.
- Review the [Release Notes](#) for information about fixes, changes, and new features.
- If you use replication, review [Section 17.4.3, “Upgrading a Replication Setup”](#).
- Upgrade procedures vary by platform and how the initial installation was performed. Use the procedure that applies to your current MySQL installation:
 - If your current MySQL installation is a binary installation or an RPM or Debian package-based installation, refer to the procedure described in [Section 2.11.1.5, “Upgrading MySQL Binary or Package-based Installations on Unix/Linux”](#).
 - If your current MySQL installation was installed on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, refer to the procedure described in [Section 2.11.1.6, “Upgrading MySQL with the MySQL Yum Repository”](#).
 - If your current MySQL installation was installed on Ubuntu using the MySQL APT repository, refer to [Section 2.11.1.7, “Upgrading MySQL with the MySQL APT Repository”](#).
 - If your current MySQL installation was installed on SLES using the MySQL SLES repository, refer to [Section 2.11.1.8, “Upgrading MySQL with the MySQL SLES Repository”](#).
 - If your current MySQL installation was installed using Docker, refer to [Section 2.11.1.9, “Upgrading a Docker Installation of MySQL”](#).
 - If you run MySQL Server on Windows, refer to the upgrade procedure described in [Section 2.3.8, “Upgrading MySQL on Windows”](#).

- If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, it may be useful to create a test instance for assessing the conversions that are required and the work involved to perform them. Make a copy of your MySQL instance that contains the `mysql` database and other databases without the data. Run the upgrade procedure on the test instance to evaluate the work involved to perform the actual data conversion on the original instance.
- Rebuilding and reinstalling MySQL language interfaces is recommended when you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP `mysql` extensions, the Perl `DBD::mysql` module, and the Python `MySQLdb` module.

2.11.1.2 Upgrade Paths

- Upgrade from MySQL 5.7 to 8.0 is supported. However, upgrade is only supported between General Availability (GA) releases. For MySQL 8.0, it is required that you upgrade from a MySQL 5.7 GA release (5.7.9 or higher). Upgrades from non-GA releases of MySQL 5.7 are not supported.
- Upgrading to the latest release is recommended before upgrading to the next version. For example, upgrade to the latest MySQL 5.7 release before upgrading to MySQL 8.0.
- Upgrade that skips versions is not supported. For example, upgrading directly from MySQL 5.6 to 8.0 is not supported.
- Once a release series reaches General Availability (GA) status, upgrade within the release series (from one GA version to another GA version) is supported. For example, upgrading from MySQL 8.0.x to 8.0.y is supported. (Upgrade involving development-status releases is not supported.) Skipping a release is also supported. For example, upgrading from MySQL 8.0.x to 8.0.z is supported. MySQL 8.0.11 is the first GA status release within the MySQL 8.0 release series.

2.11.1.3 Changes in MySQL 8.0

Before upgrading to MySQL 8.0, review the changes described in this section to identify those that apply to your current MySQL installation and applications. Perform any recommended actions.

Changes marked as either **Known issue** or **Incompatible change** are incompatibilities with earlier versions of MySQL, and may require your attention *before upgrading*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the description.

- [Data Dictionary Changes](#)
- [caching_sha2_password as the Preferred Authentication Plugin](#)
- [Configuration Changes](#)
- [Server Changes](#)
- [InnoDB Changes](#)
- [SQL Changes](#)

Data Dictionary Changes

MySQL Server 8.0 incorporates a global data dictionary containing information about database objects in transactional tables. In previous MySQL series, dictionary data was stored in metadata files and nontransactional system tables. As a result, the upgrade procedure is somewhat different from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking

specific prerequisites. For more information, see [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#). A data dictionary-enabled server entails some general operational differences; see [Section 14.7, “Data Dictionary Usage Differences”](#).

caching_sha2_password as the Preferred Authentication Plugin

The `caching_sha2_password` and `sha256_password` authentication plugins provide more secure password encryption than the `mysql_native_password` plugin, and `caching_sha2_password` provides better performance than `sha256_password`. Due to these superior security and performance characteristics of `caching_sha2_password`, it is as of MySQL 8.0 the preferred authentication plugin, and is also the default authentication plugin rather than `mysql_native_password`. This change affects both the server and the `libmysqlclient` client library:

- For the server, the default value of the `default_authentication_plugin` system variable changes from `mysql_native_password` to `caching_sha2_password`.

This change applies only to new accounts created after installing or upgrading to MySQL 8.0 or higher. For accounts already existing in an upgraded installation, their authentication plugin remains unchanged. Existing users who wish to switch to `caching_sha2_password` can do so using the `ALTER USER` statement:

```
ALTER USER user
  IDENTIFIED WITH caching_sha2_password
  BY 'password' ;
```

- The `libmysqlclient` library treats `caching_sha2_password` as the default authentication plugin rather than `mysql_native_password`.

The following sections discuss the implications of the more prominent role of `caching_sha2_password`:

- [caching_sha2_password Compatibility Issues and Solutions](#)
- [caching_sha2_password-Compatible Clients and Connectors](#)
- [caching_sha2_password and the root Administrative Account](#)
- [caching_sha2_password and Replication](#)

caching_sha2_password Compatibility Issues and Solutions

Important

If your MySQL installation must serve pre-8.0 clients and you encounter compatibility issues after upgrading to MySQL 8.0 or higher, the simplest way to address those issues and restore pre-8.0 compatibility is to reconfigure the server to revert to the previous default authentication plugin (`mysql_native_password`). For example, use these lines in the server option file:

```
[mysqld]
default_authentication_plugin=mysql_native_password
```

That setting enables pre-8.0 clients to connect to 8.0 servers until such time as the clients and connectors in use at your installation are upgraded to know about `caching_sha2_password`. However, the setting should be viewed as temporary, not as a long term or permanent solution, because it causes new accounts created with the setting in effect to forego the improved authentication security provided by `caching_sha2_password`.

The use of `caching_sha2_password` offers more secure password hashing than `mysql_native_password` (and consequent improved client connection authentication). However, it also has compatibility implications that may affect existing MySQL installations:

- Clients and connectors that have not been updated to know about `caching_sha2_password` may have trouble connecting to a MySQL 8.0 server configured with `caching_sha2_password` as the default authentication plugin, even to use accounts that do not authenticate with `caching_sha2_password`. This issue occurs because the server specifies the name of its default authentication plugin to clients. If a client or connector is based on a client/server protocol implementation that does not gracefully handle an unrecognized default authentication plugin, it may fail with an error such as one of these:

```
Authentication plugin 'caching_sha2_password' is not supported
```

```
Authentication plugin 'caching_sha2_password' cannot be loaded:
dlopen(/usr/local/mysql/lib/plugin/caching_sha2_password.so, 2):
image not found
```

```
Warning: mysqli_connect(): The server requested authentication
method unknown to the client [caching_sha2_password]
```

For information about writing connectors to gracefully handle requests from the server for unknown default authentication plugins, see [Authentication Plugin Connector-Writing Considerations](#).

- Clients that use an account that authenticates with `caching_sha2_password` must use either a secure connection (made using TCP using TLS/SSL credentials, a Unix socket file, or shared memory), or an unencrypted connection that supports password exchange using an RSA key pair. This security requirement does not apply to `mysql_native_password`, so the switch to `caching_sha2_password` may require additional configuration (see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#)). However, client connections in MySQL 8.0 prefer use of TLS/SSL by default, so clients that already conform to that preference may need no additional configuration.
- Clients and connectors that have not been updated to know about `caching_sha2_password` *cannot* connect to accounts that authenticate with `caching_sha2_password` because they do not recognize this plugin as valid. (This is a particular instance of how client/server authentication plugin compatibility requirements apply, as discussed at [Authentication Plugin Client/Server Compatibility](#).) To work around this issue, relink clients against `libmysqlclient` from MySQL 8.0 or higher, or obtain an updated connector that recognizes `caching_sha2_password`.
- Because `caching_sha2_password` is also now the default authentication plugin in the `libmysqlclient` client library, authentication requires an extra round trip in the client/server protocol for connections from MySQL 8.0 clients to accounts that use `mysql_native_password` (the previous default authentication plugin), unless the client program is invoked with a `--default-auth=mysql_native_password` option.

The `libmysqlclient` client library for pre-8.0 MySQL versions is able to connect to MySQL 8.0 servers (except for accounts that authenticate with `caching_sha2_password`). That means pre-8.0 clients based on `libmysqlclient` should also be able to connect. Examples:

- Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based.
- The DBD::mysql driver for Perl DBI is `libmysqlclient`-based.
- MySQL Connector/Python has a C Extension module that is `libmysqlclient`-based. To use it, include the `use_pure=False` option at connect time.

When an existing MySQL 8.0 installation is upgraded to MySQL 8.0.4 or higher, some older `libmysqlclient`-based clients may “automatically” upgrade if they are dynamically linked, because they use the new client library installed by the upgrade. For example, if the `DBD::mysql` driver for Perl DBI uses dynamic linking, it can use the `libmysqlclient` in place after an upgrade to MySQL 8.0.4 or higher, with this result:

- Prior to the upgrade, DBI scripts that use `DBD::mysql` can connect to a MySQL 8.0 server, except for accounts that authenticate with `caching_sha2_password`.
- After the upgrade, the same scripts become able to use `caching_sha2_password` accounts as well.

However, the preceding results occur because `libmysqlclient` instances from MySQL 8.0 installations prior to 8.0.4 are binary compatible: They both use a shared library major version number of 21. For clients linked to `libmysqlclient` from MySQL 5.7 or older, they link to a shared library with a different version number that is not binary compatible. In this case, the client must be recompiled against `libmysqlclient` from 8.0.4 or higher for full compatibility with MySQL 8.0 servers and `caching_sha2_password` accounts.

MySQL Connector/J 5.1 through 8.0.8 is able to connect to MySQL 8.0 servers, except for accounts that authenticate with `caching_sha2_password`. (Connector/J 8.0.9 or higher is required to connect to `caching_sha2_password` accounts.)

Clients that use an implementation of the client/server protocol other than `libmysqlclient` may need to be upgraded to a newer version that understands the new authentication plugin. For example, in PHP, MySQL connectivity usually is based on `mysqlnd`, which currently does not know about `caching_sha2_password`. Until an updated version of `mysqlnd` is available, the way to enable PHP clients to connect to MySQL 8.0 is to reconfigure the server to revert to `mysql_native_password` as the default authentication plugin, as previously discussed.

If a client or connector supports an option to explicitly specify a default authentication plugin, use it to name a plugin other than `caching_sha2_password`. Examples:

- Some MySQL clients support a `--default-auth` option. (Standard MySQL clients such as `mysql` and `mysqladmin` support this option but can successfully connect to 8.0 servers without it. However, other clients may support a similar option. If so, it is worth trying it.)
- Programs that use the `libmysqlclient` C API can call the `mysql_options()` function with the `MYSQL_DEFAULT_AUTH` option.
- MySQL Connector/Python scripts that use the native Python implementation of the client/server protocol can specify the `auth_plugin` connection option. (Alternatively, use the Connector/Python C Extension, which is able to connect to MySQL 8.0 servers without the need for `auth_plugin`.)

caching_sha2_password-Compatible Clients and Connectors

If a client or connector is available that has been updated to know about `caching_sha2_password`, using it is the best way to ensure compatibility when connecting to a MySQL 8.0 server configured with `caching_sha2_password` as the default authentication plugin.

These clients and connectors have been upgraded to support `caching_sha2_password`:

- The `libmysqlclient` client library in MySQL 8.0 (8.0.4 or higher). Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based, so they are compatible as well.
- The `libmysqlclient` client library in MySQL 5.7 (5.7.23 or higher). Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based, so they are compatible as well.

- MySQL Connector/C++ 1.1.11 or higher or 8.0.7 or higher.
- MySQL Connector/J 8.0.9 or higher.
- MySQL Connector/NET 8.0.10 or higher (through the classic MySQL protocol).
- MySQL Connector/Node.js 8.0.9 or higher.
- PHP: the X DevAPI PHP extension (mysql_xdevapi) supports `caching_sha2_password`.

PHP: the PDO_MySQL and ext/mysqli extensions do not support `caching_sha2_password`. In addition, when used with PHP versions before 7.1.16 and PHP 7.2 before 7.2.4, they fail to connect with `default_authentication_plugin=caching_sha2_password` even if `caching_sha2_password` is not used.

`caching_sha2_password` and the root Administrative Account

For upgrades to MySQL 8.0, the authentication plugin existing accounts remains unchanged, including the plugin for the `'root'@'localhost'` administrative account.

For new MySQL 8.0 installations, when you initialize the data directory (using the instructions at [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#)), the `'root'@'localhost'` account is created, and that account uses `caching_sha2_password` by default. To connect to the server following data directory initialization, you must therefore use a client or connector that supports `caching_sha2_password`. If you can do this but prefer that the `root` account use `mysql_native_password` after installation, install MySQL and initialize the data directory as you normally would. Then connect to the server as `root` and use `ALTER USER` as follows to change the account authentication plugin and password:

```
ALTER USER 'root'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';
```

If the client or connector that you use does not yet support `caching_sha2_password`, you can use a modified data directory-initialization procedure that associates the `root` account with `mysql_native_password` as soon as the account is created. To do so, use either of these techniques:

- Supply a `--default-authentication-plugin=mysql_native_password` option along with `--initialize` or `--initialize-insecure`.
- Set `default_authentication_plugin` to `mysql_native_password` in an option file, and name that option file using a `--defaults-file` option along with `--initialize` or `--initialize-insecure`. (In this case, if you continue to use that option file for subsequent server startups, new accounts will be created with `mysql_native_password` rather than `caching_sha2_password` unless you remove the `default_authentication_plugin` setting from the option file.)

`caching_sha2_password` and Replication

In replication scenarios for which all servers have been upgraded to MySQL 8.0.4 or higher, slave/replica connections to master/primary servers can use accounts that authenticate with `caching_sha2_password`. For such connections, the same requirement applies as for other clients that use accounts that authenticate with `caching_sha2_password`: Use a secure connection or RSA-based password exchange.

To connect to a `caching_sha2_password` account for master/slave replication:

- For MySQL built using OpenSSL, use any of the following `CHANGE MASTER TO` options:

```
MASTER_SSL = 1
GET_MASTER_PUBLIC_KEY = 1
MASTER_PUBLIC_KEY_PATH='path to RSA public key file'
```

- For MySQL built using wolfSSL, use `MASTER_SSL=1` with `CHANGE MASTER TO`.

Alternatively, you can use the RSA public key-related options if the required keys are supplied at server startup.

To connect to a `caching_sha2_password` account for Group Replication:

- For MySQL built using OpenSSL, set any of the following system variables:

```
SET GLOBAL group_replication_recovery_use_ssl = ON;
SET GLOBAL group_replication_recovery_get_public_key = 1;
SET GLOBAL group_replication_recovery_public_key_path = 'path to RSA public key file';
```

- For MySQL built using wolfSSL, set this system variable:

```
SET GLOBAL group_replication_recovery_use_ssl = ON;
```

Alternatively, you can use the RSA public key-related options if the required keys are supplied at server startup.

Configuration Changes

- **Incompatible change:** A MySQL storage engine is now responsible for providing its own partitioning handler, and the MySQL server no longer provides generic partitioning support. `InnoDB` is the only storage engine providing a native partitioning handler that is supported in MySQL 8.0. (The `NDB` storage engine also provides native partitioning support, but it is not yet supported in MySQL 8.0.) A partitioned table using any other storage engine must be altered—either to convert it to `InnoDB`, or to remove its partitioning—*before* upgrading the server, else it cannot be used afterwards.

For information about converting `MyISAM` tables to `InnoDB`, see [Section 15.8.1.4, “Converting Tables from MyISAM to InnoDB”](#).

A table creation statement that would result in a partitioned table using a storage engine without such support fails with an error (`ER_CHECK_NOT_IMPLEMENTED`) in MySQL 8.0. If you import databases from a dump file created in MySQL 5.7 (or earlier) using `mysqldump` into a MySQL 8.0 server, you must make sure that any statements creating partitioned tables do not also specify an unsupported storage engine, either by removing any references to partitioning, or by specifying the storage engine as `InnoDB` or allowing it to be set as `InnoDB` by default.

Note

The procedure given at [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#), describes how to identify partitioned tables that must be altered before upgrading to MySQL 8.0.

See [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for further information.

- **Incompatible change:** Several server error codes are not used and have been removed (for a list, see [Features Removed in MySQL 8.0](#)). Applications that test specifically for any of them should be updated.
- **Important change:** The default character set has changed from `latin1` to `utf8mb4`. These system variables are affected:

- The default value of the `character_set_server` and `character_set_database` system variables has changed from `latin1` to `utf8mb4`.
- The default value of the `collation_server` and `collation_database` system variables has changed from `latin1_swedish_ci` to `utf8mb4_0900_ai_ci`.

As a result, the default character set and collation for new objects differ from previously unless an explicit character set and collation are specified. This includes databases and objects within them, such as tables, views, and stored programs. Assuming that the previous defaults were used, one way to preserve them is to start the server with these lines in the `my.cnf` file:

```
[mysqld]
character_set_server=latin1
collation_server=latin1_swedish_ci
```

In a replicated setting, when upgrading from MySQL 5.7 to 8.0, it is advisable to change the default character set back to the character set used in MySQL 5.7 before upgrading. After the upgrade is completed, the default character set can be changed to `utf8mb4`.

- **Incompatible change:** As of MySQL 8.0.11, it is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are based on the setting defined when the server is initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

Server Changes

- In MySQL 8.0.11, several deprecated features related to account management have been removed, such as use of the `GRANT` statement to modify nonprivilege characteristics of user accounts, the `NO_AUTO_CREATE_USER` SQL mode, the `PASSWORD()` function, and the `old_passwords` system variable.

Replication from MySQL 5.7 to 8.0 of statements that refer to these removed features can cause replication failure. Applications that use any of the removed features should be revised to avoid them and use alternatives when possible, as described in [Features Removed in MySQL 8.0](#).

To avoid a startup failure on MySQL 8.0, remove any instance of `NO_AUTO_CREATE_USER` from `sql_mode` system variable settings in MySQL option files.

Loading a dump file that includes the `NO_AUTO_CREATE_USER` SQL mode in stored program definitions into a MySQL 8.0 server causes a failure. As of MySQL 5.7.24 and MySQL 8.0.13, `mysqldump` removes `NO_AUTO_CREATE_USER` from stored program definitions. Dump files created with an earlier version of `mysqldump` must be modified manually to remove instances of `NO_AUTO_CREATE_USER`.

- In MySQL 8.0.11, these deprecated compatibility SQL modes were removed: `DB2`, `MAXDB`, `MSSQL`, `MYSQL323`, `MYSQL40`, `ORACLE`, `POSTGRESQL`, `NO_FIELD_OPTIONS`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`. They can no longer be assigned to the `sql_mode` system variable or used as permitted values for the `mysqldump --compatible` option.

Removal of `MAXDB` means that the `TIMESTAMP` data type for `CREATE TABLE` or `ALTER TABLE` is no longer treated as `DATETIME`.

Replication from MySQL 5.7 to 8.0 of statements that refer to the removed SQL modes can cause replication failure. This includes replication of `CREATE` statements for stored programs (stored procedures and functions, triggers, and events) that are executed while the current `sql_mode` value

includes any of the removed modes. Applications that use any of the removed modes should be revised to avoid them.

- As of MySQL 8.0.3, spatial data types permit an [SRID](#) attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. See [Section 11.5.1, “Spatial Data Types”](#).

A spatial column with an explicit [SRID](#) attribute is SRID-restricted: The column takes only values with that ID, and [SPATIAL](#) indexes on the column become subject to use by the optimizer. The optimizer ignores [SPATIAL](#) indexes on spatial columns with no [SRID](#) attribute. See [Section 8.3.3, “SPATIAL Index Optimization”](#). If you wish the optimizer to consider [SPATIAL](#) indexes on spatial columns that are not SRID-restricted, each such column should be modified:

- Verify that all values within the column have the same SRID. To determine the SRIDs contained in a geometry column *col_name*, use the following query:

```
SELECT DISTINCT ST_SRID(col_name) FROM tbl_name;
```

If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

- Redefine the column to have an explicit [SRID](#) attribute.
- Recreate the [SPATIAL](#) index.
- Several spatial functions were removed in MySQL 8.0.0 due to a spatial function namespace change that implemented an [ST_](#) prefix for functions that perform an exact operation, or an [MBR](#) prefix for functions that perform an operation based on minimum bounding rectangles. The use of removed spatial functions in generated column definitions could cause an upgrade failure. Before upgrading, run `mysqlcheck --check-upgrade` for removed spatial functions and replace any that you find with their [ST_](#) or [MBR](#) named replacements. For a list of removed spatial functions, refer to [Features Removed in MySQL 8.0](#).
- The [BACKUP_ADMIN](#) privilege is automatically granted to users with the [RELOAD](#) privilege when performing an in-place upgrade to MySQL 8.0.3 or higher.

InnoDB Changes

- [INFORMATION_SCHEMA](#) views based on InnoDB system tables were replaced by internal system views on data dictionary tables. Affected InnoDB [INFORMATION_SCHEMA](#) views were renamed:

Table 2.15 Renamed InnoDB Information Schema Views

Old Name	New Name
INNODB_SYS_COLUMNS	INNODB_COLUMNS
INNODB_SYS_DATAFILES	INNODB_DATAFILES
INNODB_SYS_FIELDS	INNODB_FIELDS
INNODB_SYS_FOREIGN	INNODB_FOREIGN
INNODB_SYS_FOREIGN_COLS	INNODB_FOREIGN_COLS
INNODB_SYS_INDEXES	INNODB_INDEXES
INNODB_SYS_TABLES	INNODB_TABLES
INNODB_SYS_TABLESPACES	INNODB_TABLESPACES
INNODB_SYS_TABLESTATS	INNODB_TABLESTATS

Old Name	New Name
<code>INNODB_SYS_VIRTUAL</code>	<code>INNODB_VIRTUAL</code>

After upgrading to MySQL 8.0.3 or higher, update any scripts that reference previous `InnoDB INFORMATION_SCHEMA` view names.

- The `zlib` library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11.

The `zlib` `compressBound()` function in `zlib` 1.2.11 returns a slightly higher estimate of the buffer size required to compress a given length of bytes than it did in `zlib` version 1.2.3. The `compressBound()` function is called by `InnoDB` functions that determine the maximum row size permitted when creating compressed `InnoDB` tables or inserting rows into compressed `InnoDB` tables. As a result, `CREATE TABLE ... ROW_FORMAT=COMPRESSED` or `INSERT` operations with row sizes very close to the maximum row size that were successful in earlier releases could now fail.

If you have compressed `InnoDB` tables with large rows, it is recommended that you test compressed table `CREATE TABLE` statements on a MySQL 8.0 test instance prior to upgrading.

- With the introduction of the `--innodb-directories` feature, the location of file-per-table and general tablespace files created with an absolute path or in a location outside of the data directory should be added to the `innodb_directories` argument value. Otherwise, `InnoDB` is not able to locate these files during recovery. To view tablespace file locations, query the `INFORMATION_SCHEMA.FILES` table:

```
SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES \G
```

- Undo logs no longer reside in the system tablespace in MySQL 8.0. Upgrading from MySQL 5.7 to MySQL 8.0 moves undo logs from the system tablespace (the previous default location) to separate undo tablespaces. For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

SQL Changes

- **Incompatible change:** As of MySQL 8.0.13, the deprecated `ASC` or `DESC` qualifiers for `GROUP BY` clauses have been removed. Queries that previously relied on `GROUP BY` sorting may produce results that differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

Queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses should be amended. Otherwise, upgrading to MySQL 8.0.13 or higher may fail, as may replicating to MySQL 8.0.13 or higher slave servers.

- Some keywords may be reserved in MySQL 8.0 that were not reserved in MySQL 5.7. See [Section 9.3, “Keywords and Reserved Words”](#). This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See [Section 9.2, “Schema Object Names”](#).
- After upgrading, it is recommended that you test optimizer hints specified in application code to ensure that the hints are still required to achieve the desired optimization strategy. Optimizer enhancements can sometimes render certain optimizer hints unnecessary. In some cases, an unnecessary optimizer hint may even be counterproductive.

2.11.1.4 Preparing Your Installation for Upgrade

Before upgrading to MySQL 8.0, it is necessary to ensure the upgrade readiness of your installation by using your MySQL 5.7 server to perform several preliminary checks. The upgrade process may fail otherwise.

The same checks can be performed using the MySQL Shell `checkForServerUpgrade` utility. For more information, see [MySQL Shell Utilities](#).

Preliminary checks:

1. There must be no tables that use obsolete data types, obsolete functions, orphan `.frm` files, [InnoDB](#) tables that use nonnative partitioning, or triggers that have a missing or empty definer or an invalid creation context (indicated by the `character_set_client`, `collation_connection`, `Database Collation` attributes displayed by `SHOW TRIGGERS` or the `INFORMATION_SCHEMA TRIGGERS` table).

To identify tables and triggers that fail these requirements, execute this command:

```
mysqlcheck -u root -p --all-databases --check-upgrade
```

If `mysqlcheck` reports any errors, correct the issues.

2. There must be no partitioned tables that use a storage engine that does not have native partitioning support. To identify such tables, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE NOT IN ('innodb', 'ndbcluster')
AND CREATE_OPTIONS LIKE '%partitioned%';
```

Any table reported by the query must be altered to use [InnoDB](#) or be made nonpartitioned. To change a table storage engine to [InnoDB](#), execute this statement:

```
ALTER TABLE table_name ENGINE = INNODB;
```

For information about converting [MyISAM](#) tables to [InnoDB](#), see [Section 15.8.1.4, “Converting Tables from MyISAM to InnoDB”](#).

To make a partitioned table nonpartitioned, execute this statement:

```
ALTER TABLE table_name REMOVE PARTITIONING;
```

3. There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary. To identify tables with those names, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE LOWER(TABLE_SCHEMA) = 'mysql'
and LOWER(TABLE_NAME) IN
(
  'catalogs',
  'character_sets',
  'collations',
  'column_statistics',
  'column_type_elements',
  'columns',
  'dd_properties',
  'events',
  'foreign_key_column_usage',
  'foreign_keys',
  'index_column_usage',
  'index_partitions',
  'index_stats',
  'indexes',
  'parameter_type_elements',
  'parameters',
  'resource_groups',
```

```
'routines',
'schemata',
'st_spatial_reference_systems',
'table_partition_values',
'table_partitions',
'table_stats',
'tables',
'tablespace_files',
'tablespace_files',
'tablespace_files',
'triggers',
'view_routine_usage',
'view_table_usage'
);
```

Any tables reported by the query must be renamed (use [RENAME TABLE](#)). This may also entail changes to applications that use the affected tables.

4. There must be no tables that have foreign key constraint names longer than 64 characters. To identify tables with too-long constraint names, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME IN
  (SELECT LEFT(SUBSTR(ID, INSTR(ID, '/') + 1),
    INSTR(SUBSTR(ID, INSTR(ID, '/') + 1), '_ibfk_') - 1)
  FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN
  WHERE LENGTH(SUBSTR(ID, INSTR(ID, '/') + 1)) > 64);
```

Any tables reported by the query must be altered to have constraint names no longer than 64 characters (use [ALTER TABLE](#)).

5. There must be no tables or stored procedures with individual [ENUM](#) or [SET](#) column elements that exceed 255 characters or 1020 bytes in length. Prior to MySQL 8.0, the maximum combined length of [ENUM](#) or [SET](#) column elements was 64K. In MySQL 8.0, the maximum character length of an individual [ENUM](#) or [SET](#) column element is 255 characters, and the maximum byte length is 1020 bytes. (The 1020 byte limit supports multibyte character sets). Before upgrading to MySQL 8.0, modify any [ENUM](#) or [SET](#) column elements that exceed the new limits. Failing to do so causes the upgrade to fail with an error.
6. Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared [InnoDB](#) tablespaces, which include the system tablespace and general tablespaces. Identify table partitions in shared tablespaces by querying [INFORMATION_SCHEMA](#):

```
SELECT DISTINCT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE NAME LIKE '%P#%' AND SPACE_TYPE NOT LIKE 'Single';
```

Move table partitions from shared tablespaces to file-per-table tablespaces using [ALTER TABLE ... REORGANIZE PARTITION](#):

```
ALTER TABLE table_name REORGANIZE PARTITION partition_name
  INTO (partition_definition TABLESPACE=innodb_file_per_table);
```

7. Your MySQL 5.7 installation must not use features that are not supported by MySQL 8.0. Any changes here are necessarily installation specific, but the following examples illustrate the kind of things to look for:

- Tables that use a storage engine not supported in MySQL 8.0 must be altered to use a supported engine. For example, MySQL 8.0 does not yet support MySQL Cluster, so [NDB](#) tables must be altered to use a different storage engine.
- Some server startup options and system variables have been removed in MySQL 8.0. See [Features Removed in MySQL 8.0](#), and [Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”](#). If you use any of these, an upgrade requires configuration changes.

Example: Because the data dictionary provides information about database objects, the server no longer checks directory names in the data directory to find databases. Consequently, the `--ignore-db-dir` option is extraneous and has been removed. To handle this, remove any instances of `--ignore-db-dir` from your startup configuration. In addition, remove or move the named data directory subdirectories before upgrading to MySQL 8.0. (Alternatively, let the 8.0 server add those directories to the data dictionary as databases, then remove each of those databases using `DROP DATABASE.`)

2.11.1.5 Upgrading MySQL Binary or Package-based Installations on Unix/Linux

This section describes how to upgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical upgrade methods are described.

- [In-Place Upgrade](#)
- [Logical Upgrade](#)

In-Place Upgrade

An in-place upgrade involves shutting down the old MySQL version, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and running `mysql_upgrade`.

Note

If you are upgrading an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

To perform an in-place upgrade:

1. Review the information in [Section 2.11.1.1, “Before You Begin”](#).
2. Ensure the upgrade readiness of your installation by completing the preliminary checks in [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#).
3. If you use XA transactions with [InnoDB](#), run `XA RECOVER` before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.
4. With your MySQL 5.7 server, if there are encrypted [InnoDB](#) tablespaces, rotate the keyring master key by executing this statement:

```
ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

5. If you normally run your MySQL 5.7 server configured with `innodb_fast_shutdown` set to 2 (cold shutdown), configure it to perform a fast or slow shutdown by executing either of these statements:

```
SET GLOBAL innodb_fast_shutdown = 1; -- fast shutdown
SET GLOBAL innodb_fast_shutdown = 0; -- slow shutdown
```

With a fast or slow shutdown, **InnoDB** leaves its undo logs and data files in a state that can be dealt with in case of file format differences between releases.

6. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

7. Upgrade the MySQL binary installation or packages. If upgrading a binary installation, unpack the new MySQL binary distribution package. See [Obtain and Unpack the Distribution](#). For package-based installations, replace the old packages with the new ones.

Note

For supported Linux distributions, the preferred method for replacing the MySQL packages is to use the MySQL software repositories; see [Section 2.11.1.6](#), “Upgrading MySQL with the MySQL Yum Repository”, [Section 2.11.1.7](#), “Upgrading MySQL with the MySQL APT Repository”, or [Upgrading MySQL with the MySQL SLES Repository](#) for instructions.

8. Start the MySQL 8.0 server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

If there are encrypted **InnoDB** tablespaces, use the `--early-plugin-load` option to load the keyring plugin.

When you start the MySQL 8.0 server, it automatically detects whether data dictionary tables are present. If not, the server creates them in the data directory, populates them with metadata, and then proceeds with its normal startup sequence. During this process, the server upgrades metadata for all database objects, including databases, tablespaces, system and user tables, views, and stored programs (stored procedures and functions, triggers, Event Scheduler events). The server also removes files that previously were used for metadata storage. For example, after upgrading, you will notice that your tables no longer have `.frm` files.

If this step succeeds, the server performs a cleanup:

- In the data directory, the server creates a directory named `backup_metadata_57` and moves into it files named `db.opt` and files with a suffix of `.frm`, `.par`, `.TRG`, `.TRN`, or `.isl`. (These are files previously used for metadata storage.)

Files in the `backup_metadata_57` directory retain the original file system hierarchy. For example, if `t1.frm` was located in the `my_schema1` directory under the data directory, the server moves it to the `backup_metadata_57/my_schema1` directory.

- In the `mysql` database, the server renames the `event` and `proc` tables to `event_backup_57` and `proc_backup_57`.

If this step fails, the server reverts all changes to the data directory. In this case, you should remove all redo log files, start your MySQL 5.7 server on the same data directory, and fix the cause of any errors. Then perform another slow shutdown of the 5.7 server and start the MySQL 8.0 server to try again.

9. After the MySQL 8.0 server starts successfully, execute `mysql_upgrade`:

```
mysql_upgrade -u root -p
```

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. It makes any remaining changes required in the `mysql` system database between MySQL 5.7 and MySQL 8.0, so that you can take advantage of new privileges or capabilities. `mysql_upgrade` also brings the Performance Schema, `INFORMATION_SCHEMA`, and `sys` schema objects up to date for MySQL 8.0.

Note

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.14, “Server-Side Help”](#).

10. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

The first time you started the MySQL 8.0 server (in an earlier step), you may have noticed messages written to the error log regarding nonupgraded tables. If `mysql_upgrade` has been run successfully, there should be no such messages the second time you start the server.

Logical Upgrade

A logical upgrade involves exporting SQL from the old MySQL version using a backup or export utility such as `mysqldump` or `mysqlpump`, installing the new MySQL version, and applying the SQL to the new MySQL version.

For information about using `mysqldump` or `mysqlpump`, see [Section 4.5, “MySQL Client Programs”](#). For MySQL installation instructions, see [Chapter 2, Installing and Upgrading MySQL](#).

Note

Applying SQL extracted from a previous MySQL release to a new MySQL release may result in errors due to incompatibilities introduced by new, changed, deprecated, or removed features and capabilities. Consequently, SQL extracted from a previous MySQL release may require modification to enable a logical upgrade.

To identify incompatibilities before upgrading to the latest MySQL 8.0 release, check your MySQL installation using the MySQL Shell `checkForServerUpgrade` utility. For more information, see [MySQL Shell Utilities](#). The checks performed on a MySQL 5.7 installation by the MySQL Shell `checkForServerUpgrade` utility are described in [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#).

2.11.1.6 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#), for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version off the old data files) with the MySQL Yum repository.

Notes

- Before performing any update to MySQL, follow carefully the instructions in [Section 2.11.1, “Upgrading MySQL”](#). Among other instructions discussed there, it is especially important to back up your database before the update.
- The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from [MySQL Developer Zone's MySQL Download page](#); if that is not the case, following the instructions in [Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository](#).

Selecting a Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release series you have chosen during installation (see [Selecting a Release Series](#) for details), which means, for example, a 5.7.x installation will NOT be updated to a 8.0.x release automatically. To update to another release series, you need to first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in [Selecting a Release Series](#). For upgrading from MySQL 5.7 to 8.0, perform the *reverse* of the steps illustrated in [Selecting a Release Series](#), disabling the subrepository for the MySQL 5.7 series and enabling that for the MySQL 8.0 series.

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.6 and wish to upgrade to 8.0, upgrade to MySQL 5.7 first before upgrading to 8.0.

Important

For important information about upgrading from MySQL 5.7 to 8.0, see [Upgrading from MySQL 5.7 to 8.0](#).

Upgrading MySQL

Upgrade MySQL and its components by the following command, for platforms that are not dnf-enabled:

```
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time; for platforms that are not dnf-enabled:

```
sudo yum update
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade
```

Restarting MySQL

The MySQL server always restarts after an update by Yum. Once the server restarts, run `mysql_upgrade` to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see [Section 4.4.5](#), “`mysql_upgrade` — Check and Upgrade MySQL Tables” for details.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, for platforms that are not dnf-enabled, update the package with the following command, replacing `package-name` with the name of the package:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

Upgrading the Shared Client Libraries

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

If you recompile applications and dynamically link them with the updated libraries: As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 8.0 shared client libraries and some older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions' software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries will require those updated libraries on systems where the applications are deployed. And, as expected, if those libraries are not in place, the applications requiring the shared libraries will fail. So, be sure to deploy the packages for the shared libraries from MySQL on those systems. You can do this by adding the MySQL Yum repository to the systems (see [Adding the MySQL Yum Repository](#)) and install the latest shared libraries using the instructions given in [Installing Additional MySQL Products and Components with Yum](#).

2.11.1.7 Upgrading MySQL with the MySQL APT Repository

On Debian and Ubuntu platforms, you can perform an in-place upgrade of MySQL and its components with the MySQL APT repository. See [Upgrading MySQL with the MySQL APT Repository](#) in [A Quick Guide to Using the MySQL APT Repository](#).

2.11.1.8 Upgrading MySQL with the MySQL SLES Repository

On the SUSE Linux Enterprise Server (SLES) platform, you can perform an in-place upgrade of MySQL and its components with the MySQL SLES repository. See [Upgrading MySQL with the MySQL SLES Repository](#) in [A Quick Guide to Using the MySQL SLES Repository](#).

2.11.1.9 Upgrading a Docker Installation of MySQL

To upgrade a Docker installation of MySQL, refer to [Upgrading a MySQL Server Container](#).

2.11.1.10 Upgrade Troubleshooting

- A schema mismatch in a MySQL 5.7 instance between the `.frm` file of a table and the InnoDB data dictionary can cause an upgrade to MySQL 8.0 to fail. Such mismatches may be due to `.frm` file corruption. To address this issue, dump and restore affected tables before attempting the upgrade again.
- If problems occur, such as that the new `mysqld` server does not start, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.
- If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.20` to `libmysqlclient.so.21`).
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

2.11.2 Downgrading MySQL

Downgrade from MySQL 8.0 to MySQL 5.7 (or from a MySQL 8.0 release to a previous MySQL 8.0 release) is not supported. The only supported alternative is to restore a backup taken *before* upgrading. It is therefore imperative that you backup your data before starting the upgrade process.

2.11.3 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild or repair tables or indexes, which may be necessitated by:

- Changes to how MySQL handles data types or character sets. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation.
- Required table repairs or upgrades reported by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include:

- [Dump and Reload Method](#)
- [ALTER TABLE Method](#)
- [REPAIR TABLE Method](#)

Dump and Reload Method

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before*

upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

If you need to rebuild an [InnoDB](#) table because a [CHECK TABLE](#) operation indicates that a table upgrade is required, use [mysqldump](#) to create a dump file and [mysql](#) to reload the file. If the [CHECK TABLE](#) operation indicates that there is a corruption or causes [InnoDB](#) to fail, refer to [Section 15.20.2, “Forcing InnoDB Recovery”](#) for information about using the [innodb_force_recovery](#) option to restart [InnoDB](#). To understand the type of problem that [CHECK TABLE](#) may be encountering, refer to the [InnoDB](#) notes in [Section 13.7.3.2, “CHECK TABLE Syntax”](#).

To rebuild a table by dumping and reloading it, use [mysqldump](#) to create a dump file and [mysql](#) to reload the file:

```
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the [--all-databases](#) option:

```
mysqldump --all-databases > dump.sql
mysql < dump.sql
```

ALTER TABLE Method

To rebuild a table with [ALTER TABLE](#), use a “null” alteration; that is, an [ALTER TABLE](#) statement that “changes” the table to use the storage engine that it already has. For example, if [t1](#) is an [InnoDB](#) table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the [ALTER TABLE](#) statement, use [SHOW CREATE TABLE](#) to display the table definition.

REPAIR TABLE Method

The [REPAIR TABLE](#) method is only applicable to [MyISAM](#), [ARCHIVE](#), and [CSV](#) tables.

You can use [REPAIR TABLE](#) if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a [MyISAM](#) table, use this statement:

```
REPAIR TABLE t1;
```

[mysqlcheck --repair](#) provides command-line access to the [REPAIR TABLE](#) statement. This can be a more convenient means of repairing tables because you can use the [--databases](#) or [--all-databases](#) option to repair all tables in specific databases or all databases, respectively:

```
mysqlcheck --repair --databases db_name ...  
mysqlcheck --repair --all-databases
```

2.11.4 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
mysqladmin -h 'other_hostname' create db_name  
mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
mysqladmin create db_name  
mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
mysqladmin create db_name  
gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
mkdir DUMPDIR  
mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
mysqladmin create db_name           # create database  
cat DUMPDIR/*.sql | mysql db_name   # create tables in database  
mysqlimport db_name DUMPDIR/*.txt  # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

2.12 Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. *DBI does not work* if you have an older version of Perl. You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 8.0.

2.12.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD:mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory->

2.12.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or higher.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.12.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD:mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD:mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

3.6.8 Calculating Visits Per Day	289
3.6.9 Using <code>AUTO_INCREMENT</code>	290
3.7 Using MySQL with Apache	292

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 5, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you

should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 8.0.15-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter SQL statements.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing and Upgrading MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section B.5.2, “Common Errors When Using MySQL Programs”](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little

about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.8.0-m17 | 2015-12-21   |
+-----+-----+
1 row in set (0.02 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 8.0.13    |
```

```
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2018-08-24 00:56:40 |
+-----+
1 row in set (0.00 sec)
```

A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;

+-----+-----+
| USER() | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2018-08-24 |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER()
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
<code>mysql></code>	Ready for new query
<code>-></code>	Waiting for next line of multiple-line query
<code>'></code>	Waiting for next line, waiting for completion of a string that began with a single quote (<code>'</code>)
<code>"></code>	Waiting for next line, waiting for completion of a string that began with a double quote (<code>"</code>)
<code>`></code>	Waiting for next line, waiting for completion of an identifier that began with a backtick (<code>`</code>)
<code>/*></code>	Waiting for next line, waiting for completion of a comment that began with <code>/*</code>

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()  
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()  
-> ;  
+-----+  
| USER() |  
+-----+  
| jon@localhost |  
+-----+
```

The `'>` and `>` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `>` prompt, it means that you have entered a line containing a string that begins with a `'` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;  
'>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;  
'> '\c  
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The ``>` prompt is similar to the `'>` and `>` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `>`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

3.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL website. It is available in both compressed `tar` file and Zip formats at <https://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql    |
| test     |
| tmp      |
+-----+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 13.7.6.14, “SHOW DATABASES Syntax”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case-sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'micah'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 6.2, “The MySQL Access Privilege System”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this statement:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-ppassword`, not as `-p password`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note

You can see at any time which database is currently selected using `SELECT DATABASE()`.

3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can normally pick any length from `1` to `65535`, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet                  |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20) | YES  |     | NULL    |       |
```

owner	varchar(20)	YES		NULL		
species	varchar(20)	YES		NULL		
sex	char(1)	YES		NULL		
birth	date	YES		NULL		
death	date	YES		NULL		

You can use [DESCRIBE](#) any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 11, Data Types](#).

3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The [LOAD DATA](#) and [INSERT](#) statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in 'YYYY-MM-DD' format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the [CREATE TABLE](#) statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use [NULL](#) values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler      Gwen      bird      \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

what_to_select indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions_to_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL
Puffball	Diane	hamster	f	1999-03-30	NULL

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Bowser | Diane | dog      | m    | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Chirpy | Gwen  | bird     | f    | 1998-09-11 | NULL       |
| Puffball | Diane | hamster  | f    | 1999-03-30 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
```

Buffy	Harold	dog	f	1989-05-13	NULL
-------	--------	-----	---	------------	------

The preceding query uses the [AND](#) logical operator. There is also an [OR](#) operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

name	owner	species	sex	birth	death
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

[AND](#) and [OR](#) may be intermixed, although [AND](#) has higher precedence than [OR](#). If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the [name](#) and [birth](#) columns:

```
mysql> SELECT name, birth FROM pet;
```

name	birth
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

owner
Harold
Gwen
Harold
Benny
Diane
Gwen
Gwen
Benny

Diane

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
```

owner
Benny
Diane
Gwen
Harold

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
```

name	species	birth
Fluffy	cat	1993-02-04
Claws	cat	1994-03-17
Buffy	dog	1989-05-13
Fang	dog	1990-08-27
Bowser	dog	1989-08-31

3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
```

name	birth
Buffy	1989-05-13
Bowser	1989-08-31
Fang	1990-08-27
Fluffy	1993-02-04
Claws	1994-03-17
Slim	1996-04-29
Whistler	1997-12-09
Chirpy	1998-09-11
Puffball	1999-03-30

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
```

name	birth
Puffball	1999-03-30
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Claws	1994-03-17
Fluffy	1993-02-04
Fang	1990-08-27
Bowser	1989-08-31
Buffy	1989-05-13

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
```

name	species	birth
Chirpy	bird	1998-09-11
Whistler	bird	1997-12-09
Claws	cat	1994-03-17
Fluffy	cat	1993-02-04
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
Buffy	dog	1989-05-13
Puffball	hamster	1999-03-30
Slim	snake	1996-04-29

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two dates for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet;
```

name	birth	CURDATE()	age
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
Fang	1990-08-27	2003-08-19	12

Bowser	1989-08-31	2003-08-19	13
Chirpy	1998-09-11	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Puffball	1999-03-30	2003-08-19	4

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY name;
```

name	birth	CURDATE()	age
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14
Chirpy	1998-09-11	2003-08-19	4
Claws	1994-03-17	2003-08-19	9
Fang	1990-08-27	2003-08-19	12
Fluffy	1993-02-04	2003-08-19	10
Puffball	1999-03-30	2003-08-19	4
Slim	1996-04-29	2003-08-19	7
Whistler	1997-12-09	2003-08-19	5

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY age;
```

name	birth	CURDATE()	age
Chirpy	1998-09-11	2003-08-19	4
Puffball	1999-03-30	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Claws	1994-03-17	2003-08-19	9
Fluffy	1993-02-04	2003-08-19	10
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
-> TIMESTAMPDIFF(YEAR,birth,death) AS age
-> FROM pet WHERE death IS NOT NULL ORDER BY age;
```

name	birth	death	age
Bowser	1989-08-31	1995-07-29	5

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 3.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

name	birth	MONTH(birth)
Fluffy	1993-02-04	2
Claws	1994-03-17	3
Buffy	1989-05-13	5
Fang	1990-08-27	8
Bowser	1989-08-31	8
Chirpy	1998-09-11	9
Whistler	1997-12-09	12
Slim	1996-04-29	4
Puffball	1999-03-30	3

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

name	birth
Buffy	1989-05-13

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between 1 and 12. And `MOD(something,12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

3.3.4.6 Working with NULL Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
| NULL | NULL | NULL | NULL |
+-----+-----+-----+-----+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, `0` or `NULL` means false and anything else means true. The default truth value from a boolean operation is `1`.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
| 0 | 1 | 0 | 1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section B.5.4.3, “Problems with NULL Values”](#).

3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use `_` to match any single character and `%` to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Do not use `=` or `<>` when you use SQL patterns. Use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with `b`:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

To find names ending with `fy`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a `w`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

To find names containing exactly five characters, use five instances of the `_` pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP_LIKE()` function (or the `REGEXP` or `RLIKE` operators, which are synonyms for `REGEXP_LIKE()`).

The following list describes some characteristics of extended regular expressions:

- `.` matches any single character.
- A character class `[...]` matches any character within the brackets. For example, `[abc]` matches `a`, `b`, or `c`. To name a range of characters, use a dash. `[a-z]` matches any letter, whereas `[0-9]` matches any digit.
- `*` matches zero or more instances of the thing preceding it. For example, `x*` matches any number of `x` characters, `[0-9]*` matches any number of digits, and `.*` matches any number of anything.
- A regular expression pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use `^` at the beginning or `$` at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP_LIKE()`.

To find names beginning with `b`, use `^` to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b');
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29

To force a regular expression comparison to be case sensitive, use a case-sensitive collation, or use the `BINARY` keyword to make one of the strings a binary string, or specify the `c` match-control character. Each of these queries matches only lowercase `b` at the beginning of a name:

```
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b' COLLATE utf8mb4_0900_as_cs);
SELECT * FROM pet WHERE REGEXP_LIKE(name, BINARY '^b');
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b', 'c');
```

To find names ending with `fy`, use `$` to match the end of the name:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'fy$');
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a `w`, use this query:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'w');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value as would be true with an SQL pattern.

To find names containing exactly five characters, use `^` and `$` to match the beginning and end of the name, and five instances of `.` in between:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.....$');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

You could also write the previous query using the `{n}` ("repeat-*n*-times") operator:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.{5}$');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

For more information about the syntax for regular expressions, see [Section 12.5.2, “Regular Expressions”](#).

3.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
```

COUNT(*)
9

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

owner	COUNT(*)
Benny	2
Diane	2
Gwen	3
Harold	2

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

species	COUNT(*)
bird	2
cat	2
dog	3
hamster	1
snake	1

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

sex	COUNT(*)
NULL	1
f	4
m	4

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	NULL	1
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE species = 'dog' OR species = 'cat'
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
cat	f	1
cat	m	1
dog	f	1
dog	m	2

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE sex IS NOT NULL
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'menagerie.pet.owner';
this is incompatible with sql_mode=only_full_group_by
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is nondeterministic. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold |      8 |
+-----+-----+
1 row in set (0.00 sec)
```

See also [Section 12.19.3, “MySQL Handling of GROUP BY”](#). See [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#) for information about `COUNT(expr)` behavior and related optimizations.

3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib

name	date	type	remark
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
-> TIMESTAMPDIF(YEAR,birth,date) AS age,
-> remark
-> FROM pet INNER JOIN event
-> ON pet.name = event.name
-> WHERE event.type = 'litter';
```

name	age	remark
Fluffy	2	4 kittens, 3 female, 1 male
Buffy	4	5 puppies, 2 female, 3 male
Buffy	5	3 puppies, 3 female

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
-> FROM pet AS p1 INNER JOIN pet AS p2
-> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
```

name	sex	name	sex	species
Fluffy	f	Claws	m	cat
Buffy	f	Fang	m	dog
Buffy	f	Bowser	m	dog

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
```

DATABASE()
menagerie

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```
mysql> SHOW TABLES;
```

Tables_in_menagerie
event
pet

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 13.7.6.37, “SHOW TABLES Syntax”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
```

Field	Type	Null	Key	Default	Extra
name	varchar(20)	YES		NULL	
owner	varchar(20)	YES		NULL	
species	varchar(20)	YES		NULL	
sex	char(1)	YES		NULL	

birth	date	YES		NULL		
death	date	YES		NULL		
+-----+-----+-----+-----+-----+-----+						

Field indicates the column name, **Type** is the data type for the column, **NULL** indicates whether the column can contain **NULL** values, **Key** indicates whether the column is indexed, and **Default** specifies the column's default value. **Extra** displays special information about columns: If a column was created with the **AUTO_INCREMENT** option, the value will be **auto_increment** rather than empty.

DESC is a short form of **DESCRIBE**. See [Section 13.8.1, “DESCRIBE Syntax”](#), for more information.

You can obtain the **CREATE TABLE** statement necessary to create an existing table using the **SHOW CREATE TABLE** statement. See [Section 13.7.6.10, “SHOW CREATE TABLE Syntax”](#).

If you have indexes on a table, **SHOW INDEX FROM *tbl_name*** produces information about them. See [Section 13.7.6.22, “SHOW INDEX Syntax”](#), for more about this statement.

3.5 Using mysql in Batch Mode

In the previous sections, you used **mysql** interactively to enter statements and view the results. You can also run **mysql** in batch mode. To do this, put the statements you want to run in a file, then tell **mysql** to read its input from the file:

```
shell> mysql < batch-file
```

If you are running **mysql** under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use **mysql** this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the **--force** command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell **mysql** to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the statements.
- Some situations do not allow for interactive use, for example, when you run a query from a [cron](#) job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+
| species |
+-----+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+-----+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the statements that are executed, use `mysql -v`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See [Section 4.5.1.5, “Executing SQL Statements from a Text File”](#), for more information.

3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
  article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
  dealer CHAR(20) DEFAULT '' NOT NULL,
  price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
  (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
  (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0001 | A      | 3.45  |
| 0001 | B      | 3.99  |
| 0002 | A      | 10.99 |
| 0003 | B      | 1.45  |
| 0003 | C      | 1.69  |
| 0003 | D      | 1.25  |
| 0004 | D      | 19.95 |
+-----+-----+-----+
```

3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;

+-----+
| article |
+-----+
| 4       |
+-----+
```

3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0004 | D      | 19.95 |
+-----+-----+-----+
```

Other solutions are to use a [LEFT JOIN](#) or to sort all rows descending by price and get only the first row using the MySQL-specific [LIMIT](#) clause:

```
SELECT s1.article, s1.dealer, s1.price
```

```

FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;

```

**Note**

If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```

SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article;

```

article	price
0001	3.99
0002	10.99
0003	1.69
0004	19.95

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```

SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);

```

article	dealer	price
0001	B	3.99
0002	A	10.99
0003	C	1.69
0004	D	19.95

The preceding example uses a correlated subquery, which can be inefficient (see [Section 13.2.11.7, “Correlated Subqueries”](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`.

Uncorrelated subquery:

```

SELECT s1.article, dealer, s1.price
FROM shop s1

```

```
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and thus the corresponding `s2.article` value is `NULL`. See [Section 13.2.10.2, “JOIN Syntax”](#).

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 9.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
```

article	dealer	price
0003	D	1.25
0004	D	19.95

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 13.5, “Prepared SQL Statement Syntax”](#), for more information.

3.6.6 Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See [Chapter 15, *The InnoDB Storage Engine*](#), and [Section 1.8.2.3, “Foreign Key Differences”](#).

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)

- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+-----+
| id | name                |
+-----+
| 1  | Antonio Paz        |
| 2  | Lilliana Angelovska |
+-----+

SELECT * FROM shirt;
+-----+
| id | style  | color  | owner |
+-----+
| 1  | polo   | blue   | 1     |
| 2  | dress  | white  | 1     |
| 3  | t-shirt| blue   | 1     |
| 4  | dress  | orange | 2     |
| 5  | polo   | red    | 2     |
| 6  | dress  | blue   | 2     |
| 7  | t-shirt| white  | 2     |
+-----+

SELECT s.* FROM person p INNER JOIN shirt s
    ON s.owner = p.id
    WHERE p.name LIKE 'Lilliana%'
    AND s.color <> 'white';

+-----+
| id | style  | color  | owner |
+-----+
```

4	dress	orange	2
5	polo	red	2
6	dress	blue	2

When used in this fashion, the [REFERENCES](#) clause is not displayed in the output of [SHOW CREATE TABLE](#) or [DESCRIBE](#):

```
SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,
  `color` enum('red','blue','orange','white','black') NOT NULL,
  `owner` smallint(5) unsigned NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
```

The use of [REFERENCES](#) in this way as a comment or “reminder” in a column definition works with [MyISAM](#) tables.

3.6.7 Searching on Two Keys

An [OR](#) using a single key is well optimized, as is the handling of [AND](#).

The one tricky case is that of searching on two different keys combined with [OR](#):

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 8.2.1.3, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a [UNION](#) that combines the output of two separate [SELECT](#) statements. See [Section 13.2.10.3, “UNION Syntax”](#).

Each [SELECT](#) searches only one key and can be optimized:

```
SELECT field1_index, field2_index
  FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
  FROM test_table WHERE field2_index = '1';
```

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
  day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
  (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year,month;
```

Which returns:

```
+-----+-----+-----+
| year | month | days |
+-----+-----+-----+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+-----+-----+-----+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9 Using AUTO_INCREMENT

The [AUTO_INCREMENT](#) attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
  ('dog'),('cat'),('penguin'),
  ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+-----+-----+
| id | name   |
+-----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin|
| 4  | lax    |
| 5  | whale  |
| 6  | ostrich|
+-----+-----+
```

No value was specified for the [AUTO_INCREMENT](#) column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless the [NO_AUTO_VALUE_ON_ZERO](#) SQL mode is enabled. For example:

```
INSERT INTO animals (id,name) VALUES(0,'groundhog');
```

If the column is declared [NOT NULL](#), it is also possible to assign [NULL](#) to the column to generate sequence numbers. For example:

```
INSERT INTO animals (id,name) VALUES(NULL,'squirrel');
```

When you insert any other value into an [AUTO_INCREMENT](#) column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the largest column value. For example:

```
INSERT INTO animals (id,name) VALUES(100,'rabbit');
INSERT INTO animals (id,name) VALUES(NULL,'mouse');
SELECT * FROM animals;
```

id	name
1	dog
2	cat
3	penguin
4	lax
5	whale
6	ostrich
7	groundhog
8	squirrel
100	rabbit
101	mouse

Updating an existing [AUTO_INCREMENT](#) column value also resets the [AUTO_INCREMENT](#) sequence.

You can retrieve the most recent automatically generated [AUTO_INCREMENT](#) value with the [LAST_INSERT_ID\(\)](#) SQL function or the [mysql_insert_id\(\)](#) C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the [AUTO_INCREMENT](#) column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the [UNSIGNED](#) attribute if possible to allow a greater range. For example, if you use [TINYINT](#), the maximum permissible sequence number is 127. For [TINYINT UNSIGNED](#), the maximum is 255. See [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#) for the ranges of all the integer types.

Note

For a multiple-row insert, [LAST_INSERT_ID\(\)](#) and [mysql_insert_id\(\)](#) actually return the [AUTO_INCREMENT](#) key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an [AUTO_INCREMENT](#) value other than 1, set that value with [CREATE TABLE](#) or [ALTER TABLE](#), like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For information about [AUTO_INCREMENT](#) usage specific to [InnoDB](#), see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

MyISAM Notes

- For [MyISAM](#) tables, you can specify [AUTO_INCREMENT](#) on a secondary column in a multiple-column index. In this case, the generated value for the [AUTO_INCREMENT](#) column is calculated as [MAX\(auto_increment_column\) + 1 WHERE prefix=given-prefix](#). This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
```

```

    grp ENUM('fish','mammal','bird') NOT NULL,
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
    ('mammal','dog'),('mammal','cat'),
    ('bird','penguin'),('fish','lax'),('mammal','whale'),
    ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;

```

Which returns:

grp	id	name
fish	1	lax
mammal	1	dog
mammal	2	cat
mammal	3	whale
bird	1	penguin
bird	2	ostrich

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

- If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

Further Reading

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: [Section 13.1.18, “CREATE TABLE Syntax”](#), and [Section 13.1.8, “ALTER TABLE Syntax”](#).
- How `AUTO_INCREMENT` behaves depending on the `NO_AUTO_VALUE_ON_ZERO` SQL mode: [Section 5.1.10, “Server SQL Modes”](#).
- How to use the `LAST_INSERT_ID()` function to find the row that contains the most recent `AUTO_INCREMENT` value: [Section 12.14, “Information Functions”](#).
- Setting the `AUTO_INCREMENT` value to be used: [Section 5.1.7, “Server System Variables”](#).
- [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#)
- `AUTO_INCREMENT` and replication: [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment` and `auto_increment_offset`) that can be used for replication: [Section 5.1.7, “Server System Variables”](#).

3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
    "%h",%{Y%m%d%H%M%S}t,%>s,"%b",\ "%{Content-Type}o", \
    "%U",\ "%{Referer}i",\ "%{User-Agent}i"
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

4.7.2 <code>my_print_defaults</code> — Display Options from Option Files	527
4.7.3 <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols	528
4.8 Miscellaneous Programs	528

4.8.1 <code>lz4_decompress</code> — Decompress mysqlpump LZ4-Compressed Output	528
4.8.2 <code>perror</code> — Explain Error Codes	529
4.8.3 <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa	530
4.8.4 <code>zlib_decompress</code> — Decompress mysqlpump ZLIB-Compressed Output	530
4.9 MySQL Program Environment Variables	530

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one. Each program's description indicates its invocation syntax and the options that it supports.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, *Installing and Upgrading MySQL*](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 4.2, "Using MySQL Programs"](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 4.3.1, "mysqld — The MySQL Server"](#).

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 4.3.2, "mysqld_safe — MySQL Server Startup Script"](#).

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 4.3.3, "mysql.server — MySQL Server Startup Script"](#).

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 4.3.4, "mysqld_multi — Manage Multiple MySQL Servers"](#).

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 4.4.1, “`comp_err` — Compile MySQL Error Message File”](#).

- `mysql_secure_installation`

This program enables you to improve the security of your MySQL installation. See [Section 4.4.2, “`mysql_secure_installation` — Improve MySQL Installation Security”](#).

- `mysql_ssl_rsa_setup`

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections, if those files are missing. Files created by `mysql_ssl_rsa_setup` can be used for secure connections using SSL or RSA. See [Section 4.4.3, “`mysql_ssl_rsa_setup` — Create SSL/RSA Files”](#).

- `mysql_tzinfo_to_sql`

This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). See [Section 4.4.4, “`mysql_tzinfo_to_sql` — Load the Time Zone Tables”](#).

- `mysql_upgrade`

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.5, “`mysql_upgrade` — Check and Upgrade MySQL Tables”](#).

MySQL client programs that connect to the MySQL server:

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 4.5.1, “`mysql` — The MySQL Command-Line Tool”](#).

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See [Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”](#).

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 4.5.3, “`mysqlcheck` — A Table Maintenance Program”](#).

- `mysqldump`

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#).

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA INFILE`. See [Section 4.5.5, “`mysqlimport` — A Data Import Program”](#).

- `mysqlpump`

A client that dumps a MySQL database into a file as SQL. See [Section 4.5.6, “mysqlpump — A Database Backup Program”](#).

- `mysqlsh`

MySQL Shell is an advanced client and code editor for MySQL Server. See [MySQL Shell 8.0 \(part of MySQL 8.0\)](#). In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. X DevAPI enables you to work with both relational and document data, see [Chapter 20, Using MySQL as a Document Store](#). AdminAPI enables you to work with InnoDB cluster, see [Chapter 21, InnoDB Cluster](#).

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See [Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

- `mysqlslap`

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 4.5.8, “mysqlslap — Load Emulation Client”](#).

MySQL administrative and utility programs:

- `innochecksum`

An offline InnoDB offline file checksum utility. See [Section 4.6.2, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- `myisam_ftdump`

A utility that displays information about full-text indexes in MyISAM tables. See [Section 4.6.3, “myisam_ftdump — Display Full-Text Index information”](#).

- `myisamchk`

A utility to describe, check, optimize, and repair MyISAM tables. See [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- `myisamlog`

A utility that processes the contents of a MyISAM log file. See [Section 4.6.5, “myisamlog — Display MyISAM Log File Contents”](#).

- `myisampack`

A utility that compresses MyISAM tables to produce smaller read-only tables. See [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- `mysql_config_editor`

A utility that enables you to store authentication credentials in a secure, encrypted login path file named `.mylogin.cnf`. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

MySQL program-development utilities:

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See [Section 4.7.1, “mysql_config — Display Options for Compiling Clients”](#).

- `my_print_defaults`

A utility that shows which options are present in option groups of option files. See [Section 4.7.2, “my_print_defaults — Display Options from Option Files”](#).

- `resolve_stack_dump`

A utility program that resolves a numeric stack trace dump to symbols. See [Section 4.7.3, “resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols”](#).

Miscellaneous utilities:

- `lz4_decompress`

A utility that decompresses `mysqlpump` output that was created using LZ4 compression. See [Section 4.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”](#).

- `perror`

A utility that displays the meaning of system or MySQL error codes. See [Section 4.8.2, “perror — Explain Error Codes”](#).

- `resolveip`

A utility program that resolves a host name to an IP address or vice versa. See [Section 4.8.3, “resolveip — Resolve Host name to IP Address or Vice Versa”](#).

- `zlib_decompress`

A utility that decompresses `mysqlpump` output that was created using ZLIB compression. See [Section 4.8.4, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”](#).

Oracle Corporation also provides the [MySQL Workbench](#) GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include [MySQL Notifier](#) and [MySQL for Excel](#).

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

Environment Variable	Meaning
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file; used for connections to <code>localhost</code>

Environment Variable	Meaning
<code>MYSQL_TCP_PORT</code>	The default port number; used for TCP/IP connections
<code>MYSQL_PWD</code>	The default password
<code>MYSQL_DEBUG</code>	Debug trace options when debugging
<code>TMPDIR</code>	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see [Section 4.9, “MySQL Program Environment Variables”](#).

Use of `MYSQL_PWD` is insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

4.2 Using MySQL Programs

4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. `shell>` represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csch` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (`-`, `--`) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 4.2.4, “Specifying Program Options”](#).

Nooption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nooption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nooption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 4.2.11, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2 Connecting to the MySQL Server

This section describes how to establish a connection to the MySQL server. For additional information if you are unable to connect, see [Section 6.2.9, “Troubleshooting Problems Connecting to MySQL”](#).

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`. For more information on connecting clients such as MySQL Shell by specifying a path, see [Section 4.2.3, “Connecting Using a Path”](#).

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=password mydb
shell> mysql -h localhost -u myname -ppassword mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` option and specify the password value, there must be *no space* between `-p` or `--password=` and the password following it.
- If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
```

```
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

If the server is configured to accept IPv6 connections, clients can connect over IPv6 using `--host>:::1`. See [Section 5.1.11, “IPv6 Support”](#).

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--host=host_name`, `-h host_name`

The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` and the password following it. The default is to send no password.

- `--pipe`, `-W`

On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--port=port_num`, `-P port_num`

The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```

To force a TCP/IP connection to be used instead, specify a `--protocol` option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case-sensitive.

<code>--protocol</code> Value	Connection Protocol	Permissible Operating Systems
<code>TCP</code>	TCP/IP connection to local or remote server	All
<code>SOCKET</code>	Unix socket file connection to local server	Unix only
<code>PIPE</code>	Named-pipe connection to local or remote server	Windows only
<code>MEMORY</code>	Shared-memory connection to local server	Windows only

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name, -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case-sensitive.

The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

[Section 4.2.7, “Using Option Files”](#), discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows only). The password can be specified using `MYSQL_PWD`, although this is insecure; see [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). For a list of variables, see [Section 4.9, “MySQL Program Environment Variables”](#).

4.2.3 Connecting Using a Path

In addition to specifying the connection parameters to an instance of MySQL documented at [Section 4.2.2, “Connecting to the MySQL Server”](#), you can specify the connection to MySQL server using a path. This section consists of:

- [Connection Path Parameters](#)
- [Connecting using a URI String](#)

- [Connecting using a Data Dictionary](#)

The following MySQL clients support specifying the connection to MySQL server using a path:

- MySQL Shell
- MySQL Router
- MySQL Connectors which implement X DevAPI

Many of the parameters you specify in a path are similar to those used with the command options, and this section documents all of the valid path parameters. The connection's parameters can be specified as:

- a URI type string, such as `myuser@example.com:3306/main-schema`. See [Connecting using a URI String](#) for the full syntax.
- a data dictionary of key and value pairs, such as `{user:'myuser', host:'example.com', port:3306, schema:'main-schema'}`. See [Connecting using a Data Dictionary](#) for the full syntax.

Connection Path Parameters

This section describes the parameters available when specifying a connection to MySQL as a path. The following options are valid for use in either a URI type string or in a data dictionary:

- `scheme`: specifies the connection protocol to use. Use `mysqlx` for X Protocol connections and `mysql` for classic MySQL protocol connections. If no protocol is specified, the server attempts to guess the protocol.
- `user`: specifies the MySQL user account to be used for the authentication process.
- `password`: specifies the password to be used for the authentication process.

Warning

Storing the password in the connection path is insecure and not recommended.

- `host`: specifies the server instance the connection refers to. Can be either an IPv4 address, an IPv6 address or a hostname. If not specified, `localhost` is used by default.
- `port`: specifies a network port which the target MySQL server is listening on for connections. If not specified, 33060 is used by default for X Protocol connections, and 3306 is the default for classic MySQL protocol connections.
- `socket`: path to a Unix socket or Windows named-pipe. Values are local file paths and must be encoded in URI type strings, using percent encoding or surrounding the path with parentheses, which removes the need to percent encode characters such as the common directory separator `/`. To connect as `root@localhost` using the Unix socket `/tmp/mysql.sock` either specify the path using parenthesis, for example `root@localhost?socket=(/tmp/mysql.sock)`, or using percent encoding, for example `root@localhost?socket=%2Ftmp%2Fmysql.sock`.
- `schema`: specifies the database to be set as default when the connection is established.
- `?attribute=value`: specifies a data dictionary that contains options.

The connection parameters are case insensitive and can only be defined once. If a parameter is defined more than once, an error is generated.

In addition to the parameters listed in the previous list, the following options are also valid when a dictionary is used:

- `ssl-mode`: the SSL mode to be used for the connection.
- `ssl-ca`: the path to the X.509 certificate authority in PEM format.
- `ssl-capath`: the path to the directory that contains the X.509 certificates authorities in PEM format.
- `ssl-cert`: The path to the X.509 certificate in PEM format.
- `ssl-key`: The path to the X.509 key in PEM format.
- `ssl-crl`: The path to file that contains certificate revocation lists.
- `ssl-crlpath`: The path to the directory that contains certificate revocation list files.
- `ssl-cipher`: the SSL cipher to use.
- `tls-version`: List of protocols permitted for secure connections
- `auth-method`: Authentication method used for the connection. Defaults to `AUTO`, meaning that the server attempts to guess. Can be one of the following:
 - `AUTO`
 - `MYSQL41`
 - `SHA256_MEMORY`
 - `FROM_CAPABILITIES`
 - `FALLBACK`
 - `PLAIN`

When using an X Protocol connection, any configured auth-method is overridden to this sequence of authentication methods: `MYSQL41`, `SHA256_MEMORY`, `PLAIN`.

- `get-server-public-key`: Request public key from the server required for RSA key pair-based password exchange. Use when connecting to MySQL 8.0 servers over classic MySQL protocol with SSL mode `DISABLED`. You must specify the protocol in this case, for example:

```
mysql://user@localhost:3306?get-server-key=true
```

- `server-public-key-path`: The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. Use when connecting to MySQL 8.0 servers over classic MySQL protocol with SSL mode `DISABLED`.

The `?attribute=value` options data dictionary can contain the following options:

- `mycnfPath`: the path to the MySQL configuration file of the instance.
- `outputMycnfPath`: alternative output path to write the MySQL configuration file of the instance.
- `password`: the password to be used by the connection.
- `clusterAdmin`: the name of the InnoDB cluster administrator user to be created. The supported format is the standard MySQL account name format.
- `clusterAdminPassword`: the password for the InnoDB cluster administrator account.
- `clearReadOnly`: a boolean value used to confirm that `super_read_only` must be disabled.

- `interactive`: a boolean value used to disable the interactive wizards which start after issuing commands. For example prompts provided when global variables are not populated, confirmation prompts after changing a instance's configuration.
- `restart`: a boolean value used to indicate that a remote restart of the target instance should be performed to finalize the operation.
- `connect-timeout`: an integer value used to configure the number of seconds clients, such as MySQL Shell, wait until the client stops trying to connect to an unresponsive MySQL server.

Connecting using a URI String

You can specify a connection to MySQL Server using a URI type string format. Such strings can be used with the MySQL Shell with the `--uri` command option, the MySQL Shell `\connect` command, MySQL Connectors which implement X DevAPI, and tools such as MySQL Router.

A URI type string has the following format:

```
[scheme://][user[:[password]]@]target[:port][[/schema]][?attribute1=value1&attribute2=value2...
```

Important

Percent encoding must be used for reserved characters in the elements of the URI type string. For example, if you specify a string that includes the `@` character, the character must be replaced by `%40`. If you include a zone ID in an IPv6 address, the `%` character used as the separator must be replaced with `%25`.

The parameters you can use in a URI type string for a connection are described at [Connection Path Parameters](#).

If no password is specified using the URI type string, which is recommended, then the password is prompted for. The following examples show how to specify URI type strings with the user name `user`, in each case the password is prompted for:

- A classic MySQL protocol connection to a local server instance listening at port 3333.

```
mysql://user@localhost:3333
```

- An X Protocol connection to a local server instance listening at port 33065.

```
mysqlx://user@localhost:33065
```

- An X Protocol connection to a remote server instance, using a host name, an IPv4 address and an IPv6 address.

```
mysqlx://user@server.example.com/
mysqlx://user@198.51.100.14:123
mysqlx://user@[2001:db8:85a3:8d3:1319:8a2e:370:7348]
```

- An optional path can be specified, which represents a database schema.

```
mysqlx://user@198.51.100.1/world%5Fx
mysqlx://user@198.51.100.2:33060/world
```

- An optional query can be specified, consisting of values in the form of a `key=value` pair or as a single `key`. The `,` character is used as a separator for values, a combination of multiple pairs and keys can

be specified. Values can be of type list, list values are ordered by appearance. Strings must be either percent encoded or surrounded by parenthesis. The following are equivalent.

```
ssluser@127.0.0.1?ssl-ca=%2Froot%2Fclientcert%2Fca-cert.pem\
&ssl-cert=%2Froot%2Fclientcert%2Fclient-cert.pem\
&ssl-key=%2Froot%2Fclientcert%2Fclient-key

ssluser@127.0.0.1?ssl-ca=(/root/clientcert/ca-cert.pem)\
&ssl-cert=(/root/clientcert/client-cert.pem)\
&ssl-key=(/root/clientcert/client-key)
```

The previous examples assume that connections require a password, and with interactive clients the specified user's password is requested at the login prompt. If the user has a password-less account, which is insecure and not recommended, or if socket peer-credential authentication is in use (for example with Unix socket connections), you must explicitly specify in the URI type string that no password is being provided and the password prompt is not required. To do this, place a `:` after the `user` in the URI type string but do not specify a password after it. For example:

```
mysqlx://user:@localhost
```

Connecting using a Data Dictionary

You can specify a connection to MySQL Server using a data dictionary of key and value pairs. Data dictionaries can be used with MySQL Shell methods such as `shell.connect()` or `dba.createCluster()`, and with MySQL Connectors which implement X DevAPI.

Data dictionaries are surrounded by `{` and `}` characters and the `,` character is used as a separator between key and value pairs. The `:` character is used between keys and values, and strings must be delimited, for example using the `'` character. It is not necessary to percent encode strings in data dictionaries, unlike URI type strings.

A data dictionary has the following format:

```
{ key: value, key: value, ... }
```

The parameters you can use in a data dictionary for a connection are described at [Connection Path Parameters](#).

If no password is specified using a data dictionary, which is recommended, then the password is prompted for. The following examples show how to specify data dictionaries with the user name `user`, in each case the password is prompted for:

- An X Protocol connection to a local server instance listening at port 33065.

```
{user:'user', host:'localhost', port:33065}
```

- A classic MySQL protocol X Protocol connection to a local server instance listening at port 3333.

```
{user:'user', host:'localhost', port:3333}
```

- An X Protocol connection to a remote server instance, using a host name, an IPv4 address and an IPv6 address.

```
{user:'user', host:'server.example.com'}
{user:'user', host:198.51.100.14:123}
```

```
{user:'user', host:[2001:db8:85a3:8d3:1319:8a2e:370:7348]}
```

- An optional schema can be specified, which represents a database.

```
{user:'user', host:'localhost', schema:'world'}
```

The previous examples assume that connections require a password, and with interactive clients the specified user's password is requested at the login prompt. If the user has a password-less account, which is insecure and not recommended, or if socket peer-credential authentication is in use (for example with Unix socket connections), you must explicitly specify that no password is being provided and the password prompt is not required. To do this, provide an empty string using `' '` after the `password` key. For example:

```
{user:'user', password:'', host:'localhost'}
```

4.2.4 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 4.2.11, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 5.8.3, “Running Multiple MySQL Instances on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

For the server, one exception applies: The `mysqld-auto.cnf` option file in the data directory is processed last, so it takes precedence even over command-line options.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

4.2.5 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case-sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an `=` sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (`-`) and underscore (`_`) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)
- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024 , 1024^2 or 1024^3 . As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024^4 , 1024^5 or 1024^6 . Suffix letters can be uppercase or lowercase.

For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
shell> mysqladmin --count=1K --sleep=10 ping
```

- When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
shell> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
```

```

+-----+
| root | gigan |
|      | gigan |
|      | localhost |
| jon  | localhost |
| root | localhost |
+-----+
shell>

```

**Note**

The long form (`--execute`) is followed by an equals sign (=).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```

shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW();"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 8.0.11    |
+-----+
+-----+
| NOW()     |
+-----+
| 2018-08-05 20:00:20 |
+-----+

```

4.2.6 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```

--disable-column-names
--skip-column-names
--column-names=0

```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```

--column-names
--enable-column-names
--column-names=1

```

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case-sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-back_log=200`, the server produces this error:

```
Maximum value of 'back_log' cannot be set
```

4.2.7 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

A MySQL program started with the `--no-defaults` option reads no option files other than `.mylogin.cnf`.

A server started with the `persisted_globals_load` system variable disabled does not read `mysqld-auto.cnf`.

Many option files are plain text files, created using any text editor. The exceptions are:

- The `.mylogin.cnf` file that contains login path options. This is an encrypted file created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#). A “login path” is an option group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` option.

To specify an alternative login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

- The `mysqld-auto.cnf` file in the data directory. This JSON-format file contains persisted system variable settings. It is created by the server upon execution of `SET PERSIST` or `SET PERSIST_ONLY` statements. See [Section 5.1.8.3, “Persisted System Variables”](#). Management of `mysqld-auto.cnf` should be left to the server and not performed manually.

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Table 4.1 Option Files Read on Windows Systems

File Name	Purpose
%WINDIR%\my.ini, %WINDIR%\my.cnf	Global options
C:\my.ini, C:\my.cnf	Global options
BASEDIR\my.ini, BASEDIR\my.cnf	Global options
defaults-extra-file	The file specified with <code>--defaults-extra-file</code> , if any
%APPDATA%\MySQL\mylogin.cnf	Login path options (clients only)
DATADIR\mysqld-auto.cnf	System variables persisted with <code>SET PERSIST</code> or <code>SET PERSIST_ONLY</code> (server only)

In the preceding table, %WINDIR% represents the location of your Windows directory. This is commonly C:\WINDOWS. Use the following command to determine its exact location from the value of the WINDIR environment variable:

```
C:\> echo %WINDIR%
```

%APPDATA% represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the APPDATA environment variable:

```
C:\> echo %APPDATA%
```

BASEDIR represents the MySQL base installation directory. When MySQL 8.0 has been installed using MySQL Installer, this is typically C:\PROGRAMDIR\MySQL\MySQL 8.0 Server where PROGRAMDIR represents the programs directory (usually Program Files on English-language versions of Windows). See Section 2.3.3, “MySQL Installer for Windows”.

DATADIR represents the MySQL data directory. As used to find mysqld-auto.cnf, its default value is the data directory location built in when MySQL was compiled, but can be changed by `--datadir` specified as an option-file or command-line option processed before mysqld-auto.cnf is processed.

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Table 4.2 Option Files Read on Unix and Unix-Like Systems

File Name	Purpose
/etc/my.cnf	Global options
/etc/mysql/my.cnf	Global options

File Name	Purpose
<code>SYSCONFDIR/my.cnf</code>	Global options
<code>\$MYSQL_HOME/my.cnf</code>	Server-specific options (server only)
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file</code> , if any
<code>~/my.cnf</code>	User-specific options
<code>~/mylogin.cnf</code>	User-specific login path options (clients only)
<code>DATADIR/mysqld-auto.cnf</code>	System variables persisted with <code>SET PERSIST</code> or <code>SET PERSIST_ONLY</code> (server only)

In the preceding table, `~` represents the current user's home directory (the value of `$HOME`).

`SYSCONFDIR` represents the directory specified with the `SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` sets it to `BASEDIR`, the MySQL base installation directory.

`DATADIR` represents the MySQL data directory. As used to find `mysqld-auto.cnf`, its default value is the data directory location built in when MySQL was compiled, but can be changed by `--datadir` specified as an option-file or command-line option processed before `mysqld-auto.cnf` is processed.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

The following description of option file syntax applies to files that you edit manually. This excludes `.mylogin.cnf`, which is created using `mysql_config_editor` and is encrypted, and `mysqld-auto.cnf`, which the server creates in JSON format.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.)

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 4.2.5, "Using Options on the Command Line"](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with `#` or `;`. A `#` comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case-sensitive.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the `=` character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a `#` comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences `\b`, `\t`, `\n`, `\r`, `\\`, and `\s` in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

- A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, `\s` is converted to a space.
- A backslash not followed by a valid escape sequence character remains unchanged. For example, `\S` is retained as is.

The preceding rules mean that a literal backslash can be given as `\\`, or as `\` if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if `"x"` is not a valid escape sequence character, `\x` becomes `"x"` rather than `\x`. See [Section 9.1.1, "String Literals"](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use `\` as a path name separator. A separator in a Windows path name must be written as `\\` if it is followed by an escape sequence character. It can be written as `\\` or `\` if it is not. Alternatively, `/` may be used in Windows path names and will be treated as `\`. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 8.0` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 8.0"
basedir="C:\\Program Files\\MySQL\\MySQL Server 8.0"
basedir="C:/Program Files/MySQL/MySQL Server 8.0"
basedir=C:\\Program\\sFiles\\MySQL\\MySQL\\sServer\\s8.0
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs provided in MySQL distributions (but *not* by `mysqld`). To understand how third-party client programs that use the C API can use option files, see the C API documentation at [Section 27.7.7.50, "mysql_options\(\)"](#).

The `[client]` group enables you to specify options that apply to all clients. For example, `[client]` is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

List more general option groups first and more specific groups later. For example, a `[client]` group is more general because it is read by all client programs, whereas a `[mysqldump]` group is read only by

`mysqldump`. Options specified later override options specified earlier, so putting the option groups in the order `[client]`, `[mysqldump]` enables `mysqldump`-specific options to override `[client]` options.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=128M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my password"

[mysql]
no-auto-rehash
connect_timeout=2
```

To create option groups to be read only by `mysqld` servers from specific MySQL release series, use groups with names of `[mysqld-5.7]`, `[mysqld-8.0]`, and so forth. The following group indicates that the `sql_mode` setting should be used only by MySQL servers with 8.0.x version numbers:

```
[mysqld-8.0]
sql_mode=TRADITIONAL
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

MySQL makes no guarantee about the order in which option files in the directory will be read.

Note

Any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

4.2.8 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, or `--login-path`.
- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see [Section 4.2.7, “Using Option Files”](#).) If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exceptions: Even with `--defaults-file`, `mysqld` reads `mysqld-auto.cnf` and client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

A client program reads the option group corresponding to the named login path, in addition to option groups that the program reads by default. Consider this command:

```
shell> mysql --login-path=mypath
```

By default, the `mysql` client reads the `[client]` and `[mysql]` option groups. So for the command shown, `mysql` reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

Client programs read the login path file even when the `--no-defaults` option is used.

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that client programs read the `.mylogin.cnf` login path file, if it exists, even when `--no-defaults` is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--print-defaults`

Print the program name and all options that it gets from option files. Password values are masked.

4.2.9 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#), and [Section 5.1.8, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024, 1024² or 1024³. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.) As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024⁴, 1024⁵ or 1024⁶. Suffix letters can be uppercase or lowercase.

In an option file, variable settings are given without the leading dashes:

```
[mysql]
```

```
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
```

```
[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

4.2.10 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equals sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```

shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 8.0.15 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@%          |
+-----+
1 row in set (0.00 sec)

```

Omitting the required value for one of these option yields an error, such as the one shown here:

```

shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument

```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```

shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)

```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equals sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```

shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

```

After shutting down the server, restart it as follows:

```

shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```

shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                  ./mysqld_safe --log-error my-errors

```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```

shell> tail /usr/local/mysql/var/tonfisk.err
2013-09-24T15:36:22.278034Z 0 [ERROR] Too many arguments (first extra is 'my-errors').
2013-09-24T15:36:22.278059Z 0 [Note] Use --verbose --help to get a list of available options!
2013-09-24T15:36:22.278076Z 0 [ERROR] Aborting
2013-09-24T15:36:22.279704Z 0 [Note] InnoDB: Starting shutdown...
2013-09-24T15:36:23.777471Z 0 [Note] InnoDB: Shutdown completed; log sequence number 2319086
2013-09-24T15:36:23.780134Z 0 [Note] mysqld: Shutdown complete

```

Because the `--log-error` option supplies a default value, you must use an equals sign to assign a different value to it, as shown here:

```

shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

shell>

```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```

[mysql]

host
user

```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```

shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)

```

However, in option files, an equals sign is not assumed. Suppose the `my.cnf` file is as shown here:

```

[mysql]

user jon

```

Trying to start `mysql` in this case causes a different error:

```

shell> mysql
mysql: unknown option '--user jon'

```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equals sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 8.0.15 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 8.0.15 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &

130924 10:41:46 mysqld_safe Logging to '/home/jon/bin/mysql/var/tonfisk.err'.
130924 10:41:46 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
130924 10:41:47 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
```

The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
shell> tail -n 3 ../var/tonfisk.err
```

```
130924 10:41:46 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
2013-09-24T15:41:47.217180Z 0 [ERROR] /home/jon/bin/mysql/libexec/mysqld: option '--relay-log' requires an
2013-09-24T15:41:47.217479Z 0 [ERROR] Aborting
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using “`relay_log_index`” as the base name. (Bug #25192)

4.2.11 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 4.9, “MySQL Program Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

Note

Some installation packages contain a debugging version of the server named `mysqld-debug`. Invoke this version instead of `mysqld` for debugging support, memory allocation checking, and trace file support (see [Section 28.5.1.2, “Creating Trace Files”](#)).

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 5.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, *Installing and Upgrading MySQL*](#).

4.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes `systemd` support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For more information, see [Section 2.5.9, “Managing MySQL Server with `systemd`”](#).

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to

`mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 5.1.6, “Server Command Options”](#).

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 4.2.7, “Using Option Files”](#).

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` accepts options on the command line and in option files, as described in the following table. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.3 `mysqld_safe` Options

Format	Description
<code>--basedir</code>	Path to MySQL installation directory
<code>--core-file-size</code>	Size of core file that <code>mysqld</code> should be able to create
<code>--datadir</code>	Path to data directory
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--help</code>	Display help message and exit
<code>--ledir</code>	Path to directory where server is located
<code>--log-error</code>	Write error log to named file
<code>--malloc-lib</code>	Alternative malloc library to use for <code>mysqld</code>
<code>--mysqld</code>	Name of server program to start (in <code>ledir</code> directory)
<code>--mysqld-safe-log-timestamps</code>	Timestamp format for logging
<code>--mysqld-version</code>	Suffix for server program name
<code>--nice</code>	Use <code>nice</code> program to set server scheduling priority
<code>--no-defaults</code>	Read no option files
<code>--open-files-limit</code>	Number of files that <code>mysqld</code> should be able to open
<code>--pid-file</code>	Path name of server process ID file
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	Port number on which to listen for TCP/IP connections
<code>--skip-kill-mysqld</code>	Do not try to kill stray <code>mysqld</code> processes
<code>--skip-syslog</code>	Do not write error messages to syslog; use error log file
<code>--socket</code>	Socket file on which to listen for Unix socket connections
<code>--syslog</code>	Write error messages to syslog

Format	Description
<code>--syslog-tag</code>	Tag suffix for messages written to syslog
<code>--timezone</code>	Set TZ time zone environment variable to named value
<code>--user</code>	Run mysqld as user having name <code>user_name</code> or numeric user ID <code>user_id</code>

- `--help`

Display a help message and exit.

- `--basedir=dir_name`

The path to the MySQL installation directory.

- `--core-file-size=size`

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

Note

Disabling `innodb_buffer_pool_in_core_file` can help reduce core file size.

- `--datadir=dir_name`

The path to the data directory.

- `--defaults-extra-file=file_name`

Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--ledir=dir_name`

If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--log-error=file_name`

Write the error log to the given file. See [Section 5.4.2, “The Error Log”](#).

- `--mysqld-safe-log-timestamps`

This option controls the format for timestamps in log output produced by `mysqld_safe`. The following list describes the permitted values. For any other value, `mysqld_safe` logs a warning and uses `UTC` format.

- `UTC`, `utc`

ISO 8601 UTC format (same as `--log_timestamps=UTC` for the server). This is the default.

- `SYSTEM`, `system`

ISO 8601 local time format (same as `--log_timestamps=SYSTEM` for the server).

- `HYPHEN`, `hyphen`

`YY-MM-DD h:mm:ss` format, as in `mysqld_safe` for MySQL 5.6.

- `LEGACY`, `legacy`

`YYMMDD hh:mm:ss` format, as in `mysqld_safe` prior to MySQL 5.6.

- `--malloc-lib=[lib_name]`

The name of the library to use for memory allocation instead of the system `malloc()` library. The option value must be one of the directories `/usr/lib`, `/usr/lib64`, `/usr/lib/i386-linux-gnu`, or `/usr/lib/x86_64-linux-gnu`.

The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.
- If the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib`. If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.
- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Note

On systems that manage the server using `systemd`, `mysqld_safe` is not available. Instead, specify the allocation library by setting `LD_PRELOAD` in `/etc/sysconfig/mysql`.

Linux users can use the `libtcmalloc_minimal.so` library on any platform for which a `tcmalloc` package is installed in `/usr/lib` by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The base name is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--nice=priority`

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--open-files-limit=count`

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`.

Note

You must start `mysqld_safe` as `root` for this to function properly.

- `--pid-file=file_name`

The path name that `mysqld` should use for its process ID file.

- `--plugin-dir=dir_name`

The path name of the plugin directory.

- `--port=port_num`

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld`

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

The Unix socket file that the server should use when listening for local connections.

- `--syslog, --skip-syslog`

`--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

When `syslog` is used for error logging, the `daemon.err` facility/severity is used for all log messages.

Using these options to control `mysqld` logging is deprecated. To write error log output to the system log, use the instructions at [Section 5.4.2.3, “Error Logging to the System Log”](#). To control the facility, use the server `log_syslog_facility` system variable.

- `--syslog-tag=tag`

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with identifiers of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the identifiers, use `--syslog-tag=tag`, which modifies the identifiers to be `mysqld_safe-tag` and `mysqld-tag`.

Using this option to control `mysqld` logging is deprecated. Use the server `log_syslog_tag` system variable instead. See [Section 5.4.2.3, “Error Logging to the System Log”](#).

- `--timezone=timezone`

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See [Section 2.1.4, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

`mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times per second it has attempted to start. If these utilities are present and the attempted starts per second is greater than 5, `mysqld_safe` waits 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--log-error=file_name`: Write error messages to the named error file.
- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.

If none of these options is given, the default is `--skip-syslog`.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Note

Controlling `mysqld` logging from `mysqld_safe` is deprecated. Use the server's native `syslog` support instead. For more information, see [Section 5.4.2.3, “Error Logging to the System Log”](#).

4.3.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named `mysql.server`, which starts the MySQL server using `mysqld_safe`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

`mysql.server` is the script name as used within the MySQL source tree. The installed name might be different; for example, `mysqld` or `mysql`. In the following discussion, adjust the name `mysql.server` as appropriate for your system.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes `systemd` support for managing MySQL server startup and shutdown. On these platforms, `mysql.server` and `mysqld_safe` are not installed because they are unnecessary. For more information, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

To start or stop the server manually using the `mysql.server` script, invoke it from the command line with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

`mysql.server` changes location to the MySQL installation directory, then invokes `mysqld_safe`. To run the server as some specific user, add an appropriate `user` option to the `[mysqld]` group of the global `/etc/my.cnf` option file, as shown later in this section. (It is possible that you must edit `mysql.server` if you’ve installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your `/etc/rc*` files:

- If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysqld` or `mysql`. See [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for more information on the Linux RPM packages.
- If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install the script manually. It can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the `/etc/init.d` directory with the name `mysql` and make it executable:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

- On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. Install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup. The `rc(8)` manual page states that scripts in this directory are executed only if their base name matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored.
- As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

- For other systems, consult your operating system documentation to see how to install startup scripts.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, but to be current you should rename such sections to `[mysql.server]`.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the options shown in the following table. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

Table 4.4 mysql.server Option-File Options

Option Name	Description	Type
<code>basedir</code>	Path to MySQL installation directory	Directory name
<code>datadir</code>	Path to MySQL data directory	Directory name
<code>pid-file</code>	File in which server should write its process ID	File name
<code>service-startup-timeout</code>	How long to wait for server startup	Integer

- `basedir=dir_name`

The path to the MySQL installation directory.

- `datadir=dir_name`

The path to the MySQL data directory.

- `pid-file=file_name`

The path name of the file in which the server should write its process ID.

If this option is not given, `mysql.server` uses a default value of `host_name.pid`. The PID file value passed to `mysqld_safe` overrides any value specified in the `[mysqld_safe]` option file group. Because `mysql.server` reads the `[mysqld]` option file group but not the `[mysqld_safe]` group, you can ensure that `mysqld_safe` gets the same value when invoked from `mysql.server` as when invoked manually by putting the same `pid-file` setting in both the `[mysqld_safe]` and `[mysqld]` groups.

- `service-startup-timeout=seconds`

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

4.3.4 `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_multi` is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or `GNR`. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the `GNR` list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each `GNR` value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the `GNR` for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The `GNR` value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the `GNR` list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysql_d_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysql_d_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysql_d_multi --example
```

`mysql_d_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for `[mysql_d_multi]` and `[mysqldN]` option groups. The `[mysql_d_multi]` group can be used for options to `mysql_d_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file will be used for that instance.

`mysql_d_multi` supports the following options.

- `--help`

Display a help message and exit.

- `--example`

Display a sample option file.

- `--log=file_name`

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the

descriptions for these options in [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).)
Example:

```
[mysqld38]  
mysqld = mysqld-debug  
ledir = /opt/local/mysql/libexec
```

- `--no-log`

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Silent mode; disable warnings.

- `--tcp-ip`

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Be more verbose.

- `--version`

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has

the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See [Section 6.2, “The MySQL Access Privilege System”](#). You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)
- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`). Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault.
- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld      = /usr/local/mysql/bin/mysqld_safe
mysqladmin  = /usr/local/mysql/bin/mysqladmin
user        = multi_admin
password    = my_password

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/data2/hostname.pid2
datadir     = /usr/local/mysql/data2
language    = /usr/local/mysql/share/mysql/english
user        = unix_user1

[mysqld3]
mysqld      = /path/to/mysqld_safe
ledir       = /path/to/mysqld-binary/
mysqladmin  = /path/to/mysqladmin
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/data3/hostname.pid3
datadir     = /usr/local/mysql/data3
language    = /usr/local/mysql/share/mysql/swedish
```

```
user      = unix_user2

[mysqld4]
socket    = /tmp/mysql.sock4
port      = 3309
pid-file  = /usr/local/mysql/data4/hostname.pid4
datadir   = /usr/local/mysql/data4
language  = /usr/local/mysql/share/mysql/estonia
user      = unix_user3

[mysqld6]
socket    = /tmp/mysql.sock6
port      = 3311
pid-file  = /usr/local/mysql/data6/hostname.pid6
datadir   = /usr/local/mysql/data6
language  = /usr/local/mysql/share/mysql/japanese
user      = unix_user4
```

See [Section 4.2.7, “Using Option Files”](#).

4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the text file located at `sql/share/errmsg-utf8.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the [MySQL Internals Manual](#).

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--charset=dir_name, -C dir_name`

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:O,file_name`. The default is `d:t:O,/tmp/comp_err.trace`.

- `--debug-info, -T`

Print some debugging information when the program exits.

- `--header_file=file_name, -H file_name`

The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name, -F file_name`

The name of the input file. The default is `../sql/share/errmsg-utf8.txt`.

- `--name_file=file_name, -N file_name`

The name of the error name file. The default is `mysqld_ename.h`.

- `--out_dir=dir_name, -D dir_name`

The name of the output base directory. The default is `../sql/share/`.

- `--out_file=file_name, -O file_name`

The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name, -S file_name`

The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version, -V`

Display version information and exit.

4.4.2 `mysql_secure_installation` — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.10.4, “Securing the Initial MySQL Account”](#).

Normal usage is to connect to the local MySQL server; invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

When executed, `mysql_secure_installation` prompts you to determine which actions to perform.

The `validate_password` component can be used for password strength checking. If the plugin is not installed, `mysql_secure_installation` prompts the user whether to install it. Any passwords entered later are checked using the plugin if it is enabled.

Most of the usual MySQL client options such as `--host` and `--port` can be used on the command line and in option files. For example, to connect to the local server over IPv6 using port 3307, use this command:

```
shell> mysql_secure_installation --host=::1 --port=3307
```

`mysql_secure_installation` supports the following options, which can be specified on the command line or in the `[mysql_secure_installation]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.5 mysql_secure_installation Options

Format	Description	Introduced
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files	
<code>--defaults-file</code>	Read only named option file	
<code>--defaults-group-suffix</code>	Option group suffix value	
<code>--help</code>	Display help message and exit	
<code>--host</code>	Host to connect to (IP address or host name)	
<code>--no-defaults</code>	Read no option files	
<code>--password</code>	Accepted but always ignored. Whenever <code>mysql_secure_installation</code> is invoked, the user is prompted for a password, regardless.	
<code>--port</code>	TCP/IP port number for connection	
<code>--print-defaults</code>	Print default options	
<code>--protocol</code>	Connection protocol to use	
<code>--socket</code>	For connections to localhost, the Unix socket file to use	
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities	
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files	
<code>--ssl-cert</code>	File that contains X.509 certificate	
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption	
<code>--ssl-crl</code>	File that contains certificate revocation lists	
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files	
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11
<code>--ssl-key</code>	File that contains X.509 key	
<code>--tls-version</code>	Protocols permitted for encrypted connections	
<code>--use-default</code>	Execute with no user interactivity	
<code>--user</code>	MySQL user name to use when connecting to server	

- `--help, -?`

Display a help message and exit.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysql_secure_installation` normally reads the `[client]` and `[mysql_secure_installation]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_secure_installation` also reads the `[client_other]` and `[mysql_secure_installation_other]` groups.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password=password, -p password`

This option is accepted but ignored. Whether or not this option is used, `mysql_secure_installation` always prompts the user for a password.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--use-default`

Execute noninteractively. This option can be used for unattended installation operations.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

4.4.3 mysql_ssl_rsa_setup — Create SSL/RSA Files

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing. `mysql_ssl_rsa_setup` can also be used to create new SSL files if the existing ones have expired.

**Note**

`mysql_ssl_rsa_setup` uses the `openssl` command, so its use is contingent on having OpenSSL installed on your machine.

Another way to generate SSL and RSA files, for MySQL distributions compiled using OpenSSL, is to have the server generate them automatically. See [Section 6.4.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

**Important**

`mysql_ssl_rsa_setup` helps lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by `mysql_ssl_rsa_setup` are self-signed, which is not very secure. After you gain experience using the files created by `mysql_ssl_rsa_setup`, consider obtaining a CA certificate from a registered certificate authority.

Invoke `mysql_ssl_rsa_setup` like this:

```
shell> mysql_ssl_rsa_setup [options]
```

Typical options are `--datadir` to specify where to create the files, and `--verbose` to see the `openssl` commands that `mysql_ssl_rsa_setup` executes.

`mysql_ssl_rsa_setup` attempts to create SSL and RSA files using a default set of file names. It works as follows:

1. `mysql_ssl_rsa_setup` checks for the `openssl` binary at the locations specified by the `PATH` environment variable. If `openssl` is not found, `mysql_ssl_rsa_setup` does nothing. If `openssl` is present, `mysql_ssl_rsa_setup` looks for default SSL and RSA files in the MySQL data directory specified by the `--datadir` option, or the compiled-in data directory if the `--datadir` option is not given.
2. `mysql_ssl_rsa_setup` checks the data directory for SSL files with the following names:

```
ca.pem
server-cert.pem
server-key.pem
```

3. If any of those files are present, `mysql_ssl_rsa_setup` creates no SSL files. Otherwise, it invokes `openssl` to create them, plus some additional files:

```
ca.pem           Self-signed CA certificate
ca-key.pem       CA private key
server-cert.pem  Server certificate
server-key.pem   Server private key
client-cert.pem  Client certificate
client-key.pem   Client private key
```

These files enable secure client connections using SSL; see [Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”](#).

4. `mysql_ssl_rsa_setup` checks the data directory for RSA files with the following names:

```
private_key.pem  Private member of private/public key pair
public_key.pem   Public member of private/public key pair
```

5. If any of these files are present, `mysql_ssl_rsa_setup` creates no RSA files. Otherwise, it invokes `openssl` to create them. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

For information about the characteristics of files created by `mysql_ssl_rsa_setup`, see [Section 6.4.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

At startup, the MySQL server automatically uses the SSL files created by `mysql_ssl_rsa_setup` to enable SSL if no explicit SSL options are given other than `--ssl` (possibly along with `--ssl-cipher`). If you prefer to designate the files explicitly, invoke clients with the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options at startup to name the `ca.pem`, `server-cert.pem`, and `server-key.pem` files, respectively.

The server also automatically uses the RSA files created by `mysql_ssl_rsa_setup` to enable RSA if no explicit RSA options are given.

If the server is SSL-enabled, clients use SSL by default for the connection. To specify certificate and key files explicitly, use the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options to name the `ca.pem`, `client-`

`cert.pem`, and `client-key.pem` files, respectively. However, some additional client setup may be required first because `mysql_ssl_rsa_setup` by default creates those files in the data directory. The permissions for the data directory normally enable access only to the system account that runs the MySQL server, so client programs cannot use files located there. To make the files available, copy them to a directory that is readable (but *not* writable) by clients:

- For local clients, the MySQL installation directory can be used. For example, if the data directory is a subdirectory of the installation directory and your current location is the data directory, you can copy the files like this:

```
cp ca.pem client-cert.pem client-key.pem ..
```

- For remote clients, distribute the files using a secure channel to ensure they are not tampered with during transit.

If the SSL files used for a MySQL installation have expired, you can use `mysql_ssl_rsa_setup` to create new ones:

1. Stop the server.
2. Rename or remove the existing SSL files. You may wish to make a backup of them first. (The RSA files do not expire, so you need not remove them. `mysql_ssl_rsa_setup` will see that they exist and not overwrite them.)
3. Run `mysql_ssl_rsa_setup` with the `--datadir` option to specify where to create the new files.
4. Restart the server.

`mysql_ssl_rsa_setup` supports the following command-line options, which can be specified on the command line or in the `[mysql_ssl_rsa_setup]` and `[mysqld]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.6 mysql_ssl_rsa_setup Options

Format	Description
<code>--datadir</code>	Path to data directory
<code>--help</code>	Display help message and exit
<code>--suffix</code>	Suffix for X.509 certificate Common Name attribute
<code>--uid</code>	Name of effective user to use for file permissions
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit

- `--help, ?`

Display a help message and exit.

- `--datadir=dir_name`

The path to the directory that `mysql_ssl_rsa_setup` should check for default SSL and RSA files and in which it should create files if they are missing. The default is the compiled-in data directory.

- `--suffix=str`

The suffix for the Common Name attribute in X.509 certificates. The suffix value is limited to 17 characters. The default is based on the MySQL version number.

- `--uid=name, -v`

The name of the user who should be the owner of any created files. The value is a user name, not a numeric user ID. In the absence of this option, files created by `mysql_ssl_rsa_setup` are owned by the user who executes it. This option is valid only if you execute the program as `root` on a system that supports the `chown()` system call.

- `--verbose, -v`

Verbose mode. Produce more output about what the program does. For example, the program shows the `openssl` commands it runs, and produces output to indicate whether it skips SSL or RSA file creation because some default file already exists.

- `--version, -V`

Display version information and exit.

4.4.4 `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 5.1.12, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

4.4.5 `mysql_upgrade` — Check and Upgrade MySQL Tables

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see [Section 2.11.3, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies.

You should execute `mysql_upgrade` each time you upgrade MySQL.

`mysql_upgrade` communicates directly with the MySQL server, sending it the SQL statements required to perform an upgrade.

Caution

You should always back up your current MySQL installation *before* performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See [Section 2.11.1, “Upgrading MySQL”](#), for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running. Then invoke it like this to check and repair tables and to upgrade the system tables:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

If you have multiple MySQL server instances running, invoke `mysql_upgrade` with connection parameters appropriate for connecting to the desired server. For example, with servers running on the local host on ports 3306 through 3308, upgrade each of them by connecting to the appropriate port:

```
shell> mysql_upgrade --protocol=tcp -P 3306 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3307 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3308 [other_options]
```

For local host connections on Unix, the `--protocol=tcp` option forces a connection using TCP/IP rather than the Unix socket file.

Note

If you run the server with the `disabled_storage_engines` system variable set to disable certain storage engines (for example, `MyISAM`), `mysql_upgrade` might fail with an error like this:

```
mysql_upgrade: [ERROR] 3161: Storage engine MyISAM is disabled
(Table creation is disallowed).
```

To handle this, restart the server with `disabled_storage_engines` disabled. Then you should be able to run `mysql_upgrade` successfully. After that, restart the server with `disabled_storage_engines` set to its original value.

`mysql_upgrade` processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.

For details about what table-checking operations entail, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see [Section 13.7.3.2, “CHECK TABLE Syntax”](#)).

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

`mysql_upgrade` checks `user` table rows and, for any row with an empty `plugin` column, sets that column to `'mysql_native_password'` if the credentials use a hash format compatible with that plugin. Rows with a pre-4.1 password hash must be upgraded manually.

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.14, “Server-Side Help”](#).

Unless invoked with the `--skip-sys-schema` option, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. `mysql_upgrade` returns an error if a `sys` schema exists but has no `version` view, on the assumption that its absence indicates a user-created schema:

```
Error occurred: A sys schema exists with no sys.version view. If
you have a user created sys schema, this must be renamed for the
upgrade to succeed.
```

To upgrade in this case, remove or rename the existing `sys` schema first.

`mysql_upgrade` checks for partitioned `InnoDB` tables that were created using the generic partitioning handler and attempts to upgrade them to `InnoDB` native partitioning. You can upgrade such tables individually in the `mysql` client using the `ALTER TABLE ... UPGRADE PARTITIONING` SQL statement.

By default, `mysql_upgrade` runs as the MySQL `root` user. If the `root` password is expired when you run `mysql_upgrade`, you will see a message that your password is expired and that `mysql_upgrade` failed as a result. To correct this, reset the `root` password to unexpire it and run `mysql_upgrade` again. First, connect to the server as `root`:

```
shell> mysql -u root -p
Enter password: ****  <- enter root password here
```

Reset the password using `ALTER USER`:

```
mysql> ALTER USER USER() IDENTIFIED BY 'root-password';
```

Then exit `mysql` and run `mysql_upgrade` again:

```
shell> mysql_upgrade [options]
```

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.7 mysql_upgrade Options

Format	Description	Introduced
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server	
<code>--character-sets-dir</code>	Directory where character sets are installed	
<code>--compress</code>	Compress all information sent between client and server	
<code>--debug</code>	Write debugging log	
<code>--debug-check</code>	Print debugging information when program exits	
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits	
<code>--default-auth</code>	Authentication plugin to use	
<code>--default-character-set</code>	Specify default character set	
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files	
<code>--defaults-file</code>	Read only named option file	
<code>--defaults-group-suffix</code>	Option group suffix value	
<code>--force</code>	Force execution even if <code>mysql_upgrade</code> has already been executed for current version of MySQL	
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3
<code>--help</code>	Display help message and exit	
<code>--host</code>	Connect to MySQL server on given host	
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>	
<code>--max-allowed-packet</code>	Maximum packet length to send to or receive from server	
<code>--net-buffer-length</code>	Buffer size for TCP/IP and socket communication	
<code>--no-defaults</code>	Read no option files	
<code>--password</code>	Password to use when connecting to server	
<code>--pipe</code>	On Windows, connect to server using named pipe	
<code>--plugin-dir</code>	Directory where plugins are installed	
<code>--port</code>	TCP/IP port number for connection	
<code>--print-defaults</code>	Print default options	
<code>--protocol</code>	Connection protocol to use	
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections	
<code>--skip-sys-schema</code>	Do not install or upgrade the sys schema	
<code>--socket</code>	For connections to localhost, the Unix socket file to use	
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities	
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files	

Format	Description	Introduced
<code>--ssl-cert</code>	File that contains X.509 certificate	
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption	
<code>--ssl-crl</code>	File that contains certificate revocation lists	
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files	
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11
<code>--ssl-key</code>	File that contains X.509 key	
<code>--ssl-mode</code>	Security state of connection to server	
<code>--tls-version</code>	Protocols permitted for encrypted connections	
<code>--upgrade-system-tables</code>	Update only system tables, not data	
<code>--user</code>	MySQL user name to use when connecting to server	
<code>--verbose</code>	Verbose mode	
<code>--version-check</code>	Check for proper server version	
<code>--write-binlog</code>	Write all statements to binary log	

- `--help`

Display a short help message and exit.

- `--basedir=dir_name`

The path to the MySQL installation directory.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_upgrade.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_upgrade` normally reads the `[client]` and `[mysql_upgrade]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_upgrade` also reads the `[client_other]` and `[mysql_upgrade_other]` groups.

- `--force`

Ignore the `mysql_upgrade_info` file and force execution even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--max-allowed-packet=value`

The maximum size of the buffer for client/server communication. The default value is 24MB. The minimum and maximum values are 4KB and 2GB.

- `--net-buffer-length=value`

The initial size of the buffer for client/server communication. The default value is 1MB – 1KB. The minimum and maximum values are 4KB and 16MB.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql_upgrade` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql_upgrade` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--skip-sys-schema`

`mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. The `--skip-sys-schema` option suppresses this behavior.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the

SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--upgrade-system-tables, -s`

Upgrade only the system tables, do not upgrade data.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server. The default user name is `root`.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version-check, -k`

Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`.

- `--write-binlog`

By default, binary logging by `mysql_upgrade` is disabled. Invoke the program with `--write-binlog` if you want its actions to be written to the binary log.

When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade`.

4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

4.5.1 `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Note

Alternatively, MySQL Shell offers access to the X DevAPI. For details, see [MySQL Shell 8.0 \(part of MySQL 8.0\)](#).

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password db_name
```

```
Enter password: your_password
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

Typing **Control+C** interrupts the current statement if there is one, or cancels any partial input line otherwise.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See [Section 4.5.1.3, “mysql Logging”](#).

4.5.1.1 mysql Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.8 mysql Options

Format	Description	Introduced	Removed
<code>--auto-rehash</code>	Enable automatic rehashing		
<code>--auto-vertical-output</code>	Enable automatic vertical result set display		
<code>--batch</code>	Do not use history file		
<code>--binary-as-hex</code>	Display binary values in hexadecimal notation	8.0.2	
<code>--binary-mode</code>	Disable <code>\r\n</code> - to - <code>\n</code> translation and treatment of <code>\0</code> as end-of-query		
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--character-sets-dir</code>	Directory where character sets are installed		
<code>--column-names</code>	Write column names in results		
<code>--column-type-info</code>	Display result set metadata		
<code>--comments</code>	Whether to retain or strip comments in statements sent to the server		
<code>--compress</code>	Compress all information sent between client and server		
<code>--connect-expired-password</code>	Indicate to server that client can handle expired-password sandbox mode.		
<code>--connect_timeout</code>	Number of seconds before connection timeout		
<code>--database</code>	The database to use		
<code>--debug</code>	Write debugging log; supported only if MySQL was built with debugging support		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		

Format	Description	Introduced	Removed
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--delimiter</code>	Set the statement delimiter		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--execute</code>	Execute the statement and quit		
<code>--force</code>	Continue even if an SQL error occurs		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--histignore</code>	Patterns specifying which statements to ignore for logging		
<code>--host</code>	Connect to MySQL server on given host		
<code>--html</code>	Produce HTML output		
<code>--ignore-spaces</code>	Ignore spaces after function names		
<code>--init-command</code>	SQL statement to execute after connecting		
<code>--line-numbers</code>	Write line numbers for errors		
<code>--local-infile</code>	Enable or disable for LOCAL capability for LOAD DATA INFILE		
<code>--login-path</code>	Read login path options from .mylogin.cnf		
<code>--max_allowed_packet</code>	Maximum packet length to send to or receive from server		
<code>--max_join_size</code>	The automatic limit for rows in a join when using --safe-updates		
<code>--named-commands</code>	Enable named mysql commands		
<code>--net_buffer_length</code>	Buffer size for TCP/IP and socket communication		
<code>--no-auto-rehash</code>	Disable automatic rehashing		
<code>--no-beep</code>	Do not beep when errors occur		
<code>--no-defaults</code>	Read no option files		
<code>--one-database</code>	Ignore statements except those for the default database named on the command line		
<code>--pager</code>	Use the given command for paging query output		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--prompt</code>	Set the prompt to the specified format		
<code>--protocol</code>	Connection protocol to use		

Format	Description	Introduced	Removed
<code>--quick</code>	Do not cache each query result		
<code>--raw</code>	Write column values without escape conversion		
<code>--reconnect</code>	If the connection to the server is lost, automatically try to reconnect		
<code>--i-am-a-dummy, --safe-updates</code>	Allow only UPDATE and DELETE statements that specify key values		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--select_limit</code>	The automatic limit for SELECT statements when using <code>--safe-updates</code>		
<code>--server-public-key-path</code>	Path name to file containing RSA public key		
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--show-warnings</code>	Show warnings after each statement if there are any		
<code>--sigint-ignore</code>	Ignore SIGINT signals (typically the result of typing Control+C)		
<code>--silent</code>	Silent mode		
<code>--skip-auto-rehash</code>	Disable automatic rehashing		
<code>--skip-column-names</code>	Do not write column names in results		
<code>--skip-line-numbers</code>	Skip line numbers for errors		
<code>--skip-named-commands</code>	Disable named mysql commands		
<code>--skip-pager</code>	Disable paging		
<code>--skip-reconnect</code>	Disable reconnecting		
<code>--socket</code>	For connections to localhost, the Unix socket file or Windows named pipe to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--syslog</code>	Log interactive statements to syslog		
<code>--table</code>	Display output in tabular format		
<code>--tee</code>	Append a copy of output to named file		
<code>--tls-version</code>	Protocols permitted for encrypted connections		

Format	Description	Introduced	Removed
<code>--unbuffered</code>	Flush the buffer after each query		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		
<code>--vertical</code>	Print query output rows vertically (one line per column value)		
<code>--wait</code>	If the connection cannot be established, wait and retry instead of aborting		
<code>--xml</code>	Produce XML output		

- `--help, -?`

Display a help message and exit.

- `--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

Note

This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- `--auto-vertical-output`

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch, -B`

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--binary-as-hex`

When this option is given, `mysql` displays binary data using hexadecimal notation (`0xvalue`). This occurs whether the overall output display format is tabular, vertical, HTML, or XML.

- `--binary-mode`

This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator. `--`

`binary-mode` disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--column-names`

Write column names in results.

- `--column-type-info`

Display result set metadata.

- `--comments, -c`

Whether to strip or preserve comments in statements sent to the server. The default is `--skip-comments` (strip comments), enable with `--comments` (preserve comments).

Note

The `mysql` client always passes optimizer hints to the server, regardless of whether this option is given.

Comment stripping is deprecated. This feature and the options to control it will be removed in a future MySQL release.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--connect-expired-password`

Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See [Section 6.3.9, “Server Handling of Expired Passwords”](#).)

- `--database=db_name, -D db_name`

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use *charset_name* as the default character set for the client and connection.

This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

For more information, see [Section 10.4, “Connection Character Sets and Collations”](#), and [Section 10.14, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--delimiter=str`

Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands`

Disable named commands. Use the `*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 4.5.1.2, “mysql Commands”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--execute=statement, -e statement`

Execute the statement and quit. The default output format is like that produced with `--batch`. See [Section 4.2.5, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.

- `--force, -f`

Continue even if an SQL error occurs.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--histignore`

A colon-separated list of one or more patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list (`"*IDENTIFIED*: *PASSWORD*"`). The value specified for this option affects logging of statements written to the history file, and to `syslog` if the `--syslog` option is given. For more information, see [Section 4.5.1.3, “mysql Logging”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--html, -H`

Produce HTML output.

- `--ignore-spaces, -i`

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see [Section 5.1.10, “Server SQL Modes”](#)).

- `--init-command=str`

SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers`

Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. For `mysql`, this capability is disabled by default. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling local data loading also requires that the server permits it; see [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#)

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--named-commands, -G`

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See [Section 4.5.1.2, “mysql Commands”](#).

- `--no-auto-rehash, -A`

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep, -b`

Do not beep when errors occur.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--one-database, -o`

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.

- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.

- `--pager[=command]`

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. [Section 4.5.1.2, “mysql Commands”](#), discusses output paging further.

- `--password[=password]`, `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe`, `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num`, `-P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--prompt=format_str`

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 4.5.1.2, “mysql Commands”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick`, `-q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw, -r`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \       |
+-----+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect`

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates, --i-am-a-dummy, -U`

If this option is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. In addition, restrictions are placed on `SELECT` statements that produce (or are estimated to produce) very large result sets. If you have set this option in an option file, you can use `--skip-safe-updates` on the command line to override it. For more information about this option, see [Using Safe-Updates Mode \(--safe-updates\)](#).

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

This option is available only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--show-warnings`

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

- `--silent, -s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names, -N`

Do not write column names in results.

- `--skip-line-numbers, -L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.

- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--syslog, -j`

This option causes `mysql` to send interactive statements to the system logging facility. On Unix, this is `syslog`; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the `/var/log/messages` file.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'test', QUERY:'SHOW TABLES;'
```

For more information, see [Section 4.5.1.3, “mysql Logging”](#).

- `--table, -t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name`

Append a copy of output to the given file. This option works only in interactive mode. [Section 4.5.1.2, “mysql Commands”](#), discusses tee files further.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--unbuffered, -n`

Flush the buffer after each query.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait, -w`

If the connection cannot be established, wait and retry instead of aborting.

- `--xml, -X`

Produce XML output.

```
<field name="column_name">NULL</field>
```

The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), for details.

The XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>

<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="Variable_name">version</field>
    <field name="Value">5.0.40-debug</field>
  </row>

  <row>
    <field name="Variable_name">version_comment</field>
    <field name="Value">Source distribution</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_machine</field>
    <field name="Value">i686</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_os</field>
    <field name="Value">suse-linux-gnu</field>
  </row>
</resultset>
```

(See Bug #25946.)

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The number of seconds before connection timeout. (Default value is 0.)

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `max_join_size`

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `net_buffer_length`

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

4.5.1.2 mysql Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?          (?) Synonym for 'help'.
clear      (\c) Clear the current input statement.
connect    (\r) Reconnect to the server. Optional arguments are db and host.
delimiter  (\d) Set statement delimiter.
edit       (\e) Edit command with $EDITOR.
ego        (\G) Send command to mysql server, display result vertically.
exit       (\q) Exit mysql. Same as quit.
go         (\g) Send command to mysql server.
help       (\h) Display this help.
nopager    (\n) Disable pager, print to stdout.
notee      (\t) Don't write into outfile.
pager      (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (\p) Print current command.
prompt     (\R) Change your mysql prompt.
quit       (\q) Quit mysql.
rehash     (\#) Rebuild completion hash.
source     (\.) Execute an SQL script file. Takes a file name as an argument.
status     (\s) Get status information from the server.
system     (\!) Execute a system shell command.
tee        (\T) Set outfile [to_outfile]. Append everything into given
           outfile.
use        (\u) Use another database. Takes database name as argument.
charset    (\C) Switch to another charset. Might be needed for processing
           binlog with multi-byte charsets.
warnings   (\W) Show warnings after every statement.
nowarning  (\w) Don't show warnings after every statement.
resetconnection(\x) Clean session context.

For server side help, type 'help contents'
```

If `mysql` is invoked with the `--binary-mode` option, all `mysql` commands are disabled except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

Each command has both a long and short form. The long form is not case-sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line `/* ... */` comments is not supported.

- `help [arg], \h [arg], \? [arg], ? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 4.5.1.4, “mysql Server-Side Help”](#).

- `charset charset_name, \C charset_name`

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]], \r [db_name host_name]]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (`;`).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (`'`), double quote (`"`), or backtick (```) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (`\`) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `x`, you will be unable to use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `x`.

When the delimiter recognized by `mysql` is set to something other than the default of `;`, instances of that character are sent to the server without interpretation. However, the server itself still interprets `;` as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Section 27.7.19, “C API Multiple Statement Execution Support”](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 23.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Disable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`

Print the current input statement without executing it.

- `prompt [str], \R [str]`

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit, \q`

Exit `mysql`.

- `rehash, \#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `resetconnection, \x`

Reset the connection to clear the session state.

Resetting a connection has effects similar to `mysql_change_user()` or an auto-reconnect except that the connection is not closed and reopened, and re-authentication is not done. See [Section 27.7.7.3](#), “`mysql_change_user()`” and see [Section 27.7.24](#), “C API Automatic Reconnection Control”.

This example shows how `resetconnection` clears a value maintained in the session state:

```
mysql> SELECT LAST_INSERT_ID(3);
+-----+
| LAST_INSERT_ID(3) |
+-----+
| 3 |
+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 3 |
+-----+

mysql> resetconnection;

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 0 |
+-----+
```

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\\`.

Quote characters are taken as part of the file name itself. For best results, the name should not include space characters.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running with `--safe-updates` enabled, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- `tee [file_name], \T [file_name]`

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \  
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description
<code>\C</code>	The current connection identifier
<code>\c</code>	A counter that increments for each statement you issue

Option	Description
\D	The full current date
\d	The default database
\h	The server host
\l	The current delimiter
\m	Minutes of the current time
\n	A newline character
\O	The current month in three-letter format (Jan, Feb, ...)
\o	The current month in numeric format
\P	am/pm
\p	The current TCP/IP port or socket file
\R	The current time, in 24-hour military time (0–23)
\r	The current time, standard 12-hour time (1–12)
\S	Semicolon
\s	Seconds of the current time
\t	A tab character
\U	Your full <code>user_name@host_name</code> account name
\u	Your user name
\v	The server version
\w	The current day of the week in three-letter format (Mon, Tue, ...)
\Y	The current year, four digits
\y	The current year, two digits
_	A space
\	A space (a space follows the backslash)
\'	Single quote
\"	Double quote
\\	A literal \ backslash character
\x	<code>x</code> , for any “ <code>x</code> ” not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\u@\h) [\d]>\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 4.2.7, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]
prompt="\r:\m:\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

4.5.1.3 mysql Logging

The `mysql` client can do these types of logging for statements executed interactively:

- On Unix, `mysql` writes the statements to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.
- On all platforms, if the `--syslog` option is given, `mysql` writes the statements to the system logging facility. On Unix, this is `syslog`; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the `/var/log/messages` file.

The following discussion describes characteristics that apply to all logging types and provides information specific to each logging type.

- [How Logging Occurs](#)
- [Controlling the History File](#)
- [syslog Logging Characteristics](#)

How Logging Occurs

For each enabled logging destination, statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` or `--execute` option.
- Statements are ignored and not logged if they match any pattern in the “ignore” list. This list is described later.

- `mysql` logs each nonignored, nonempty statement line individually.
- If a nonignored statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
-> 'Today is'
-> ,
-> CURDATE()
-> ;
```

In this case, `mysql` logs the “SELECT”, “Today is”, “,”, “CURDATE()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()\n` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

`mysql` ignores for logging purposes statements that match any pattern in the “ignore” list. By default, the pattern list is `"*IDENTIFIED*: *PASSWORD*"`, to ignore statements that refer to passwords. Pattern matching is not case sensitive. Within patterns, two characters are special:

- `?` matches any single character.
- `*` matches any sequence of zero or more characters.

To specify additional patterns, use the `--histignore` option or set the `MYSQL_HISTIGNORE` environment variable. (If both are specified, the option value takes precedence.) The value should be a colon-separated list of one or more patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for `UPDATE` and `DELETE` statements in addition to statements that refer to passwords, invoke `mysql` like this:

```
shell> mysql --histignore="*UPDATE*: *DELETE*"
```

Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

syslog Logging Characteristics

If the `--syslog` option is given, `mysql` writes interactive statements to the system logging facility. Message logging has the following characteristics.

Logging occurs at the “information” level. This corresponds to the `LOG_INFO` priority for `syslog` on Unix/Linux `syslog` capability and to `EVENTLOG_INFORMATION_TYPE` for the Windows Event Log. Consult your system documentation for configuration of your logging capability.

Message size is limited to 1024 bytes.

Messages consist of the identifier `MysqlClient` followed by these values:

- `SYSTEM_USER`

The system user name (login name) or `--` if the user is unknown.

- `MYSQL_USER`

The MySQL user name (specified with the `--user` option) or `--` if the user is unknown.

- `CONNECTION_ID`:

The client connection identifier. This is the same as the `CONNECTION_ID()` function value within the session.

- `DB_SERVER`

The server host or `--` if the host is unknown.

- `DB`

The default database or `--` if no database has been selected.

- `QUERY`

The text of the logged statement.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'test', QUERY:'SHOW TABLES;'
```

4.5.1.4 mysql Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.14, “Server-Side Help”](#)).

If there is no match for the search string, the search fails:

```
mysql> help me
```

Nothing found

Please try to run 'help contents' for a list of all accessible topics

Use `help contents` to see a list of the help categories:

```
mysql> help contents
```

You asked for help about help category: "Contents"

For more information, type 'help <item>', where <item> is one of the following categories:

- Account Management
- Administration
- Data Definition
- Data Manipulation
- Data Types
- Functions
- Functions and Modifiers for Use with GROUP BY
- Geographic Features
- Language Structure
- Plugins
- Storage Engines
- Stored Routines
- Table Maintenance
- Transactions
- Triggers

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
```

Many help items for your request exist.

To make a more specific request, please type 'help <item>', where <item> is one of the following topics:

- SHOW
- SHOW BINARY LOGS
- SHOW ENGINE
- SHOW LOGS

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
```

Name: 'SHOW BINARY LOGS'

Description:

Syntax:

SHOW BINARY LOGS

SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in [purge-binary-logs], that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
```

Log_name	File_size
binlog.000015	724935
binlog.000016	733481

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP rep%` returns a list of topics that begin with `rep`:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
  REPAIR TABLE
  REPEAT FUNCTION
  REPEAT LOOP
  REPLACE
  REPLACE FUNCTION
```

4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see [Section 3.5, “Using mysql in Batch Mode”](#).

4.5.1.6 mysql Tips

This section describes some techniques that can help you use `mysql` more effectively.

Input-Line Editing

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` will show the bindings when it starts.

Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console; the `mysql` client for Windows is able to use these APIs. The Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8` (or `utf8mb4`) option. This option is necessary because `utf16le` is one of the character sets that cannot be used as the client character set. See [Impermissible Client Character Sets](#).

With those changes, `mysql` will use the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8
```

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 30,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200

Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty

Using Safe-Updates Mode (--safe-updates)

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). Safe-updates mode is helpful for cases when you might have issued an `UPDATE` or `DELETE` statement but forgotten the `WHERE` clause indicating which rows to modify. Normally, such statements update or delete all rows in the table. With `--safe-updates`, you can modify rows only by specifying the key values that identify them, or a `LIMIT` clause, or both. This helps prevent accidents. Safe-updates mode also restricts `SELECT` statements that produce (or are estimated to produce) very large result sets.

The `--safe-updates` option causes `mysql` to execute the following statement when it connects to the MySQL server, to set the session values of the `sql_safe_updates`, `sql_select_limit`, and `max_join_size` system variables:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

The `SET` statement affects statement processing as follows:

- Enabling `sql_safe_updates` causes `UPDATE` and `DELETE` statements to produce an error if they do not specify a key constraint in the `WHERE` clause, or provide a `LIMIT` clause, or both. For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- Setting `sql_select_limit` to 1,000 causes the server to limit all `SELECT` result sets to 1,000 rows unless the statement includes a `LIMIT` clause.
- Setting `max_join_size` to 1,000,000 causes multiple-table `SELECT` statements to produce an error if the server estimates it must examine more than 1,000,000 row combinations.

To specify result set limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options when you invoke `mysql`:

```
mysql --safe-updates --select_limit=500 --max_join_size=10000
```

It is possible for `UPDATE` and `DELETE` statements to produce an error in safe-updates mode even with a key specified in the `WHERE` clause, if the optimizer decides not to use the index on the key column:

- Range access on the index cannot be used if memory usage exceeds that permitted by the `range_optimizer_max_mem_size` system variable. The optimizer then falls back to a table scan. See [Limiting Memory Use for Range Optimization](#).
- If key comparisons require type conversion, the index may not be used (see [Section 8.3.1, “How MySQL Uses Indexes”](#)). Suppose that an indexed string column `c1` is compared to a numeric value using `WHERE c1 = 2222`. For such comparisons, the string value is converted to a number and the operands are compared numerically (see [Section 12.2, “Type Conversion in Expression Evaluation”](#)), preventing use of the index. If safe-updates mode is enabled, an error occurs.

As of MySQL 8.0.13, safe-updates mode also includes these behaviors:

- `EXPLAIN` with `UPDATE` and `DELETE` statements does not produce safe-updates errors. This enables use of `EXPLAIN` plus `SHOW WARNINGS` to see why an index is not used, which can be helpful in cases such as when a `range_optimizer_max_mem_size` violation or type conversion occurs and the optimizer does not use an index even though a key column was specified in the `WHERE` clause.
- When a safe-updates error occurs, the error message includes the first diagnostic that was produced, to provide information about the reason for failure. For example, the message may indicate that the `range_optimizer_max_mem_size` value was exceeded or type conversion occurred, either of which can preclude use of an index.
- For multiple-table deletes and updates, an error is produced with safe updates enabled only if any target table uses a table scan.

Disabling mysql Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test
```

```
Query OK, 1 row affected (1.30 sec)
```

```
mysql> SELECT * FROM t;
```

```
+-----+
| a      |
+-----+
| NULL   |
+-----+
```

```
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Section 27.7.24, “C API Automatic Reconnection Control”](#).

4.5.2 mysqladmin — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named `db_name`.

- `debug`

Tell the server to write debug information to the error log. The connected user must have the `SUPER` privilege. Format and content of this information is subject to change.

This includes information about the Event Scheduler. See [Section 23.4.5, “Event Scheduler Status”](#).

- `drop db_name`

Delete the database named `db_name` and all its tables.

- `extended-status`

Display the server status variables and their values.

- `flush-hosts`

Flush all information in the host cache.

- `flush-logs [log_type ...]`

Flush all logs.

The `mysqladmin flush-logs` command permits optional log types to be given, to specify which logs to flush. Following the `flush-logs` command, you can provide a space-separated list of one or more of the following log types: `binary`, `engine`, `error`, `general`, `relay`, `slow`. These correspond to the log types that can be specified for the `FLUSH LOGS` SQL statement.

- `flush-privileges`

Reload the grant tables (same as `reload`).

- `flush-status`

Clear status variables.

- `flush-tables`

Flush all tables.

- `flush-threads`

Flush the thread cache.

- `kill id,id,...`

Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

To kill threads belonging to other users, the connected user must have the `CONNECTION_ADMIN` or `SUPER` privilege.

- `password new_password`

Set a new password. This changes the password to `new_password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

Warning

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If the `new_password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

In MySQL 8.0, the new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

Caution

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same

command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 13.7.6.29, “SHOW PROCESSLIST Syntax”](#).)

- `reload`

Reload the grant tables.

- `refresh`

Flush all tables and close and open log files.

- `shutdown`

Stop the server.

- `start-slave`

Start replication on a slave server.

- `status`

Display a short server status message.

- `stop-slave`

Stop replication on a slave server.

- `variables`

Display the server system variables and their values.

- `version`

Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost | | Query | 0 | | show processlist |
+-----+-----+-----+-----+-----+-----+-----+
Uptime: 1473624 Threads: 1 Questions: 39487
Slow queries: 0 Opens: 541 Flush tables: 1
```

```
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

The number of seconds the MySQL server has been running.

- `Threads`

The number of active threads (clients).

- `Questions`

The number of questions (queries) from clients since the server was started.

- `Slow queries`

The number of queries that have taken more than `long_query_time` seconds. See [Section 5.4.5, “The Slow Query Log”](#).

- `Opens`

The number of tables the server has opened.

- `Flush tables`

The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.9 mysqladmin Options

Format	Description	Introduced	Removed
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--compress</code>	Compress all information sent between client and server		
<code>--connect_timeout</code>	Number of seconds before connection timeout		
<code>--count</code>	Number of iterations to make for repeated command execution		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		

Format	Description	Introduced	Removed
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--force</code>	Continue even if an SQL error occurs		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--host</code>	Connect to MySQL server on given host		
<code>--login-path</code>	Read login path options from .mylogin.cnf		
<code>--no-beep</code>	Do not beep when errors occur		
<code>--no-defaults</code>	Read no option files		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--relative</code>	Show the difference between the current and previous values when used with the <code>--sleep</code> option		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--show-warnings</code>	Show warnings after statement execution		
<code>--shutdown_timeout</code>	The maximum number of seconds to wait for server shutdown		
<code>--silent</code>	Silent mode		
<code>--sleep</code>	Execute commands repeatedly, sleeping for delay seconds in between		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		

Format	Description	Introduced	Removed
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		
<code>--vertical</code>	Print query output rows vertically (one line per column value)		
<code>--wait</code>	If the connection cannot be established, wait and retry instead of aborting		

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count=N, -c N`

The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--no-beep, -b`

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqladmin` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--relative, -r`

Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--show-warnings`

Show warnings resulting from execution of statements sent to the server.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

4.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` must be used when the `mysqld` server is running, which means that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 13.7.3, “Table Maintenance Statements”](#).

All storage engines do not necessarily support all four maintenance operations. In such cases, an error message is displayed. For example, if `test.t` is an `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 2.11.3, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

Command	Meaning
<code>mysqlrepair</code>	The default option is <code>--repair</code>
<code>mysqlanalyze</code>	The default option is <code>--analyze</code>
<code>mysqloptimize</code>	The default option is <code>--optimize</code>

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.10 mysqlcheck Options

Format	Description	Introduced	Removed
<code>--all-databases</code>	Check all tables in all databases		
<code>--all-in-1</code>	Execute a single statement for each database that names all the tables from that database		
<code>--analyze</code>	Analyze the tables		
<code>--auto-repair</code>	If a checked table is corrupted, automatically fix it		
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--character-sets-dir</code>	Directory where character sets are installed		
<code>--check</code>	Check the tables for errors		
<code>--check-only-changed</code>	Check only tables that have changed since the last check		
<code>--check-upgrade</code>	Invoke CHECK TABLE with the FOR UPGRADE option		
<code>--compress</code>	Compress all information sent between client and server		
<code>--databases</code>	Interpret all arguments as database names		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--extended</code>	Check and repair tables		
<code>--fast</code>	Check only tables that have not been closed properly		
<code>--force</code>	Continue even if an SQL error occurs		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--host</code>	Connect to MySQL server on given host		
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>		
<code>--medium-check</code>	Do a check that is faster than an <code>--extended</code> operation		

Format	Description	Introduced	Removed
<code>--no-defaults</code>	Read no option files		
<code>--optimize</code>	Optimize the tables		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--quick</code>	The fastest method of checking		
<code>--repair</code>	Perform a repair that can fix almost anything except unique keys that are not unique		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--silent</code>	Silent mode		
<code>--skip-database</code>	Omit this database from performed operations		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tables</code>	Overrides the <code>--databases</code> or <code>-B</code> option		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--use-frm</code>	For repair operations on MyISAM tables		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		

Format	Description	Introduced	Removed
<code>--write-binlog</code>	Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds NO_WRITE_TO_BINLOG to these statements.		

- `--help, -?`

Display a help message and exit.

- `--all-databases, -A`

Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the `INFORMATION_SCHEMA` and `performance_schema` databases are not checked. They can be checked by explicitly naming them with the `--databases` option.

- `--all-in-1, -1`

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze, -a`

Analyze the tables.

- `--auto-repair`

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--check, -c`

Check the tables for errors. This is the default operation.

- `--check-only-changed, -C`

Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade, -g`

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server.

- `--compress`

Compress all information sent between the client and the server if both support compression.

- `--databases, -B`

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

- `--extended, -e`

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--fast, -F`

Check only tables that have not been closed properly.

- `--force, -f`

Continue even if an SQL error occurs.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--medium-check, -m`

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--optimize, -o`

Optimize the tables.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlcheck` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair, -r`

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--silent, -s`

Silent mode. Print only error messages.

- `--skip-database=db_name`

Do not include the named database (case-sensitive) in the operations performed by `mysqlcheck`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--use-frm`

For repair operations on [MyISAM](#) tables, get the table structure from the data dictionary so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Display version information and exit.

- `--write-binlog`

This option is enabled by default, so that [ANALYZE TABLE](#), [OPTIMIZE TABLE](#), and [REPAIR TABLE](#) statements generated by [mysqlcheck](#) are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

4.5.4 [mysqldump](#) — A Database Backup Program

The [mysqldump](#) client utility performs [logical backups](#), producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server. The [mysqldump](#) command can also generate output in CSV, other delimited text, or XML format.

- [Performance and Scalability Considerations](#)
- [Invocation Syntax](#)
- [Option Syntax - Alphabetical Summary](#)
- [Connection Options](#)
- [Option-File Options](#)
- [DDL Options](#)
- [Debug Options](#)
- [Help Options](#)
- [Internationalization Options](#)
- [Replication Options](#)
- [Format Options](#)

- [Filtering Options](#)
- [Performance Options](#)
- [Transactional Options](#)
- [Option Groups](#)
- [Examples](#)
- [Restrictions](#)

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, and `LOCK TABLES` if the `--single-transaction` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

Note

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
shell> mysqldump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Impermissible Client Character Sets](#)), so the dump file will not load correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```
shell> mysqldump [options] --result-file=dump.sql
```

Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a [physical](#) backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily `InnoDB` tables, or if you have a mix of `InnoDB` and `MyISAM` tables, consider using the `mysqlbackup` command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for `InnoDB` backups with minimal disruption; it can also back up tables from `MyISAM` and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See [Section 29.2, “MySQL Enterprise Backup Overview”](#).

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping

large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` option instead of the `--opt` or `--extended-insert` option.

For additional information about `mysqldump`, see [Section 7.4, “Using mysqldump for Backups”](#).

Invocation Syntax

There are in general three ways to use `mysqldump`—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` or `--all-databases` option.

To see a list of the options your version of `mysqldump` supports, issue the command `mysqldump --help`.

Option Syntax - Alphabetical Summary

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.11 mysqldump Options

Format	Description	Introduced	Removed
<code>--add-drop-database</code>	Add DROP DATABASE statement before each CREATE DATABASE statement		
<code>--add-drop-table</code>	Add DROP TABLE statement before each CREATE TABLE statement		
<code>--add-drop-trigger</code>	Add DROP TRIGGER statement before each CREATE TRIGGER statement		
<code>--add-locks</code>	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements		
<code>--all-databases</code>	Dump all tables in all databases		
<code>--allow-keywords</code>	Allow creation of column names that are keywords		
<code>--apply-slave-statements</code>	Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output		
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--character-sets-dir</code>	Directory where character sets are installed		
<code>--column-statistics</code>	Write ANALYZE TABLE statements to generate statistics histograms	8.0.2	
<code>--comments</code>	Add comments to dump file		
<code>--compact</code>	Produce more compact output		

Format	Description	Introduced	Removed
<code>--compatible</code>	Produce output that is more compatible with other database systems or with older MySQL servers		
<code>--complete-insert</code>	Use complete INSERT statements that include column names		
<code>--compress</code>	Compress all information sent between client and server		
<code>--create-options</code>	Include all MySQL-specific table options in CREATE TABLE statements		
<code>--databases</code>	Interpret all name arguments as database names		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--delete-master-logs</code>	On a master replication server, delete the binary logs after performing the dump operation		
<code>--disable-keys</code>	For each table, surround INSERT statements with statements to disable and enable keys		
<code>--dump-date</code>	Include dump date as "Dump completed on" comment if <code>--comments</code> is given		
<code>--dump-slave</code>	Include CHANGE MASTER statement that lists binary log coordinates of slave's master		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--events</code>	Dump events from dumped databases		
<code>--extended-insert</code>	Use multiple-row INSERT syntax		
<code>--fields-enclosed-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-escaped-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-optionally-enclosed-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-terminated-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--flush-logs</code>	Flush MySQL server log files before starting dump		

Format	Description	Introduced	Removed
<code>--flush-privileges</code>	Emit a FLUSH PRIVILEGES statement after dumping mysql database		
<code>--force</code>	Continue even if an SQL error occurs during a table dump		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--hex-blob</code>	Dump binary columns using hexadecimal notation		
<code>--host</code>	Host to connect to (IP address or hostname)		
<code>--ignore-error</code>	Ignore specified errors		
<code>--ignore-table</code>	Do not dump given table		
<code>--include-master-host-port</code>	Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave		
<code>--insert-ignore</code>	Write INSERT IGNORE rather than INSERT statements		
<code>--lines-terminated-by</code>	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--lock-all-tables</code>	Lock all tables across all databases		
<code>--lock-tables</code>	Lock all tables before dumping them		
<code>--log-error</code>	Append warnings and errors to named file		
<code>--login-path</code>	Read login path options from .mylogin.cnf		
<code>--master-data</code>	Write the binary log file name and position to the output		
<code>--max_allowed_packet</code>	Maximum packet length to send to or receive from server		
<code>--net_buffer_length</code>	Buffer size for TCP/IP and socket communication		
<code>--network-timeout</code>	Increase network timeouts to permit larger table dumps	8.0.1	
<code>--no-autocommit</code>	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements		
<code>--no-create-db</code>	Do not write CREATE DATABASE statements		
<code>--no-create-info</code>	Do not write CREATE TABLE statements that re-create each dumped table		
<code>--no-data</code>	Do not dump table contents		
<code>--no-defaults</code>	Read no option files		
<code>--no-set-names</code>	Same as --skip-set-charset		
<code>--no-tablespaces</code>	Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output		

Format	Description	Introduced	Removed
<code>--opt</code>	Shorthand for <code>--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset</code> .		
<code>--order-by-primary</code>	Dump each table's rows sorted by its primary key, or by its first unique index		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--quick</code>	Retrieve rows for a table from the server a row at a time		
<code>--quote-names</code>	Quote identifiers within backtick characters		
<code>--replace</code>	Write REPLACE statements rather than INSERT statements		
<code>--result-file</code>	Direct output to a given file		
<code>--routines</code>	Dump stored routines (procedures and functions) from dumped databases		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--set-charset</code>	Add SET NAMES default_character_set to output		
<code>--set-gtid-purged</code>	Whether to add SET @@GLOBAL.GTID_PURGED to output		
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--single-transaction</code>	Issue a BEGIN SQL statement before dumping data from server		
<code>--skip-add-drop-table</code>	Do not add a DROP TABLE statement before each CREATE TABLE statement		
<code>--skip-add-locks</code>	Do not add locks		
<code>--skip-comments</code>	Do not add comments to dump file		
<code>--skip-compact</code>	Do not produce more compact output		
<code>--skip-disable-keys</code>	Do not disable keys		
<code>--skip-extended-insert</code>	Turn off extended-insert		
<code>--skip-opt</code>	Turn off options set by <code>--opt</code>		
<code>--skip-quick</code>	Do not retrieve rows for a table from the server a row at a time		
<code>--skip-quote-names</code>	Do not quote identifiers		
<code>--skip-set-charset</code>	Do not write SET NAMES statement		

Format	Description	Introduced	Removed
<code>--skip-triggers</code>	Do not dump triggers		
<code>--skip-tz-utc</code>	Turn off tz-utc		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tab</code>	Produce tab-separated data files		
<code>--tables</code>	Override --databases or -B option		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--triggers</code>	Dump triggers for each dumped table		
<code>--tz-utc</code>	Add SET TIME_ZONE='+00:00' to dump file		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		
<code>--where</code>	Dump only rows selected by given WHERE condition		
<code>--xml</code>	Produce XML output		

Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--network-timeout, -M`

Enable large tables to be dumped by setting `max_allowed_packet` to its maximum value and network read and write timeouts to a large value. This option is enabled by default. To disable it, use `--skip-network-timeout`.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqldump` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqldump` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `net_buffer_length` bytes long. If you increase this variable, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

Option-File Options

These options are used to control which option files to read.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7](#), “`mysql_config_editor` — MySQL Configuration Utility”.)

- `--print-defaults`

Print the program name and all options that it gets from option files.

DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- `--add-drop-database`

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- `--all-tablespaces, -Y`

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDB` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to `NDB` Cluster tables, which are not supported in MySQL 8.0.

- `--no-create-db, -n`

Suppress the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that create each dumped table.

Note

This option does *not* exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- `--no-tablespaces, -y`

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--replace`

Write `REPLACE` statements rather than `INSERT` statements.

Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--dump-date`

If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--force, -f`

Ignore all errors; continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

If the `--ignore-error` option is also given to ignore specific errors, `--force` takes precedence.

- `--log-error=file_name`

Log warnings and errors by appending them to the named file. The default is to do no logging.

- `--skip-comments`

See the description for the `--comments` option.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

Help Options

The following options display information about the `mysqldump` command itself.

- `--help, -?`

Display a help message and exit.

- `--version, -V`

Display version information and exit.

Internationalization Options

The following options change how the `mysqldump` command represents character data with national language settings.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8`.

- `--no-set-names, -N`

Turns off the `--set-charset` setting, the same as specifying `--skip-set-charset`.

- `--set-charset`

Write `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

Replication Options

The `mysqldump` command is frequently used to create an empty instance, or an instance including data, on a slave server in a replication configuration. The following options apply to dumping and restoring data on replication master and slave servers.

- `--apply-slave-statements`

For a slave dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output.

- `--delete-master-logs`

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data`.

- `--dump-slave[=value]`

This option is similar to `--master-data` except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave's master. The `CHANGE MASTER TO` statement reads the values of `Relay_Master_Log_File` and `Exec_Master_Log_Pos` from the `SHOW SLAVE STATUS` output and uses them for `MASTER_LOG_FILE` and `MASTER_LOG_POS` respectively. These are the master server coordinates from which the slave should start replicating.

Note

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause the wrong position to be used. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

`--dump-slave` causes the coordinates from the master to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

Warning

This option should not be used if the server where the dump is going to be applied uses `gtid_mode=ON` and `MASTER_AUTOPOSITION=1`.

The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the slave SQL thread before the dump and restart it again after.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

- `--include-master-host-port`

For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the slave's master.

- `--master-data[=value]`

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master, using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

- `--set-gtid-purged=value`

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@global.gtid_purged` statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is `AUTO`.

Value	Meaning
<code>OFF</code>	Add no <code>SET</code> statement to the output.
<code>ON</code>	Add a <code>SET</code> statement to the output. An error occurs if GTIDs are not enabled on the server.
<code>AUTO</code>	Add a <code>SET</code> statement to the output if GTIDs are enabled on the server.

A partial dump from a server that is using GTID-based replication requires the `--set-gtid-purged={ON|OFF}` option to be specified. Use `ON` if the intention is to deploy a new replication slave using only some of the data from the dumped server. Use `OFF` if the intention is to repair a table by copying it within a topology. Use `OFF` if the intention is to copy a table between replication topologies that are disjoint and will remain so.

The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

- `--set-gtid-purged=OFF`: `SET @@SESSION.SQL_LOG_BIN=0;` is not added to the output.
- `--set-gtid-purged=ON`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output.
- `--set-gtid-purged=AUTO`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output if GTIDs are enabled on the server you are backing up (that is, if `AUTO` evaluates to `ON`).

Note

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- `--compact`

Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The only permitted value for this option is `ansi`, which has the same meaning as the corresponding option for setting the server SQL mode. See [Section 5.1.10, “Server SQL Modes”](#).

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--lines-terminated-by=...`

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

- `--quote-names, -Q`

Quote identifiers (such as database, table, and column names) within ``` characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within `"` characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--result-file=file_name, -r file_name`

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--tab=dir_name, -T dir_name`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server

writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. Because the server creates `*.txt` files in the directory that you specify, the directory must be writable by the server and the MySQL account that you use must have the `FILE` privilege. Because `mysqldump` creates `*.sql` in the same directory, it must be writable by your system login account.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml, -X`

Write dump output as well-formed XML.

NULL, 'NULL', and Empty Values: For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

Value:	XML Representation:
<code>NULL</code> (<i>unknown value</i>)	<code><field name="column_name" xsi:nil="true" /></code>
<code>' '</code> (<i>empty string</i>)	<code><field name="column_name"></field></code>
<code>'NULL'</code> (<i>string value</i>)	<code><field name="column_name">NULL</field></code>

The output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See [Section 4.5.1.1, “mysql Options”](#).)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

```

Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a [WHERE](#) clause.

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

Prior to MySQL 8.0, the `--routines` and `--events` options for `mysqldump` and `mysqlpump` were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `mysql.proc` and `mysql.event` tables containing stored routine and event definitions. As of MySQL 8.0, the `mysql.event` and `mysql.proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

This option may be used to dump the `performance_schema` database, which normally is not dumped even with the `--all-databases` option. (Also use the `--skip-lock-tables` option.)

- `--events, -E`

Include Event Scheduler events for the dumped databases in the output. This option requires the [EVENT](#) privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events.

- `--ignore-error=error[,error]...`

Ignore the specified errors. The option value is a comma-separated list of error numbers specifying the errors to ignore during `mysqldump` execution. If the `--force` option is also given to ignore all errors, `--force` takes precedence.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--no-data, -d`

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--routines, -R`

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global `SELECT` privilege.

The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines.

- `--tables`

Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

To be able to dump a table's triggers, you must have the `TRIGGER` privilege for the table.

Multiple triggers are permitted. `mysqldump` dumps triggers in activation order so that when the dump file is reloaded, triggers are created in the same activation order. However, if a `mysqldump` dump file contains multiple triggers for a table that have the same trigger event and action time, an error occurs for attempts to load the dump file into an older server that does not support multiple triggers. (For a workaround, see [Downgrade Notes](#); you can convert triggers to be compatible with older servers.)

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf' "  
-w"userid>1"
```

```
-w"userid<1"
```

Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as [MySQL Enterprise Backup](#) for [InnoDB](#)-only and mixed-use databases.

Performance is also affected by the [transactional options](#), primarily for the dump operation.

- `--column-statistics`

Add `ANALYZE TABLE` statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of [MyISAM](#) tables.

- `--extended-insert, -e`

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--opt`

This option, enabled by default, is shorthand for the combination of `--add-drop-table` `--add-locks` `--create-options` `--disable-keys` `--extended-insert` `--lock-tables` `--quick` `--set-charset`. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` to turn off several default settings. See the discussion of [mysqldump option groups](#) for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--quick, -q`

This option is useful for dumping large tables. It forces [mysqldump](#) to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--skip-opt`

See the description for the `--opt` option.

Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables`, `--master-data`, or `--single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--master-data`, or `--single-transaction`.

- `--flush-privileges`

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

**Note**

For upgrades to MySQL 5.7.2 or higher from older versions, do not use `--flush-privileges`. For upgrade instructions in this case, see [Section 2.11.1.3, “Changes in MySQL 8.0”](#).

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

- `--no-autocommit`

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--order-by-primary`

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but makes the dump operation take considerably longer.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--single-transaction`

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

To dump large tables, combine the `--single-transaction` option with the `--quick` option.

Option Groups

- The `--opt` option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because `--opt` is on by default. Thus you rarely if ever specify `--opt`. Instead, you can turn these settings off as a group by specifying `--skip-opt`, the optionally re-enable certain settings by specifying the associated options later on the command line.
- The `--compact` option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the `--skip-compact` form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

Examples

To make a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
shell> mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --master-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 5.4.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2  
      > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see [Section 7.2, “Database Backup Methods”](#), and [Section 7.3, “Example Backup and Recovery Strategy”](#).

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

Restrictions

`mysqldump` does not dump the `performance_schema` or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` option. For `performance_schema`, also use the `--skip-lock-tables` option.

`mysqldump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqldump` does not dump InnoDB `CREATE TABLESPACE` statements.

`mysqldump` includes statements to recreate the `general_log` and `slow_query_log` tables for dumps of the `mysql` database. Log table contents are not dumped.

If you encounter problems backing up views due to insufficient privileges, see [Section C.5, “Restrictions on Views”](#) for a workaround.

4.5.5 mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.12 mysqlimport Options

Format	Description	Introduced	Removed
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--columns</code>	This option takes a comma-separated list of column names as its value		
<code>--compress</code>	Compress all information sent between client and server		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		

Format	Description	Introduced	Removed
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--delete</code>	Empty the table before importing the text file		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--fields-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-escaped-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-optionally-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--fields-terminated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--force</code>	Continue even if an SQL error occurs		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--host</code>	Connect to MySQL server on given host		
<code>--ignore</code>	See the description for the <code>--replace</code> option		
<code>--ignore-lines</code>	Ignore the first N lines of the data file		
<code>--lines-terminated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE		
<code>--local</code>	Read input files locally from the client host		
<code>--lock-tables</code>	Lock all tables for writing before processing any text files		
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>		
<code>--low-priority</code>	Use <code>LOW_PRIORITY</code> when loading the table.		
<code>--no-defaults</code>	Read no option files		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--replace</code>	The <code>--replace</code> and <code>--ignore</code> options control handling of input rows that duplicate existing rows on unique key values		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--silent</code>	Produce output only when errors occur		

Format	Description	Introduced	Removed
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--use-threads</code>	Number of threads for parallel file-loading		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--columns=column_list, -c column_list`

This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#).

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlimport` normally reads the `[client]` and `[mysqlimport]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlimport` also reads the `[client_other]` and `[mysqlimport_other]` groups.

- `--delete, -D`

Empty the table before importing the text file.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

- `--force, -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts

that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

See the description for the `--replace` option.

- `--ignore-lines=N`

Ignore the first `N` lines of the data file.

- `--lines-terminated-by=...`

This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

- `--local, -L`

By default, files are read by the server on the server host. With this option, `mysqlimport` reads input files locally on the client host. Enabling local data loading also requires that the server permits it; see [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#)

- `--lock-tables, -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--low-priority`

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults`

is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlimport` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlimport` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace, -r`

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--silent, -s`

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--use-threads=N`

Load files in parallel using *N* threads.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
shell> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
shell> od -c impptest.txt
00000000  1  0  0  \t  M  a  x           S  y  d  o  w  \n  1  0
00000020  1  \t  C  o  u  n  t           D  r  a  c  u  l  a  \n
00000040
shell> mysqlimport --local test impptest.txt
test.impptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM impptest' test
+-----+-----+
| id  | n                |
+-----+-----+
| 100 | Max Sydow        |
| 101 | Count Dracula    |
+-----+-----+
```

4.5.6 mysqlpump — A Database Backup Program

- [mysqlpump Invocation Syntax](#)
- [mysqlpump Option Summary](#)
- [mysqlpump Option Descriptions](#)
- [mysqlpump Object Selection](#)
- [mysqlpump Parallel Processing](#)
- [mysqlpump Restrictions](#)

The `mysqlpump` client utility performs [logical backups](#), producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server.

`mysqlpump` features include:

- Parallel processing of databases, and of objects within databases, to speed up the dump process

- Better control over which databases and database objects (tables, stored programs, user accounts) to dump
- Dumping of user accounts as account-management statements (`CREATE USER`, `GRANT`) rather than as inserts into the `mysql` system database
- Capability of creating compressed output
- Progress indicator (the values are estimates)
- For dump file reloading, faster secondary index creation for `InnoDB` tables by adding indexes after rows are inserted

**Note**

`mysqlpump` uses MySQL features introduced in MySQL 5.7, and thus assumes use with MySQL 5.7 or higher.

`mysqlpump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, and `LOCK TABLES` if the `--single-transaction` option is not used. The `SELECT` privilege on the `mysql` system database is required to dump user definitions. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

**Note**

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
shell> mysqlpump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Section 10.4, “Connection Character Sets and Collations”](#)), so the dump file will not load correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```
shell> mysqlpump [options] --result-file=dump.sql
```

mysqlpump Invocation Syntax

By default, `mysqlpump` dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)). To specify this behavior explicitly, use the `--all-databases` option:

```
shell> mysqlpump --all-databases
```

To dump a single database, or certain tables within that database, name the database on the command line, optionally followed by table names:

```
shell> mysqlpump db_name
shell> mysqlpump db_name tbl_name1 tbl_name2 ...
```

To treat all name arguments as database names, use the `--databases` option:

```
shell> mysqlpump --databases db_name1 db_name2 ...
```

By default, `mysqlpump` does not dump user account definitions, even if you dump the `mysql` system database that contains the grant tables. To dump grant table contents as logical definitions in the form of `CREATE USER` and `GRANT` statements, use the `--users` option and suppress all database dumping:

```
shell> mysqlpump --exclude-databases=% --users
```

In the preceding command, `%` is a wildcard that matches all database names for the `--exclude-databases` option.

`mysqlpump` supports several options for including or excluding databases, tables, stored programs, and user definitions. See [mysqlpump Object Selection](#).

To reload a dump file, execute the statements that it contains. For example, use the `mysql` client:

```
shell> mysqlpump [options] > dump.sql
shell> mysql < dump.sql
```

The following discussion provides additional `mysqlpump` usage examples.

To see a list of the options `mysqlpump` supports, issue the command `mysqlpump --help`.

mysqlpump Option Summary

`mysqlpump` supports the following options, which can be specified on the command line or in the `[mysqlpump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.13 mysqlpump Options

Format	Description	Introduced	Removed
<code>--add-drop-database</code>	Add DROP DATABASE statement before each CREATE DATABASE statement		
<code>--add-drop-table</code>	Add DROP TABLE statement before each CREATE TABLE statement		
<code>--add-drop-user</code>	Add DROP USER statement before each CREATE USER statement		
<code>--add-locks</code>	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements		
<code>--all-databases</code>	Dump all databases		
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--character-sets-dir</code>	Directory where character sets are installed		
<code>--column-statistics</code>	Write ANALYZE TABLE statements to generate statistics histograms	8.0.2	
<code>--complete-insert</code>	Use complete INSERT statements that include column names		
<code>--compress</code>	Compress all information sent between client and server		
<code>--compress-output</code>	Output compression algorithm		
<code>--databases</code>	Interpret all name arguments as database names		
<code>--debug</code>	Write debugging log		

Format	Description	Introduced	Removed
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--default-parallelism</code>	Default number of threads for parallel processing		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--defer-table-indexes</code>	For reloading, defer index creation until after loading table rows		
<code>--events</code>	Dump events from dumped databases		
<code>--exclude-databases</code>	Databases to exclude from dump		
<code>--exclude-events</code>	Events to exclude from dump		
<code>--exclude-routines</code>	Routines to exclude from dump		
<code>--exclude-tables</code>	Tables to exclude from dump		
<code>--exclude-triggers</code>	Triggers to exclude from dump		
<code>--exclude-users</code>	Users to exclude from dump		
<code>--extended-insert</code>	Use multiple-row INSERT syntax		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--hex-blob</code>	Dump binary columns using hexadecimal notation		
<code>--host</code>	Host to connect to (IP address or hostname)		
<code>--include-databases</code>	Databases to include in dump		
<code>--include-events</code>	Events to include in dump		
<code>--include-routines</code>	Routines to include in dump		
<code>--include-tables</code>	Tables to include in dump		
<code>--include-triggers</code>	Triggers to include in dump		
<code>--include-users</code>	Users to include in dump		
<code>--insert-ignore</code>	Write INSERT IGNORE rather than INSERT statements		
<code>--log-error-file</code>	Append warnings and errors to named file		
<code>--login-path</code>	Read login path options from .mylogin.cnf		
<code>--max-allowed-packet</code>	Maximum packet length to send to or receive from server		
<code>--net-buffer-length</code>	Buffer size for TCP/IP and socket communication		
<code>--no-create-db</code>	Do not write CREATE DATABASE statements		

Format	Description	Introduced	Removed
<code>--no-create-info</code>	Do not write CREATE TABLE statements that re-create each dumped table		
<code>--no-defaults</code>	Read no option files		
<code>--parallel-schemas</code>	Specify schema-processing parallelism		
<code>--password</code>	Password to use when connecting to server		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--replace</code>	Write REPLACE statements rather than INSERT statements		
<code>--result-file</code>	Direct output to a given file		
<code>--routines</code>	Dump stored routines (procedures and functions) from dumped databases		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--set-charset</code>	Add SET NAMES default_character_set to output		
<code>--set-gtid-purged</code>	Whether to add SET @@GLOBAL.GTID_PURGED to output	8.0.1	
<code>--single-transaction</code>	Dump tables within single transaction		
<code>--skip-definer</code>	Omit DEFINER and SQL SECURITY clauses from view and stored program CREATE statements		
<code>--skip-dump-rows</code>	Do not dump table rows		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--triggers</code>	Dump triggers for each dumped table		
<code>--tz-utc</code>	Add SET TIME_ZONE='+00:00' to dump file		

Format	Description	Introduced	Removed
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--users</code>	Dump user accounts		
<code>--version</code>	Display version information and exit		
<code>--watch-progress</code>	Display progress indicator		

mysqldump Option Descriptions

- `--help, -?`

Display a help message and exit.

- `--add-drop-database`

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement.

- `--add-drop-table`

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-user`

Write a `DROP USER` statement before each `CREATE USER` statement.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

This option does not work with parallelism because `INSERT` statements from different tables can be interleaved and `UNLOCK TABLES` following the end of the inserts for one table could release locks on tables for which inserts remain.

`--add-locks` and `--single-transaction` are mutually exclusive.

- `--all-databases, -A`

Dump all databases (with certain exceptions noted in [mysqldump Restrictions](#)). This is the default behavior if no other is specified explicitly.

`--all-databases` and `--databases` are mutually exclusive.

Prior to MySQL 8.0, the `--routines` and `--events` options for `mysqldump` and `mysqldump` were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `mysql.proc` and `mysql.event` tables containing stored routine and event definitions. As of MySQL 8.0, the `mysql.event` and `mysql.proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--column-statistics`

Add `ANALYZE TABLE` statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

- `--complete-insert`

Write complete `INSERT` statements that include column names.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--compress-output=algorithm`

By default, `mysqlpump` does not compress output. This option specifies output compression using the specified algorithm. Permitted algorithms are `LZ4` and `ZLIB`.

To uncompress compressed output, you must have an appropriate utility. If the system commands `lz4` and `openssl` `zlib` are not available, MySQL distributions include `lz4_decompress` and `zlib_decompress` utilities that can be used to decompress `mysqlpump` output that was compressed using the `--compress-output=LZ4` and `--compress-output=ZLIB` options. For more information, see [Section 4.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”](#), and [Section 4.8.4, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”](#).

- `--databases, -B`

Normally, `mysqlpump` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` statements are included in the output before each new database.

`--all-databases` and `--databases` are mutually exclusive.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlpump.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#). If no character set is specified, `mysqlpump` uses `utf8`.

- `--default-parallelism=N`

The default number of threads for each parallel processing queue. The default is 2.

The `--parallel-schemas` option also affects parallelism and can be used to override the default number of threads. For more information, see [mysqlpump Parallel Processing](#).

With `--default-parallelism=0` and no `--parallel-schemas` options, `mysqlpump` runs as a single-threaded process and creates no queues.

With parallelism enabled, it is possible for output from different databases to be interleaved.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlpump` normally reads the `[client]` and `[mysqlpump]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlpump` also reads the `[client_other]` and `[mysqlpump_other]` groups.

- `--defer-table-indexes`

In the dump output, defer index creation for each table until after its rows have been loaded. This works for all storage engines, but for `InnoDB` applies only for secondary indexes.

This option is enabled by default; use `--skip-defer-table-indexes` to disable it.

- `--events`

Include Event Scheduler events for the dumped databases in the output. Event dumping requires the `EVENT` privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events.

This option is enabled by default; use `--skip-events` to disable it.

- `--exclude-databases=db_list`

Do not dump the databases in `db_list`, which is a comma-separated list of one or more database names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-events=event_list`

Do not dump the databases in *event_list*, which is a comma-separated list of one or more event names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-routines=routine_list`

Do not dump the events in *routine_list*, which is a comma-separated list of one or more routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-tables=table_list`

Do not dump the tables in *table_list*, which is a comma-separated list of one or more table names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-triggers=trigger_list`

Do not dump the triggers in *trigger_list*, which is a comma-separated list of one or more trigger names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-users=user_list`

Do not dump the user accounts in *user_list*, which is a comma-separated list of one or more account names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--extended-insert=N`

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

The option value indicates the number of rows to include in each `INSERT` statement. The default is 250. A value of 1 produces one `INSERT` statement per table row.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host.

- `--include-databases=db_list`

Dump the databases in `db_list`, which is a comma-separated list of one or more database names. The dump includes all objects in the named databases. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--include-events=event_list`

Dump the events in `event_list`, which is a comma-separated list of one or more event names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--include-routines=routine_list`

Dump the routines in `routine_list`, which is a comma-separated list of one or more routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--include-tables=table_list`

Dump the tables in `table_list`, which is a comma-separated list of one or more table names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--include-triggers=trigger_list`

Dump the triggers in `trigger_list`, which is a comma-separated list of one or more trigger names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--include-users=user_list`

Dump the user accounts in `user_list`, which is a comma-separated list of one or more user names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).
- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.
- `--log-error-file=file_name`

Log warnings and errors by appending them to the named file. If this option is not given, `mysqlpump` writes warnings and errors to the standard error output.
- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).
- `--max-allowed-packet=N`

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.
- `--net-buffer-length=N`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` option), `mysqlpump` creates rows up to `N` bytes long. If you use this option to increase the value, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

- `--no-create-db`

Suppress any `CREATE DATABASE` statements that might otherwise be included in the output.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that create each dumped table.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--parallel-schemas=[N:]db_list`

Create a queue for processing the databases in `db_list`, which is a comma-separated list of one or more database names. If `N` is given, the queue uses `N` threads. If `N` is not given, the `--default-parallelism` option determines the number of queue threads.

Multiple instances of this option create multiple queues. `mysqlpump` also creates a default queue to use for databases not named in any `--parallel-schemas` option, and for dumping user definitions if command options select them. For more information, see [mysqlpump Parallel Processing](#).

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlpump` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlpump` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace`

Write `REPLACE` statements rather than `INSERT` statements.

- `--result-file=file_name`

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--routines`

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global `SELECT` privilege.

The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines.

This option is enabled by default; use `--skip-routines` to disable it.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--set-charset`

Write `SET NAMES default_character_set` to the output.

This option is enabled by default. To disable it and suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--set-gtid-purged=value`

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@global.gtid_purged` statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is `AUTO`.

Value	Meaning
OFF	Add no SET statement to the output.
ON	Add a SET statement to the output. An error occurs if GTIDs are not enabled on the server.
AUTO	Add a SET statement to the output if GTIDs are enabled on the server.

The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

- `--set-gtid-purged=OFF`: `SET @@SESSION.SQL_LOG_BIN=0;` is not added to the output.
- `--set-gtid-purged=ON`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output.
- `--set-gtid-purged=AUTO`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output if GTIDs are enabled on the server you are backing up (that is, if `AUTO` evaluates to `ON`).
- `--single-transaction`

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqlpump` to retrieve the table contents to obtain incorrect contents or fail.

`--add-locks` and `--single-transaction` are mutually exclusive.

- `--skip-definer`

Omit `DEFINER` and `SQL SECURITY` clauses from the `CREATE` statements for views and stored programs. The dump file, when reloaded, creates objects that use the default `DEFINER` and `SQL SECURITY` values. See [Section 23.6, “Access Control for Stored Programs and Views”](#).

- `--skip-dump-rows, -d`

Do not dump table rows.

- `--socket={file_name|pipe_name}, -S {file_name|pipe_name}`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--triggers`

Include triggers for each dumped table in the output.

This option is enabled by default; use `--skip-triggers` to disable it.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqlpump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time.

This option is enabled by default; use `--skip-tz-utc` to disable it.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--users`

Dump user accounts as logical definitions in the form of `CREATE USER` and `GRANT` statements.

User definitions are stored in the grant tables in the `mysql` system database. By default, `mysqlpump` does not include the grant tables in `mysql` database dumps. To dump the contents of the grant tables as logical definitions, use the `--users` option and suppress all database dumping:

```
shell> mysqlpump --exclude-databases=% --users
```

- `--version, -V`

Display version information and exit.

- `--watch-progress`

Periodically display a progress indicator that provides information about the completed and total number of tables, rows, and other objects.

This option is enabled by default; use `--skip-watch-progress` to disable it.

mysqlpump Object Selection

`mysqlpump` has a set of inclusion and exclusion options that enable filtering of several object types and provide flexible control over which objects to dump:

- `--include-databases` and `--exclude-databases` apply to databases and all objects within them.
- `--include-tables` and `--exclude-tables` apply to tables. These options also affect triggers associated with tables unless the trigger-specific options are given.
- `--include-triggers` and `--exclude-triggers` apply to triggers.
- `--include-routines` and `--exclude-routines` apply to stored procedures and functions. If a routine option matches a stored procedure name, it also matches a stored function of the same name.
- `--include-events` and `--exclude-events` apply to Event Scheduler events.
- `--include-users` and `--exclude-users` apply to user accounts.

Any inclusion or exclusion option may be given multiple times. The effect is additive. Order of these options does not matter.

The value of each inclusion and exclusion option is a comma-separated list of names of the appropriate object type. For example:

```
--exclude-databases=test,world
--include-tables=customer,invoice
```

Wildcard characters are permitted in the object names:

- `%` matches any sequence of zero or more characters.
- `_` matches any single character.

For example, `--include-tables=t%,__tmp` matches all table names that begin with `t` and all five-character table names that end with `tmp`.

For users, a name specified without a host part is interpreted with an implied host of `%`. For example, `u1` and `u1@%` are equivalent. This is the same equivalence that applies in MySQL generally (see [Section 6.2.4, “Specifying Account Names”](#)).

Inclusion and exclusion options interact as follows:

- By default, with no inclusion or exclusion options, `mysqlpump` dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)).
- If inclusion options are given in the absence of exclusion options, only the objects named as included are dumped.

- If exclusion options are given in the absence of inclusion options, all objects are dumped except those named as excluded.
- If inclusion and exclusion options are given, all objects named as excluded and not named as included are not dumped. All other objects are dumped.

If multiple databases are being dumped, it is possible to name tables, triggers, and routines in a specific database by qualifying the object names with the database name. The following command dumps databases `db1` and `db2`, but excludes tables `db1.t1` and `db2.t2`:

```
shell> mysqlpump --include-databases=db1,db2 --exclude-tables=db1.t1,db2.t2
```

The following options provide alternative ways to specify which databases to dump:

- The `--all-databases` option dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)). It is equivalent to specifying no object options at all (the default `mysqlpump` action is to dump everything).
- The `--include-databases=%` is similar to `--all-databases`, but selects all databases for dumping, even those that are exceptions for `--all-databases`.
- The `--databases` option causes `mysqlpump` to treat all name arguments as names of databases to dump. It is equivalent to an `--include-databases` option that names the same databases.

mysqlpump Parallel Processing

`mysqlpump` can use parallelism to achieve concurrent processing. You can select concurrency between databases (to dump multiple databases simultaneously) and within databases (to dump multiple objects from a given database simultaneously).

By default, `mysqlpump` sets up one queue with two threads. You can create additional queues and control the number of threads assigned to each one, including the default queue:

- `--default-parallelism=N` specifies the default number of threads used for each queue. In the absence of this option, `N` is 2.

The default queue always uses the default number of threads. Additional queues use the default number of threads unless you specify otherwise.

- `--parallel-schemas=[N:]db_list` sets up a processing queue for dumping the databases named in `db_list` and optionally specifies how many threads the queue uses. `db_list` is a comma-separated list of database names. If the option argument begins with `N:`, the queue uses `N` threads. Otherwise, the `--default-parallelism` option determines the number of queue threads.

Multiple instances of the `--parallel-schemas` option create multiple queues.

Names in the database list are permitted to contain the same `%` and `_` wildcard characters supported for filtering options (see [mysqlpump Object Selection](#)).

`mysqlpump` uses the default queue for processing any databases not named explicitly with a `--parallel-schemas` option, and for dumping user definitions if command options select them.

In general, with multiple queues, `mysqlpump` uses parallelism between the sets of databases processed by the queues, to dump multiple databases simultaneously. For a queue that uses multiple threads, `mysqlpump` uses parallelism within databases, to dump multiple objects from a given database

simultaneously. Exceptions can occur; for example, `mysqlpump` may block queues while it obtains from the server lists of objects in databases.

With parallelism enabled, it is possible for output from different databases to be interleaved. For example, `INSERT` statements from multiple tables dumped in parallel can be interleaved; the statements are not written in any particular order. This does not affect reloading because output statements qualify object names with database names or are preceded by `USE` statements as required.

The granularity for parallelism is a single database object. For example, a single table cannot be dumped in parallel using multiple threads.

Examples:

```
shell> mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
```

`mysqlpump` sets up a queue to process `db1` and `db2`, another queue to process `db3`, and a default queue to process all other databases. All queues use two threads.

```
shell> mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
      --default-parallelism=4
```

This is the same as the previous example except that all queues use four threads.

```
shell> mysqlpump --parallel-schemas=5:db1,db2 --parallel-schemas=3:db3
```

The queue for `db1` and `db2` uses five threads, the queue for `db3` uses three threads, and the default queue uses the default of two threads.

As a special case, with `--default-parallelism=0` and no `--parallel-schemas` options, `mysqlpump` runs as a single-threaded process and creates no queues.

mysqlpump Restrictions

`mysqlpump` does not dump the `performance_schema`, `ndbinfo`, or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` or `--include-databases` option.

`mysqlpump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqlpump` does not dump `InnoDB CREATE TABLESPACE` statements.

`mysqlpump` dumps user accounts in logical form using `CREATE USER` and `GRANT` statements (for example, when you use the `--include-users` or `--users` option). For this reason, dumps of the `mysql` system database do not by default include the grant tables that contain user definitions: `user`, `db`, `tables_priv`, `columns_priv`, `procs_priv`, or `proxies_priv`. To dump any of the grant tables, name the `mysql` database followed by the table names:

```
shell> mysqlpump mysql user db ...
```

4.5.7 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 13.7.6, “SHOW Syntax”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`*`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when you try to display the columns for a table with a `_` in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra `%` last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.14 mysqlshow Options

Format	Description	Introduced	Removed
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--compress</code>	Compress all information sent between client and server		
<code>--count</code>	Show the number of rows per table		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--default-character-set</code>	Specify default character set		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--host</code>	Connect to MySQL server on given host		

Format	Description	Introduced	Removed
<code>--keys</code>	Show table indexes		
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>		
<code>--no-defaults</code>	Read no option files		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--show-table-type</code>	Show a column indicating the table type		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--status</code>	Display extra information about each table		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count`

Show the number of rows per table. This can be slow for non-MyISAM tables.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.14, “Character Set Configuration”](#).

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlshow` normally reads the `[client]` and `[mysqlshow]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlshow` also reads the `[client_other]` and `[mysqlshow_other]` groups.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--get-server-public-key`

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--keys, -k`

Show table indexes.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlshow` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--status, -i`

Display extra information about each table.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.5.8 mysqlslap — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
--number-int-cols=2 --number-char-cols=3
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `;` and multiple insert statements delimited by `;`. The `--query` file will have multiple queries delimited by `;`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
--iterations=5 --query=query.sql --create=create.sql
--delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.15 mysqlslap Options

Format	Description	Introduced	Removed
<code>--auto-generate-sql</code>	Generate SQL statements automatically when they are not supplied in files or using command options		
<code>--auto-generate-sql-add-autoincrement</code>	Add <code>AUTO_INCREMENT</code> column to automatically generated tables		
<code>--auto-generate-sql-execute-number</code>	Specify how many queries to generate automatically		
<code>--auto-generate-sql-guid-primary</code>	Add a GUID-based primary key to automatically generated tables		

Format	Description	Introduced	Removed
<code>--auto-generate-sql-load-type</code>	Specify the test load type		
<code>--auto-generate-sql-secondary-indexes</code>	Specify how many secondary indexes to add to automatically generated tables		
<code>--auto-generate-sql-unique-query-number</code>	How many different queries to generate for automatic tests.		
<code>--auto-generate-sql-unique-write-number</code>	How many different queries to generate for <code>--auto-generate-sql-write-number</code>		
<code>--auto-generate-sql-write-number</code>	How many row inserts to perform on each thread		
<code>--commit</code>	How many statements to execute before committing.		
<code>--compress</code>	Compress all information sent between client and server		
<code>--concurrency</code>	Number of clients to simulate when issuing the SELECT statement		
<code>--create</code>	File or string containing the statement to use for creating the table		
<code>--create-schema</code>	Schema in which to run the tests		
<code>--csv</code>	Generate output in comma-separated values format		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		
<code>--delimiter</code>	Delimiter to use in SQL statements		
<code>--detach</code>	Detach (close and reopen) each connection after each N statements		
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin		
<code>--engine</code>	Storage engine to use for creating the table		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--host</code>	Connect to MySQL server on given host		
<code>--iterations</code>	Number of times to run the tests		
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>		
<code>--no-defaults</code>	Read no option files		
<code>--no-drop</code>	Do not drop any schema created during the test run		

Format	Description	Introduced	Removed
<code>--number-char-cols</code>	Number of VARCHAR columns to use if <code>--auto-generate-sql</code> is specified		
<code>--number-int-cols</code>	Number of INT columns to use if <code>--auto-generate-sql</code> is specified		
<code>--number-of-queries</code>	Limit each client to approximately this number of queries		
<code>--only-print</code>	Do not connect to databases. mysqlslap only prints what it would have done		
<code>--password</code>	Password to use when connecting to server		
<code>--pipe</code>	On Windows, connect to server using named pipe		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--post-query</code>	File or string containing the statement to execute after the tests have completed		
<code>--post-system</code>	String to execute using <code>system()</code> after the tests have completed		
<code>--pre-query</code>	File or string containing the statement to execute before running the tests		
<code>--pre-system</code>	String to execute using <code>system()</code> before running the tests		
<code>--print-defaults</code>	Print default options		
<code>--protocol</code>	Connection protocol to use		
<code>--query</code>	File or string containing the SELECT statement to use for retrieving data		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--silent</code>	Silent mode		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--sql-mode</code>	Set SQL mode for client session		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	

Format	Description	Introduced	Removed
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Verbose mode		
<code>--version</code>	Display version information and exit		

- `--help, -?`
Display a help message and exit.
- `--auto-generate-sql, -a`
Generate SQL statements automatically when they are not supplied in files or using command options.
- `--auto-generate-sql-add-autoincrement`
Add an `AUTO_INCREMENT` column to automatically generated tables.
- `--auto-generate-sql-execute-number=N`
Specify how many queries to generate automatically.
- `--auto-generate-sql-guid-primary`
Add a GUID-based primary key to automatically generated tables.
- `--auto-generate-sql-load-type=type`
Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.
- `--auto-generate-sql-secondary-indexes=N`
Specify how many secondary indexes to add to automatically generated tables. By default, none are added.
- `--auto-generate-sql-unique-query-number=N`
How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.
- `--auto-generate-sql-unique-write-number=N`
How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.
- `--auto-generate-sql-write-number=N`
How many row inserts to perform. The default is 100.
- `--commit=N`

How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--concurrency=N, -c N`

The number of parallel clients to simulate.

- `--create=value`

The file or string containing the statement to use for creating the table.

- `--create-schema=value`

The schema in which to run the tests.

**Note**

If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlslap.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

- `--delimiter=str, -F str`

The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--engine=engine_name, -e engine_name`

The storage engine to use for creating tables.

- `--get-server-public-key`

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--iterations=N, -i N`

The number of times to run the tests.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--no-drop`

Prevent `mysqlslap` from dropping any schema it creates during the test run.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--number-char-cols=N, -x N`

The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`

The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

```
shell> mysqlslap --delimiter=";" --number-of-queries=10
      --query="use test;insert into t values(null)"
```

- `--only-print`

Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlslap` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--post-query=value`

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str`

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--query=value, -q value`

The file or string containing the `SELECT` statement to use for retrieving data.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--silent, -s`

Silent mode. No output.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--sql-mode=mode`

Set the SQL mode for the client session.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

4.6.1 `ibd2sdi` — InnoDB Tablespace SDI Extraction Utility

`ibd2sdi` is a utility for extracting [serialized dictionary information](#) (SDI) from [InnoDB](#) tablespace files. SDI data is present all persistent [InnoDB](#) tablespace files.

`ibd2sdi` can be run on [file-per-table](#) tablespace files (`*.ibd` files), [general tablespace](#) files (`*.ibd` files), [system tablespace](#) files (`ibdata*` files), and the data dictionary tablespace (`mysql.ibd`). It is not supported for use with temporary tablespaces or undo tablespaces.

`ibd2sdi` can be used at runtime or while the server is offline. During [DDL](#) operations, [ROLLBACK](#) operations, and undo log purge operations related to SDI, there may be a short interval of time when `ibd2sdi` fails to read SDI data stored in the tablespace.

`ibd2sdi` performs an uncommitted read of SDI from the specified tablespace. Redo logs and undo logs are not accessed.

Invoke the `ibd2sdi` utility like this:

```
shell> ibd2sdi [options] file_name1 [file_name2 file_name3 ...]
```

`ibd2sdi` supports multi-file tablespaces like the [InnoDB](#) system tablespace, but it cannot be run on more than one tablespace at a time. For multi-file tablespaces, specify each file:

```
shell> ibd2sdi ibdata1 ibdata2
```

The files of a multi-file tablespace must be specified in order of the ascending page number. If two successive files have the same space ID, the later file must start with the last page number of the previous file + 1.

`ibd2sdi` outputs SDI (containing id, type, and data fields) in [JSON](#) format.

`ibd2sdi` Options

`ibd2sdi` supports the following options:

- `--help`, `-h`

Displays command-line help.

```
shell> ibd2sdi --help
Usage: ./ibd2sdi [-v] [-c <strict-check>] [-d <dump file name>] [-n] filename1 [filenames]
See http://dev.mysql.com/doc/refman/8.0/en/ibd2sdi.html for usage hints.
-h, --help          Display this help and exit.
-v, --version       Display version information and exit.
-#, --debug[=name] Output debug log. See
                    http://dev.mysql.com/doc/refman/8.0/en/dbug-package.html
-d, --dump-file=name
                    Dump the tablespace SDI into the file passed by user.
                    Without the filename, it will default to stdout
-s, --skip-data     Skip retrieving data from SDI records. Retrieve only id
                    and type.
-i, --id=#          Retrieve the SDI record matching the id passed by user.
-t, --type=#        Retrieve the SDI records matching the type passed by
```

```

                                user.
-c, --strict-check=name        Specify the strict checksum algorithm by the user.
                                Allowed values are innodb, crc32, none.
-n, --no-check                 Ignore the checksum verification.
-p, --pretty                   Pretty format the SDI output.If false, SDI would be not
                                human readable but it will be of less size
                                (Defaults to on; use --skip-pretty to disable.)

Variables (--variable-name=value)
and boolean options {FALSE|TRUE}  Value (after reading options)
-----
debug                             (No default value)
dump-file                         (No default value)
skip-data                         FALSE
id                                0
type                              0
strict-check                       crc32
no-check                          FALSE
pretty                            TRUE

```

- `--version, -v`

Displays MySQL version information.

```

shell> ibd2sdi --version
ibd2sdi Ver 8.0.3-dmr for Linux on x86_64 (Source distribution)

```

- `--debug[=debug_options], -# [debug_options]`

Prints a debug log. For debug options, refer to [Section 28.5.3, “The DEBUG Package”](#).

```

shell> ibd2sdi --debug=d:t /tmp/ibd2sdi.trace

```

- `--dump-file=, -d`

Dumps serialized dictionary information (SDI) into the specified dump file. If a dump file is not specified, the tablespace SDI is dumped to `stdout`.

```

shell> ibd2sdi --dump-file=file_name ../data/test/t1.ibd

```

- `--skip-data, -s`

Skips retrieval of `data` field values from the serialized dictionary information (SDI) and only retrieves the `id` and `type` field values, which are primary keys for SDI records.

```

shell> ibd2sdi --skip-data ../data/test/t1.ibd
["ibd2sdi"
,
{
  "type": 1,
  "id": 330
},
{
  "type": 2,
  "id": 7
},
]

```

- `--id=#, -i #`

Retrieves serialized dictionary information (SDI) matching the specified table or tablespace object id. An object id is unique to the object type. Table and tablespace object id's are also found in the `id` column of the `mysql.tables` and `mysql.tablespace` data dictionary tables. For information about data dictionary tables, see [Section 14.1, “Data Dictionary Schema”](#).

```
shell> ibd2sdi --id=7 ../data/test/t1.ibd
["ibd2sdi"
,
{
  "type": 2,
  "id": 7,
  "object": {
    {
      "mysqld_version_id": 80003,
      "dd_version": 80003,
      "sdi_version": 1,
      "dd_object_type": "Tablespace",
      "dd_object": {
        "name": "test/t1",
        "comment": "",
        "options": "",
        "se_private_data": "flags=16417;id=2;server_version=80003;space_version=1;",
        "engine": "InnoDB",
        "files": [
          {
            "ordinal_position": 1,
            "filename": "../test/t1.ibd",
            "se_private_data": "id=2;"
          }
        ]
      }
    }
  }
}
]
```

- `--type=#, -t #`

Retrieves serialized dictionary information (SDI) matching the specified object type. SDI is provided for table (type=1) and tablespace (type=2) objects.

```
shell> ibd2sdi --type=2 ../data/test/t1.ibd
["ibd2sdi"
,
{
  "type": 2,
  "id": 7,
  "object": {
    {
      "mysqld_version_id": 80003,
      "dd_version": 80003,
      "sdi_version": 1,
      "dd_object_type": "Tablespace",
      "dd_object": {
        "name": "test/t1",
        "comment": "",
        "options": "",
        "se_private_data": "flags=16417;id=2;server_version=80003;space_version=1;",
        "engine": "InnoDB",
        "files": [
          {
            "ordinal_position": 1,
            "filename": "../test/t1.ibd",

```

```

        "se_private_data": "id=2;"
      }
    ]
  }
}
]

```

- `--strict-check, -c`

Specifies a strict checksum algorithm for validating the checksum of pages that are read. Options include `innodb`, `crc32`, and `none`.

In this example, the strict version of the `innodb` checksum algorithm is specified:

```
shell> ibd2sdi --strict-check=innodb ../data/test/t1.ibd
```

In this example, the strict version of `crc32` checksum algorithm is specified:

```
shell> ibd2sdi -c crc32 ../data/test/t1.ibd
```

If you do not specify the `--strict-check` option, validation is performed against non-strict `innodb`, `crc32` and `none` checksums.

- `--no-check, -n`

Skips checksum validation for pages that are read.

```
shell> ibd2sdi --no-check ../data/test/t1.ibd
```

- `--pretty, -p`

Outputs SDI data in JSON pretty print format. Enabled by default. If disabled, SDI is not human readable but is smaller in size. Use `--skip-pretty` to disable.

```
shell> ibd2sdi --skip-pretty ../data/test/t1.ibd
```

4.6.2 innocentchecksum — Offline InnoDB File Checksum Utility

`innocentchecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause `InnoDB` to deliberately shut down a running server, it may be preferable to use this tool rather than waiting for an in-production server to encounter the damaged pages.

`innocentchecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace. Attempting to run `innocentchecksum` on a tablespace that the server already has open will result in an “Unable to lock file” error.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innocentchecksum` like this:

```
shell> innocentchecksum [options] file_name
```

innochecksum Options

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `--help, -?`

Displays command line help. Example usage:

```
shell> innochecksum --help
```

- `--info, -I`

Synonym for `--help`. Displays command line help. Example usage:

```
shell> innochecksum --info
```

- `--version, -V`

Displays version information. Example usage:

```
shell> innochecksum --version
```

- `--verbose, -v`

Verbose mode; prints a progress indicator to the log file every five seconds. In order for the progress indicator to be printed, the log file must be specified using the `--log option`. To turn on `verbose` mode, run:

```
shell> innochecksum --verbose
```

To turn off verbose mode, run:

```
shell> innochecksum --verbose=FALSE
```

The `--verbose` option and `--log` option can be specified at the same time. For example:

```
shell> innochecksum --verbose --log=/var/lib/mysql/test/logtest.txt
```

To locate the progress indicator information in the log file, you can perform the following search:

```
shell> cat ./logtest.txt | grep -i "okay"
```

The progress indicator information in the log file appears similar to the following:

```
page 1663 okay: 2.863% done
page 8447 okay: 14.537% done
page 13695 okay: 23.568% done
page 18815 okay: 32.379% done
page 23039 okay: 39.648% done
page 28351 okay: 48.789% done
page 33023 okay: 56.828% done
page 37951 okay: 65.308% done
page 44095 okay: 75.881% done
page 49407 okay: 85.022% done
```

```
page 54463 okay: 93.722% done
...
```

- `--count, -c`

Print a count of the number of pages in the file and exit. Example usage:

```
shell> innochecksum --count ../data/test/tab1.ibd
```

- `--start-page=num, -s num`

Start at this page number. Example usage:

```
shell> innochecksum --start-page=600 ../data/test/tab1.ibd
```

or:

```
shell> innochecksum -s 600 ../data/test/tab1.ibd
```

- `--end-page=num, -e num`

End at this page number. Example usage:

```
shell> innochecksum --end-page=700 ../data/test/tab1.ibd
```

or:

```
shell> innochecksum --p 700 ../data/test/tab1.ibd
```

- `--page=num, -p num`

Check only this page number. Example usage:

```
shell> innochecksum --page=701 ../data/test/tab1.ibd
```

- `--strict-check, -C`

Specify a strict checksum algorithm. Options include `innodb`, `crc32`, and `none`.

In this example, the `innodb` checksum algorithm is specified:

```
shell> innochecksum --strict-check=innodb ../data/test/tab1.ibd
```

In this example, the `crc32` checksum algorithm is specified:

```
shell> innochecksum -C crc32 ../data/test/tab1.ibd
```

The following conditions apply:

- If you do not specify the `--strict-check` option, `innochecksum` validates against `innodb`, `crc32` and `none`.
- If you specify the `none` option, only checksums generated by `none` are allowed.

- If you specify the `innodb` option, only checksums generated by `innodb` are allowed.
- If you specify the `crc32` option, only checksums generated by `crc32` are allowed.
- `--no-check, -n`

Ignore the checksum verification when rewriting a checksum. This option may only be used with the `innochecksum --write` option. If the `--write` option is not specified, `innochecksum` will terminate.

In this example, an `innodb` checksum is rewritten to replace an invalid checksum:

```
shell> innochecksum --no-check --write innodb ../data/test/tab1.ibd
```

- `--allow-mismatches, -a`

The maximum number of checksum mismatches allowed before `innochecksum` terminates. The default setting is 0. If `--allow-mismatches=N`, where $N \geq 0$, N mismatches are permitted and `innochecksum` terminates at $N+1$. When `--allow-mismatches` is set to 0, `innochecksum` terminates on the first checksum mismatch.

In this example, an existing `innodb` checksum is rewritten to set `--allow-mismatches` to 1.

```
shell> innochecksum --allow-mismatches=1 --write innodb ../data/test/tab1.ibd
```

With `--allow-mismatches` set to 1, if there is a mismatch at page 600 and another at page 700 on a file with 1000 pages, the checksum is updated for pages 0-599 and 601-699. Because `--allow-mismatches` is set to 1, the checksum tolerates the first mismatch and terminates on the second mismatch, leaving page 600 and pages 700-999 unchanged.

- `--write=name, -w num`

Rewrite a checksum. When rewriting an invalid checksum, the `--no-check` option must be used together with the `--write` option. The `--no-check` option tells `innochecksum` to ignore verification of the invalid checksum. You do not have to specify the `--no-check` option if the current checksum is valid.

An algorithm must be specified when using the `--write` option. Possible values for the `--write` option are:

- `innodb`: A checksum calculated in software, using the original algorithm from InnoDB.
- `crc32`: A checksum calculated using the `crc32` algorithm, possibly done with a hardware assist.
- `none`: A constant number.

The `--write` option rewrites entire pages to disk. If the new checksum is identical to the existing checksum, the new checksum is not written to disk in order to minimize I/O.

`innochecksum` obtains an exclusive lock when the `--write` option is used.

In this example, a `crc32` checksum is written for `tab1.ibd`:

```
shell> innochecksum -w crc32 ../data/test/tab1.ibd
```

In this example, a `crc32` checksum is rewritten to replace an invalid `crc32` checksum:

```
shell> innochecksum --no-check --write crc32 ../data/test/tab1.ibd
```

- `--page-type-summary, -S`

Display a count of each page type in a tablespace. Example usage:

```
shell> innochecksum --page-type-summary ../data/test/tab1.ibd
```

Sample output for `--page-type-summary`:

```
File:../data/test/tab1.ibd
=====PAGE TYPE SUMMARY=====
#PAGE_COUNT PAGE_TYPE
=====
      2      Index page
      0      Undo log page
      1      Inode page
      0      Insert buffer free list page
      2      Freshly allocated page
      1      Insert buffer bitmap
      0      System page
      0      Transaction system page
      1      File Space Header
      0      Extent descriptor page
      0      BLOB page
      0      Compressed BLOB page
      0      Other type of page
=====
Additional information:
Undo page type: 0 insert, 0 update, 0 other
Undo page state: 0 active, 0 cached, 0 to_free, 0 to_purge, 0 prepared, 0 other
```

- `--page-type-dump, -D`

Dump the page type information for each page in a tablespace to `stderr` or `stdout`. Example usage:

```
shell> innochecksum --page-type-dump=/tmp/a.txt ../data/test/tab1.ibd
```

- `--log, -l`

Log output for the `innochecksum` tool. A log file name must be provided. Log output contains checksum values for each tablespace page. For uncompressed tables, LSN values are also provided. The `--log` replaces the `--debug` option, which was available in earlier releases. Example usage:

```
shell> innochecksum --log=/tmp/log.txt ../data/test/tab1.ibd
```

or:

```
shell> innochecksum -l /tmp/log.txt ../data/test/tab1.ibd
```

- `-` option.

Specify the `-` option to read from standard input. If the `-` option is missing when “read from standard in” is expected, `innochecksum` will output `innochecksum` usage information indicating that the “-” option was omitted. Example usages:

```
shell> cat t1.ibd | innochecksum -
```

In this example, `innochecksum` writes the `crc32` checksum algorithm to `a.ibd` without changing the original `t1.ibd` file.

```
shell> cat t1.ibd | innochecksum --write=crc32 - > a.ibd
```

Running innochecksum on Multiple User-defined Tablespace Files

The following examples demonstrate how to run `innochecksum` on multiple user-defined tablespace files (`.ibd` files).

Run `innochecksum` for all tablespace (`.ibd`) files in the “test” database:

```
shell> innochecksum ./data/test/*.ibd
```

Run `innochecksum` for all tablespace files (`.ibd` files) that have a file name starting with “t”:

```
shell> innochecksum ./data/test/t*.ibd
```

Run `innochecksum` for all tablespace files (`.ibd` files) in the `data` directory:

```
shell> innochecksum ./data/*.ibd
```

Note

Running `innochecksum` on multiple user-defined tablespace files is not supported on Windows operating systems, as Windows shells such as `cmd.exe` do not support glob pattern expansion. On Windows systems, `innochecksum` must be run separately for each user-defined tablespace file. For example:

```
cmd> innochecksum.exe t1.ibd
cmd> innochecksum.exe t2.ibd
cmd> innochecksum.exe t3.ibd
```

Running innochecksum on Multiple System Tablespace Files

By default, there is only one InnoDB system tablespace file (`ibdata1`) but multiple files for the system tablespace can be defined using the `innodb_data_file_path` option. In the following example, three files for the system tablespace are defined using the `innodb_data_file_path` option: `ibdata1`, `ibdata2`, and `ibdata3`.

```
shell> ./bin/mysqld --no-defaults --innodb-data-file-path="ibdata1:10M;ibdata2:10M;ibdata3:10M:autoextend"
```

The three files (`ibdata1`, `ibdata2`, and `ibdata3`) form one logical system tablespace. To run `innochecksum` on multiple files that form one logical system tablespace, `innochecksum` requires the `-` option to read tablespace files in from standard input, which is equivalent to concatenating multiple files to create one single file. For the example provided above, the following `innochecksum` command would be used:

```
shell> cat ibdata* | innochecksum -
```

Refer to the `innochecksum` options information for more information about the “-” option.

Note

Running `innochecksum` on multiple files in the same tablespace is not supported on Windows operating systems, as Windows shells such as `cmd.exe` do not

support glob pattern expansion. On Windows systems, `innochecksum` must be run separately for each system tablespace file. For example:

```
cmd> innochecksum.exe ibdata1
cmd> innochecksum.exe ibdata2
cmd> innochecksum.exe ibdata3
```

4.6.3 myisam_ftdump — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id    INT NOT NULL,
  txt   TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this on Unix-like systems:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

On Windows, use:

```
shell> myisam_ftdump -c mytexttable 1 | sort /R
```

`myisam_ftdump` supports the following options:

- `--help, -h -?`
Display a help message and exit.
- `--count, -c`
Calculate per-word statistics (counts and global weights).
- `--dump, -d`
Dump the index, including data offsets and word weights.
- `--length, -l`
Report the length distribution.
- `--stats, -s`
Report global index statistics. This is the default operation if no other operation is specified.
- `--verbose, -v`
Verbose mode. Print more output about what the program does.

4.6.4 `myisamchk` — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See [Section 13.7.3.2, “CHECK TABLE Syntax”](#), and [Section 13.7.3.5, “REPAIR TABLE Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all `MyISAM` tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all `MyISAM` tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
    --key_buffer_size=64M --myisam_sort_buffer_size=64M \
    --read_buffer_size=1M --write_buffer_size=1M \
    /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see [Section 4.6.4.6, “myisamchk Memory Usage”](#).

For additional information about using `myisamchk`, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Important

You must ensure that no other program is using the tables while you are running `myisamchk`. The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more `MyISAM` tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`.

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See [Section 13.7.3.2, “CHECK TABLE Syntax”](#).

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` group of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.16 myisamchk Options

Format	Description
<code>--analyze</code>	Analyze the distribution of key values
<code>--backup</code>	Make a backup of the .MYD file as file_name-time.BAK
<code>--block-search</code>	Find the record that a block at the given offset belongs to
<code>--check</code>	Check the table for errors
<code>--check-only-changed</code>	Check only tables that have changed since the last check
<code>--correct-checksum</code>	Correct the checksum information for the table
<code>--data-file-length</code>	Maximum length of the data file (when re-creating data file when it is full)
<code>--debug</code>	Write debugging log
<code>--decode_bits</code>	Decode_bits
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--description</code>	Print some descriptive information about the table
<code>--extend-check</code>	Do very thorough table check or repair that tries to recover every possible row from the data file
<code>--fast</code>	Check only tables that haven't been closed properly
<code>--force</code>	Do a repair operation automatically if myisamchk finds any errors in the table
<code>--force</code>	Overwrite old temporary files. For use with the -r or -o option
<code>--ft_max_word_len</code>	Maximum word length for FULLTEXT indexes
<code>--ft_min_word_len</code>	Minimum word length for FULLTEXT indexes
<code>--ft_stopword_file</code>	Use stopwords from this file instead of built-in list
<code>--HELP</code>	Display help message and exit
<code>--help</code>	Display help message and exit
<code>--information</code>	Print informational statistics about the table that is checked
<code>--key_buffer_size</code>	Size of buffer used for index blocks for MyISAM tables
<code>--keys-used</code>	A bit-value that indicates which indexes to update
<code>--max-record-length</code>	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them
<code>--medium-check</code>	Do a check that is faster than an --extend-check operation
<code>--myisam_block_size</code>	Block size to be used for MyISAM index pages

Format	Description
--myisam_sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--no-defaults	Read no option files
--parallel-recover	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)
--print-defaults	Print default options
--quick	Achieve a faster repair by not modifying the data file.
--read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans
--read-only	Do not mark the table as checked
--recover	Do a repair that can fix almost any problem except unique keys that aren't unique
--safe-recover	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found
--set-auto-increment	Force AUTO_INCREMENT numbering for new records to start at the given value
--set-collation	Specify the collation to use for sorting table indexes
--silent	Silent mode
--sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--sort-index	Sort the index tree blocks in high-low order
--sort_key_blocks	sort_key_blocks
--sort-records	Sort records according to a particular index
--sort-recover	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large
--stats_method	Specifies how MyISAM index statistics collection code should treat NULLs
--tmpdir	Directory to be used for storing temporary files
--unpack	Unpack a table that was packed with myisampack
--update-state	Store information in the .MYI file to indicate when the table was checked and whether the table crashed
--verbose	Verbose mode
--version	Display version information and exit
--write_buffer_size	Write buffer size

4.6.4.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

Display a help message and exit. Options are grouped by type of operation.

- `--HELP, -H`

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/myisamchk.trace`.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `myisamchk` normally reads the `[myisamchk]` group. If the `--defaults-group-suffix=_other` option is given, `myisamchk` also reads the `[myisamchk_other]` group.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--silent, -s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264
<code>myisam_block_size</code>	1024
<code>myisam_sort_key_blocks</code>	16
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	nulls_unequal
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`myisam_sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`. `sort_buffer_size` is a deprecated synonym for `myisam_sort_buffer_size`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in [Section 5.1.7, “Server System Variables”](#), and [Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on `MyISAM` tables. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as `repair` or `analyze`), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.4.2 myisamchk Check Options

`myisamchk` supports the following options for table checking operations:

- `--check, -c`

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed, -C`

Check only tables that have changed since the last check.

- `--extend-check, -e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see [Section 4.6.4.5, “Obtaining Table Information with myisamchk”](#).

- `--fast, -F`

Check only tables that haven't been closed properly.

- `--force, -f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information, -i`

Print informational statistics about the table that is checked.

- `--medium-check, -m`

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state, -U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

4.6.4.3 myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` or `--safe-recover` is given):

- `--backup, -B`

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--correct-checksum`

Correct the checksum information for the table.

- `--data-file-length=len, -D len`

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check, -e`

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see [Section 4.6.4.5, “Obtaining Table Information with myisamchk”](#).

- `--force, -f`

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

For `myisamchk`, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks, -l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover, -p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick, -q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover, -o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover, -n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=dir_name, -t dir_name`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (:) on Unix and the semicolon (;) on Windows.

- `--unpack, -u`

Unpack a table that was packed with `myisampack`.

4.6.4.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Find the record that a block at the given offset belongs to.

- `--description, -d`

Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See [Section 4.6.4.5, “Obtaining Table Information with myisamchk”](#).

- `--set-auto-increment[=value], -A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

4.6.4.5 Obtaining Table Information with myisamchk

To obtain a description of a [MyISAM](#) table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a [MyISAM](#) table or the name of its index file, as described in [Section 4.6.4](#), “`myisamchk` — MyISAM Table-Maintenance Utility”. Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id          INT NOT NULL AUTO_INCREMENT,
  last_name   VARCHAR(20) NOT NULL,
  first_name  VARCHAR(20) NOT NULL,
  birth       DATE,
  death       DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000 ENGINE=MYISAM;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw----  1 mysql  mysql  9347072 Aug 19 11:47 person.MYD
-rw-rw----  1 mysql  mysql  6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dvv` output:

```
MyISAM file:      person
Record format:    Packed
Character set:    utf8mb4_0900_ai_ci (255)
File-version:     1
Creation time:    2017-03-30 21:21:30
Status:           checked,analyzed,optimized keys,sorted index pages
Auto increment key: 1 Last value:      306688
Data records:      306688 Deleted blocks: 0
Datafile parts:    306688 Deleted data: 0
```

```

Datafile pointer (bytes):      4   Keyfile pointer (bytes):      3
Datafile length:             9347072   Keyfile length:         6066176
Max datafile length:         4294967294   Max keyfile length:    17179868159
Recordlength:                54

table description:
Key Start Len Index   Type                Rec/key      Root  Blocksize
1   2     4   unique long                1                1024
2   6    80   multip. varchar prefix    0                1024
   87    80   varchar                0
3  168    3   multip. uint24 NULL      0                1024

Field Start Length Nullpos Nullbit Type
1     1     1
2     2     4
3     6    81
4    87    81
5    168    3     1     1   no zeros
6    171    3     1     2   no zeros

```

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`
Name of the `MyISAM` (index) file.
- `Record format`
The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)
- `Chararacter set`
The table default character set.
- `File-version`
Version of `MyISAM` format. Always 1.
- `Creation time`
When the data file was created.
- `Recover time`
When the index/data file was last reconstructed.
- `Status`
Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.
- `Auto increment key, Last value`
The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.
- `Data records`

The number of rows in the table.

- Deleted blocks

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- Datafile parts

For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as [Data records](#).

- Deleted data

How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- Datafile pointer

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- Keyfile pointer

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- Max datafile length

How long the table data file can become, in bytes.

- Max keyfile length

How long the table index file can become, in bytes.

- Recordlength

How much space each row takes, in bytes.

The [table description](#) part of the output includes a list of all keys in the table. For each key, [myisamchk](#) displays some low-level information:

- Key

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two [table description](#) lines for the second index. This indicates that it is a multiple-part index with two parts.

- Start

Where in the row this portion of the index starts.

- Len

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index

a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multipl.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

The column number.

- `Start`

The byte position of the column within table rows.

- `Length`

The length of the column in bytes.

- `Nullpos, Nullbit`

For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`
Do not store endspace.
- `no endspace, not_always`
Do not store endspace and do not do endspace compression for all values.
- `no endspace, no empty`
Do not store endspace. Do not store empty values.
- `table-lookup`
The column was converted to an `ENUM`.
- `zerofill(N)`
The most significant `N` bytes in the value are always 0 and are not stored.
- `no zeros`
Do not store zeros.
- `always zero`
Zero values are stored using one bit.
- `Huff tree`
The number of the Huffman tree associated with the column.
- `Bits`
The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records: 306688   Deleted blocks:      0
- check file-size
- check record delete-chain

Record blocks:      306688  Delete blocks:      0
Record data:        7934464  Deleted data:       0
Lost space:         256512  Linkdata:          1156096
```

```
User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Key`

The key number.

- `Keyblocks used`

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- `Max levels`

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- `Blocks/Record`

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Recordblocks`

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

How many blocks (links) are deleted.

- `Recorddata`

How many bytes in the data file are used.

- `Deleted data`

How many bytes in the data file are deleted (unused).

- `Lost space`

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

4.6.4.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --myisam_sort_buffer_size=256M \  
          --key_buffer_size=512M \  
          --read_buffer_size=64M \  
          --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=dir_name` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:

```
(largest_key + row_pointer_length) * number_of_rows * 2
```

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see [Section 4.6.4.5, “Obtaining Table Information with myisamchk”](#)). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

4.6.5 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?`, `-I`

Display a help message and exit.

- `-c N`

Execute only `N` commands.

- `-f N`

Specify the maximum number of open files.

- `-F filepath/`

Specify the file path with a trailing slash.

- `-i`

Display extra information before exiting.

- `-o offset`
Specify the starting offset.
- `-p N`
Remove *N* components from path.
- `-r`
Perform a recovery operation.
- `-R record_pos_file record_pos`
Specify record position file and record position.
- `-u`
Perform an update operation.
- `-v`
Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.
- `-w write_file`
Specify the write file.
- `-V`
Display version information.

4.6.6 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).
- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, use `myisamchk -rq` to rebuild its indexes. [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--help, -?`

Display a help message and exit.

- `--backup, -b`

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--force, -f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified.

- `--silent, -s`

Silent mode. Write output only when errors occur.

- `--test, -t`

Do not actually pack the table, just test packing it.

- `--tmpdir=dir_name, -T dir_name`

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose, -v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r-- 1 monty my 994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my 53248 Apr 17 19:00 station.MYI

shell> myisamchk -dvv station

myisampack displays the following kinds of information:

- [normal](#)

The number of columns for which no extra packing is used.

- `empty-space`

The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

4.6.7 mysql_config_editor — MySQL Configuration Utility

The `mysql_config_editor` utility enables you to store authentication credentials in an obfuscated login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unobfuscated format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a “login path,” which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unobfuscated example:

```
[client]
user = mydefaultname
password = mydefaultpass
host = 127.0.0.1
```

```
[mypath]
user = myothername
password = myotherpass
host = localhost
```

When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see [Section 4.2.7, “Using Option Files”](#).

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.

Programs use groups in the login path file as follows:

- `mysql_config_editor` operates on the `client` login path by default if you specify no `--login-path=name` option to indicate explicitly which login path to use.
- Without a `--login-path` option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

```
shell> mysql
```

By default, the `mysql` client reads the `[client]` and `[mysql]` groups from other option files, so it reads them from the login path file as well.

- With a `--login-path` option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

```
shell> mysql --login-path=mypath
```

The `mysql` client reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

- Client programs read the login path file even when the `--no-defaults` option is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present.

`mysql_config_editor` obfuscates the `.mylogin.cnf` file so it cannot be read as cleartext, and its contents when unobfuscated by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. `mysql_config_editor` provides a `print` command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The obfuscation used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unobfuscated `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true. But the obfuscation used will not deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could unobfuscate the `.mylogin.cnf` file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and client programs do not use it, either.

Invoke `mysql_config_editor` like this:

```
shell> mysql_config_editor [program_options] command [command_options]
```

If the login path file does not exist, `mysql_config_editor` creates it.

Command arguments are given as follows:

- `program_options` consists of general `mysql_config_editor` options.
- `command` indicates what action to perform on the `.mylogin.cnf` login path file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents.
- `command_options` indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
shell> mysql_config_editor --help set
shell> mysql_config_editor set --help
```

The first command line displays a general `mysql_config_editor` help message, and ignores the `set` command. The second command line displays a help message specific to the `set` command.

Suppose that you want to establish a `client` login path that defines your default connection parameters, and an additional login path named `remote` for connecting to the MySQL server the host `remote.example.com`. You want to log in as follows:

- By default, to the local server with a user name and password of `localuser` and `localpass`
- To the remote server with a user name and password of `remoteuser` and `remotepass`

To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
shell> mysql_config_editor set --login-path=client
      --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
shell> mysql_config_editor set --login-path=remote
      --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

`mysql_config_editor` uses the `client` login path by default, so the `--login-path=client` option can be omitted from the first command without changing its effect.

To see what `mysql_config_editor` writes to the `.mylogin.cnf` file, use the `print` command:

```
shell> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify `--all` to display all login paths or `--login-path=name` to display a named login path, the `print` command displays the `client` login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple “personalities” for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the remote server, use this command:

```
shell> mysql --login-path=remote
```

Here, `mysql` reads the `[client]` and `[mysql]` option groups from other option files, and the `[client]`, `[mysql]`, and `[remote]` groups from the login path file.

To connect to the local server, use this command:

```
shell> mysql --login-path=client
```

Because `mysql` reads the `client` and `mysql` login paths by default, the `--login-path` option does not add anything in this case. That command is equivalent to this one:

```
shell> mysql
```

Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end. For example, a `client` login path is more general because it is read by all client programs, whereas a `mysqldump` login path is read only by `mysqldump`. Options specified later override options specified earlier, so putting the login paths in the order `client`, `mysqldump` enables `mysqldump`-specific options to override `client` options.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
shell> mysql --login-path=remote --host=remote2.example.com
```

mysql_config_editor General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see [mysql_config_editor Commands and Command-Specific Options](#).

Table 4.17 mysql_config_editor General Options

Format	Description
<code>--debug</code>	Write debugging log
<code>--help</code>	Display help message and exit

Format	Description
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit

- `--help, -?`

Display a general help message and exit.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

```
shell> mysql_config_editor command --help
```

- `--debug[=debug_options], -# debug_options`

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_config_editor.trace`.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- `--version, -V`

Display version information and exit.

mysql_config_editor Commands and Command-Specific Options

This section describes the permitted `mysql_config_editor` commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, `mysql_config_editor` supports general options that can be used preceding any command. For descriptions of these options, see [mysql_config_editor General Options](#).

`mysql_config_editor` supports these commands:

- `help`

Display a general help message and exit. This command takes no following options.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

```
shell> mysql_config_editor command --help
```

- `print [options]`

Print the contents of the login path file in unobfuscated form, with the exception that passwords are displayed as `*****`.

The default login path name is `client` if no login path is named. If both `--all` and `--login-path` are given, `--all` takes precedence.

The `print` command permits these options following the command name:

- `--help, -?`

Display a help message for the `print` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--all`

Print the contents of all login paths in the login path file.

- `--login-path=name, -G name`

Print the contents of the named login path.

- `remove [options]`

Remove a login path from the login path file, or modify a login path by removing options from it.

This command removes from the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `remove` removes the entire login path. For example, this command removes only the `user` option from the `mypath` login path rather than the entire `mypath` login path:

```
shell> mysql_config_editor remove --login-path=mypath --user
```

This command removes the entire `mypath` login path:

```
shell> mysql_config_editor remove --login-path=mypath
```

The `remove` command permits these options following the command name:

- `--help, -?`

Display a help message for the `remove` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host, -h`

Remove the host name from the login path.

- `--login-path=name, -G name`

The login path to remove or modify. The default login path name is `client` if this option is not given.

- `--password, -p`

Remove the password from the login path.

- `--port, -P`

Remove the TCP/IP port number from the login path.

- `--socket, -S`

Remove the Unix socket file name from the login path.

- `--user, -u`

Remove the user name from the login path.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- `reset [options]`

Empty the contents of the login path file.

The `reset` command permits these options following the command name:

- `--help, -?`

Display a help message for the `reset` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `set [options]`

Write a login path to the login path file.

This command writes to the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

The `set` command permits these options following the command name:

- `--help, -?`

Display a help message for the `set` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host=host_name, -h host_name`

The host name to write to the login path.

- `--login-path=name, -G name`

The login path to create. The default login path name is `client` if this option is not given.

- `--password, -p`

Prompt for a password to write to the login path. After `mysql_config_editor` displays the prompt, type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.

To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file will include a line like this:

```
password =
```

- `--port=port_num, -P port_num`

The TCP/IP port number to write to the login path.

- `--socket=file_name, -S file_name`

The Unix socket file name to write to the login path.

- `--user=user_name, -u user_name`

The user name to write to the login path.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` to disable it.

4.6.8 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 5.4.4, “The Binary Log”](#), and [Section 17.2.4, “Replication Relay and Status Logs”](#).

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 17.2.1, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309 9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The

difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

Note

When using event groups, the file offsets of events may be grouped together and the comments of events may be grouped together. Do not mistake these grouped events for blank file offsets.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

When running `mysqlbinlog` against a large binary log, be careful that the filesystem has enough space for the resulting files. To configure the directory that `mysqlbinlog` uses for temporary files, use the `TMPDIR` environment variable.

`mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.7, “Using Option Files”](#).

Table 4.18 mysqlbinlog Options

Format	Description	Introduced	Removed
<code>--base64-output</code>	Print binary log entries using base-64 encoding		
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server		
<code>--binlog-row-event-max-size</code>	Binary log max event size		
<code>--character-sets-dir</code>	Directory where character sets are installed		
<code>--connection-server-id</code>	Used for testing and debugging. See text for applicable default values and other particulars.		
<code>--database</code>	List entries for just this database		
<code>--debug</code>	Write debugging log		
<code>--debug-check</code>	Print debugging information when program exits		
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits		
<code>--default-auth</code>	Authentication plugin to use		
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files		
<code>--defaults-file</code>	Read only named option file		
<code>--defaults-group-suffix</code>	Option group suffix value		

Format	Description	Introduced	Removed
<code>--disable-log-bin</code>	Disable binary logging		
<code>--exclude-gtids</code>	Do not show any of the groups in the GTID set provided		
<code>--force-if-open</code>	Read binary log files even if open or not closed properly		
<code>--force-read</code>	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning		
<code>--get-server-public-key</code>	Request RSA public key from server	8.0.3	
<code>--help</code>	Display help message and exit		
<code>--hexdump</code>	Display a hex dump of the log in comments		
<code>--host</code>	Connect to MySQL server on given host		
<code>--idempotent</code>	Cause the server to use idempotent mode while processing binary log updates from this session only		
<code>--include-gtids</code>	Show only the groups in the GTID set provided		
<code>--local-load</code>	Prepare local temporary files for LOAD DATA INFILE in the specified directory		
<code>--login-path</code>	Read login path options from .mylogin.cnf		
<code>--no-defaults</code>	Read no option files		
<code>--offset</code>	Skip the first N entries in the log		
<code>--password</code>	Password to use when connecting to server		
<code>--plugin-dir</code>	Directory where plugins are installed		
<code>--port</code>	TCP/IP port number for connection		
<code>--print-defaults</code>	Print default options		
<code>--print-table-metadata</code>	Print table metadata		
<code>--protocol</code>	Connection protocol to use		
<code>--raw</code>	Write events in raw (binary) format to output files		
<code>--read-from-remote-master</code>	Read the binary log from a MySQL master rather than reading a local log file		
<code>--read-from-remote-server</code>	Read binary log from MySQL server rather than local log file		
<code>--result-file</code>	Direct output to named file		
<code>--rewrite-db</code>	Create rewrite rules for databases when playing back from logs written in row-based format. Can be used multiple times.		
<code>--secure-auth</code>	Do not send passwords to server in old (pre-4.1) format		8.0.3
<code>--server-id</code>	Extract only those events created by the server having the given server ID		
<code>--server-id-bits</code>	Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum;		

Format	Description	Introduced	Removed
	supported only by MySQL Cluster version of mysqlbinlog		
<code>--server-public-key-path</code>	Path name to file containing RSA public key	8.0.4	
<code>--set-charset</code>	Add a SET NAMES charset_name statement to the output		
<code>--shared-memory-base-name</code>	The name of shared memory to use for shared-memory connections		
<code>--short-form</code>	Display only the statements contained in the log		
<code>--skip-gtids</code>	Do not print any GTIDs; use this when writing a dump file from binary logs containing GTIDs.		
<code>--socket</code>	For connections to localhost, the Unix socket file to use		
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities		
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files		
<code>--ssl-cert</code>	File that contains X.509 certificate		
<code>--ssl-cipher</code>	List of permitted ciphers for connection encryption		
<code>--ssl-crl</code>	File that contains certificate revocation lists		
<code>--ssl-crlpath</code>	Directory that contains certificate revocation list files		
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on the client side	8.0.11	
<code>--ssl-key</code>	File that contains X.509 key		
<code>--ssl-mode</code>	Security state of connection to server		
<code>--start-datetime</code>	Read binary log from first event with timestamp equal to or later than datetime argument		
<code>--start-position</code>	Read binary log from first event with position equal to or greater than argument		
<code>--stop-datetime</code>	Stop reading binary log at first event with timestamp equal to or greater than datetime argument		
<code>--stop-never</code>	Stay connected to server after reading last binary log file		
<code>--stop-never-slave-server-id</code>	Slave server ID to report when connecting to server		
<code>--stop-position</code>	Stop reading binary log at first event with position equal to or greater than argument		
<code>--tls-version</code>	Protocols permitted for encrypted connections		
<code>--to-last-log</code>	Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log		
<code>--user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>	Reconstruct row events as SQL statements		
<code>--verify-binlog-checksum</code>	Verify checksums in binary log		

Format	Description	Introduced	Removed
<code>--version</code>	Display version information and exit		

- `--help, -?`

Display a help message and exit.

- `--base64-output=value`

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case-sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--binlog-row-event-max-size=N`

Property	Value
Command-Line Format	<code>--binlog-row-event-max-size=#</code>
Type	Numeric
Default Value	4294967040
Minimum Value	256
Maximum Value	18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--connection-server-id=server_id`

`--connection-server-id` specifies the server ID that `mysqlbinlog` reports when it connects to the server. It can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process.

If the `--read-from-remote-server` option is specified, `mysqlbinlog` reports a server ID of 0, which tells the server to disconnect after sending the last log file (nonblocking behavior). If the `--stop-never` option is also specified to maintain the connection to the server, `mysqlbinlog` reports a server ID of 1 by default instead of 0, and `--connection-server-id` can be used to replace that server ID if required. See [Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”](#).

- `--database=db_name, -d db_name`

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

Statement-based logging. The `--database` option works as follows:

- While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.
- Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.
- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created*, *altered*, or *dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

Row-based logging. `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

When used together with the `--rewrite-db` option, the `--rewrite-db` option is applied first; then the `--database` option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlbinlog.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlbinlog` normally reads the `[client]` and `[mysqlbinlog]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlbinlog` also reads the `[client_other]` and `[mysqlbinlog_other]` groups.

- `--disable-log-bin, -D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. Manipulating the session value of the `sql_log_bin` system variable is a restricted operation, so this option requires that you have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `--exclude-gtids=gtid_set`

Do not display any of the groups listed in the `gtid_set`.

- `--force-if-open, -F`

Read binary log files even if they are open or were not closed properly.

- `--force-read, -f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--hexdump, -H`

Display a hex dump of the log in comments, as described in [Section 4.6.8.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging.

- `--host=host_name, -h host_name`

Get the binary log from the MySQL server on the given host.

- `--idempotent`

Tell the MySQL Server to use idempotent mode while processing updates; this causes suppression of any duplicate-key or key-not-found errors that the server encounters in the current session while processing updates. This option may prove useful whenever it is desirable or necessary to replay one or more binary logs to a MySQL Server which may not contain all of the data to which the logs refer.

The scope of effect for this option includes the current `mysqlbinlog` client and session only.

- `--include-gtids=gtid_set`

Display only the groups listed in the `gtid_set`.

- `--local-load=dir_name, -l dir_name`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

Important

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--offset=N, -o N`

Skip the first `N` entries in the log.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlbinlog` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See [Section 6.3.10, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--print-table-metadata`

Print table related metadata from the binary log. Configure the amount of table related metadata binary logged using `binlog-row-metadata`.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--raw`

By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` option can be used to make a backup of a server's binary log. With the `--stop-never` option, the backup is “live” because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` option. For more information, see [Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

- `--read-from-remote-master=type`

Read binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-master=BINLOG-DUMP-GTIDS` is combined with `--exclude-gtids`, transactions can be filtered out on the master, avoiding unnecessary network traffic.

See also the description for `--read-from-remote-server`.

- `--read-from-remote-server, -R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

This option is like `--read-from-remote-master=BINLOG-DUMP-NON-GTIDS`.

- `--result-file=name, -r name`

Without the `--raw` option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `result-file` option value is treated as a prefix that modifies output file names.

- `--rewrite-db='from_name->to_name'`

When reading from a row-based or statement-based log, rewrite all occurrences of `from_name` to `to_name`. Rewriting is done on the rows, for row-based logs, as well as on the `USE` clauses, for statement-based logs.

Warning

Statements in which table names are qualified with database names are not rewritten to use the new name when using this option.

The rewrite rule employed as a value for this option is a string having the form `'from_name->to_name'`, as shown previously, and for this reason must be enclosed by quotation marks.

To employ multiple rewrite rules, specify the option multiple times, as shown here:

```
shell> mysqlbinlog --rewrite-db='dbcurrent->dbold' --rewrite-db='dbtest->dbcurrent' \
      binlog.00001 > /tmp/statements.sql
```

When used together with the `--database` option, the `--rewrite-db` option is applied first; then `--database` option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

This means that, for example, if `mysqlbinlog` is started with `--rewrite-db='mydb->yourdb'` `--database=yourdb`, then all updates to any tables in databases `mydb` and `yourdb` are included in the output. On the other hand, if it is started with `--rewrite-db='mydb->yourdb'` `--database=mydb`, then `mysqlbinlog` outputs no statements at all: since all updates to `mydb` are first rewritten as updates to `yourdb` before applying the `--database` option, there remain no updates that match `--database=mydb`.

- `--secure-auth`
- `--server-id=id`

Display only those events created by the server having the given server ID.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `--set-charset=charset_name`

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--short-form, -s`

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems. It is deprecated, and will be removed in a future release.

- `--skip-gtids[=(true|false)]`

Do not display any GTIDs in the output. This is needed when writing to a dump file from one or more binary logs containing GTIDs, as shown in this example:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

The use of this option is otherwise not normally recommended in production.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--start-position=N, -j N`

Start reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the *datetime* value.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-never`

This option is used with `--read-from-remote-server`. It tells `mysqlbinlog` to remain connected to the server. Otherwise `mysqlbinlog` exits when the last log file has been transferred from the server. `--stop-never` implies `--to-last-log`, so only the first log file to transfer need be named on the command line.

`--stop-never` is commonly used with `--raw` to make a live binary log backup, but also can be used without `--raw` to maintain a continuous text display of log events as the server generates them.

With `--stop-never`, by default, `mysqlbinlog` reports a server ID of 1 when it connects to the server. Use `--connection-server-id` to explicitly specify an alternative ID to report. It can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process. See [Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”](#).

- `--stop-never-slave-server-id=id`

This option is deprecated and will be removed in a future release. Use the `--connection-server-id` option instead to specify a server ID for `mysqlbinlog` to report.

- `--stop-position=N`

Stop reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--tls-version=protocol_list`

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `--to-last-log, -t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to a remote server.

- `--verbose, -v`

Reconstruct row events and display them as commented SQL statements. If this option is given twice (by passing in either `--vv` or `--verbose --verbose`), the output includes comments to indicate column data types and some metadata, and row query log events if so configured.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- `--verify-binlog-checksum, -c`

Verify checksums in binary log files.

- `--version, -V`

Display version information and exit.

The `mysqlbinlog` version number shown when using this option is 3.4.

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#)). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain BLOB values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This

enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

Processing multiple files. If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

From MySQL 8.0.12, you can also supply multiple binary log files to `mysqlbinlog` as streamed input using a shell pipe. An archive of compressed binary log files can be decompressed and provided directly to `mysqlbinlog`. In this example, `binlog-files_1.gz` contains multiple binary log files for processing. The pipeline extracts the contents of `binlog-files_1.gz`, pipes the binary log files to `mysqlbinlog` as standard input, and pipes the output of `mysqlbinlog` into the `mysql` client for execution:

```
shell> gzip -cd binlog-files_1.gz | ./mysqlbinlog - | ./mysql -uroot -p
```

You can specify more than one archive file, for example:

```
shell> gzip -cd binlog-files_1.gz binlog-files_2.gz | ./mysqlbinlog - | ./mysql -uroot -p
```

For streamed input, do not use `--stop-position`, because `mysqlbinlog` cannot identify the last log file to apply this option.

LOAD DATA INFILE operations. `mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those

statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like *original_file_name-#-#*.

4.6.8.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.1|
# 00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |og.....|
# 00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |.....|
# 00000047 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00 |.....C.8.....|
# 00000057 04 04 04 04 12 00 00 4b 00 04 1a |.....K...|
# Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
# at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. For more information about binary log format, see [MySQL Internals: The Binary Log](#).

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The event type code.
- **Master ID:** The server ID of the master that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original master log file.
- **Flags:** Event flag values.

4.6.8.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
```

```

id INT NOT NULL,
name VARCHAR(20) NOT NULL,
date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;

```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```

shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAANoAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAIBAAQABEAAAAAAAAEAA//8AQAAAVhcHBsZQ==
'/*!*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAAGQBAAQABEAAAAAAAAEAA///AEAAAFYXBwbGX4AQAAARwZWfyIbIP
'/*!*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAJABAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAQABEAAAAAAAAEAA//4AQAAARwZWfyIbIP
'/*!*/;

```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` or `-v` option. The output will contain lines beginning with `###`:

```

shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAANoAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAIBAAQABEAAAAAAAAEAA//8AQAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=

```

```
fAS3SBgBAAAANGAAAGQBAAAQABEAAAAAAAAEAA///AEAAAFYXBwGX4AQAAARwZWfYIbIP
'/*!*/;
### UPDATE test.t
### WHERE

###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAAEAA//4AQAAARwZWfYIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```
shell> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t

###   @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAC4BAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBgBAAAANGAAAGQBAAAQABEAAAAAAAAEAA///AEAAAFYXBwGX4AQAAARwZWfYIbIP
'/*!*/;
### UPDATE test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAAEAA//4AQAAARwZWfYIbIP
```

```

'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```

shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'

```

Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.
- Character set information is not available in the binary log, which affects string column display:
 - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
 - For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

4.6.8.3 Using mysqlbinlog to Back Up Binary Log Files

By default, `mysqlbinlog` reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to `mysql`). `mysqlbinlog` can read log files directly from the local file system, or, with the `--read-from-remote-server` option, it can connect to a server and request binary log contents from that server. `mysqlbinlog` writes text output to its standard output, or to the file named as the value of the `--result-file=file_name` option if that option is given.

`mysqlbinlog` can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. `mysqlbinlog` can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous (“live”) backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a slave replication server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a slave replication server connecting to its master server.)
- The `--raw` option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server`, it is common to specify other options: `--host` indicates where the server is running, and you may also need to specify connection options such as `--user` and `--password`.

Several other options are useful in conjunction with `--raw`:

- `--stop-never`: Stay connected to the server after reaching the end of the last log file and continue to read new events.
- `--connection-server-id=id`: The server ID that `mysqlbinlog` reports when it connects to a server. When `--stop-never` is used, the default reported server ID is 1. If this causes a conflict with the ID of a slave server or another `mysqlbinlog` process, use `--connection-server-id` to specify an alternative server ID. See [Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”](#).
- `--result-file`: A prefix for output file names, as described later.

To back up a server's binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name      | File_size |
+-----+-----+
| binlog.000130 | 27459     |
| binlog.000131 | 13719     |
| binlog.000132 | 43268     |
+-----+-----+
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132

mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command will not read it, but the second command will.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000130
```

With `--stop-never`, it is not necessary to specify `--to-last-log` to read to the last log file because that option is implied.

Output File Naming

Without `--raw`, `mysqlbinlog` produces text output and the `--result-file` option, if given, specifies the name of the single file to which all output is written. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` option. In conjunction with `--raw`, the `--result-file` option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the `--result-file` value with the directory path. If the `--result-file` value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

<code>--result-file</code> Option	Output File Names
<code>--result-file=x</code>	<code>xbinlog.000999</code> and up

<code>--result-file</code> Option	Output File Names
<code>--result-file=/tmp/</code>	<code>/tmp/binlog.000999</code> and up
<code>--result-file=/tmp/x</code>	<code>/tmp/xbinlog.000999</code> and up

Example: mysqldump + mysqlbinlog for Backup and Restore

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host `host_name` and its first binary log file is named `binlog.000999`. Enter each command on a single line.

Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
--stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases`, `--events`, and `--routines` to back up all data, and `--master-data=2` to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2> dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server crashes), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
| mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

4.6.8.4 Specifying the mysqlbinlog Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.
- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.

- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 1 by default, but this can be changed with `--connection-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a nonzero server ID.

4.6.9 `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see [Section 5.4.5, “The Slow Query Log”](#)). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

Table 4.19 `mysqldumpslow` Options

Format	Description
<code>-a</code>	Do not abstract all numbers to N and strings to S
<code>-n</code>	Abstract numbers with at least the specified digits
<code>--debug</code>	Write debugging information
<code>-g</code>	Only consider statements that match the pattern
<code>--help</code>	Display help message and exit
<code>-h</code>	Host name of the server in the log file name
<code>-i</code>	Name of the server instance
<code>-l</code>	Do not subtract lock time from total time
<code>-r</code>	Reverse the sort order
<code>-s</code>	How to sort output
<code>-t</code>	Display only first num queries
<code>--verbose</code>	Verbose mode

- `--help`

Display a help message and exit.

- `-a`

Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug, -d`

Run in debug mode.

- `-g pattern`

Consider only queries that match the (grep-style) pattern.

- `-h host_name`

Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i name`

Name of server instance (if using `mysql.server` startup script).

- `-l`

Do not subtract lock time from total time.

- `-n N`

Abstract numbers with at least `N` digits within names.

- `-r`

Reverse the sort order.

- `-s sort_type`

How to sort the output. The value of `sort_type` should be chosen from the following list:

- `t, at`: Sort by query time or average query time
- `l, al`: Sort by lock time or average lock time
- `r, ar`: Sort by rows sent or average rows sent
- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t N`

Display only the first `N` queries in the output.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow
```

```

Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1

```

4.7 MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```

shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash

```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1 `mysql_config` — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

Note

`pkg-config` can be used as an alternative to `mysql_config` for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For more information, see [Section 27.7.4.2, “Building C API Client Programs Using pkg-config”](#).

`mysql_config` supports the following options.

- `--cflags`

C Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--cxxflags`

Like `--cflags`, but for C++ compiler flags.

- `--include`

Compiler options to find MySQL include files.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library. In MySQL 8.0, all client libraries are thread-safe, so this option need not be used. The `--libs` option can be used in all cases.

- `--plugindir`

The default plugin directory path name, defined when configuring MySQL.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--variable=var_name`

Display the value of the named configuration variable. Permitted `var_name` values are `pkgincludedir` (the header file directory), `pkglibdir` (the library directory), and `plugindir` (the plugin directory).

- `--version`

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
--cflags           [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--cxxflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include          [-I/usr/local/mysql/include/mysql]
--libs             [-L/usr/local/mysql/lib/mysql -lmysqlclient
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
--libs_r           [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
--plugindir        [/usr/local/mysql/lib/plugin]
--socket           [/tmp/mysql.sock]
--port            [3306]
--version          [5.8.0-m17]
--variable=VAR     VAR is one of:
                   pkgincludedir [/usr/local/mysql/include]
                   pkglibdir      [/usr/local/mysql/lib]
                   plugindir      [/usr/local/mysql/lib/plugin]
```

You can use `mysql_config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
gcc -c `mysql_config --cflags` progname.c
gcc -o progname progname.o `mysql_config --libs`
```

4.7.2 my_print_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=password
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help, -?`
Display a help message and exit.
- `--config-file=file_name, --defaults-file=file_name, -c file_name`
Read only the given option file.
- `--debug=debug_options, -# debug_options`
Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.
- `--defaults-extra-file=file_name, --extra-file=file_name, -e file_name`
Read this option file after the global option file but (on Unix) before the user option file.
- `--defaults-group-suffix=suffix, -g suffix`
In addition to the groups named on the command line, read groups that have the given suffix.
- `--login-path=name, -l name`
Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).
- `--no-defaults, -n`
Return an empty string.
- `--show, -s`
`my_print_defaults` masks passwords by default. Use this option to display passwords in cleartext.
- `--verbose, -v`
Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

4.7.3 `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack trace from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help, -h`

Display a help message and exit.

- `--numeric-dump-file=file_name, -n file_name`

Read the stack trace from the given file.

- `--symbols-file=file_name, -s file_name`

Use the given symbols file.

- `--version, -V`

Display version information and exit.

For more information, see [Section 28.5.1.5, “Using a Stack Trace”](#).

4.8 Miscellaneous Programs

4.8.1 `lz4_decompress` — Decompress mysqlpump LZ4-Compressed Output

The `lz4_decompress` utility decompresses `mysqlpump` output that was created using LZ4 compression.

Note

If MySQL was configured with the `-DWITH_LZ4=system` option, `lz4_decompress` is not built. In this case, the system `lz4` command can be used instead.

Invoke `lz4_decompress` like this:

```
shell> lz4_decompress input_file output_file
```

Example:

```
shell> mysqlpump --compress-output=LZ4 > dump.lz4
```

```
shell> lz4_decompress dump.lz4 dump.txt
```

To see a help message, invoke `lz4_decompress` with no arguments.

To decompress `mysqlpump` ZLIB-compressed output, use `zlib_decompress`. See [Section 4.8.4](#), “`zlib_decompress` — Decompress `mysqlpump` ZLIB-Compressed Output”.

4.8.2 perror — Explain Error Codes

`perror` displays the error message for MySQL or operating system error codes. Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

`perror` attempts to be flexible in understanding its arguments. For example, for the `ER_WRONG_VALUE_FOR_VAR` error, `perror` understands any of these arguments: `1231`, `001231`, `MY-1231`, or `MY-001231`, or `ER_WRONG_VALUE_FOR_VAR`.

```
shell> perror 1231
```

```
MySQL error code MY-001231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.20
```

If an error number is in the range where MySQL and operating system errors overlap, `perror` displays both error messages:

```
shell> perror 1 13
```

```
OS error code 1: Operation not permitted
MySQL error code MY-000001: Can't create/write to file '%s' (OS errno %d - %s)
OS error code 13: Permission denied
MySQL error code MY-000013: Can't get stat of '%s' (OS errno %d - %s)
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```
shell> perror --ndb errorcode
```

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help`, `--info`, `-I`, `-?`

Display a help message and exit.

- `--ndb`

Print the error message for a MySQL Cluster error code.

- `--silent`, `-s`

Silent mode. Print only the error message.

- `--verbose`, `-v`

Verbose mode. Print error code and message. This is the default behavior.

- `--version`, `-V`

Display version information and exit.

4.8.3 resolveip — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help, --info, -?, -I`

Display a help message and exit.

- `--silent, -s`

Silent mode. Produce less output.

- `--version, -V`

Display version information and exit.

4.8.4 zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output

The `zlib_decompress` utility decompresses `mysqlpump` output that was created using ZLIB compression.

Note

If MySQL was configured with the `-DWITH_ZLIB=system` option, `zlib_decompress` is not built. In this case, the system `openssl zlib` command can be used instead.

Invoke `zlib_decompress` like this:

```
shell> zlib_decompress input_file output_file
```

Example:

```
shell> mysqlpump --compress-output=ZLIB > dump.zlib
shell> zlib_decompress dump.zlib dump.txt
```

To see a help message, invoke `zlib_decompress` with no arguments.

To decompress `mysqlpump` LZ4-compressed output, use `lz4_decompress`. See [Section 4.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”](#).

4.9 MySQL Program Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases,

it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 4.2.7, “Using Option Files”](#).

Variable	Description
<code>AUTHENTICATION_PAM_LOG</code>	PAM authentication plugin debug logging settings.
<code>CC</code>	The name of your C compiler (for running CMake).
<code>CXX</code>	The name of your C++ compiler (for running CMake).
<code>CC</code>	The name of your C compiler (for running CMake).
<code>DBI_USER</code>	The default user name for Perl DBI.
<code>DBI_TRACE</code>	Trace options for Perl DBI.
<code>HOME</code>	The default path for the mysql history file is <code>\$HOME/.mysql_history</code> .
<code>LD_RUN_PATH</code>	Used to specify the location of <code>libmysqlclient.so</code> .
<code>LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN</code>	Enable mysql_clear_password authentication plugin; see Section 6.5.1.4, “Client-Side Cleartext Pluggable Authentication” .
<code>LIBMYSQL_PLUGIN_DIR</code>	Directory in which to look for client plugins.
<code>LIBMYSQL_PLUGINS</code>	Client plugins to preload.
<code>MYSQL_DEBUG</code>	Debug trace options when debugging.
<code>MYSQL_GROUP_SUFFIX</code>	Option group suffix value (like specifying <code>--defaults-group-suffix</code>).
<code>MYSQL_HISTFILE</code>	The path to the mysql history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .
<code>MYSQL_HISTIGNORE</code>	Patterns specifying statements that mysql should not log to <code>\$HOME/.mysql_history</code> , or <code>syslog</code> if <code>--syslog</code> is given.
<code>MYSQL_HOME</code>	The path to the directory in which the server-specific <code>my.cnf</code> file resides.
<code>MYSQL_HOST</code>	The default host name used by the mysql command-line client.
<code>MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD</code>	Maximum key length for CREATE_DH_PARAMETERS() . See Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD</code>	Maximum DSA key length for CREATE_ASYMMETRIC_PRIV_KEY() . See Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD</code>	Maximum RSA key length for CREATE_ASYMMETRIC_PRIV_KEY() . See Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_PS1</code>	The command prompt to use in the mysql command-line client.
<code>MYSQL_PWD</code>	The default password when connecting to mysqld . Using this is insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security” .
<code>MYSQL_TCP_PORT</code>	The default TCP/IP port number.
<code>MYSQL_TEST_LOGIN_FILE</code>	The name of the <code>.mylogin.cnf</code> login path file.

Variable	Description
<code>MYSQL_TEST_TRACE_CRASH</code>	Whether the test protocol trace plugin crashes clients. See note following table.
<code>MYSQL_TEST_TRACE_DEBUG</code>	Whether the test protocol trace plugin produces output. See note following table.
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file name; used for connections to <code>localhost</code> .
<code>MYSQLEX_TCP_PORT</code>	The X Plugin default TCP/IP port number.
<code>MYSQLEX_UNIX_PORT</code>	The X Plugin default Unix socket file name; used for connections to <code>localhost</code> .
<code>NOTIFY_SOCKET</code>	Socket used by <code>mysqld</code> to communicate with <code>systemd</code> .
<code>PATH</code>	Used by the shell to find MySQL programs.
<code>PKG_CONFIG_PATH</code>	Location of <code>mysqlclient.pc</code> <code>pkg-config</code> file. See note following table.
<code>TMPDIR</code>	The directory in which temporary files are created.
<code>TZ</code>	This should be set to your local time zone. See Section B.5.3.7, “Time Zone Problems” .
<code>UMASK</code>	The user-file creation mode when creating files. See note following table.
<code>UMASK_DIR</code>	The user-directory creation mode when creating directories. See note following table.
<code>USER</code>	The default user name on Windows when connecting to <code>mysqld</code> .

For information about the `mysql` history file, see [Section 4.5.1.3, “mysql Logging”](#).

`MYSQL_TEST_LOGIN_FILE` is the path name of the login path file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\mylogin.cnf` directory on Windows and `$HOME/.mylogin.cnf` on non-Windows systems. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

The `MYSQL_TEST_TRACE_DEBUG` and `MYSQL_TEST_TRACE_CRASH` variables control the test protocol trace client plugin, if MySQL is built with that plugin enabled. For more information, see [Using the Test Protocol Trace Plugin](#).

The default `UMASK` and `UMASK_DIR` values are `0640` and `0750`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because `0600` octal is `384` decimal.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from `0600` to `0666` (all values octal).
- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `(~($UMASK & 0666))`, so that newly created directories have a mode in the range from `0700` to `0777` (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

It may be necessary to set `PKG_CONFIG_PATH` if you use `pkg-config` for building MySQL programs. See [Section 27.7.4.2, “Building C API Client Programs Using pkg-config”](#).

5.8.2 Running Multiple MySQL Instances on Windows	958
5.8.3 Running Multiple MySQL Instances on Unix	961
5.8.4 Using Client Programs in a Multiple-Server Environment	962

MySQL Server ([mysqld](#)) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration
- The data directory, particularly the `mysql` system database
- The server log files
- Management of multiple servers on a single machine

For additional information on administrative topics, see also:

- [Chapter 6, Security](#)
- [Chapter 7, Backup and Recovery](#)
- [Chapter 17, Replication](#)

5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
- Server status variables. These variables contain counters and statistics about runtime operation.
- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
- Configuring and using IPv6 support.
- Configuring and using time zone support.
- Server-side help capabilities.
- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

For listings of MySQL server variables and options that have been added, deprecated, or removed in MySQL 8.0, see [Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”](#).

Note

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 13.7.6.16, “SHOW ENGINES Syntax”](#).

5.1.1 Configuring the Server

The MySQL server, `mysqld`, has many command options and system variables that can be set at startup to configure its operation. To determine the default command option and system variable values used by the server, execute this command:

```
shell> mysqld --verbose --help
```

The command produces a list of all `mysqld` options and configurable system variables. Its output includes the default option and variable values and looks something like this:

```

abort-slave-event-count      0
allow-suspicious-udfs       FALSE
archive                      ON
auto-increment-increment    1
auto-increment-offset       1
autocommit                   TRUE
automatic-sp-privileges      TRUE
avoid-temporal-upgrade       FALSE
back-log                     80
basedir                      /home/jon/bin/mysql-8.0/
...
tmpdir                       /tmp
transaction-alloc-block-size 8192
transaction-isolation        REPEATABLE-READ
transaction-prealloc-size    4096
transaction-read-only        FALSE
transaction-write-set-extraction OFF
updatable-views-with-limit   YES
validate-user-plugins        TRUE
verbose                      TRUE
wait-timeout                 28800

```

To see the current system variable values actually used by the server as it runs, connect to it and execute this statement:

```
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```

shell> mysqladmin variables
shell> mysqladmin extended-status

```

For a full description of all command options, system variables, and status variables, see these sections:

- [Section 5.1.6, “Server Command Options”](#)
- [Section 5.1.7, “Server System Variables”](#)
- [Section 5.1.9, “Server Status Variables”](#)

More detailed monitoring information is available from the Performance Schema; see [Chapter 25, MySQL Performance Schema](#). In addition, the MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema; see [Chapter 26, MySQL sys Schema](#).

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See [Section 4.2.7, “Using Option Files”](#).

5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at

runtime. For general instructions on setting parameters at startup or runtime, see [Section 5.1.6, “Server Command Options”](#), and [Section 5.1.7, “Server System Variables”](#).

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file.

Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

After completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a setting, either add a `#` to the beginning of the line or remove it.

For non-Windows platforms, no default option file is created during either the server installation or the data directory initialization process. Create your option file by following the instructions given in [Section 4.2.7, “Using Option Files”](#). Without an option file, the server just starts with its default settings—see [Section 5.1.2, “Server Configuration Defaults”](#) on how to check those settings.

For additional information about option file format and syntax, see [Section 4.2.7, “Using Option Files”](#).

5.1.3 Server Option, System Variable, and Status Variable Reference

The following table lists all command-line options, system variables, and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. For system and status variables, the scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the options and variables. Where appropriate, direct links to further information about the items are provided.

Table 5.1 Command-Line Option, System Variable, and Status Variable Summary

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
abort-slave-event-count	Yes	Yes				
Aborted_clients				Yes	Global	No
Aborted_connects				Yes	Global	No
Acl_cache_items_count				Yes	Global	No
activate_all_roles_on_login	Yes	Yes	Yes		Global	Yes
allow-suspicious-udfs	Yes	Yes				
ansi	Yes	Yes

Notes:

1. This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.4 Server System Variable Reference

The following table lists all system variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. The scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Table 5.2 System Variable Summary

Name	Cmd-Line	Option File	System Var	Var Scope	Dynamic
activate_all_roles_on_login	Yes	Yes	Yes	Global	Yes
audit_log_buffer_size	Yes	Yes	Yes	Global	No
audit_log_compression	Yes	Yes	Yes	Global	No

Name	Cmd-Line	Option File	System Var	Var Scope	Dynamic
audit_log_connection_policy	Yes	Yes	Yes	Global	Yes
audit_log_current_session			Yes	Both	No
audit_log_encryption	Yes	Yes	Yes	Global	No
audit_log_exclude_accounts	Yes	Yes	Yes	Global	Yes
audit_log_file	Yes	Yes	Yes	Global	No
audit_log_filter_id			Yes	Both	No
audit_log_flush			Yes	Global	Yes
audit_log_format	Yes	Yes	Yes	Global	No
audit_log_include_accounts	Yes	Yes	Yes	Global	Yes
audit_log_policy	Yes	Yes	Yes	Global	No
audit_log_read_buffer_size	Yes	Yes	Yes	Varies	Varies
audit_log_rotate_on_size	Yes	Yes	Yes	Global	Yes
audit_log_statement_policy	Yes	Yes	Yes	Global	Yes
audit_log_strategy	Yes	Yes	Yes	Global	No
authentication_ldapsasl_auth_method_name	Yes	Yes	Yes	Global	Yes
authentication_ldapsasl_bind_base_dn	Yes	Yes	Yes	Global	Yes

Notes:

1. This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.5 Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Table 5.3 Status Variable Summary

Variable Name	Variable Type	Variable Scope
Aborted_clients	Integer	Global
Aborted_connects	Integer	Global
Acl_cache_items_count	Integer	Global
Audit_log_current_size	Integer	Global
Audit_log_event_max_drop_size	Integer	Global
Audit_log_events	Integer	Global
Audit_log_events_filtered	Integer	Global
Audit_log_events_lost	Integer	Global
Audit_log_events_written	Integer	Global
Audit_log_total_size	Integer	Global
Audit_log_write_waits	Integer	Global
Binlog_cache_disk_use	Integer	Global
Binlog_cache_use	Integer	Global
Binlog_stmt_cache_disk_use	Integer	Global

Variable Name	Variable Type	Variable Scope
<code>Binlog_stmt_cache_use</code>	Integer	Global
<code>Bytes_received</code>	Integer	Both
<code>Bytes_sent</code>	Integer	Both
<code>Caching_sha2_password_rsa_public</code>	String	Global
<code>Com_admin_commands</code>	Integer	Both
<code>Com_alter_db</code>	Integer	Both
<code>Com_alter_event</code>	Integer	Both
<code>Com_alter_function</code>	Integer	Both
<code>Com_alter_procedure</code>	Integer	Both

5.1.6 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 4.2.4, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 4.2.7, “Using Option Files”](#). That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```

Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 6.1.4, “Security-Related `mysqld` Options and Variables”](#).
- SSL-related options: See [Section 6.4.2, “Command Options for Encrypted Connections”](#).
- Binary log control options: See [Section 5.4.4, “The Binary Log”](#).
- Replication-related options: See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 5.6.1, “Installing and Uninstalling Plugins”](#).
- Options specific to particular storage engines: See [Section 15.13, “InnoDB Startup Options and System Variables”](#) and [Section 16.2.1, “MyISAM Startup Options”](#).

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form `--var_name=value`. For example, `--sort_buffer_size=384M` sets the `sort_buffer_size` variable to a value of 384MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup.

You can change the values of most system variables at runtime with the `SET` statement. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

[Section 5.1.7, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see [Section 5.1.1, “Configuring the Server”](#).

- `--help, -?`

Property	Value
Command-Line Format	<code>--help</code>

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

Property	Value
Command-Line Format	<code>--allow-suspicious-udfs</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 28.4.2.6, “UDF Security Precautions”](#).

- `--ansi`

Property	Value
Command-Line Format	<code>--ansi</code>

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See [Section 1.8, “MySQL Standards Compliance”](#), and [Section 5.1.10, “Server SQL Modes”](#).

- `--basedir=dir_name, -b dir_name`

Property	Value
Command-Line Format	<code>--basedir=dir_name</code>
System Variable	<code>basedir</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value (>= 8.0.2)	parent of mysqld installation directory
Default Value (<= 8.0.1)	configuration-dependent default

The path to the MySQL installation directory. This option sets the `basedir` system variable.

The server executable determines its own full path name at startup and uses the parent of the directory in which it is located as the default `basedir` value. This in turn enables the server to use that `basedir` when searching for server-related information such as the `share` directory containing error messages.

- `--big-tables`

Property	Value
Command-Line Format	<code>--big-tables</code>
System Variable	<code>big_tables</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. The server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=addr`

Property	Value
Command-Line Format	<code>--bind-address=addr</code>
System Variable	<code>bind_address</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>*</code>

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces. To specify how the server should listen for TCP/IP connections, use the `--bind-address` option at server startup:

- Prior to MySQL 8.0.13, `--bind-address` accepts a single address value, which may specify a single non-wildcard IP address or host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`).
- As of MySQL 8.0.13, `--bind-address` accepts a single value as just described, or a list of comma-separated values. When the option names a list of multiple values, each value must specify a single non-wildcard IP address or host name; none can specify a wildcard address format (`*`, `0.0.0.0`, or `::`).

IP addresses can be specified as IPv4 or IPv6 addresses. For any option value that is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default. If the option specifies a list of multiple values, this value is not permitted.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. If the option specifies a list of multiple values, this value is not permitted.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the option specifies a list of multiple values, this value is not permitted.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `:::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If binding to any address fails, the server produces an error and does not start.

Examples:

- `--bind-address=*`

The server listens on all IPv4 or IPv6 addresses, as specified by the `*` wildcard.

- `--bind-address=198.51.100.20`

The server listens only on the `198.51.100.20` IPv4 address.

- `--bind-address=198.51.100.20,2001:db8:0:f101::1`

The server listens on the `198.51.100.20` IPv4 address and the `2001:db8:0:f101::1` IPv6 address.

- `--bind-address=198.51.100.20,*`

This produces an error because wildcard addresses are not permitted when `--bind-address` names a list of multiple values.

When `--bind-address` names a single value (wildcard or non-wildcard), the server listens on a single socket, which for a wildcard address may be bound to multiple network interfaces. When `--bind-address` names a list of multiple values, the server listens on one socket per value, with each socket bound to a single network interface. The number of sockets is linear with the number of values specified. Depending on operating system connection-acceptance efficiency, long value lists might incur a performance penalty for accepting TCP/IP connections.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `:::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@':::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `--binlog-format={ROW|STATEMENT|MIXED}`

Property	Value
Command-Line Format	<code>--binlog-format=format</code>
System Variable	<code>binlog_format</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	ROW
Valid Values	ROW STATEMENT MIXED

Specify whether to use row-based, statement-based, or mixed replication. Statement-based is the default in MySQL 8.0. See [Section 17.2.1, “Replication Formats”](#).

Under some conditions, changing this variable at runtime is not possible, or causes replication to fail. See [Section 5.4.4.2, “Setting The Binary Log Format”](#), for more information.

Setting the binary logging format without enabling binary logging sets the `binlog_format` global system variable and logs a warning.

- `--character-sets-dir=dir_name`

Property	Value
Command-Line Format	<code>--character-sets-dir=dir_name</code>
System Variable	<code>character_sets_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory where character sets are installed. See [Section 10.14, “Character Set Configuration”](#).

- `--character-set-client-handshake`

Property	Value
Command-Line Format	<code>--character-set-client-handshake</code>
Type	Boolean
Default Value	TRUE

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name`

Property	Value
Command-Line Format	<code>--character-set-filesystem=name</code>
System Variable	<code>character_set_filesystem</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	binary

The file system character set. This option sets the `character_set_filesystem` system variable.

- `--character-set-server=charset_name, -C charset_name`

Property	Value
Command-Line Format	<code>--character-set-server</code>
System Variable	<code>character_set_server</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	utf8mb4
Default Value (8.0.0)	latin1

Use `charset_name` as the default server character set. See [Section 10.14, “Character Set Configuration”](#). If you use this option to specify a nondefault character set, you should also use `--collation-server` to specify the collation.

- `--chroot=dir_name, -r dir_name`

Property	Value
Command-Line Format	<code>--chroot=dir_name</code>

Property	Value
Type	Directory name

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name`

Property	Value
Command-Line Format	<code>--collation-server</code>
System Variable	<code>collation_server</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4_0900_ai_ci</code>
Default Value (8.0.0)	<code>latin1_swedish_ci</code>

Use `collation_name` as the default server collation. See [Section 10.14, “Character Set Configuration”](#).

- `--console`

Property	Value
Command-Line Format	<code>--console</code>
Platform Specific	Windows

(Windows only.) Cause the default error log destination to be the console. This affects log writers that base their own output destination on the default destination. See [Section 5.4.2, “The Error Log”](#). `mysqld` does not close the console window if this option is used.

`--console` takes precedence over `--log-error` if both are given.

- `--core-file`

Property	Value
Command-Line Format	<code>--core-file</code>
Type	Boolean
Default Value	OFF

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On macOS, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be

additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

To reduce the size of core files, the `innodb_buffer_pool_in_core_file` option can be disabled to prevent InnoDB buffer pool pages from being written to core files.

- `--daemonize, -D`

Property	Value
Command-Line Format	<code>--daemonize[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option causes the server to run as a traditional, forking daemon, permitting it to work with operating systems that use systemd for process control. For more information, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

`--daemonize` is mutually exclusive with `--initialize` and `--initialize-insecure`.

If the server is started using the `--daemonize` option and is not connected to a tty device, a default error logging option of `--log-error=""` is used in the absence of an explicit logging option, to direct error output to the default log file.

`-D` is a synonym for `--daemonize`.

- `--datadir=dir_name, -h dir_name`

Property	Value
Command-Line Format	<code>--datadir=dir_name</code>
System Variable	<code>datadir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path to the MySQL server data directory. This option sets the `datadir` system variable. See the description of that variable.

- `--debug[=debug_options], -# [debug_options]`

Property	Value
Command-Line Format	<code>--debug[=debug_options]</code>
System Variable	<code>debug</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (Windows)	<code>d:t:i:0,\mysqld.trace</code>
Default Value (Unix)	<code>d:t:i:o,/tmp/mysqld.trace</code>

If MySQL is configured with the `-DWITH_DEBUG=1` CMake option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows.

Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see [Section 28.5.3, “The DBUG Package”](#).

- `--debug-sync-timeout[=N]`

Property	Value
Command-Line Format	<code>--debug-sync-timeout[=#]</code>
Type	Integer

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `--default-storage-engine=type`

Property	Value
Command-Line Format	<code>--default-storage-engine=name</code>
System Variable	<code>default_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	InnoDB

Set the default storage engine for tables. See [Chapter 16, Alternative Storage Engines](#). This option sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `--default-time-zone=timezone`

Property	Value
Command-Line Format	<code>--default-time-zone=name</code>
Type	String

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, `mysqld` reads `mysqld-auto.cnf`.

Note

This must be the first option on the command line if it is used, except that if the server is started with the `--defaults-file` and `--install` (or `--install-manual`) options, `--install` (or `--install-manual`) must be first.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If the `--defaults-group-suffix=_other` option is given, `mysqld` also reads the `[mysqld_other]` group.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--delay-key-write[={OFF|ON|ALL}]`

Property	Value
Command-Line Format	<code>--delay-key-write[=name]</code>
System Variable	<code>delay_key_write</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Enumeration
Default Value	ON
Valid Values	ON OFF ALL

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for [MyISAM](#) tables. [OFF](#) disables delayed key writes. [ON](#) enables delayed key writes for those tables that were created with the [DELAY_KEY_WRITE](#) option. [ALL](#) delays key writes for all [MyISAM](#) tables. See [Section 5.1.1, “Configuring the Server”](#), and [Section 16.2.1, “MyISAM Startup Options”](#).

Note

If you set this variable to [ALL](#), you should not use [MyISAM](#) tables from within another program (such as another MySQL server or [myisamchk](#)) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name`

Property	Value
Command-Line Format	<code>--des-key-file=file_name</code>
Deprecated	Yes (removed in 8.0.3)

This option was removed in MySQL 8.0.3.

- `--early-plugin-load=plugin_list`

Property	Value
Command-Line Format	<code>--early-plugin-load=plugin_list</code>
Type	String
Default Value	empty string

This option tells the server which plugins to load before loading mandatory built-in plugins and before storage engine initialization. If multiple `--early-plugin-load` options are given, only the last one is used.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --early-plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded early for a single invocation of `mysqld` only. After a restart, the plugin is not loaded early unless `--early-plugin-load` is used again.

If the server is started using `--initialize` or `--initialize-insecure`, plugins specified by `--early-plugin-load` are not loaded.

If the server is run with `--help`, plugins specified by `--early-plugin-load` are loaded but not initialized. This behavior ensures that plugin options are displayed in the help message.

The default `--early-plugin-load` value is empty. To load the `keyring_file` plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

The `InnoDB` tablespace encryption feature relies on the `keyring_file` plugin for encryption key management, and the `keyring_file` plugin must be loaded prior to storage engine initialization to facilitate `InnoDB` recovery for encrypted tables. Administrators who want the `keyring_file` plugin loaded at startup should use the appropriate nonempty option value; for example, `keyring_file.so` on Unix and Unix-like systems and `keyring_file.dll` on Windows.

For information about `InnoDB` tablespace encryption, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#). For general information about plugin loading, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

- `--enable-named-pipe`

Property	Value
Command-Line Format	<code>--enable-named-pipe</code>
Platform Specific	Windows

Enable support for named pipes. This option applies only on Windows.

- `--event-scheduler[=value]`

Property	Value
Command-Line Format	<code>--event-scheduler[=value]</code>
System Variable	<code>event_scheduler</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value (>= 8.0.3)	ON
Default Value (<= 8.0.2)	OFF
Valid Values	ON OFF DISABLED

Enable or disable, and start or stop, the event scheduler.

For detailed information, see [The `--event-scheduler` Option](#).

- `--exit-info[=flags], -T [flags]`

Property	Value
Command-Line Format	<code>--exit-info[=flags]</code>
Type	Integer

This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

Property	Value
Command-Line Format	<code>--external-locking</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.11.5, “External Locking”](#).

- `--flush`

Property	Value
Command-Line Format	<code>--flush</code>
System Variable	<code>flush</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#).

Note

If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `--gdb`

Property	Value
Command-Line Format	<code>--gdb</code>
Type	Boolean
Default Value	<code>FALSE</code>

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [Section 28.5, “Debugging and Porting MySQL”](#).

On Windows, this option also suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. However, forking makes determining the server process to attach to for debugging more difficult, so starting the server with `--gdb` suppresses forking. For a server started with this option, `RESTART` simply exits and does not restart.

In non-debug settings, `--no-monitor` may be used to suppress forking the monitor process.

- `--general-log[={0|1}]`

Property	Value
Command-Line Format	<code>--general-log</code>
System Variable	<code>general_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--initialize, -I`

Property	Value
Command-Line Format	<code>--initialize</code>
Type	Boolean
Default Value	<code>OFF</code>

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. For more information, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using `mysqld`”](#).

When the server is started with `--initialize`, some functionality is unavailable that limits the statements permitted in any file named by the `--init-file` option. For more information, see the description of that option. In addition, the `disabled_storage_engines` system variable has no effect.

`--initialize` is mutually exclusive with `--daemonize`.

`-I` is a synonym for `--initialize`.

- `--initialize-insecure`

Property	Value
Command-Line Format	<code>--initialize-insecure</code>
Type	Boolean
Default Value	OFF

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. This option implies `--initialize`. For more information, see the description of that option, and [Section 2.10.1.1, “Initializing the Data Directory Manually Using `mysqld`”](#).

`--initialize-insecure` is mutually exclusive with `--daemonize`.

- `--init-file=file_name`

Property	Value
Command-Line Format	<code>--init-file=file_name</code>
System Variable	<code>init_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

If the server is started with the `--initialize` or `--initialize-insecure` option, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

- `--innodb-xxx`

Set an option for the `InnoDB` storage engine. The `InnoDB` options are listed in [Section 15.13, “InnoDB Startup Options and System Variables”](#).

- `--install [service_name]`

Property	Value
Command-Line Format	<code>--install [service_name]</code>
Platform Specific	Windows

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

**Note**

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

Property	Value
Command-Line Format	<code>--install-manual [service_name]</code>
Platform Specific	Windows

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

**Note**

If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

Property	Value
Command-Line Format	<code>--language=name</code>
Deprecated	Yes; use <code>lc-messages-dir</code>
System Variable	<code>language</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	<code>/usr/local/mysql/share/mysql/english/</code>

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 10.11, “Setting the Error Message Language”](#).

`--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated (and handled as an alias for `--lc-messages-dir`). The `--language` option will be removed in a future MySQL release.

- `--large-pages`

Property	Value
Command-Line Format	<code>--large-pages</code>
System Variable	<code>large_pages</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Platform Specific	Linux
Type	Boolean
Default Value	<code>FALSE</code>

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 8.12.3.2, “Enabling Large Page Support”](#). For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

Property	Value
Command-Line Format	<code>--lc-messages=name</code>
System Variable	<code>lc_messages</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>en_US</code>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See [Section 10.11, “Setting the Error Message Language”](#).

- `--lc-messages-dir=dir_name`

Property	Value
Command-Line Format	<code>--lc-messages-dir=dir_name</code>
System Variable	<code>lc_messages_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See [Section 10.11, “Setting the Error Message Language”](#).

- `--local-service`

Property	Value
Command-Line Format	<code>--local-service</code>

(Windows only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

- `--log-error[=file_name]`

Property	Value
Command-Line Format	<code>--log-error[=file_name]</code>
System Variable	<code>log_error</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Set the default error log destination to the named file. This affects log writers that base their own output destination on the default destination. See [Section 5.4.2, “The Error Log”](#).

If the option names no file, the default error log destination on Unix and Unix-like systems is a file named `host_name.err` in the data directory. The default destination on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the default destination is that file (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

If error log output cannot be redirected to the error log file, an error occurs and startup fails.

On Windows, `--console` takes precedence over `--log-error` if both are given. In this case, the default error log destination is the console rather than a file.

- `--log-isam[=file_name]`

Property	Value
Command-Line Format	<code>--log-isam[=file_name]</code>
Type	File name

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-output=value,...`

Property	Value
Command-Line Format	<code>--log-output=name</code>
System Variable	<code>log_output</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Set
Default Value	FILE
Valid Values	TABLE FILE NONE

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. `TABLE` select logging to the `general_log` and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` and `--slow_query_log` options. For `FILE` logging, the `--general_log_file` and `--slow_query_log_file` options determine the log file location. For more information, see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `--log-queries-not-using-indexes`

Property	Value
Command-Line Format	<code>--log-queries-not-using-indexes</code>
System Variable	<code>log_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See [Section 5.4.5, “The Slow Query Log”](#). This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-raw`

Property	Value
Command-Line Format	<code>--log-raw[=value]</code>
Type	Boolean
Default Value	OFF

Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful

for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

If a query rewrite plugin is installed, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

For more information, see [Section 6.1.2.3, “Passwords and Logging”](#).

- `--log-short-format`

Property	Value
Command-Line Format	<code>--log-short-format</code>
Type	Boolean
Default Value	<code>FALSE</code>

Log less information to the slow query log, if it has been activated.

- `--log-tc=file_name`

Property	Value
Command-Line Format	<code>--log-tc=file_name</code>
Type	File name
Default Value	<code>tc.log</code>

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

- `--log-tc-size=size`

Property	Value
Command-Line Format	<code>--log-tc-size=#</code>
Type	Integer
Default Value	<code>6 * page size</code>
Minimum Value	<code>6 * page size</code>
Maximum Value (64-bit platforms)	<code>18446744073709551615</code>
Maximum Value (32-bit platforms)	<code>4294967295</code>

The size in bytes of the memory-mapped transaction coordinator log. The default and minimum values are 6 times the page size, and the value must be a multiple of the page size.

- `--log-warnings[=level], -W [level]`

Property	Value
Command-Line Format	<code>--log-warnings[=#]</code>
Deprecated	Yes (removed in 8.0.3)

Property	Value
System Variable	log_warnings
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This option was removed in MySQL 8.0.3. Use the [log_error_verbosity](#) system variable instead.

- `--low-priority-updates`

Property	Value
Command-Line Format	<code>--low-priority-updates</code>
System Variable	low_priority_updates
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>FALSE</code>

Give table-modifying operations ([INSERT](#), [REPLACE](#), [DELETE](#), [UPDATE](#)) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking ([MyISAM](#), [MEMORY](#), [MERGE](#)). See [Section 8.11.2, “Table Locking Issues”](#).

- `--min-examined-row-limit=number`

Property	Value
Command-Line Format	<code>--min-examined-row-limit=#</code>
System Variable	min_examined_row_limit
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

When this option is set, queries which examine fewer than *number* rows are not written to the slow query log. The default is 0.

- `--memlock`

Property	Value
Command-Line Format	<code>--memlock</code>
Type	Boolean
Default Value	<code>FALSE</code>

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the memlock limit in [Section 8.12.3.2, “Enabling Large Page Support”](#).

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

Property	Value
Command-Line Format	<code>--myisam-block-size=#</code>
Type	Integer
Default Value	<code>1024</code>
Minimum Value	<code>1024</code>
Maximum Value	<code>16384</code>

The block size to be used for `MyISAM` index pages.

- `--myisam-recover-options[=option[,option]...]`

Property	Value
Command-Line Format	<code>--myisam-recover-options[=name]</code>
Type	Enumeration
Default Value	OFF
Valid Values	OFF DEFAULT BACKUP FORCE QUICK

Set the [MyISAM](#) storage engine recovery mode. The option value is any combination of the values of [OFF](#), [DEFAULT](#), [BACKUP](#), [FORCE](#), or [QUICK](#). If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying [DEFAULT](#), and specifying with an explicit value of `" "` disables recovery (same as a value of [OFF](#)). If recovery is enabled, each time `mysqld` opens a [MyISAM](#) table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

Option	Description
OFF	No recovery.
DEFAULT	Recovery without backup, forcing, or quick checking.
BACKUP	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
FORCE	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
QUICK	Do not check the rows in the table if there are not any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options [BACKUP](#), [FORCE](#). This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 16.2.1, “MyISAM Startup Options”](#).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-dd-upgrade`

Property	Value
Command-Line Format	<code>--no-dd-upgrade</code>
Introduced	8.0.4
Type	Boolean
Default Value	<code>FALSE</code>

Prevents the automatic upgrade of data dictionary tables when starting the MySQL server. This option would typically be used when starting the MySQL server following an in-place upgrade of the MySQL server to a new version, which may include changes to data dictionary table definitions.

When `--no-dd-upgrade` is specified, and the server finds that the data dictionary version of the server is different from the version stored in the data dictionary, startup fails with an error stating that data dictionary upgrade is prohibited.

During a normal startup, the data dictionary version of the server is compared to the version stored in the data dictionary to determine if data dictionary table definitions should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating data dictionary tables.

- `--no-monitor`

Property	Value
Command-Line Format	<code>--no-monitor</code>
Introduced	8.0.12
Platform Specific	Windows
Type	Boolean
Default Value	<code>FALSE</code>

(Windows only). This option suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. For a server started with this option, `RESTART` simply exits and does not restart.

`--no-monitor` is not available prior to MySQL 8.0.12. The `--gdb` option can be used as a workaround.

- `--old-alter-table`

Property	Value
Command-Line Format	<code>--old-alter-table</code>
System Variable	<code>old_alter_table</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this option is given, the server does not use the optimized method of processing an [ALTER TABLE](#) operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of [ALTER TABLE](#), see [Section 13.1.8, “ALTER TABLE Syntax”](#).

- `--old-style-user-limits`

Property	Value
Command-Line Format	<code>--old-style-user-limits</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See [Section 6.3.6, “Setting Account Resource Limits”](#).

- `--open-files-limit=count`

Property	Value
Command-Line Format	<code>--open-files-limit=#</code>
System Variable	<code>open_files_limit</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	5000, with possible adjustment
Minimum Value	0
Maximum Value	platform dependent

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. Internally, the maximum value for this option is the maximum unsigned integer value, but the actual maximum is platform dependent. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

On Unix, the value cannot be set greater than `ulimit -n`.

- `--performance-schema-xxx`

Configure a Performance Schema option. For details, see [Section 25.13, “Performance Schema Command Options”](#).

- `--pid-file=file_name`

Property	Value
Command-Line Format	<code>--pid-file=file_name</code>
System Variable	<code>pid_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this option, you must specify a value. If you do not specify this option, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See [Section 5.4.2, “The Error Log”](#).

- `--plugin-xxx`

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb_file_per_table` option for InnoDB can be specified as `--plugin-innodb_file_per_table`.

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 4.2.6, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb_file_per_table` disables `innodb_file_per_table`.

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--plugin-load=plugin_list`

Property	Value
Command-Line Format	<code>--plugin-load=plugin_list</code>
Type	String

This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one is used. Additional plugins to load may be specified using `--plugin-load-add` options.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because otherwise semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

For additional information about plugin loading, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

- `--plugin-load-add=plugin_list`

Property	Value
Command-Line Format	<code>--plugin-load-add=plugin_list</code>
Type	String

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load`. `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

`--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x/y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

For additional information about plugin loading, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

- `--port=port_num, -P port_num`

Property	Value
Command-Line Format	<code>--port=#</code>
System Variable	<code>port</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>3306</code>
Minimum Value	<code>0</code>
Maximum Value	<code>65535</code>

The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

Property	Value
Command-Line Format	<code>--port-open-timeout=#</code>
Type	Integer
Default Value	<code>0</code>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files. Password values are masked. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

For additional information about this option, see [Section 4.2.8, “Command-Line Options that Affect Option-File Handling”](#).

- `--remove [service_name]`

Property	Value
Command-Line Format	<code>--remove [service_name]</code>
Platform Specific	Windows

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

- `--safe-user-create`

Property	Value
Command-Line Format	<code>--safe-user-create</code>
Type	Boolean
Default Value	<code>FALSE</code>

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

Property	Value
Command-Line Format	<code>--secure-auth</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>secure_auth</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>
Valid Values	<code>ON</code>

This option was removed in MySQL 8.0.3.

- `--secure-file-priv=dir_name`

Property	Value
Command-Line Format	<code>--secure-file-priv=dir_name</code>
System Variable	<code>secure_file_priv</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>platform specific</code>
Valid Values	<code>empty string</code> <code>dirname</code> <code>NULL</code>

This option sets the `secure_file_priv` system variable, which is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. For more information, see the description of `secure_file_priv`.

- `--shared-memory`

Property	Value
Command-Line Format	<code>--shared-memory[={0,1}]</code>
System Variable	<code>shared_memory</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	<code>FALSE</code>

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name`

Property	Value
Command-Line Format	<code>--shared-memory-base-name=name</code>
System Variable	<code>shared_memory_base_name</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	<code>MYSQL</code>

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert`

Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See [Section 8.11.3, “Concurrent Inserts”](#).

- `--skip-event-scheduler`

Property	Value
Command-Line Format	<code>--skip-event-scheduler</code> <code>--disable-event-scheduler</code>

Turns the Event Scheduler `OFF`. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED`; see [The `--event-scheduler` Option](#), for more information.

- `--skip-grant-tables`

Property	Value
Command-Line Format	<code>--skip-grant-tables</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.

If the server is started with the `--skip-grant-tables` option to disable authentication checks, the server enables `--skip-networking` automatically to prevent remote connections.

This option also causes the server to suppress during its startup sequence the loading of user-defined functions (UDFs), scheduled events, and plugins that were installed with the `INSTALL PLUGIN` statement. To cause plugins to be loaded anyway, use the `--plugin-load` option. `--skip-grant-tables` also causes the `disabled_storage_engines` system variable to have no effect.

This option does not cause loading of server components to be suppressed during server startup.

`FLUSH PRIVILEGES` might be executed implicitly by other actions performed after startup. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-host-cache`

Property	Value
Command-Line Format	<code>--skip-host-cache</code>

Disable use of the internal host cache for faster name-to-IP resolution. In this case, the server performs a DNS lookup every time a client connects. See [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

- `--skip-innodb`

Disable the `InnoDB` storage engine. In this case, because the default storage engine is `InnoDB`, the server will not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

The `InnoDB` storage engine cannot be disabled, and the `--skip-innodb` option is deprecated and has no effect. Its use results in a warning. This option will be removed in a future MySQL release.

- `--skip-name-resolve`

Property	Value
Command-Line Format	<code>--skip-name-resolve</code>
System Variable	<code>skip_name_resolve</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses. See [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=127.0.0.1` or `--host>:::1`.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host>:::1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':::1' IDENTIFIED BY 'root-password';
```

- `--skip-networking`

Property	Value
Command-Line Format	<code>--skip-networking</code>
System Variable	<code>skip_networking</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Do not listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).

If the server is started with the `--skip-grant-tables` option to disable authentication checks, the server enables `--skip-networking` to prevent remote connections.

- `--ssl*`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.2, “Command Options for Encrypted Connections”](#).

- `--standalone`

Property	Value
Command-Line Format	<code>--standalone</code>
Platform Specific	Windows

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages`

Property	Value
Command-Line Format	<code>--super-large-pages</code>
Platform Specific	Solaris
Type	Boolean
Default Value	<code>FALSE</code>

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links`, `--skip-symbolic-links`

Property	Value
Command-Line Format	<code>--symbolic-links</code>
Deprecated	8.0.2
Type	Boolean
Default Value ($\geq 8.0.2$)	<code>OFF</code>
Default Value ($\leq 8.0.1$)	<code>ON</code>

Enable or disable symbolic link support. On Unix, enabling symbolic links means that you can link a [MyISAM](#) index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` option of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).

Note

Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default. The related `have_symlink` system variable also is deprecated and will be removed in a future version of MySQL.

This option has no meaning on Windows.

- `--skip-show-database`

Property	Value
Command-Line Format	<code>--skip-show-database</code>
System Variable	<code>skip_show_database</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See [Section 5.1.7, “Server System Variables”](#).

- `--skip-stack-trace`

Property	Value
Command-Line Format	<code>--skip-stack-trace</code>

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [Section 28.5, “Debugging and Porting MySQL”](#).

- `--slow-query-log[={0|1}]`

Property	Value
Command-Line Format	<code>--slow-query-log</code>
System Variable	<code>slow_query_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--slow-start-timeout=timeout`

Property	Value
Command-Line Format	<code>--slow-start-timeout=#</code>
Type	Integer
Default Value	<code>15000</code>

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path`

Property	Value
Command-Line Format	<code>--socket={file_name pipe_name}</code>
System Variable	<code>socket</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value (Other)	<code>/tmp/mysql.sock</code>
Default Value (Windows)	MySQL

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

Property	Value
Command-Line Format	<code>--sql-mode=name</code>
System Variable	<code>sql_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Set
Default Value ($\geq 8.0.11$)	ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION
Default Value ($\leq 8.0.4$)	ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_AUTO_CREATE_USER NO_ENGINE_SUBSTITUTION
Valid Values ($\geq 8.0.11$)	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE

Property	Value
	NO_ENGINE_SUBSTITUTION NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL
Valid Values ($\geq 8.0.1$, $\leq 8.0.4$)	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY

Property	Value
	PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL
Valid Values (8.0.0)	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES

Set the SQL mode. See [Section 5.1.10, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `--sysdate-is-now`

Property	Value
Command-Line Format	<code>--sysdate-is-now</code>
Type	Boolean
Default Value	<code>FALSE</code>

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in [Section 12.7, “Date and Time Functions”](#) and for `SET TIMESTAMP` in [Section 5.1.7, “Server System Variables”](#).

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

Property	Value
Command-Line Format	<code>--tc-heuristic-recover=name</code>
Type	Enumeration
Default Value	<code>COMMIT</code>
Valid Values	<code>COMMIT</code> <code>ROLLBACK</code>

The type of decision to use in the heuristic recovery process. To use this option, two or more storage engines that support [XA](#) transactions must be installed.

- `--temp-pool`

Property	Value
Command-Line Format	<code>--temp-pool</code>
Deprecated	Yes (removed in 8.0.1)
Type	Boolean
Default Value (Other)	<code>FALSE</code>
Default Value (Linux)	<code>TRUE</code>

This option is obsolete and was removed in MySQL 8.0.1.

- `--transaction-isolation=level`

Property	Value
Command-Line Format	<code>--transaction-isolation=name</code>
System Variable	<code>transaction_isolation</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>REPEATABLE-READ</code>
Valid Values	<code>READ-UNCOMMITTED</code> <code>READ-COMMITTED</code> <code>REPEATABLE-READ</code> <code>SERIALIZABLE</code>

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See [Section 13.3.7, “SET TRANSACTION Syntax”](#).

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `transaction_isolation` system variable.

- `--transaction-read-only`

Property	Value
Command-Line Format	<code>--transaction-read-only</code>
System Variable	<code>transaction_read_only</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `transaction_read_only` system variable. See [Section 13.3.7, “SET TRANSACTION Syntax”](#).

- `--tmpdir=dir_name, -t dir_name`

Property	Value
Command-Line Format	<code>--tmpdir=dir_name</code>
System Variable	<code>tmpdir</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	Directory name

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#). A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}, -u {user_name|user_id}`

Property	Value
Command-Line Format	<code>--user=name</code>
Type	String

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See [Section 6.1.1, “Security Guidelines”](#).

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

5.1.7 Server System Variables

The MySQL server maintains many system variables that configure its operation. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

At runtime, setting a global system variable value normally requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege. Setting a session system variable value normally requires no special privileges and can

be done by any user, although there are exceptions. For more information, see [Section 5.1.8.1, “System Variable Privileges”](#)

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based only on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement or the Performance Schema system variable tables. See [Section 25.11.13, “Performance Schema System Variable Tables”](#).

This section provides a description of each system variable. For a system variable summary table, see [Section 5.1.4, “Server System Variable Reference”](#). For more information about manipulation of system variables, see [Section 5.1.8, “Using System Variables”](#).

For additional system variable information, see these sections:

- [Section 5.1.8, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 5.1.8.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 5.1.1, “Configuring the Server”](#).
- [Section 15.13, “InnoDB Startup Options and System Variables”](#), lists `InnoDB` system variables.
- For information on server system variables specific to replication, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

Note

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive), as well as `1` and `0`. See [Section 4.2.6, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative

path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `activate_all_roles_on_login`

Property	Value
Command-Line Format	<code>--activate-all-roles-on-login</code>
Introduced	8.0.2
System Variable	<code>activate_all_roles_on_login</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to enable automatic activation of all granted roles when users log in to the server:

- If `activate_all_roles_on_login` is enabled, the server activates all roles granted to each account at login time. This takes precedence over default roles specified with `SET DEFAULT ROLE`.
- If `activate_all_roles_on_login` is disabled, the server activates the default roles specified with `SET DEFAULT ROLE`, if any, at login time.

Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

`activate_all_roles_on_login` applies only at login time, and at the beginning of execution for stored programs and views that execute in definer context. To change the active roles within a session, use `SET ROLE`. To change the active roles for a stored program, the program body should execute `SET ROLE`.

- `authentication_windows_log_level`

Property	Value
Command-Line Format	<code>--authentication-windows-log-level</code>
Introduced	8.0.11
System Variable	<code>authentication_windows_log_level</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	4

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 6.5.1.6, “Windows Pluggable Authentication”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

Value	Description
0	No logging
1	Log only error messages
2	Log level 1 messages and warning messages
3	Log level 2 messages and information notes
4	Log level 3 messages and debug messages

- `authentication_windows_use_principal_name`

Property	Value
Command-Line Format	<code>--authentication-windows-use-principal-name</code>
Introduced	8.0.11
System Variable	<code>authentication_windows_use_principal_name</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 6.5.1.6, “Windows Pluggable Authentication”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

- `autocommit`

Property	Value
Command-Line Format	<code>--autocommit[=#]</code>
System Variable	<code>autocommit</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- `automatic_sp_privileges`

Property	Value
System Variable	<code>automatic_sp_privileges</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	TRUE

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).

- `auto_generate_certs`

Property	Value
Command-Line Format	<code>--auto-generate-certs[={OFF ON}]</code>
System Variable	<code>auto_generate_certs</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	ON

This variable is available if the server was compiled using OpenSSL (see [Section 6.4.4, “OpenSSL Versus wolfSSL”](#)). It controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see [Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”](#).

For more information about SSL file autogeneration, including file names and characteristics, see [Section 6.4.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The `sha256_password_auto_generate_rsa_keys` and `caching_sha2_password_auto_generate_rsa_keys` system variables are related but control autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- `avoid_temporal_upgrade`

Property	Value
Command-Line Format	<code>--avoid-temporal-upgrade={OFF ON}</code>
Deprecated	Yes
System Variable	<code>avoid_temporal_upgrade</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated and will be removed in a future MySQL release.

- `back_log`

Property	Value
System Variable	<code>back_log</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	1
Maximum Value	65535

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is the value of `max_connections`, which enables the permitted backlog to adjust to the maximum permitted number of connections.

- `basedir`

Property	Value
Command-Line Format	--basedir=dir_name
System Variable	basedir
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value (>= 8.0.2)	parent of mysqld installation directory
Default Value (<= 8.0.1)	configuration-dependent default

The path to the MySQL installation base directory.

- `big_tables`

Property	Value
Command-Line Format	--big-tables
System Variable	big_tables
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable. When in-memory *internal* temporary tables are managed by the `TempTable` storage engine (the default), and the maximum amount of memory that can be occupied by the `TempTable` storage engine is exceeded, the `TempTable` storage engine starts storing data to temporary files on disk. When in-memory temporary tables are managed by the `MEMORY` storage engine, in-memory tables are automatically converted to disk-based tables as required. For more information, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `bind_address`

Property	Value
Command-Line Format	<code>--bind-address=addr</code>
System Variable	<code>bind_address</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	*

The value of the `--bind-address` option.

- `block_encryption_mode`

Property	Value
Command-Line Format	<code>--block-encryption-mode=#</code>
System Variable	<code>block_encryption_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>aes-128-ecb</code>

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where *keylen* is the key length in bits and *mode* is the encryption mode. The value is not case-sensitive. Permitted *keylen* values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or wolfSSL:

- For OpenSSL, permitted *mode* values are: `ECB`, `CBC`, `CFB1`, `CFB8`, `CFB128`, `OFB`
- For wolfSSL, permitted *mode* values are: `ECB`, `CBC`

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.

- `bulk_insert_buffer_size`

Property	Value
Command-Line Format	<code>--bulk-insert-buffer-size=#</code>
System Variable	<code>bulk_insert_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	8388608
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1](#), “System Variable Privileges”.

- `caching_sha2_password_auto_generate_rsa_keys`

Property	Value
Command-Line Format	<code>--caching-sha2-password-auto-generate-rsa-keys[={OFF ON}]</code>
Introduced	8.0.4
System Variable	<code>caching_sha2_password_auto_generate_rsa_keys</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable is available if the server was compiled using OpenSSL (see [Section 6.4.4](#), “OpenSSL Versus wolfSSL”). The server uses it to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

For more information about RSA file autogeneration, including file names and characteristics, see [Section 6.4.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- `caching_sha2_password_private_key_path`

Property	Value
Command-Line Format	<code>--caching-sha2-password-private-key-path=file_name</code>
Introduced	8.0.3
System Variable	<code>caching_sha2_password_private_key_path</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>private_key.pem</code>

This variable specifies the path name of the RSA private key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

Important

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `caching_sha2_password`, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `caching_sha2_password_public_key_path`

Property	Value
Command-Line Format	<code>--caching-sha2-password-public-key-path=file_name</code>
Introduced	8.0.3
System Variable	<code>caching_sha2_password_public_key_path</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Type	File name
Default Value	<code>public_key.pem</code>

This variable specifies the path name of the RSA public key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

For information about `caching_sha2_password`, including information about how clients request the RSA public key, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

- `character_set_client`

Property	Value
System Variable	<code>character_set_client</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4</code>
Default Value (8.0.0)	<code>utf8</code>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 10.4, “Connection Character Sets and Collations”](#).) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See [Impermissible Client Character Sets](#).

- `character_set_connection`

Property	Value
System Variable	<code>character_set_connection</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4</code>
Default Value (8.0.0)	<code>utf8</code>

The character set used for literals specified without a character set introducer and for number-to-string conversion. For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

- `character_set_database`

Property	Value
System Variable	<code>character_set_database</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4</code>
Default Value (8.0.0)	<code>latin1</code>
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The global `character_set_database` and `collation_database` system variables are deprecated and will be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- `character_set_filesystem`

Property	Value
Command-Line Format	<code>--character-set-filesystem=name</code>
System Variable	<code>character_set_filesystem</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Property	Value
Default Value	<code>binary</code>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8mb4'`.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `character_set_results`

Property	Value
System Variable	<code>character_set_results</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4</code>
Default Value (8.0.0)	<code>utf8</code>

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

- `character_set_server`

Property	Value
Command-Line Format	<code>--character-set-server</code>
System Variable	<code>character_set_server</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	<code>utf8mb4</code>
Default Value (8.0.0)	<code>latin1</code>

The server's default character set.

- `character_set_system`

Property	Value
System Variable	<code>character_set_system</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>utf8</code>

The character set used by the server for storing identifiers. The value is always `utf8`.

- [character_sets_dir](#)

Property	Value
Command-Line Format	<code>--character-sets-dir=dir_name</code>
System Variable	character_sets_dir
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory where character sets are installed.

- [check_proxy_users](#)

Property	Value
Command-Line Format	<code>--check-proxy-users=[={OFF ON}]</code>
System Variable	check_proxy_users
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: [mysql_native_password](#), [sha256_password](#).

If the [check_proxy_users](#) system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request. However, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

- For the [mysql_native_password](#) plugin, enable [mysql_native_password_proxy_users](#).
- For the [sha256_password](#) plugin, enable [sha256_password_proxy_users](#).

For information about user proxying, see [Section 6.3.11, “Proxy Users”](#).

- [collation_connection](#)

Property	Value
System Variable	collation_connection
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The collation of the connection character set. [collation_connection](#) is important for comparisons of literal strings. For comparisons of strings with column values, [collation_connection](#) does not matter because columns have their own collation, which has a higher collation precedence (see [Section 10.8.4, “Collation Coercibility in Expressions”](#)).

- [collation_database](#)

Property	Value
System Variable	collation_database
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	utf8mb4_0900_ai_ci
Default Value (8.0.0)	latin1_swedish_ci
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as [collation_server](#).

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The global [character_set_database](#) and [collation_database](#) system variables are deprecated and will be removed in a future version of MySQL.

Assigning a value to the session [character_set_database](#) and [collation_database](#) system variables is deprecated and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- [collation_server](#)

Property	Value
Command-Line Format	--collation-server
System Variable	collation_server

Property	Value
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (>= 8.0.1)	utf8mb4_0900_ai_ci
Default Value (8.0.0)	latin1_swedish_ci

The server's default collation.

- `completion_type`

Property	Value
Command-Line Format	<code>--completion-type=#</code>
System Variable	<code>completion_type</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>NO_CHAIN</code>
Valid Values	<code>NO_CHAIN</code> <code>CHAIN</code> <code>RELEASE</code> 0 1 2

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
<code>NO_CHAIN</code> (or 0)	<code>COMMIT</code> and <code>ROLLBACK</code> are unaffected. This is the default value.
<code>CHAIN</code> (or 1)	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT AND CHAIN</code> and <code>ROLLBACK AND CHAIN</code> , respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
<code>RELEASE</code> (or 2)	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT RELEASE</code> and <code>ROLLBACK RELEASE</code> , respectively. (The server disconnects after terminating the transaction.)

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements

listed in [Section 13.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `concurrent_insert`

Property	Value
Command-Line Format	<code>--concurrent-insert[=#]</code>
System Variable	<code>concurrent_insert</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>AUTO</code>
Valid Values	<code>NEVER</code> <code>AUTO</code> <code>ALWAYS</code> <code>0</code> <code>1</code> <code>2</code>

If `AUTO` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file. If you start `mysqld` with `--skip-new`, this variable is set to `NEVER`.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
<code>NEVER</code> (or 0)	Disables concurrent inserts
<code>AUTO</code> (or 1)	(Default) Enables concurrent insert for <code>MyISAM</code> tables that do not have holes
<code>ALWAYS</code> (or 2)	Enables concurrent inserts for all <code>MyISAM</code> tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

See also [Section 8.11.3, “Concurrent Inserts”](#).

- `connect_timeout`

Property	Value
Command-Line Format	<code>--connect-timeout=#</code>
System Variable	<code>connect_timeout</code>
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	2
Maximum Value	31536000

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- `core_file`

Property	Value
System Variable	<code>core_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to write a core file if the server crashes. This variable is set by the `--core-file` option.

Under some circumstances, disabling `innodb_buffer_pool_in_core_file` can cause `core_file` to become disabled.

- `cte_max_recursion_depth`

Property	Value
Command-Line Format	<code>--cte-max-recursion-depth=#</code>
Introduced	8.0.3
System Variable	<code>cte_max_recursion_depth</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

The common table expression (CTE) maximum recursion depth. The server terminates execution of any CTE that recurses more levels than the value of this variable. For more information, see [Limiting Common Table Expression Recursion](#).

- `datadir`

Property	Value
Command-Line Format	<code>--datadir=dir_name</code>
System Variable	<code>datadir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If the server will be started automatically (that is, in contexts for which you cannot assume what the current directory will be), it is best to specify the `datadir` value as an absolute path.

- `date_format`

This system variable was removed in MySQL 8.0.3.

- `datetime_format`

This system variable was removed in MySQL 8.0.3.

- `debug`

Property	Value
Command-Line Format	<code>--debug[=debug_options]</code>
System Variable	<code>debug</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (Windows)	<code>d:t:i:0,\mysqld.trace</code>
Default Value (Unix)	<code>d:t:i:o,/tmp/mysqld.trace</code>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

```
mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

For more information, see [Section 28.5.3, “The DEBUG Package”](#).

- `debug_sync`

Property	Value
System Variable	<code>debug_sync</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where *N* is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, *N* becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_authentication_plugin`

Property	Value
Command-Line Format	<code>--default-authentication-plugin=plugin_name</code>
System Variable	<code>default_authentication_plugin</code>
Scope	Global

Property	Value
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value (>= 8.0.4)	<code>caching_sha2_password</code>
Default Value (<= 8.0.3)	<code>mysql_native_password</code>
Valid Values (>= 8.0.3)	<code>mysql_native_password</code> <code>sha256_password</code> <code>caching_sha2_password</code>
Valid Values (<= 8.0.2)	<code>mysql_native_password</code> <code>sha256_password</code>

The default authentication plugin. These values are permitted:

- `mysql_native_password`: Use MySQL native passwords; see [Section 6.5.1.1, “Native Pluggable Authentication”](#).
- `sha256_password`: Use SHA-256 passwords; see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#).
- `caching_sha2_password`: Use SHA-256 passwords; see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

Note

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see [caching_sha2_password as the Preferred Authentication Plugin](#).

The `default_authentication_plugin` value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not explicitly specify an authentication plugin.
- For an account created with the following statement, the server associates the account with the default authentication plugin and assigns the account the given password, hashed as required by that plugin:

```
CREATE USER ... IDENTIFIED BY 'cleartext password';
```

- `default_collation_for_utf8mb4`

Property	Value
Introduced	8.0.11
System Variable	<code>default_collation_for_utf8mb4</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Enumeration
Valid Values	<code>utf8mb4_0900_ai_ci</code> <code>utf8mb4_general_ci</code>

For internal use by replication. This system variable is set to the default collation for the `utf8mb4` character set. The value of the variable is replicated from a master to a slave so that the slave can correctly process data originating from a master with a different default collation for `utf8mb4`. This variable is primarily intended to support replication from a MySQL 5.7 or older master server to a MySQL 8.0 slave server, or group replication with a MySQL 5.7 primary node and one or more MySQL 8.0 secondaries. The default collation for `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`, but `utf8mb4_0900_ai_ci` in MySQL 8.0. The variable is not present in releases earlier than MySQL 8.0, so if the slave does not receive a value for the variable, it assumes the master is from an earlier release and sets the value to the previous default collation `utf8mb4_general_ci`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The default `utf8mb4` collation is used in the following statements:

- `SHOW COLLATION` and `SHOW CHARACTER SET`.
- `CREATE TABLE` and `ALTER TABLE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause, either for the table character set or for a column character set.
- `CREATE DATABASE` and `ALTER DATABASE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause.
- Any statement containing a string literal of the form `_utf8mb4'some text'` without a `COLLATE` clause.
- `default_password_lifetime`

Property	Value
Command-Line Format	<code>--default-password-lifetime=#</code>
System Variable	<code>default_password_lifetime</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535

This variable defines the global automatic password expiration policy. The default `default_password_lifetime` value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer *N*, it indicates the permitted password lifetime; passwords must be changed every *N* days.

The global password expiration policy can be overridden as desired for individual accounts using the password expiration option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.3.8, “Password Management”](#).

- `default_storage_engine`

Property	Value
Command-Line Format	<code>--default-storage-engine=name</code>
System Variable	<code>default_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	InnoDB

The default storage engine. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_tmp_storage_engine`

Property	Value
Command-Line Format	<code>--default-tmp-storage-engine=name</code>
System Variable	<code>default_tmp_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Enumeration
Default Value	InnoDB

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_week_format`

Property	Value
Command-Line Format	<code>--default-week-format=#</code>
System Variable	<code>default_week_format</code>
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	7

The default mode value to use for the `WEEK()` function. See [Section 12.7, “Date and Time Functions”](#).

- `delay_key_write`

Property	Value
Command-Line Format	<code>--delay-key-write[=name]</code>
System Variable	<code>delay_key_write</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	ON
Valid Values	ON OFF ALL

This option applies only to `MyISAM` tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
OFF	<code>DELAY_KEY_WRITE</code> is ignored.
ON	MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.
ALL	All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all `MyISAM` tables by starting the server with the `--myisam-recover-options` option (for example, `--myisam-recover-options=BACKUP, FORCE`). See [Section 5.1.6, “Server Command Options”](#), and [Section 16.2.1, “MyISAM Startup Options”](#).

Warning

If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`

Property	Value
Command-Line Format	<code>--delayed-insert-limit=#</code>
Deprecated	Yes
System Variable	<code>delayed_insert_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `delayed_insert_timeout`

Property	Value
Command-Line Format	<code>--delayed-insert-timeout=#</code>
Deprecated	Yes
System Variable	<code>delayed_insert_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `delayed_queue_size`

Property	Value
Command-Line Format	<code>--delayed-queue-size=#</code>
Deprecated	Yes
System Variable	<code>delayed_queue_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000

Property	Value
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `disabled_storage_engines`

Property	Value
Command-Line Format	<code>--disabled-storage-engines=engine[,engine]...</code>
System Variable	<code>disabled_storage_engines</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new `MyISAM` or `FEDERATED` tables from being created, start the server with these lines in the server option file:

```
[mysqld]
disabled_storage_engines="MyISAM,FEDERATED"
```

By default, `disabled_storage_engines` is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an `ER_DISABLED_STORAGE_ENGINE` error.

`disabled_storage_engines` does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

It is permitted to set the `default_storage_engine` or `default_tmp_storage_engine` system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

`disabled_storage_engines` is disabled and has no effect if the server is started with any of these options: `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

**Note**

Setting `disabled_storage_engines` might cause an issue with `mysql_upgrade`. For details, see [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

- `disconnect_on_expired_password`

Property	Value
Command-Line Format	<code>--disconnect-on-expired-password[=#]</code>
System Variable	<code>disconnect_on_expired_password</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expires passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.
- If the client does not indicate that it can handle expires passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
 - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
 - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see [Section 6.3.9, “Server Handling of Expired Passwords”](#).

- `div_precision_increment`

Property	Value
Command-Line Format	<code>--div-precision-increment=#</code>
System Variable	<code>div_precision_increment</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	4
Minimum Value	0
Maximum Value	30

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7          |
+-----+
| 0.142857142857 |
+-----+
```

- `dragnet.log_error_filter_rules`

Property	Value
Command-Line Format	<code>--dragnet.log-error-filter-rules</code>
Introduced	8.0.4
System Variable	<code>dragnet.log_error_filter_rules</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.

The filter rules that control operation of the `log_filter_dragnet` error log filter component. If `log_filter_dragnet` is not installed, `dragnet.log_error_filter_rules` is unavailable. If `log_filter_dragnet` is installed but not enabled, changes to `dragnet.log_error_filter_rules` have no effect.

As of MySQL 8.0.12, the `dragnet.Status` status variable can be consulted to determine the result of the most recent assignment to `dragnet.log_error_filter_rules`.

Prior to MySQL 8.0.12, successful assignments to `dragnet.log_error_filter_rules` at runtime produce a note confirming the new value:

```
mysql> SET GLOBAL dragnet.log_error_filter_rules = 'IF prio <> 0 THEN unset prio.';
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 4569
Message: filter configuration accepted:
SET @@global.dragnet.log_error_filter_rules=
'IF prio!=ERROR THEN unset prio.';
```

The value displayed by `SHOW WARNINGS` indicates the “decompiled” canonical representation after the rule set has been successfully parsed and compiled into internal form. Semantically, this canonical form is identical to the value assigned to `dragnet.log_error_filter_rules`, but there may be some differences between the assigned and canonical values, as illustrated by the preceding example:

- The `<>` operator is changed to `!=`.
- The numeric priority of 0 is changed to the corresponding severity symbol `ERROR`.
- Optional spaces are removed.

For additional information, see [Section 5.4.2.5, “Error Log Filtering”](#), and [Section 5.5.3, “Error Log Components”](#).

- `end_markers_in_json`

Property	Value
System Variable	<code>end_markers_in_json</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>

Whether optimizer JSON output should add end markers. See [MySQL Internals: The end_markers_in_json System Variable](#).

- `eq_range_index_dive_limit`

Property	Value
System Variable	<code>eq_range_index_dive_limit</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	<code>200</code>
Minimum Value	<code>0</code>
Maximum Value	<code>4294967295</code>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains *N* equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer

uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up to N equality ranges, set `eq_range_index_dive_limit` to $N + 1$. To disable use of index statistics and always use index dives regardless of N , set `eq_range_index_dive_limit` to 0.

For more information, see [Equality Range Optimization of Many-Valued Comparisons](#).

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.6.17, “SHOW ERRORS Syntax”](#).

- `event_scheduler`

Property	Value
Command-Line Format	<code>--event-scheduler[=value]</code>
System Variable	<code>event_scheduler</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value ($\geq 8.0.3$)	ON
Default Value ($\leq 8.0.2$)	OFF
Valid Values	ON OFF DISABLED

This variable indicates the status of the Event Scheduler; possible values are `ON`, `OFF`, and `DISABLED`, with the default being `ON`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter](#).

- `explicit_defaults_for_timestamp`

Property	Value
Command-Line Format	<code>--explicit-defaults-for-timestamp=#</code>
Deprecated	Yes
System Variable	<code>explicit_defaults_for_timestamp</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value ($\geq 8.0.2$)	ON
Default Value ($\leq 8.0.1$)	OFF

This system variable determines whether the server enables certain nonstandard behaviors for default values and `NULL`-value handling in `TIMESTAMP` columns. By default, `explicit_defaults_for_timestamp` is enabled, which disables the nonstandard behaviors. Disabling `explicit_defaults_for_timestamp` results in a warning.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are automatically declared with the `NOT NULL` attribute. Assigning such a column a value of `NULL` is permitted and sets the column to the current timestamp.
- The first `TIMESTAMP` column in a table, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` attribute, is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` attribute, are automatically declared as `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled, a default value of `'0000-00-00 00:00:00'` may be invalid. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 5.1.10, “Server SQL Modes”](#).

The nonstandard behaviors just described are deprecated and will be removed in a future MySQL release.

If `explicit_defaults_for_timestamp` is enabled, the server disables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- It is not possible to assign a `TIMESTAMP` column a value of `NULL` to set it to the current timestamp. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.
- `TIMESTAMP` columns not explicitly declared with the `NOT NULL` attribute are automatically declared with the `NULL` attribute and permit `NULL` values. Assigning such a column a value of `NULL` sets it to `NULL`, not the current timestamp.
- `TIMESTAMP` columns declared with the `NOT NULL` attribute do not permit `NULL` values. For inserts that specify `NULL` for such a column, the result is either an error for a single-row insert or if strict SQL mode is enabled, or `'0000-00-00 00:00:00'` is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of `NULL` set it to the current timestamp.
- `TIMESTAMP` columns explicitly declared with the `NOT NULL` attribute and without an explicit `DEFAULT` attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.
- No `TIMESTAMP` column is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes. Those attributes must be explicitly specified.

- The first `TIMESTAMP` column in a table is not handled differently from `TIMESTAMP` columns following the first one.

If `explicit_defaults_for_timestamp` is disabled at server startup, this warning appears in the error log:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup.

Note

`explicit_defaults_for_timestamp` is itself deprecated because its only purpose is to permit control over deprecated `TIMESTAMP` behaviors that are to be removed in a future MySQL release. When removal of those behaviors occurs, `explicit_defaults_for_timestamp` will have no purpose and will be removed as well.

For additional information, see [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `external_user`

Property	Value
System Variable	<code>external_user</code>
Scope	Session
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 6.3.11, “Proxy Users”](#).

- `flush`

Property	Value
Command-Line Format	<code>--flush</code>
System Variable	<code>flush</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle

the synchronizing to disk. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` option.

Note

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `flush_time`

Property	Value
Command-Line Format	<code>--flush-time=#</code>
System Variable	<code>flush_time</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

Note

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `foreign_key_checks`

Property	Value
System Variable	<code>foreign_key_checks</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#).

Typically you leave this setting enabled during normal operation, to enforce [referential integrity](#). Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` will not be verified for consistency.

Dropping an index required by a foreign key constraint is not permitted, even with `foreign_key_checks=0`. The foreign key constraint must be removed before dropping the index.

- `ft_boolean_syntax`

Property	Value
Command-Line Format	<code>--ft-boolean-syntax=name</code>
System Variable	<code>ft_boolean_syntax</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>+ -><()~*:" "& </code>

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 12.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `'+ -><()~*:" "&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `|`) are reserved for future extensions.
- `ft_max_word_len`

Property	Value
Command-Line Format	<code>--ft-max-word-len=#</code>
System Variable	<code>ft_max_word_len</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	Integer
Minimum Value	10

The maximum length of the word to be included in a [MyISAM FULLTEXT](#) index.

Note

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

Property	Value
Command-Line Format	<code>--ft-min-word-len=#</code>
System Variable	<code>ft_min_word_len</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1

The minimum length of the word to be included in a [MyISAM FULLTEXT](#) index.

Note

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

Property	Value
Command-Line Format	<code>--ft-query-expansion-limit=#</code>
System Variable	<code>ft_query_expansion_limit</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	0
Maximum Value	1000

The number of top matches to use for full-text searches performed using [WITH QUERY EXPANSION](#).

- `ft_stopword_file`

Property	Value
Command-Line Format	<code>--ft-stopword-file=file_name</code>
System Variable	<code>ft_stopword_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The file from which to read the list of stopwords for full-text searches on [MyISAM](#) tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string (`' '`) disables stopwords filtering. See also [Section 12.9.4, “Full-Text Stopwords”](#).

Note

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable or the contents of the stopwords file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log`

Property	Value
Command-Line Format	<code>--general-log</code>
System Variable	<code>general_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `general_log_file`

Property	Value
Command-Line Format	<code>--general-log-file=file_name</code>
System Variable	<code>general_log_file</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>host_name.log</code>

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- `group_concat_max_len`

Property	Value
Command-Line Format	<code>--group-concat-max-len=#</code>
System Variable	<code>group_concat_max_len</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	4
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_compress`

`YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

This system variable was removed in MySQL 8.0.3.

- `have_dynamic_loading`

`YES` if `mysqld` supports dynamic loading of plugins, `NO` if not. If the value is `NO`, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_openssl`

This variable is an alias for `have_ssl`.

- `have_profiling`

`YES` if statement profiling capability is present, `NO` if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See [Section 13.7.6.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- `have_query_cache`

The query cache was removed in MySQL 8.0.3. `have_query_cache` is deprecated, always has a value of `NO`, and will be removed in a future MySQL release.

- `have_rtree_keys`

`YES` if `RTREE` indexes are available, `NO` if not. (These are used for spatial indexes in `MyISAM` tables.)

- `have_ssl`

`YES` if `mysqld` supports SSL connections, `NO` if not. `DISABLED` indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see [Section 6.4.5, “Building MySQL with Support for Encrypted Connections”](#).

- `have_statement_timeout`

Property	Value
System Variable	<code>have_statement_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Whether the statement execution timeout feature is available (see [Statement Execution Time Optimizer Hints](#)). The value can be `NO` if the background thread used by this feature could not be initialized.

- `have_symlink`

`YES` if symbolic link support is enabled, `NO` if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If the server is started with the `--skip-symbolic-links` option, the value is `DISABLED`.

This variable has no meaning on Windows.

Note

Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default. The related `have_symlink` system variable also is deprecated and will be removed in a future version of MySQL.

- `histogram_generation_max_mem_size`

Property	Value
Command-Line Format	<code>--histogram-generation-max-mem-size=#</code>
Introduced	8.0.2
System Variable	<code>histogram_generation_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value	20000000
Minimum Value	1000000
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum amount of memory available for generating histogram statistics. See [Section 8.9.6, “Optimizer Statistics”](#), and [Section 13.7.3.1, “ANALYZE TABLE Syntax”](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `host_cache_size`

Property	Value
System Variable	<code>host_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	0
Maximum Value	65536

The size of the internal host cache (see [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#)). Setting the size to 0 disables the host cache. Changing the cache size at runtime implicitly causes a `FLUSH HOSTS` operation to clear the host cache and truncate the `host_cache` table.

The default value is 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

- `hostname`

Property	Value
System Variable	<code>hostname</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The server sets this variable to the server host name at startup.

- `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `init_connect`

Property	Value
Command-Line Format	<code>--init-connect=name</code>
System Variable	<code>init_connect</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global `autocommit` system variable to specify that autocommit should be disabled by default, but as a workaround `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

For users that have the `CONNECTION_ADMIN` or `SUPER` privilege, the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `CONNECTION_ADMIN` or `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

As of MySQL 8.0.5, `init_connect` execution is skipped for any client user with an expired password. This is done because such a user cannot execute arbitrary statements, and thus `init_connect` execution will fail, leaving the client unable to connect. Skipping `init_connect` execution enables the user to connect and change password.

The server discards any result sets produced by statements in the value of `init_connect`.

- `information_schema_stats_expiry`

Property	Value
Command-Line Format	<code>--information-schema-stats-expiry=value</code>
Introduced	8.0.3

Property	Value
System Variable	information_schema_stats_expiry
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	86400
Minimum Value	0
Maximum Value	31536000

Some [INFORMATION_SCHEMA](#) tables contain columns that provide table statistics:

```

STATISTICS.CARDINALITY
TABLES.AUTO_INCREMENT
TABLES.AVG_ROW_LENGTH
TABLES.CHECKSUM
TABLES.CHECK_TIME
TABLES.CREATE_TIME
TABLES.DATA_FREE
TABLES.DATA_LENGTH
TABLES.INDEX_LENGTH
TABLES.MAX_DATA_LENGTH
TABLES.TABLE_ROWS
TABLES.UPDATE_TIME

```

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the [mysql.index_stats](#) and [mysql.table_stats](#) dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the [mysql.index_stats](#) and [mysql.table_stats](#) dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire.

The [information_schema_stats_expiry](#) session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use [ANALYZE TABLE](#).

To always retrieve the latest statistics directly from the storage engine and bypass cached values, set [information_schema_stats_expiry](#) to 0.

Querying statistics columns does not store or update statistics in the [mysql.index_stats](#) and [mysql.table_stats](#) dictionary tables under these circumstances:

- When cached statistics have not expired.
- When [information_schema_stats_expiry](#) is set to 0.
- When the server is started in [read_only](#), [super_read_only](#), [transaction_read_only](#), or [innodb_read_only](#) mode.

- When the query also fetches Performance Schema data.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

For related information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

- `init_file`

Property	Value
Command-Line Format	<code>--init-file=file_name</code>
System Variable	<code>init_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. For more information, see the description of `--init-file`.

- `innodb_xxx`

InnoDB system variables are listed in [Section 15.13, “InnoDB Startup Options and System Variables”](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

Property	Value
Command-Line Format	<code>--interactive-timeout=#</code>
System Variable	<code>interactive_timeout</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `internal_tmp_disk_storage_engine`

Property	Value
Command-Line Format	<code>--internal-tmp-disk-storage-engine=#</code>
System Variable	<code>internal_tmp_disk_storage_engine</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>INNODB</code>
Valid Values	<code>MYISAM</code> <code>INNODB</code>

The storage engine for on-disk internal temporary tables (see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#)). Permitted values are `MYISAM` and `INNODB` (the default).

The [optimizer](#) uses the storage engine defined by `internal_tmp_disk_storage_engine` for on-disk internal temporary tables.

When using `internal_tmp_disk_storage_engine=INNODB` (the default), queries that generate on-disk internal temporary tables that exceed [InnoDB row or column limits](#) will return `Row size too large` or `Too many columns` errors. The workaround is to set `internal_tmp_disk_storage_engine` to `MYISAM`.

- `internal_tmp_mem_storage_engine`

Property	Value
Command-Line Format	<code>--internal-tmp-mem-storage-engine=#</code>
Introduced	8.0.2
System Variable	<code>internal_tmp_mem_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Enumeration
Default Value	<code>TempTable</code>
Valid Values	<code>TempTable</code> <code>MEMORY</code>

The storage engine for in-memory internal temporary tables (see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#)). Permitted values are `TempTable` (the default) and `MEMORY`.

The [optimizer](#) uses the storage engine defined by `internal_tmp_mem_storage_engine` for in-memory internal temporary tables.

- `join_buffer_size`

Property	Value
Command-Line Format	<code>--join-buffer-size=#</code>
System Variable	<code>join_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	128
Maximum Value (Other, 64-bit platforms)	18446744073709547520
Maximum Value (Other, 32-bit platforms)	4294967295
Maximum Value (Windows)	4294967295

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless Batched Key Access (BKA) is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

For additional information about join buffering, see [Section 8.2.1.6, “Nested-Loop Join Algorithms”](#). For information about Batched Key Access, see [Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”](#).

- `keep_files_on_create`

Property	Value
Command-Line Format	<code>--keep-files-on-create=#</code>
System Variable	<code>keep_files_on_create</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	OFF

If a [MyISAM](#) table is created with no [DATA DIRECTORY](#) option, the [.MYD](#) file is created in the database directory. By default, if [MyISAM](#) finds an existing [.MYD](#) file in this case, it overwrites it. The same applies to [.MYI](#) files for tables created with no [INDEX DIRECTORY](#) option. To suppress this behavior, set the [keep_files_on_create](#) variable to [ON](#) (1), in which case [MyISAM](#) will not overwrite existing files and returns an error instead. The default value is [OFF](#) (0).

If a [MyISAM](#) table is created with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option and an existing [.MYD](#) or [.MYI](#) file is found, [MyISAM](#) always returns an error. It will not overwrite a file in the specified directory.

- [key_buffer_size](#)

Property	Value
Command-Line Format	--key-buffer-size=#
System Variable	key_buffer_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	8
Maximum Value (64-bit platforms)	OS_PER_PROCESS_LIMIT
Maximum Value (32-bit platforms)	4294967295

Index blocks for [MyISAM](#) tables are buffered and are shared by all threads. [key_buffer_size](#) is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for [key_buffer_size](#) is 4GB–1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the [MyISAM](#) storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to [MyISAM](#).

For even more speed when writing many rows at the same time, use [LOCK TABLES](#). See [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

You can check the performance of the key buffer by issuing a [SHOW STATUS](#) statement and examining the [Key_read_requests](#), [Key_reads](#), [Key_write_requests](#), and [Key_writes](#) status variables.

(See [Section 13.7.6, “SHOW Syntax”](#).) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `key_cache_age_threshold`

Property	Value
Command-Line Format	<code>--key-cache-age-threshold=#</code>
System Variable	<code>key_cache_age_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	100
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `key_cache_block_size`

Property	Value
Command-Line Format	<code>--key-cache-block-size=#</code>
System Variable	<code>key_cache_block_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value	1024
Minimum Value	512
Maximum Value	16384

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `key_cache_division_limit`

Property	Value
Command-Line Format	<code>--key-cache-division-limit=#</code>
System Variable	<code>key_cache_division_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value	100

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `large_files_support`

Property	Value
System Variable	<code>large_files_support</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

Property	Value
Command-Line Format	<code>--large-pages</code>
System Variable	<code>large_pages</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Linux
Type	Boolean

Property	Value
Default Value	<code>FALSE</code>

Whether large page support is enabled (via the `--large-pages` option). See [Section 8.12.3.2, “Enabling Large Page Support”](#).

- `large_page_size`

Property	Value
System Variable	<code>large_page_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 8.12.3.2, “Enabling Large Page Support”](#).

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

Property	Value
Command-Line Format	<code>--lc-messages=name</code>
System Variable	<code>lc_messages</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>en_US</code>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See [Section 10.11, “Setting the Error Message Language”](#).

- `lc_messages_dir`

Property	Value
Command-Line Format	<code>--lc-messages-dir=dir_name</code>
System Variable	<code>lc_messages_dir</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	Directory name

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See [Section 10.11, “Setting the Error Message Language”](#).

- `lc_time_names`

Property	Value
System Variable	<code>lc_time_names</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see [Section 10.15, “MySQL Server Locale Support”](#).

- `license`

Property	Value
System Variable	<code>license</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>GPL</code>

The type of license the server has.

- `local_infile`

Property	Value
System Variable	<code>local_infile</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value (>= 8.0.2)	<code>OFF</code>
Default Value (<= 8.0.1)	<code>ON</code>

This variable controls server-side [LOCAL](#) capability for [LOAD DATA](#) statements. Depending on the [local_infile](#) setting, the server refuses or permits local data loading by clients that have [LOCAL](#) enabled on the client side.

To explicitly cause the server to refuse or permit [LOAD DATA LOCAL](#) statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with [local_infile](#) disabled or enabled, respectively. [local_infile](#) can also be set at runtime. For more information, see [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- [lock_wait_timeout](#)

Property	Value
Command-Line Format	<code>--lock-wait-timeout=#</code>
System Variable	lock_wait_timeout
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	31536000
Minimum Value	1
Maximum Value	31536000

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as [LOCK TABLES](#), [FLUSH TABLES WITH READ LOCK](#), and [HANDLER](#) statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by [GRANT](#) or [REVOKE](#) statements or table logging statements. The timeout does apply to system tables accessed directly, such as with [SELECT](#) or [UPDATE](#).

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the [lock_wait_timeout](#) value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

[lock_wait_timeout](#) also defines the amount of time that a [LOCK INSTANCE FOR BACKUP](#) statement waits for a lock before giving up.

- [locked_in_memory](#)

Property	Value
System Variable	locked_in_memory
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Whether `mysqld` was locked in memory with `--memlock`.

- `log_error`

Property	Value
Command-Line Format	<code>--log-error[=file_name]</code>
System Variable	<code>log_error</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The default error log destination. If the destination is the console, the value is `stderr`. Otherwise, the destination is a file and the `log_error` value is the file name. See [Section 5.4.2, “The Error Log”](#).

- `log_error_filter_rules`

Property	Value
Command-Line Format	<code>--log-error-filter-rules</code>
Introduced	8.0.2
Removed	8.0.4
System Variable	<code>log_error_filter_rules</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>set by server</code>

The filter rules for error logging. This variable is unused. It was removed in MySQL 8.0.4.

- `log_error_services`

Property	Value
Command-Line Format	<code>--log-error-services</code>
Introduced	8.0.2
System Variable	<code>log_error_services</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>log_filter_internal;</code> <code>log_sink_internal</code>

The components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed. Any loadable (not

built in) component named in the `log_error_services` value must first be installed with `INSTALL COMPONENT`. For more information, see [Section 5.4.2.1, “Error Log Component Configuration”](#).

- `log_error_suppression_list`

Property	Value
Command-Line Format	<code>--log-error-suppression-list=value</code>
Introduced	8.0.13
System Variable	<code>log_error_suppression_list</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

This variable enables specifying which diagnostics should not be written to the error log when they occur with a severity of `WARNING` or `INFORMATION`. For example, if a particular type of warning occurs frequently but is not of interest (and thus may be considered undesirable “noise” in the error log), it can be suppressed.

The variable value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress.

The numeric value of each code to be suppressed must be in a permitted range:

- 1 up to (but not including) 1000: Global error codes that are shared by the server and clients
- 10000 and higher: Server error codes intended to be written to the error log (not sent to clients)

Attempts to assign an error code not in a permitted range produce an error and the variable value remains unchanged.

Error codes may be specified in numeric or symbolic form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

```
31
00031
MY-31
MY-00031
ER_SERVER_SHUTDOWN_COMPLETE
```

For a list of error codes and symbols, see [Section B.3, “Server Error Codes and Messages”](#).

The server can generate messages for a given error code at differing severities, so suppression for a message associated with an error code listed in `log_error_suppression_list` depends on its severity. Suppose that the variable has a value of `'10000,10001,MY-10002'`. Messages for those codes are not written to the error log if generated with a severity of `WARNING` or `INFORMATION`. Messages generated with a severity of `ERROR` or `SYSTEM` are not suppressed and are written to the error log.

The effect of `log_error_suppression_list` combines with that of `log_error_verbosity`. Consider a server started with these settings:

```
[mysqld]
log_error_verbosity=2      # error and warning messages only
log_error_suppression_list='10000,10001,MY-10002'
```

In this case, `log_error_verbosity` discards all messages with `INFORMATION` severity. Of the remaining messages, `log_error_suppression_list` discards messages with `WARNING` severity and any of the named error codes.

Note

The `log_error_verbosity` value shown in the example (2) is also its default value, so its effect on suppression of all `INFORMATION` messages is by default as just described. You must set `log_error_verbosity` to 3 if you want `log_error_suppression_list` to affect messages with `INFORMATION` severity.

Consider a server started with this setting:

```
[mysqld]
log_error_verbosity=1      # error messages only
```

In this case, `log_error_verbosity` discards all messages with `WARNING` or `INFORMATION` severity. Setting `log_error_suppression_list` has no effect because all error codes it might suppress are already discarded due to the `log_error_verbosity` setting.

`log_error_suppression_list` (like `log_error_verbosity`) affects the `log_filter_internal` error log filter, which is enabled by default. If that filter is disabled, error code suppression does not occur and must be modeled using whatever filter service is used instead where desired (for example, with individual filter rules when using `log_filter_dragnet`). For information about filter configuration, see [Section 5.4.2.1, “Error Log Component Configuration”](#).

- `log_error_verbosity`

Property	Value
Command-Line Format	<code>--log-error-verbosity=#</code>
System Variable	<code>log_error_verbosity</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (>= 8.0.4)	2
Default Value (<= 8.0.3)	3
Minimum Value	1
Maximum Value	3

The verbosity for handling events intended for the error log, as filtered by the `log_filter_internal` error log filter component, which is enabled by default. If `log_filter_internal` is disabled, `log_error_verbosity` has no effect.

The following table shows the permitted verbosity values.

Desired Log Filtering	log_error_verbosity Value
Error messages	1
Error and warning messages	2
Error, warning, and information messages	3

Selected important system messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. See the description of the latter for examples.

For additional information, see [Section 5.4.2.5, “Error Log Filtering”](#), and [Section 5.5.3, “Error Log Components”](#).

- `log_output`

Property	Value
Command-Line Format	<code>--log-output=name</code>
System Variable	<code>log_output</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Set
Default Value	<code>FILE</code>
Valid Values	<code>TABLE</code> <code>FILE</code> <code>NONE</code>

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `FILE`. `NONE`, if present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` is not `NONE`. For more information, see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `log_queries_not_using_indexes`

Property	Value
Command-Line Format	<code>--log-queries-not-using-indexes</code>
System Variable	<code>log_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Boolean
Default Value	OFF

Whether queries that do not use indexes are logged to the slow query log. See [Section 5.4.5, “The Slow Query Log”](#).

- `log_slow_admin_statements`

Property	Value
System Variable	<code>log_slow_admin_statements</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- `log_syslog`

Property	Value
Command-Line Format	<code>--log-syslog[={0 1}]</code>
Deprecated	8.0.2 (removed in 8.0.13)
System Variable	<code>log_syslog</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value (Windows, <= 8.0.1)	ON
Default Value (Unix, <= 8.0.1)	OFF
Default Value (>= 8.0.2)	ON (when error logging to system log is enabled)

Prior to MySQL 8.0, this variable controlled whether to perform error logging to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

In MySQL 8.0, the `log_sink_syseventlog` log component implements error logging to the system log (see [Section 5.4.2.3, “Error Logging to the System Log”](#)), and `log_syslog` is removed. (Prior to MySQL 8.0.13, `log_syslog` exists but is deprecated and has no effect.)

- `log_syslog_facility`

Property	Value
Command-Line Format	<code>--log-syslog-facility=value</code>
Removed	8.0.13

Property	Value
System Variable	log_syslog_facility
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	daemon

This variable was removed in MySQL 8.0.13 and replaced by [syseventlog.facility](#).

- [log_syslog_include_pid](#)

Property	Value
Command-Line Format	--log-syslog-include-pid[={0 1}]
Removed	8.0.13
System Variable	log_syslog_include_pid
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable was removed in MySQL 8.0.13 and replaced by [syseventlog.include_pid](#).

- [log_syslog_tag](#)

Property	Value
Command-Line Format	--log-syslog-tag=tag
Removed	8.0.13
System Variable	log_syslog_tag
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	empty string

This variable was removed in MySQL 8.0.13 and replaced by [syseventlog.tag](#).

- [log_timestamps](#)

Property	Value
Command-Line Format	--log-timestamps=#
System Variable	log_timestamps
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	UTC
Valid Values	UTC SYSTEM

This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

- `log_throttle_queries_not_using_indexes`

Property	Value
System Variable	<code>log_throttle_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 5.4.5, “The Slow Query Log”](#).

- `log_warnings`

Property	Value
Command-Line Format	<code>--log-warnings[=#]</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>log_warnings</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0

Property	Value
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable was removed in MySQL 8.0.3. Use the `log_error_verbosity` system variable instead.

- `long_query_time`

Property	Value
Command-Line Format	<code>--long-query-time=#</code>
System Variable	<code>long_query_time</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Numeric
Default Value	10
Minimum Value	0

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See [Section 5.4.5, “The Slow Query Log”](#).

- `low_priority_updates`

Property	Value
Command-Line Format	<code>--low-priority-updates</code>
System Variable	<code>low_priority_updates</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	FALSE

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `lower_case_file_system`

Property	Value
System Variable	<code>lower_case_file_system</code>

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case-sensitive, `ON` means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

Property	Value
Command-Line Format	<code>--lower-case-table-names[=#]</code>
System Variable	<code>lower_case_table_names</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see [Section 9.2.2, “Identifier Case Sensitivity”](#).

On Windows the default value is 1. On macOS, the default value is 2.

You should *not* set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` letter case. With `MyISAM`, accessing table names using different letter cases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable in MySQL 8.0 affects the behavior of replication filtering options with regard to case sensitivity. (Bug #51639) See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are based on the setting defined when the server is initialized,

and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

- `mandatory_roles`

Property	Value
Command-Line Format	<code>--mandatory-roles=value</code>
Introduced	8.0.2
System Variable	<code>mandatory_roles</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

Roles the server should treat as mandatory. In effect, these roles are automatically granted to every user, although setting `mandatory_roles` does not actually change any user accounts, and the granted roles are not visible in the `mysql.role_edges` system table.

The variable value is a comma-separated list of role names. Example:

```
SET PERSIST mandatory_roles = '`role1`@`%`,`role2`,`role3`,`role4@localhost`;
```

Setting `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege normally required to set a global system variable.

Role names consist of a user part and host part in `user_name@host_name` format. The host part, if omitted, defaults to `%`. For additional information, see [Section 6.2.5, “Specifying Role Names”](#).

User names and host names, if quoted, must be written in a fashion permitted for quoting within quoted strings.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see [Activating Roles](#)). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled, or only for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles that do not exist when assigned to `mandatory_roles` but are created later may require special treatment to be considered mandatory. For details, see [Defining Mandatory Roles](#).

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 13.7.6.21, “SHOW GRANTS Syntax”](#).

- `max_allowed_packet`

Property	Value
Command-Line Format	<code>--max-allowed-packet=#</code>
System Variable	<code>max_allowed_packet</code>

Property	Value
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.3$)	67108864
Default Value ($\leq 8.0.2$)	4194304
Minimum Value	1024
Maximum Value	1073741824

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 64MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server will not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

Property	Value
Command-Line Format	<code>--max-connect-errors=#</code>
System Variable	<code>max_connect_errors</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it. The default is 100.

- `max_connections`

Property	Value
Command-Line Format	<code>--max-connections=#</code>
System Variable	<code>max_connections</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	151
Minimum Value	1
Maximum Value	100000

The maximum permitted number of simultaneous client connections. By default, this is 151. See [Section B.5.2.6, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

`mysqld` actually permits `max_connections+1` clients to connect. The extra connection is reserved for use by accounts that have the `CONNECTION_ADMIN` or `SUPER` privilege. By granting the `SUPER` privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 13.7.6.29, “SHOW PROCESSLIST Syntax”](#).

Connections refused because the `max_connections` limit is reached increment the `Connection_errors_max_connections` status variable.

- `max_delayed_threads`

Property	Value
Command-Line Format	<code>--max-delayed-threads=#</code>
Deprecated	Yes
System Variable	<code>max_delayed_threads</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value	20
Minimum Value	0
Maximum Value	16384

This system variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [max_digest_length](#)

Property	Value
Command-Line Format	<code>--max-digest-length=#</code>
System Variable	max_digest_length
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	0
Maximum Value	1048576

The maximum number of bytes available for computing normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

Decreasing the [max_digest_length](#) value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates [max_digest_length](#) bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the [performance_schema_max_digest_length](#) system variable as a limit on the maximum length of digests that it stores. Consequently, if [performance_schema_max_digest_length](#) is less than [max_digest_length](#), digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests and Sampling”](#).

- [max_error_count](#)

Property	Value
Command-Line Format	<code>--max-error-count=#</code>
System Variable	max_error_count
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value (\geq 8.0.3)	1024
Default Value (\leq 8.0.2)	64
Minimum Value	0
Maximum Value	65535

The maximum number of error, warning, and information messages to be stored for display by the [SHOW ERRORS](#) and [SHOW WARNINGS](#) statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by [GET DIAGNOSTICS](#).

- [max_execution_time](#)

Property	Value
Command-Line Format	<code>--max-execution-time=#</code>
System Variable	max_execution_time
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	0

The execution timeout for [SELECT](#) statements, in milliseconds. If the value is 0, timeouts are not enabled.

[max_execution_time](#) applies as follows:

- The global [max_execution_time](#) value provides the default for the session value for new connections. The session value applies to [SELECT](#) executions executed within the session that include no [MAX_EXECUTION_TIME\(N\)](#) optimizer hint or for which *N* is 0.
- [max_execution_time](#) applies to read-only [SELECT](#) statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- [max_execution_time](#) is ignored for [SELECT](#) statements in stored programs.
- [max_heap_table_size](#)

Property	Value
Command-Line Format	<code>--max-heap-table-size=#</code>
System Variable	max_heap_table_size
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer

Property	Value
Default Value	16777216
Minimum Value	16384
Maximum Value (64-bit platforms)	1844674407370954752
Maximum Value (32-bit platforms)	4294967295

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

`max_heap_table_size` is not replicated. See [Section 17.4.1.21, “Replication and MEMORY Tables”](#), and [Section 17.4.1.39, “Replication and Variables”](#), for more information.

- `max_insert_delayed_threads`

Property	Value
Deprecated	Yes
System Variable	<code>max_insert_delayed_threads</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `max_join_size`

Property	Value
Command-Line Format	<code>--max-join-size=#</code>
System Variable	<code>max_join_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	18446744073709551615
Minimum Value	1
Maximum Value	18446744073709551615

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows. For more information, see [Using Safe-Updates Mode \(`--safe-updates`\)](#).

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

- `max_length_for_sort_data`

Property	Value
Command-Line Format	<code>--max-length-for-sort-data=#</code>
System Variable	<code>max_length_for_sort_data</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value (>= 8.0.1)	4096
Default Value (8.0.0)	1024
Minimum Value	4
Maximum Value	8388608

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 8.2.1.14, “ORDER BY Optimization”](#).

- `max_points_in_geometry`

Property	Value
Command-Line Format	<code>--max-points-in-geometry=integer</code>
System Variable	<code>max_points_in_geometry</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	65536
Minimum Value	3
Maximum Value	1048576

The maximum value of the `points_per_circle` argument to the `ST_Buffer_Strategy()` function.

- `max_prepared_stmt_count`

Property	Value
Command-Line Format	<code>--max-prepared-stmt-count=#</code>

Property	Value
System Variable	max_prepared_stmt_count
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	16382
Minimum Value	0
Maximum Value	1048576

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- [max_seeks_for_key](#)

Property	Value
Command-Line Format	<code>--max-seeks-for-key=#</code>
System Variable	max_seeks_for_key
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 13.7.6.22, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- [max_sort_length](#)

Property	Value
Command-Line Format	<code>--max-sort-length=#</code>
System Variable	max_sort_length
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	4
Maximum Value	8388608

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see [Section 8.2.1.14, “ORDER BY Optimization”](#)

- `max_sp_recursion_depth`

Property	Value
Command-Line Format	<code>--max-sp-recursion-depth[=#]</code>
System Variable	<code>max_sp_recursion_depth</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Maximum Value	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_tmp_tables`

This system variable was removed in MySQL 8.0.3.

- `max_user_connections`

Property	Value
Command-Line Format	<code>--max-user-connections=#</code>
System Variable	<code>max_user_connections</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

Property	Value
Minimum Value	0
Maximum Value	4294967295

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE USER` or `ALTER USER` statement. See [Section 6.3.6, “Setting Account Resource Limits”](#).

- `max_write_lock_count`

Property	Value
Command-Line Format	<code>--max-write-lock-count=#</code>
System Variable	<code>max_write_lock_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

After this many write locks, permit some pending read lock requests to be processed in between.

- `mecab_rc_file`

Property	Value
Command-Line Format	<code>--mecab-rc-file</code>
System Variable	<code>mecab_rc_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see [Section 12.9.9, “MeCab Full-Text Parser Plugin”](#).

For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the [MeCab Documentation](#) on the [Google Developers](#) site.

- `metadata_locks_cache_size`

Property	Value
Deprecated	Yes (removed in 8.0.13)
System Variable	<code>metadata_locks_cache_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	1
Maximum Value	1048576

This system variable was removed in MySQL 8.0.13.

- `metadata_locks_hash_instances`

Property	Value
Deprecated	Yes (removed in 8.0.13)
System Variable	<code>metadata_locks_hash_instances</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	1
Maximum Value	1024

This system variable was removed in MySQL 8.0.13.

- `min_examined_row_limit`

Property	Value
Command-Line Format	<code>--min-examined-row-limit=#</code>
System Variable	<code>min_examined_row_limit</code>
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Queries that examine fewer than this number of rows are not logged to the slow query log.

- [multi_range_count](#)

Property	Value
Command-Line Format	<code>--multi-range-count=#</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	multi_range_count
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	1
Maximum Value	4294967295

This system variable was removed in MySQL 8.0.3.

- [myisam_data_pointer_size](#)

Property	Value
Command-Line Format	<code>--myisam-data-pointer-size=#</code>
System Variable	myisam_data_pointer_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	2
Maximum Value	7

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.5.2.11, “The table is full”](#).

- `myisam_max_sort_file_size`

Property	Value
Command-Line Format	<code>--myisam-max-sort-file-size=#</code>
System Variable	<code>myisam_max_sort_file_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	9223372036854775807
Default Value (32-bit platforms)	2147483648

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If [MyISAM](#) index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

Property	Value
Command-Line Format	<code>--myisam-mmap-size=#</code>
System Variable	<code>myisam_mmap_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	7
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- `myisam_recover_options`

Property	Value
System Variable	<code>myisam_recover_options</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No

The value of the `--myisam-recover-options` option. See [Section 5.1.6, “Server Command Options”](#).

- `myisam_repair_threads`

Property	Value
Command-Line Format	<code>--myisam-repair-threads=#</code>
System Variable	<code>myisam_repair_threads</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If this value is greater than 1, **MyISAM** table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1.

Note

Multithreaded repair is still *beta-quality* code.

- `myisam_sort_buffer_size`

Property	Value
Command-Line Format	<code>--myisam-sort-buffer-size=#</code>
System Variable	<code>myisam_sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	4096
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295
Maximum Value (Windows, 64-bit platforms)	18446744073709551615
Maximum Value (Windows, 32-bit platforms)	4294967295

The size of the buffer that is allocated when sorting **MyISAM** indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

- `myisam_stats_method`

Property	Value
Command-Line Format	<code>--myisam-stats-method=name</code>
System Variable	<code>myisam_stats_method</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>nulls_unequal</code>
Valid Values	<code>nulls_equal</code> <code>nulls_unequal</code> <code>nulls_ignored</code>

How the server treats `NULL` values when collecting statistics about the distribution of index values for `MyISAM` tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap`

Property	Value
Command-Line Format	<code>--myisam-use-mmap</code>
System Variable	<code>myisam_use_mmap</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Use memory mapping for reading and writing `MyISAM` tables.

- `mysql_native_password_proxy_users`

Property	Value
Command-Line Format	<code>--mysql-native-password-proxy-users={OFF ON}</code>
System Variable	<code>mysql_native_password_proxy_users</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls whether the `mysql_native_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see [Section 6.3.11, “Proxy Users”](#).

- `named_pipe`

Property	Value
System Variable	<code>named_pipe</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	OFF

(Windows only.) Indicates whether the server supports connections over named pipes.

- `net_buffer_length`

Property	Value
Command-Line Format	<code>--net-buffer-length=#</code>
System Variable	<code>net_buffer_length</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	16384
Minimum Value	1024
Maximum Value	1048576

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- `net_read_timeout`

Property	Value
Command-Line Format	<code>--net-read-timeout=#</code>
System Variable	<code>net_read_timeout</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

Property	Value
Command-Line Format	<code>--net-retry-count=#</code>
System Variable	<code>net_retry_count</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

Property	Value
Command-Line Format	<code>--net-write-timeout=#</code>
System Variable	<code>net_write_timeout</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1

The number of seconds to wait for a block to be written to a connection before aborting the write. See also [net_read_timeout](#).

- [new](#)

Property	Value
Command-Line Format	--new
System Variable	new
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Disabled by	skip-new
Type	Boolean
Default Value	FALSE

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always [OFF](#).

- [ngram_token_size](#)

Property	Value
Command-Line Format	--ngram-token-size
System Variable	ngram_token_size
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	10

Defines the n-gram token size for the n-gram full-text parser. The [ngram_token_size](#) option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see [Section 12.9.8, “ngram Full-Text Parser”](#).

- [offline_mode](#)

Property	Value
Command-Line Format	--offline-mode=val
System Variable	offline_mode
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	OFF

Whether the server is in “offline mode”, which has these characteristics:

- Connected client users who do not have the `CONNECTION_ADMIN` or `SUPER` privilege are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.
- Connected client users who have the `CONNECTION_ADMIN` or `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.
- Replication slave threads are permitted to keep applying data to the server.

Only users who have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can control offline mode. To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. In offline mode, clients that are refused access receive an `ER_SERVER_OFFLINE_MODE` error.

- `old`

Property	Value
Command-Line Format	<code>--old</code>
System Variable	<code>old</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See [Section 8.9.4, “Index Hints”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- `old_alter_table`

Property	Value
Command-Line Format	<code>--old-alter-table</code>
System Variable	<code>old_alter_table</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.8, “ALTER TABLE Syntax”](#).

`ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted. In earlier releases, `ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` deletes data stored in the partition and drops the partition.

- `old_passwords`

Property	Value
Deprecated	Yes (removed in 8.0.11)
System Variable	<code>old_passwords</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	0
Valid Values	0 2

This system variable was removed in MySQL 8.0.11.

- `open_files_limit`

Property	Value
Command-Line Format	<code>--open-files-limit=#</code>
System Variable	<code>open_files_limit</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	5000, with possible adjustment
Minimum Value	0
Maximum Value	platform dependent

The number of files that the operating system permits `mysqld` to open. The value of this variable at runtime is the real value permitted by the system and might be different from the value you specify at server startup. The value is 0 on systems where MySQL cannot change the number of open files.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

```

1) 10 + max_connections + (table_open_cache * 2)
2) max_connections * 5
3) operating system limit if positive
4) if operating system limit is Infinity:
   open_files_limit value specified at startup, 5000 if none

```

The server attempts to obtain the number of file descriptors using the maximum of those three values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system will permit.

- `optimizer_prune_level`

Property	Value
Command-Line Format	<code>--optimizer-prune-level[=#]</code>
System Variable	<code>optimizer_prune_level</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

Property	Value
Command-Line Format	<code>--optimizer-search-depth[=#]</code>
System Variable	<code>optimizer_search_depth</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	62
Minimum Value	0
Maximum Value	62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

Property	Value
Command-Line Format	<code>--optimizer-switch=value</code>

Property	Value
System Variable	optimizer_switch
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Set
Valid Values (>= 8.0.13)	batched_key_access ={on off} block_nested_loop ={on off} condition_fanout_filter ={on off} derived_merge ={on off} duplicateweedout ={on off} engine_condition_pushdown ={on off} firstmatch ={on off} index_condition_pushdown ={on off} index_merge ={on off} index_merge_intersection ={on off} index_merge_sort_union ={on off} index_merge_union ={on off} loosescan ={on off} materialization ={on off} mrr ={on off} mrr_cost_based ={on off} semijoin ={on off} skip_scan ={on off} subquery_materialization_cost_based ={on off} use_index_extensions ={on off} use_invisible_indexes ={on off}
Valid Values (>= 8.0.3, <= 8.0.12)	batched_key_access ={on off} block_nested_loop ={on off} condition_fanout_filter ={on off} derived_merge ={on off}

Property	Value
	duplicateweedout={on off} engine_condition_pushdown={on off} firstmatch={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off} loosescan={on off} materialization={on off} mrr={on off} mrr_cost_based={on off} semijoin={on off} subquery_materialization_cost_based={on off} use_index_extensions={on off} use_invisible_indexes={on off}
Valid Values (<= 8.0.2)	batched_key_access={on off} block_nested_loop={on off} condition_fanout_filter={on off} derived_merge={on off} duplicateweedout={on off} engine_condition_pushdown={on off} firstmatch={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off}

Property	Value
	<code>loosescan={on off}</code> <code>materialization={on off}</code> <code>mrr={on off}</code> <code>mrr_cost_based={on off}</code> <code>semijoin={on off}</code> <code>subquery_materialization_cost_based={on off}</code> <code>use_index_extensions={on off}</code>

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,duplicateweedout=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,
                    condition_fanout_filter=on,derived_merge=on,
                    use_invisible_indexes=off,skip_scan=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 8.9.3, “Switchable Optimizations”](#).

- `optimizer_trace`

Property	Value
System Variable	<code>optimizer_trace</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable controls optimizer tracing. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_features`

Property	Value
System Variable	optimizer_trace_features
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable enables or disables selected optimizer tracing features. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_limit`

Property	Value
System Variable	optimizer_trace_limit
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1

The maximum number of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_max_mem_size`

Property	Value
System Variable	optimizer_trace_max_mem_size
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value (>= 8.0.4)	1048576
Default Value (<= 8.0.3)	16384

The maximum cumulative size of stored optimizer traces. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_offset`

Property	Value
System Variable	optimizer_trace_offset
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value	-1

The offset of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- [performance_schema_xxx](#)

Performance Schema system variables are listed in [Section 25.14, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- [parser_max_mem_size](#)

Property	Value
Command-Line Format	<code>--parser-max-mem-size=N</code>
System Variable	parser_max_mem_size
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	10000000
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

- [password_history](#)

Property	Value
Command-Line Format	<code>--password-history=#</code>
Introduced	8.0.3
System Variable	password_history
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

This variable defines the global policy for controlling reuse of previous passwords based on required minimum number of password changes. For an account password used previously, this variable indicates the number of subsequent account password changes that must occur before the password

can be reused. If the value is 0 (the default), there is no reuse restriction based on number of password changes.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD HISTORY DEFAULT` option.

The global number-of-changes password reuse policy can be overridden as desired for individual accounts using the `PASSWORD HISTORY` option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.3.8, “Password Management”](#).

- `password_require_current`

Property	Value
Command-Line Format	<code>--password-require-current[={OFF ON}]</code>
Introduced	8.0.13
System Variable	<code>password_require_current</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable defines the global policy for controlling whether attempts to change an account password must specify the current password to be replaced.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REQUIRE CURRENT DEFAULT` option.

The global verification-required policy can be overridden as desired for individual accounts using the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.3.8, “Password Management”](#).

- `password_reuse_interval`

Property	Value
Command-Line Format	<code>--password-reuse-interval=#</code>
Introduced	8.0.3
System Variable	<code>password_reuse_interval</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

This variable defines the global policy for controlling reuse of previous passwords based on time elapsed. For an account password used previously, this variable indicates the number of days that must

pass before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on time elapsed.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REUSE INTERVAL DEFAULT` option.

The global time-elapsed password reuse policy can be overridden as desired for individual accounts using the `PASSWORD REUSE INTERVAL` option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.3.8, “Password Management”](#).

- `persisted_globals_load`

Property	Value
Command-Line Format	<code>--persisted-globals-load[=ON OFF]</code>
System Variable	<code>persisted_globals_load</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether to load persisted configuration settings from the `mysqld-auto.cnf` file in the data directory. The server normally processes this file at startup after all other option files (see [Section 4.2.7, “Using Option Files”](#)). Disabling `persisted_globals_load` causes the server startup sequence to skip `mysqld-auto.cnf`.

To modify the contents of `mysqld-auto.cnf`, use the `SET PERSIST`, `SET PERSIST_ONLY`, and `RESET PERSIST` statements. See [Section 5.1.8.3, “Persisted System Variables”](#).

- `pid_file`

Property	Value
Command-Line Format	<code>--pid-file=file_name</code>
System Variable	<code>pid_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The path name of the process ID file. This variable can be set with the `--pid-file` option. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify the `--pid-file` option, you must specify a value. If you do not specify the `--pid-file` option, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See [Section 5.4.2, “The Error Log”](#).

-
- `plugin_dir`

Property	Value
Command-Line Format	<code>--plugin-dir=dir_name</code>
System Variable	<code>plugin_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	<code>BASEDIR/lib/plugin</code>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- `port`

Property	Value
Command-Line Format	<code>--port=#</code>
System Variable	<code>port</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>3306</code>
Minimum Value	<code>0</code>
Maximum Value	<code>65535</code>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

Property	Value
Command-Line Format	<code>--preload-buffer-size=#</code>
System Variable	<code>preload_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>32768</code>
Minimum Value	<code>1024</code>
Maximum Value	<code>1073741824</code>

The size of the buffer that is allocated when preloading indexes.

- `profiling`

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 13.7.6.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- `profiling_history_size`

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 13.7.6.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- `protocol_version`

Property	Value
System Variable	<code>protocol_version</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

Property	Value
System Variable	<code>proxy_user</code>
Scope	Session
Dynamic	No
SET_VAR Hint Applies	No
Type	String

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 6.3.11, “Proxy Users”](#).

- `pseudo_slave_mode`

Property	Value
System Variable	<code>pseudo_slave_mode</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

This variable is for internal server use.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

In MySQL 8.0.14 and later, `pseudo_slave_mode` has the following effects on the handling of a statement that sets one or more unsupported or unknown SQL modes:

- If true, the server ignores the unsupported mode and raises a warning.
- If false, the server rejects the statement with `ER_UNSUPPORTED_SQL_MODE`.

`mysqlbinlog` sets this variable to true prior to executing any other SQL.

- `pseudo_thread_id`

Property	Value
System Variable	<code>pseudo_thread_id</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

This variable is for internal server use.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `query_alloc_block_size`

Property	Value
Command-Line Format	<code>--query-alloc-block-size=#</code>
System Variable	<code>query_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	1024
Maximum Value	4294967295
Block Size	1024

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- `query_cache_limit`

Property	Value
Command-Line Format	<code>--query-cache-limit=#</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>query_cache_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1048576
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable was removed in MySQL 8.0.3.

- `query_cache_min_res_unit`

Property	Value
Command-Line Format	<code>--query-cache-min-res-unit=#</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>query_cache_min_res_unit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	4096
Minimum Value	512
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable was removed in MySQL 8.0.3.

- `query_cache_size`

Property	Value
Command-Line Format	<code>--query-cache-size=#</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>query_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Property	Value
Default Value (64-bit platforms, >= 8.0.1)	0
Default Value (64-bit platforms, 8.0.0)	1048576
Default Value (32-bit platforms, >= 8.0.1)	0
Default Value (32-bit platforms, 8.0.0)	1048576
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable was removed in MySQL 8.0.3.

- `query_cache_type`

Property	Value
Command-Line Format	<code>--query-cache-type=#</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>query_cache_type</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	0
Valid Values	0 1 2

This system variable was removed in MySQL 8.0.3.

- `query_cache_wlock_invalidate`

Property	Value
Command-Line Format	<code>--query-cache-wlock-invalidate</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>query_cache_wlock_invalidate</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	FALSE

This system variable was removed in MySQL 8.0.3.

- `query_prealloc_size`

Property	Value
Command-Line Format	<code>--query-prealloc-size=#</code>
System Variable	<code>query_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	8192
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Block Size	1024

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

Property	Value
System Variable	<code>rand_seed1</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

Property	Value
Command-Line Format	<code>--range-alloc-block-size=#</code>
System Variable	<code>range_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	4096
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520
Maximum Value	4294967295
Block Size	1024

The size of blocks that are allocated when doing range optimization.

- `range_optimizer_max_mem_size`

Property	Value
Command-Line Format	<code>--range-optimizer-max-mem-size=N</code>
System Variable	<code>range_optimizer_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	0
Maximum Value	18446744073709551615

The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see [Limiting Memory Use for Range Optimization](#).

- `rbr_exec_mode`

Property	Value
System Variable	<code>rbr_exec_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>STRICT</code>
Valid Values	<code>IDEMPOTENT</code> <code>STRICT</code>

For internal use by `mysqlbinlog`. This variable switches the server between `IDEMPOTENT` mode and `STRICT` mode. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors in `BINLOG` statements generated by `mysqlbinlog`. This mode is useful when replaying a row-based

binary log on a server that causes conflicts with existing data. `mysqlbinlog` sets this mode when you specify the `--idempotent` option by writing the following to the output:

```
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `read_buffer_size`

Property	Value
Command-Line Format	<code>--read-buffer-size=#</code>
System Variable	<code>read_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	131072
Minimum Value	8200
Maximum Value	2147479552

Each thread that does a sequential scan for a `MyISAM` table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for `ORDER BY`.
- For bulk insert into partitions.
- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

For more information about memory use during different operations, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

- `read_only`

Property	Value
Command-Line Format	<code>--read-only</code>
System Variable	<code>read_only</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Property	Value
Default Value	OFF

When the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` or `SUPER` privilege. This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`.
- Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by slave threads, if the server is a replication slave. In replication setups, it can be useful to enable `read_only` on slave servers to ensure that slaves accept updates only from the master server and not from clients.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replication slaves can be performed with `mysqlcheck --all-databases --analyze`.
- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see [Section 5.4.1](#), “Selecting General Query and Slow Query Log Output Destinations”.
- Updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients hold explicit table locks or have pending transactions, until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

Property	Value
Command-Line Format	<code>--read-rnd-buffer-size=#</code>
System Variable	<code>read_rnd_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	1
Maximum Value	2147483647

This variable is used for reads from [MyISAM](#) tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a [MyISAM](#) table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 8.2.1.14, “ORDER BY Optimization”](#). Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see [Section 8.12.3.1, “How MySQL Uses Memory”](#). For information about Multi-Range Read optimization, see [Section 8.2.1.10, “Multi-Range Read Optimization”](#).

- `regexp_stack_limit`

Property	Value
Command-Line Format	<code>--regexp-stack-limit=#</code>
Introduced	8.0.4
System Variable	<code>regexp_stack_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8000000
Minimum Value	0
Maximum Value	2147483647

The maximum available memory in bytes for the internal stack used for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 12.5.2, “Regular Expressions”](#)).

- `regexp_time_limit`

Property	Value
Command-Line Format	<code>--regexp-time-limit=#</code>

Property	Value
Introduced	8.0.4
System Variable	<code>regexp_time_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	2147483647

The time limit for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 12.5.2, “Regular Expressions”](#)). This limit is expressed as the maximum permitted number of steps performed by the match engine, and thus affects execution time only indirectly. Typically, it is on the order of milliseconds.

- `require_secure_transport`

Property	Value
Command-Line Format	<code>--require-secure-transport[={OFF ON}]</code>
System Variable	<code>require_secure_transport</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with `REQUIRE SSL`, enabling `require_secure_transport` does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable `require_secure_transport` at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an `ER_NO_SECURE_TRANSPORTS_CONFIGURED` error.

- `resultset_metadata`

Property	Value
Introduced	8.0.3

Property	Value
System Variable	<code>resultset_metadata</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>FULL</code>
Valid Values	<code>FULL</code> <code>NONE</code>

For connections for which metadata transfer is optional, the client sets the `resultset_metadata` system variable to control whether the server returns result set metadata. Permitted values are `FULL` (return all metadata; this is the default) and `NONE` (return no metadata).

For connections that are not metadata-optional, setting `resultset_metadata` to `NONE` produces an error.

For details about managing result set metadata transfer, see [Section 27.7.23, “C API Optional Result Set Metadata”](#).

- `schema_definition_cache`

Property	Value
Command-Line Format	<code>--schema-definition-cache=N</code>
System Variable	<code>schema_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>256</code>
Minimum Value	<code>256</code>
Maximum Value	<code>524288</code>

Defines a limit for the number of schema definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused schema definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `schema_definition_cache`.

A setting of `0` means that schema definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- `secure_auth`

Property	Value
Command-Line Format	<code>--secure-auth</code>
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>secure_auth</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON
Valid Values	ON

This system variable was removed in MySQL 8.0.3.

- `secure_file_priv`

Property	Value
Command-Line Format	<code>--secure-file-priv=dir_name</code>
System Variable	<code>secure_file_priv</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	platform specific
Valid Values	empty string dirname NULL

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server will not create it.
- If set to `NULL`, the server disables import and export operations.

The default value is platform specific and depends on the value of the `INSTALL_LAYOUT CMake` option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR CMake` option.

<code>INSTALL_LAYOUT</code> Value	Default <code>secure_file_priv</code> Value
STANDALONE, WIN	empty
DEB, RPM, SLES, SVR4	<code>/var/lib/mysql-files</code>
Otherwise	<code>mysql-files</code> under the <code>CMAKE_INSTALL_PREFIX</code> value

The server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `server_id`

Property	Value
Command-Line Format	<code>--server-id=#</code>
System Variable	<code>server_id</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value ($\geq 8.0.3$)	1
Default Value ($\leq 8.0.2$)	0
Minimum Value	0
Maximum Value	4294967295

Specifies the server ID. This variable is set by the `--server-id` option. The `server_id` system variable is set to 1 by default. The server can be started with this default ID, but when binary logging is enabled, an informational message is issued if you did not specify a server ID explicitly using the `--server-id` option.

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. For additional information, see [Section 17.1.6.2, “Replication Master Options and Variables”](#), and [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

For more information, see [Section 17.1.2.2, “Setting the Replication Slave Configuration”](#).

- `session_track_gtid`

Property	Value
Command-Line Format	<code>--session-track-gtid=[value]</code>
System Variable	<code>session_track_gtid</code>

Property	Value
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF OWN_GTID ALL_GTIDS

Controls whether the server tracks GTIDs within the current session and returns them to the client. Depending on the variable value, at the end of executing each transaction, the server GTIDs are captured by the tracker and returned to the client. These `session_track_gtids` values are permitted:

- **OFF**: The tracker collects no GTIDs. This is the default.
- **OWN_GTID**: The tracker collects GTIDs generated by successfully committed read/write transactions.
- **ALL_GTIDS**: The tracker collects all GTIDs in the `gtid_executed` system variable at the time the current transaction commits, regardless of whether the transaction is read/write or read only.

`session_track_gtids` cannot be set within transactional context.

For more information about session state tracking, see [Section 5.1.13, “Server Tracking of Client Session State Changes”](#).

- `session_track_schema`

Property	Value
Command-Line Format	<code>--session-track-schema=#</code>
System Variable	<code>session_track_schema</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

For more information about session state tracking, see [Section 5.1.13, “Server Tracking of Client Session State Changes”](#).

- `session_track_state_change`

Property	Value
Command-Line Format	<code>--session-track-state-change=#</code>
System Variable	<code>session_track_state_change</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:

- The default schema (database).
- Session-specific values for system variables.
- User-defined variables.
- Temporary tables.
- Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

Note

Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name is listed in the value of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see [Section 5.1.13, “Server Tracking of Client Session State Changes”](#).

- `session_track_system_variables`

Property	Value
Command-Line Format	<code>--session-track-system-variables=#</code>
System Variable	<code>session_track_system_variables</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	String
Default Value	<code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names.

To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see [Section 5.1.13, “Server Tracking of Client Session State Changes”](#).

- `session_track_transaction_info`

Property	Value
Command-Line Format	<code>--session-track-transaction-info=value</code>
System Variable	<code>session_track_transaction_info</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>STATE</code> <code>CHARACTERISTICS</code>

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These `session_track_transaction_info` values are permitted:

- `OFF`: Disable transaction state tracking. This is the default.
- `STATE`: Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.

- **CHARACTERISTICS:** Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

```

READ ONLY
READ WRITE
ISOLATION LEVEL
WITH CONSISTENT SNAPSHOT

```

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the `transaction_read_only` and `transaction_isolation` system variables to correctly determine the session defaults. (To track these variables, list them in the value of the `session_track_system_variables` system variable.)

For more information about session state tracking, see [Section 5.1.13, “Server Tracking of Client Session State Changes”](#).

- `sha256_password_auto_generate_rsa_keys`

Property	Value
Command-Line Format	<code>--sha256-password-auto-generate-rsa-keys[={OFF ON}]</code>
System Variable	<code>sha256_password_auto_generate_rsa_keys</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable is available if the server was compiled using OpenSSL (see [Section 6.4.4, “OpenSSL Versus wolfSSL”](#)). The server uses it to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#).

For more information about RSA file autogeneration, including file names and characteristics, see [Section 6.4.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- `sha256_password_private_key_path`

Property	Value
Command-Line Format	<code>--sha256-password-private-key-path=file_name</code>
System Variable	<code>sha256_password_private_key_path</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>private_key.pem</code>

This variable is available if MySQL was compiled using OpenSSL (see [Section 6.4.4, “OpenSSL Versus wolfSSL”](#)). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

Important

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#).

- `sha256_password_proxy_users`

Property	Value
Command-Line Format	<code>--sha256-password-proxy-users=[{OFF ON}]</code>
System Variable	<code>sha256_password_proxy_users</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see [Section 6.3.11, “Proxy Users”](#).

- `sha256_password_public_key_path`

Property	Value
Command-Line Format	<code>--sha256-password-public-key-path=file_name</code>
System Variable	<code>sha256_password_public_key_path</code>
Scope	Global
Dynamic	No

Property	Value
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>public_key.pem</code>

This variable is available if MySQL was compiled using OpenSSL (see [Section 6.4.4, “OpenSSL Versus wolfSSL”](#)). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including information about how clients specify the RSA public key, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#).

- `shared_memory`

Property	Value
Command-Line Format	<code>--shared-memory[={0,1}]</code>
System Variable	<code>shared_memory</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	<code>FALSE</code>

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

Property	Value
Command-Line Format	<code>--shared-memory-base-name=name</code>
System Variable	<code>shared_memory_base_name</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	<code>MYSQL</code>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `show_compatibility_56`

Property	Value
Command-Line Format	<code>--show-compatibility-56[={OFF ON}]</code>
Deprecated	Yes (removed in 8.0.1)
System Variable	<code>show_compatibility_56</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable was used in the transition period during which system and status variable information in `INFORMATION_SCHEMA` tables was moved to Performance Schema tables. That transition period ended in MySQL 8.0.1, at which time this variable was removed. For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Migrating to Performance Schema System and Status Variable Tables](#).

- `show_create_table_verbosity`

Property	Value
Command-Line Format	<code>--show-create-table-verbosity</code>
Introduced	8.0.11
System Variable	<code>show_create_table_verbosity</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

`SHOW CREATE TABLE` normally does not show the `ROW_FORMAT` table option if the row format is the default format. Enabling this variable causes `SHOW CREATE TABLE` to display `ROW_FORMAT` regardless of whether it is the default format.

- `show_old_temporals`

Property	Value
Command-Line Format	<code>--show-old-temporals={OFF ON}</code>
Deprecated	Yes
System Variable	<code>show_old_temporals</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether `SHOW CREATE TABLE` output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, `SHOW CREATE TABLE` output looks like this:

```
CREATE TABLE `mytbl` (
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
  `t` time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=utf8mb4
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable is deprecated and will be removed in a future MySQL release.

- `skip_external_locking`

Property	Value
Command-Line Format	<code>--skip-external-locking</code>
System Variable	<code>skip_external_locking</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.11.5, “External Locking”](#).

- `skip_name_resolve`

Property	Value
Command-Line Format	<code>--skip-name-resolve</code>
System Variable	<code>skip_name_resolve</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable is set from the value of the `--skip-name-resolve` option. If it is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers; in this case,

all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).

- `skip_networking`

Property	Value
Command-Line Format	<code>--skip-networking</code>
System Variable	<code>skip_networking</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to `ON` with the `--skip-networking` option.

- `skip_show_database`

Property	Value
Command-Line Format	<code>--skip-show-database</code>
System Variable	<code>skip_show_database</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege. (Any global privilege is considered a privilege for all databases.)

- `slow_launch_time`

Property	Value
Command-Line Format	<code>--slow-launch-time=#</code>
System Variable	<code>slow_launch_time</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

Property	Value
Command-Line Format	<code>--slow-query-log</code>
System Variable	<code>slow_query_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 5.4.5, “The Slow Query Log”](#).

- `slow_query_log_file`

Property	Value
Command-Line Format	<code>--slow-query-log-file=file_name</code>
System Variable	<code>slow_query_log_file</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>host_name-slow.log</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

Property	Value
Command-Line Format	<code>--socket={file_name pipe_name}</code>
System Variable	<code>socket</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value (Other)	<code>/tmp/mysql.sock</code>
Default Value (Windows)	MySQL

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- `sort_buffer_size`

Property	Value
Command-Line Format	<code>--sort-buffer-size=#</code>
System Variable	<code>sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	32768
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295
Maximum Value (Windows)	4294967295

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see [Section 8.2.1.14, “ORDER BY Optimization”](#)

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

- `sql_auto_is_null`

Property	Value
System Variable	<code>sql_auto_is_null</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	OFF

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

The default value of `sql_auto_is_null` is `OFF`.

- `sql_big_selects`

Property	Value
System Variable	<code>sql_big_selects</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	ON

If set to `OFF`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `ON`, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to `OFF`.

- `sql_buffer_result`

Property	Value
System Variable	<code>sql_buffer_result</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	OFF

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is `OFF`.

- `sql_log_off`

Property	Value
System Variable	<code>sql_log_off</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> (enable logging) <code>ON</code> (disable logging)

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is `OFF` (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

- `sql_mode`

Property	Value
Command-Line Format	<code>--sql-mode=name</code>
System Variable	<code>sql_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Set
Default Value (>= 8.0.11)	<code>ONLY_FULL_GROUP_BY</code> <code>STRICT_TRANS_TABLES</code> <code>NO_ZERO_IN_DATE</code> <code>NO_ZERO_DATE</code> <code>ERROR_FOR_DIVISION_BY_ZERO</code> <code>NO_ENGINE_SUBSTITUTION</code>
Default Value (<= 8.0.4)	<code>ONLY_FULL_GROUP_BY</code> <code>STRICT_TRANS_TABLES</code> <code>NO_ZERO_IN_DATE</code> <code>NO_ZERO_DATE</code> <code>ERROR_FOR_DIVISION_BY_ZERO</code> <code>NO_AUTO_CREATE_USER</code> <code>NO_ENGINE_SUBSTITUTION</code>
Valid Values (>= 8.0.11)	<code>ALLOW_INVALID_DATES</code> <code>ANSI_QUOTES</code>

Property	Value
	ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL
Valid Values (>= 8.0.1, <= 8.0.4)	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS

Property	Value
	NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL
Valid Values (8.0.0)	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE

Property	Value
	<code>ONLY_FULL_GROUP_BY</code>
	<code>PAD_CHAR_TO_FULL_LENGTH</code>
	<code>PIPES_AS_CONCAT</code>
	<code>REAL_AS_FLOAT</code>
	<code>STRICT_ALL_TABLES</code>
	<code>STRICT_TRANS_TABLES</code>

The current server SQL mode, which can be set dynamically. For details, see [Section 5.1.10, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

Property	Value
System Variable	<code>sql_notes</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If enabled (the default), warnings of `Note` level increment `warning_count` and the server records them. If disabled, `Note` warnings do not increment `warning_count` and the server does not record them. `mysqldump` includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

Property	Value
System Variable	<code>sql_quote_show_create</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.7.6.10, “SHOW CREATE TABLE Syntax”](#), and [Section 13.7.6.6, “SHOW CREATE DATABASE Syntax”](#).

- `sql_require_primary_key`

Property	Value
Command-Line Format	<code>--sql-require-primary-key[={OFF ON}]</code>
Introduced	8.0.13
System Variable	<code>sql_require_primary_key</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	OFF

Whether statements that create new tables or alter the structure of existing tables enforce the requirement that tables have a primary key.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Enabling this variable helps avoid performance problems in row-based replication that can occur when tables have no primary key. Suppose that a table has no primary key and an update or delete modifies multiple rows. On the master server, this operation can be performed using a single table scan but, when replicated using row-based replication, results in a table scan for each row to be modified on the slave. With a primary key, these table scans do not occur.

`sql_require_primary_key` applies to both base tables and `TEMPORARY` tables, and changes to its value are replicated to slave servers.

When enabled, `sql_require_primary_key` has these effects:

- Attempts to create a new table with no primary key fail with an error. This includes `CREATE TABLE ... LIKE`. It also includes `CREATE TABLE ... SELECT`, unless the `CREATE TABLE` part includes a primary key definition.
- Attempts to drop the primary key from an existing table fail with an error, with the exception that dropping the primary key and adding a primary key in the same `ALTER TABLE` statement is permitted.

Dropping the primary key fails even if the table also contains a `UNIQUE NOT NULL` index.

- Attempts to import a table with no primary key fail with an error.

- `sql_safe_updates`

Property	Value
System Variable	<code>sql_safe_updates</code>
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	OFF

If this variable is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. This makes it possible to catch `UPDATE` and `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is `OFF`.

For the `mysql` client, `sql_safe_updates` can be enabled by using the `--safe-updates` option. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

- `sql_select_limit`

Property	Value
System Variable	<code>sql_select_limit</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer

The maximum number of rows to return from `SELECT` statements. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $(2^{32})-1$ or $(2^{64})-1$. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

Property	Value
System Variable	<code>sql_warnings</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is `OFF`. Set the value to `ON` to produce an information string.

- `ssl_ca`

Property	Value
Command-Line Format	<code>--ssl-ca=file_name</code>
System Variable	<code>ssl_ca</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The path to a file with a list of trusted SSL Certificate Authorities.

- `ssl_capath`

Property	Value
Command-Line Format	<code>--ssl-capath=dir_name</code>
System Variable	<code>ssl_capath</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `ssl_cert`

Property	Value
Command-Line Format	<code>--ssl-cert=file_name</code>
System Variable	<code>ssl_cert</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The name of the SSL certificate file to use for establishing a secure connection.

- `ssl_cipher`

Property	Value
Command-Line Format	<code>--ssl-cipher=name</code>
System Variable	<code>ssl_cipher</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The list of permitted ciphers for SSL encryption.

- `ssl_crl`

Property	Value
Command-Line Format	<code>--ssl-crl=file_name</code>
System Variable	<code>ssl_crl</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The path to a file containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not wolfSSL). See [Section 6.4.4, “OpenSSL Versus wolfSSL”](#).

- `ssl_crlpath`

Property	Value
Command-Line Format	<code>--ssl-crlpath=dir_name</code>
System Variable	<code>ssl_crlpath</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path to a directory that contains files containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not wolfSSL). See [Section 6.4.4, “OpenSSL Versus wolfSSL”](#).

- `ssl_fips_mode`

Property	Value
Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Introduced	8.0.11
System Variable	<code>ssl_fips_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> (or 0) <code>ON</code> (or 1) <code>STRICT</code> (or 2)

Controls whether to enable FIPS mode on the server side. The `ssl_fips_mode` system variable differs from other `--ssl-xxx` options in that it is not used to control whether the server permits encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.6, “FIPS Support”](#).

These `ssl_fips_mode` values are permitted:

- `OFF` (or 0): Disable FIPS mode.
- `ON` (or 1): Enable FIPS mode.
- `STRICT` (or 2): Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` is `OFF`. In this case, setting `ssl_fips_mode` to `ON` or `STRICT` at startup causes the server to produce an error message and exit.

- `ssl_key`

Property	Value
Command-Line Format	<code>--ssl-key=file_name</code>
System Variable	<code>ssl_key</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

The name of the SSL key file to use for establishing a secure connection.

- `stored_program_cache`

Property	Value
Command-Line Format	<code>--stored-program-cache=#</code>
System Variable	<code>stored_program_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	16
Maximum Value	524288

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

The stored procedure and stored function caches exist in parallel with the stored program definition cache partition of the [dictionary object cache](#). The stored procedure and stored function caches are per connection, while the stored program definition cache is shared. The existence of objects in the stored procedure and stored function caches have no dependence on the existence of objects in the stored program definition cache, and vice versa. For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- `stored_program_definition_cache`

Property	Value
Command-Line Format	<code>--stored-program-definition-cache=N</code>
System Variable	<code>stored_program_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of stored program definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused stored program definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `stored_program_definition_cache`.

A setting of 0 means that stored program definition objects are only kept in the dictionary object cache while they are in use.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

For related information, see [Section 14.4, “Dictionary Object Cache”](#).

- `super_read_only`

Property	Value
Command-Line Format	<code>--super-read-only[={OFF ON}]</code>
System Variable	<code>super_read_only</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If the `read_only` system variable is enabled, the server permits client updates only from users who have the `SUPER` privilege. If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Changes to `super_read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

- `syseventlog.facility`

Property	Value
Command-Line Format	<code>--syseventlog.facility=value</code>
Introduced	8.0.13
System Variable	<code>syseventlog.facility</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>daemon</code>

The facility for error log output written to `syslog` (what type of program is sending the message). This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.3, “Error Logging to the System Log”](#).

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- `syseventlog.include_pid`

Property	Value
Command-Line Format	<code>--syseventlog.include-pid[={0 1}]</code>
Introduced	8.0.13
System Variable	<code>syseventlog.include_pid</code>
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether to include the server process ID in each line of error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.3, “Error Logging to the System Log”](#).

This variable does not exist on Windows.

- `syseventlog.tag`

Property	Value
Command-Line Format	<code>--syseventlog.tag=tag</code>
Introduced	8.0.13
System Variable	<code>syseventlog.tag</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The tag to be added to the server identifier in error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.3, “Error Logging to the System Log”](#).

By default, the server identifier is `mysqld` with no tag. If a tag value of `tag` is specified, it is appended to the server identifier with a leading hyphen, resulting in an identifier of `mysqld-tag`.

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- `system_time_zone`

Property	Value
System Variable	<code>system_time_zone</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 5.1.12, “MySQL Server Time Zone Support”](#).

- `table_definition_cache`

Property	Value
System Variable	<code>table_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	400
Maximum Value	524288

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
MIN(400 + table_open_cache / 2, 2000)
```

For `InnoDB`, `table_definition_cache` acts as a soft limit for the number of open table instances in the `InnoDB` data dictionary cache. If the number of open table instances exceeds the `table_definition_cache` setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by `table_definition_cache`, because parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, `table_definition_cache` defines a soft limit for the number of `InnoDB` file-per-table tablespaces that can be open at one time, which is also controlled by `innodb_open_files`. If both `table_definition_cache` and `innodb_open_files` are set, the highest setting is used. If neither variable is set, `table_definition_cache`, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by `table_definition_cache` or `innodb_open_files`, the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

The table definition cache exists in parallel with the table definition cache partition of the `dictionary object cache`. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence objects in the other. For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- `table_open_cache`

Property	Value
System Variable	table_open_cache
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (>= 8.0.4)	4000
Default Value (<= 8.0.3)	2000
Minimum Value	1
Maximum Value	524288

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See [Section 5.1.9, “Server Status Variables”](#). If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

- [table_open_cache_instances](#)

Property	Value
System Variable	table_open_cache_instances
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	64

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache / table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- [temptable_max_ram](#)

Property	Value
Command-Line Format	<code>--temptable-max-ram=#</code>
Introduced	8.0.2
System Variable	temptable_max_ram

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	2097152
Maximum Value	2 ⁶⁴ -1

Defines the maximum amount of memory that can be occupied by the [TempTable](#) storage engine before it starts storing data on disk. The default value is 1073741824 bytes (1GiB). For more information, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- [thread_cache_size](#)

Property	Value
Command-Line Format	<code>--thread-cache-size=#</code>
System Variable	thread_cache_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	0
Maximum Value	16384

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than [thread_cache_size](#) threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set [thread_cache_size](#) high enough so that most new connections use cached threads. By examining the difference between the [Connections](#) and [Threads_created](#) status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.9, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

- [thread_handling](#)

Property	Value
Command-Line Format	<code>--thread-handling=name</code>
System Variable	thread_handling

Property	Value
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>one-thread-per-connection</code>
Valid Values	<code>no-threads</code> <code>one-thread-per-connection</code> <code>loaded-dynamically</code>

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection) and `one-thread-per-connection` (the server uses one thread to handle each client connection). `no-threads` is useful for debugging under Linux; see [Section 28.5, “Debugging and Porting MySQL”](#).

- `thread_pool_algorithm`

Property	Value
Command-Line Format	<code>--thread-pool-algorithm=#</code>
Introduced	8.0.11
System Variable	<code>thread_pool_algorithm</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_high_priority_connection`

Property	Value
Command-Line Format	<code>--thread-pool-high-priority-connection=#</code>

Property	Value
Introduced	8.0.11
System Variable	thread_pool_high_priority_connection
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- [thread_pool_max_unused_threads](#)

Property	Value
Command-Line Format	<code>--thread-pool-max-unused-threads=#</code>
Introduced	8.0.11
System Variable	thread_pool_max_unused_threads
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4096

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*−1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_prio_kickup_timer`

Property	Value
Command-Line Format	<code>--thread-pool-prio-kickup-timer=#</code>
Introduced	8.0.11
System Variable	<code>thread_pool_prio_kickup_timer</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967294

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to $2^{32} - 2$.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_size`

Property	Value
Command-Line Format	<code>--thread-pool-size=#</code>
Introduced	8.0.11
System Variable	<code>thread_pool_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	64

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_stall_limit`

Property	Value
Command-Line Format	<code>--thread-pool-stall-limit=#</code>
Introduced	8.0.11
System Variable	<code>thread_pool_stall_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	4
Maximum Value	600

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_stack`

Property	Value
Command-Line Format	<code>--thread-stack=#</code>
System Variable	<code>thread_stack</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	262144
Default Value (32-bit platforms)	196608
Minimum Value	131072
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Block Size	1024

The stack size for each thread. The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This system variable was removed in MySQL 8.0.3.

- `time_zone`

Property	Value
System Variable	<code>time_zone</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 5.1.12, “MySQL Server Time Zone Support”](#).

Note

If set to `SYSTEM`, every MySQL function call that requires a timezone calculation makes a system library call to determine the current system timezone. This call may be protected by a global mutex, resulting in contention.

- `timestamp`

Property	Value
System Variable	<code>timestamp</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Numeric

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`, not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

In MySQL 8.0, `timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- `tls_version`

Property	Value
Command-Line Format	<code>--tls-version=protocol_list</code>

Property	Value
System Variable	<code>tls_version</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value ($\geq 8.0.11$)	<code>TLSv1,TLSv1.1,TLSv1.2</code>
Default Value ($\leq 8.0.4$)	<code>TLSv1,TLSv1.1,TLSv1.2</code> (OpenSSL) <code>TLSv1,TLSv1.1</code> (yaSSL)

The protocols permitted by the server for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. For details, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `tmp_table_size`

Property	Value
Command-Line Format	<code>--tmp-table-size=#</code>
System Variable	<code>tmp_table_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	<code>16777216</code>
Minimum Value	<code>1024</code>
Maximum Value	<code>18446744073709551615</code>

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is determined from whichever of the values of `tmp_table_size` and `max_heap_table_size` is smaller. If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table. The `internal_tmp_disk_storage_engine` option defines the storage engine used for on-disk temporary tables.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `tmpdir`

Property	Value
Command-Line Format	<code>--tmpdir=dir_name</code>
System Variable	<code>tmpdir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave will not use the general `tmpdir` value and you can set `tmpdir` to a nonpermanent location.

- `transaction_alloc_block_size`

Property	Value
Command-Line Format	<code>--transaction-alloc-block-size=#</code>
System Variable	<code>transaction_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	1024
Maximum Value	131072
Block Size	1024

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_isolation`

Property	Value
Command-Line Format	<code>--transaction-isolation=name</code>
System Variable	<code>transaction_isolation</code>
Scope	Global, Session
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	REPEATABLE-READ
Valid Values	READ-UNCOMMITTED READ-COMMITTED REPEATABLE-READ SERIALIZABLE

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.7, “SET TRANSACTION Syntax”](#). If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET transaction_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` server option.

This variable has nonstandard semantics for runtime changes to the session value made using the `SET` statement. For most session system variables, these statements are equivalent:

```
SET @@var_name = value;
SET @@session.var_name = value;
```

For `transaction_isolation`, these semantics apply instead:

- `SET @@transaction_isolation = value`
 - Not permitted within transactions.
 - Sets the value only for the next single transaction within the session.
- `SET @@session.transaction_isolation = value`
 - Permitted within transactions.
 - Sets the value for all subsequent transactions within the session.
 - Does not affect the current ongoing transaction.
 - If executed between transactions, overrides any preceding `SET @@transaction_isolation` statement to set the value for the next transaction.
- `transaction_prealloc_size`

Property	Value
Command-Line Format	<code>--transaction-prealloc-size=#</code>
System Variable	<code>transaction_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	4096
Minimum Value	1024
Maximum Value	131072
Block Size	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `transaction_read_only`

Property	Value
Command-Line Format	<code>--transaction-read-only</code>
System Variable	<code>transaction_read_only</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

The default transaction access mode. The value can be `OFF` (read/write, the default) or `ON` (read only).

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.7, “SET TRANSACTION Syntax”](#).

To set the default transaction access mode at startup, use the `--transaction-read-only` server option.

This variable has nonstandard semantics for runtime changes to the session value made using the `SET` statement. For most session system variables, these statements are equivalent:

```
SET @@var_name = value;
SET @@session.var_name = value;
```

For `transaction_read_only`, these semantics apply instead:

- `SET @@transaction_read_only = value`
 - Not permitted within transactions.
 - Sets the value only for the next single transaction within the session.
- `SET @@session.transaction_read_only = value`
 - Permitted within transactions.
 - Sets the value for all subsequent transactions within the session.
 - Does not affect the current ongoing transaction.
 - If executed between transactions, overrides any preceding `SET @@transaction_read_only` statement to set the value for the next transaction.
- `tx_isolation`

Property	Value
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>tx_isolation</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>REPEATABLE-READ</code>
Valid Values	<code>READ-UNCOMMITTED</code> <code>READ-COMMITTED</code> <code>REPEATABLE-READ</code> <code>SERIALIZABLE</code>

This system variable was removed in MySQL 8.0.3. Use `transaction_isolation` instead.

- `tx_read_only`

Property	Value
Deprecated	Yes (removed in 8.0.3)
System Variable	<code>tx_read_only</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This system variable was removed in MySQL 8.0.3. Use `transaction_read_only` instead.

- `unique_checks`

Property	Value
System Variable	<code>unique_checks</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	ON

If set to 1 (the default), uniqueness checks for secondary indexes in [InnoDB](#) tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to [InnoDB](#).

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `updatable_views_with_limit`

Property	Value
Command-Line Format	<code>--updatable-views-with-limit=#</code>
System Variable	<code>updatable_views_with_limit</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	1

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- 1 or YES: Issue a warning only (not an error message). This is the default value.
 - 0 or NO: Prohibit the update.
- `use_secondary_engine`

Property	Value
Introduced	8.0.13
System Variable	<code>use_secondary_engine</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	Yes

Property	Value
Type	Enumeration
Default Value	OFF
Valid Values	OFF ON FORCE

For future use.

- `validate_password.xxx`

The `validate_password` component implements a set of system variables having names of the form `validate_password.xxx`. These variables affect password testing by that component; see [Section 6.5.3.2, “Password Validation Options and Variables”](#).

- `validate_user_plugins`

Property	Value
System Variable	<code>validate_user_plugins</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` or `caching_sha2_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by the plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

- `version`

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

Property	Value
System Variable	<code>version_comment</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Property	Value
Type	String

The `CMake` configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- `version_compile_machine`

Property	Value
System Variable	<code>version_compile_machine</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The type of the server binary.

- `version_compile_os`

Property	Value
System Variable	<code>version_compile_os</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The type of operating system on which MySQL was built.

- `version_compile_zlib`

Property	Value
Introduced	8.0.11
System Variable	<code>version_compile_zlib</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The version of the compiled-in `zlib` library.

- `wait_timeout`

Property	Value
Command-Line Format	<code>--wait-timeout=#</code>
System Variable	<code>wait_timeout</code>
Scope	Global, Session

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value (Other)	31536000
Maximum Value (Windows)	2147483

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

- `windowing_use_high_precision`

Property	Value
Command-Line Format	<code>--windowing-use-high-precision=#</code>
Introduced	8.0.2
System Variable	<code>windowing_use_high_precision</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean
Default Value	ON

Whether to compute window operations without loss of precision. See [Section 8.2.1.19, “Window Function Optimization”](#).

5.1.8 Using System Variables

The MySQL server maintains many system variables that configure its operation. [Section 5.1.7, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables may also be installed by server plugins or components:

- System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the `audit_log` plugin implements a system variable named `audit_log_policy`.
- System variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.4, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 ; that is, units of kilobytes, megabytes, or gigabytes, respectively. As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024^4 , 1024^5 or 1024^6 . Thus, the following command starts the server with an `InnoDB` log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb_log_file_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
innodb_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `innodb_log_file_size` from being increased to more than 32MB at runtime, use the option `--maximum-innodb_log_file_size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 5.1.8.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. The following examples briefly illustrate this syntax:

- Set a global system variable:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value):

```
SET PERSIST max_connections = 1000;
SET @@persist.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value):

```
SET PERSIST_ONLY back_log = 1000;
SET @@persist_only.back_log = 1000;
```

- Set a session system variable:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting and persisting system variables, see [Section 5.1.8.1, “System Variable Privileges”](#)

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	151
basedir	/home/mysql/
binlog_cache_size	32768
bulk_insert_buffer_size	8388608
character_set_client	utf8
character_set_connection	utf8
character_set_database	utf8mb4

character_set_filesystem	binary	
character_set_results	utf8	
character_set_server	utf8mb4	
character_set_system	utf8	
character_sets_dir	/home/mysql/share/mysql/charsets/	
collation_connection	utf8_general_ci	
collation_database	utf8mb4_0900_ai_ci	
collation_server	utf8mb4_0900_ai_ci	
...		
innodb_autoextend_increment	8	
innodb_buffer_pool_size	8388608	
innodb_commit_concurrency	0	
innodb_concurrency_tickets	500	
innodb_data_file_path	ibdata1:10M:autoextend	
innodb_data_home_dir		
...		
version	8.0.1-dmr-log	
version_comment	Source distribution	
version_compile_machine	i686	
version_compile_os	suse-linux	
wait_timeout	28800	

With a [LIKE](#) clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `_` to match it literally. In practice, this is rarely necessary.

For [SHOW VARIABLES](#), if you specify neither [GLOBAL](#) nor [SESSION](#), MySQL returns [SESSION](#) values.

The reason for requiring the [GLOBAL](#) keyword when setting [GLOBAL](#)-only variables but not when retrieving them is to prevent problems in the future:

- Were a [SESSION](#) variable to be removed that has the same name as a [GLOBAL](#) variable, a client with privileges sufficient to modify global variables might accidentally change the [GLOBAL](#) variable rather than just the [SESSION](#) variable for its own session.
- Were a [SESSION](#) variable to be added with the same name as a [GLOBAL](#) variable, a client that intends to change the [GLOBAL](#) variable might find only its own [SESSION](#) variable changed.

5.1.8.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the [SET](#) statement to affect operation of the current server instance. [SET](#) can also be used to persist certain global system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. [RESET PERSIST](#) removes persisted settings from `mysqld-auto.cnf`.

This section describes the privileges required to assign values to system variables at runtime. This includes persistence-related privileges because some statements that modify system variable values

persist those settings to the `mysqld-auto.cnf` file. For more information about persisting system variables and the `mysqld-auto.cnf` file, see [Section 5.1.8.3, “Persisted System Variables”](#).

These privileges apply to setting global system variable values:

- To set a global system variable at runtime, use the `SET GLOBAL` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- To persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value), use the `SET PERSIST` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- To persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value), use the `SET PERSIST_ONLY` statement, which requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.
- To remove a persisted global system variable from the `mysqld-auto.cnf` file, use the `RESET PERSIST` statement:
 - For dynamic system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
 - For read-only system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.

The descriptions for individual system variables indicate any exceptions to the preceding privilege requirements. An example is `mandatory_roles`.

To set a session system variable at runtime, use the `SET SESSION` statement. In contrast to global system variable values, setting session system variable values at runtime normally requires no special privileges and can be done by any user to affect the current session. However, for some system variables, setting the session value can have effects outside the current session and thus is a restricted operation that can be done only by users who have a special privilege:

- As of MySQL 8.0.14, the privilege required is `SESSION_VARIABLES_ADMIN`. However, any user who has `SYSTEM_VARIABLES_ADMIN` or `SUPER` effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.
- Prior to MySQL 8.0.14, the privilege required is `SYSTEM_VARIABLES_ADMIN` or `SUPER`.

If a session system variable is restricted, the variable description indicates that restriction. Examples include `binlog_format`, `sql_log_bin`, and `sql_log_off`.

The reason for restricting certain session system variables is that changing them can have an effect beyond the current session. For example, setting the session `binlog_format` or `sql_log_bin` value affects binary logging for the current session, but that may have implications for the integrity of server replication and backups.

`SESSION_VARIABLES_ADMIN` enables administrators to minimize the privilege footprint of users who may previously have been granted `SYSTEM_VARIABLES_ADMIN` or `SUPER` for the purpose of enabling them to modify restricted session system variables. Suppose that an administrator has created the following role to confer the ability to set restricted session system variables:

```
CREATE ROLE set_session_sysvars;  
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
```

Any user granted the `set_session_sysvars` role (and who has that role active) is able to set restricted session system variables. However, that user is also able to set global system variables, which may be undesirable.

By modifying the role to have `SESSION_VARIABLES_ADMIN` instead of `SYSTEM_VARIABLES_ADMIN`, the role privileges can be reduced to the ability to set restricted session system variables and nothing else. To modify the role, use these statements:

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
REVOKE SYSTEM_VARIABLES_ADMIN ON *.* FROM set_session_sysvars;
```

Modifying the role has an immediate effect: Any account granted the `set_session_sysvars` role no longer has `SYSTEM_VARIABLES_ADMIN` and is not able to set global system variables without being granted that ability explicitly. A similar `GRANT/REVOKE` sequence can be applied to any account that was granted `SYSTEM_VARIABLES_ADMIN` directly rather than by means of a role.

5.1.8.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting system variables, see [Section 5.1.8.1, “System Variable Privileges”](#)

The following table lists all dynamic system variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from the `ENUM` data type used for table columns, for which the first enumeration value corresponds to 1.

Table 5.4 Dynamic System Variable Summary

Variable Name	Variable Type	Variable Scope
<code>activate_all_roles_on_login</code>	Boolean	Global
<code>audit_log_connection_policy</code>	Enumeration	Global
<code>audit_log_exclude_accounts</code>	String	Global
<code>audit_log_flush</code>	Boolean	Global
<code>audit_log_include_accounts</code>	String	Global
<code>audit_log_read_buffer_size</code>	Integer	Varies
<code>audit_log_rotate_on_size</code>	Integer	Global
<code>audit_log_statement_policy</code>	Enumeration	Global

5.1.8.3 Persisted System Variables

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain global system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. `RESET PERSIST` removes persisted settings from `mysqld-auto.cnf`.

The following discussion describes aspects of persisting system variables:

- [Overview of Persisted System Variables](#)
- [Syntax for Persisting System Variables](#)
- [Obtaining Information About Persisted System Variables](#)
- [Format and Server Handling of the `mysqld-auto.cnf` File](#)

Overview of Persisted System Variables

The capability of persisting global system variables at runtime enables server configuration that persists across server startups. Although many system variables can be set at startup from a `my.cnf` option file, or at runtime using the `SET` statement, those methods of configuring the server either require login access to the server host, or do not provide the capability of persistently configuring the server at runtime or remotely:

- Modifying an option file requires direct access to that file, which requires login access to the MySQL server host. This is not always convenient.
- Modifying system variables with `SET GLOBAL` is a runtime capability that can be done from clients run locally or from remote hosts, but the changes affect only the currently running server instance. The settings are not persistent and do not carry over to subsequent server startups.

To augment administrative capabilities for server configuration beyond what is achievable by editing option files or using `SET GLOBAL`, MySQL provides variants of `SET` syntax that persist system variable settings to a file named `mysqld-auto.cnf` file in the data directory. Examples:

```
SET PERSIST max_connections = 1000;
SET @@persist.max_connections = 1000;

SET PERSIST_ONLY back_log = 100;
SET @@persist_only.back_log = 100;
```

MySQL also provides a `RESET PERSIST` statement for removing persisted system variables from `mysqld-auto.cnf`.

Server configuration performed by persisting system variables has these characteristics:

- Persisted settings are made at runtime.
- Persisted settings are permanent. They apply across server restarts.
- Persisted settings can be made from local clients or clients who connect from a remote host. This provides the convenience of remotely configuring multiple MySQL servers from a central client host.
- To persist system variables, you need not have login access to the MySQL server host or file system access to option files. Ability to persist settings is controlled using the MySQL privilege system. See [Section 5.1.8.1, “System Variable Privileges”](#).
- An administrator with sufficient privileges can reconfigure a server by persisting system variables, then cause the server to use the changed settings immediately by executing a [RESTART](#) statement.
- Persisted settings provide immediate feedback about errors. An error in a manually entered setting might not be discovered until much later. [SET](#) statements that persist system variables avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration.

Syntax for Persisting System Variables

These [SET](#) syntax options are available for persisting system variables:

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the [PERSIST](#) keyword or the `@@persist.` qualifier:

```
SET PERSIST max_connections = 1000;  
SET @@persist.max_connections = 1000;
```

Like [SET GLOBAL](#), [SET PERSIST](#) sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the [PERSIST_ONLY](#) keyword or the `@@persist_only.` qualifier:

```
SET PERSIST_ONLY back_log = 1000;  
SET @@persist_only.back_log = 1000;
```

Like [PERSIST](#), [PERSIST_ONLY](#) writes the variable setting to `mysqld-auto.cnf`. However, unlike [PERSIST](#), [PERSIST_ONLY](#) does not modify the global variable runtime value. This makes [PERSIST_ONLY](#) suitable for configuring read-only system variables that can be set only at server startup.

For more information about [SET](#), see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

These [RESET PERSIST](#) syntax options are available for removing persisted system variables:

- To remove all persisted variables from `mysqld-auto.cnf`, use [RESET PERSIST](#) without naming any system variable:

```
RESET PERSIST;
```

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

```
RESET PERSIST variable_name;
```

```
RESET PERSIST system_var_name;
```

This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

```
RESET PERSIST IF EXISTS system_var_name;
```

For more information about `RESET PERSIST`, see [Section 13.7.7.7, “RESET PERSIST Syntax”](#).

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted. See [Section 5.1.8.4, “Nonpersistent System Variables”](#).

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable will not exist when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

Obtaining Information About Persisted System Variables

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See [Section 25.11.13.1, “Performance Schema persisted_variables Table”](#).

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See [Section 25.11.13.2, “Performance Schema variables_info Table”](#).

`RESET PERSIST` affects the contents of the `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the `variables_info` table until the server is restarted.

Format and Server Handling of the `mysqld-auto.cnf` File

The `mysqld-auto.cnf` file uses a `JSON` format like this (reformatted slightly for readability):

```
{
  "Version": 1,
  "mysql_server": {
    "max_connections": {
      "Value": "152",
      "Metadata": {
        "Timestamp": 1.519921356e+15,
        "User": "root",
        "Host": "localhost"
      }
    }
  },
  "transaction_isolation": {
```

```

    "Value": "READ-COMMITTED",
    "Metadata": {
      "Timestamp": 1.519921553e+15,
      "User": "root",
      "Host": "localhost"
    }
  },
  "mysql_server_static_options": {
    "innodb_api_enable_md1": {
      "Value": "0",
      "Metadata": {
        "Timestamp": 1.519921573e+15,
        "User": "root",
        "Host": "localhost"
      }
    }
  },
  "log_slave_updates": {
    "Value": "1",
    "Metadata": {
      "Timestamp": 1.519921582e+15,
      "User": "root",
      "Host": "localhost"
    }
  }
}
}
}
}

```

At startup, the server processes the `mysqld-auto.cnf` file after all other option files (see [Section 4.2.7, “Using Option Files”](#)). The server handles the file contents as follows:

- If the `persisted_globals_load` system variable is disabled, the server ignores the `mysqld-auto.cnf` file.
- Only read-only variables persisted using `SET PERSIST_ONLY` appear in the `"mysql_server_static_options"` section. All variables present inside this section are appended to the command line and processed with other command-line options.
- All remaining persisted variables are set by executing the equivalent of a `SET GLOBAL` statement later, just before the server starts listening for client connections. These settings therefore do not take effect until late in the startup process, which might be unsuitable for certain system variables. For example, a variable such as `log_error_verbosity` that affects logging to the error log takes effect later in the startup process if persisted to `mysqld-auto.cnf` than if set in `my.cnf`. It may be preferable to set such variables in `my.cnf` rather than in `mysqld-auto.cnf`.

Management of the `mysqld-auto.cnf` file should be left to the server. Manipulation of the file should be performed only using `SET` and `RESET PERSIST` statements, not manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:

```
RESET PERSIST;
```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persisted_globals_load` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysqld-auto.cnf` file. However, as noted previously, removing this file results in a loss of all persisted settings.

5.1.8.4 Nonpersistent System Variables

`SET PERSIST` and `SET PERSIST_ONLY` enable global system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#)). However, not all system variables can be persisted. Here are some reasons why a variable might be persist-restricted:

- A system variable might be read only. In this case, it cannot be set at all, whether at server startup or at runtime.
- A system variable might be intended only for internal use.
- A system variable might involve sensitive data. A variable such as `secure_file_priv` should be settable only by a user who has direct access to the server host file system, not a remote user why by setting this variable and restarting the server could cause a privilege escalation for remote users to access the server host file system.
- Session system variables cannot be persisted. They cannot be set at server startup, so there is no reason to persist them.

These system variables cannot be persisted:

```

5.1.8.5 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 8.10.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
  --extra_cache.key_buffer_size=128K \
  --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
--hot_cache.key_buffer_size=2M \
--cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.9 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 13.7.6.35, "SHOW STATUS Syntax"](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
...	
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_files	3
Created_tmp_tables	2
...	
Threads_created	217
Threads_running	88
Uptime	1389872

Several status variables provide statement counts. To determine the number of statements executed, use these relationships:

```
SUM(Com_xxx)
= Questions + statements executed within stored programs
= Queries
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see [Section 5.1.5, “Server Status Variable Reference”](#).

The status variables have the following meanings.

- [Aborted_clients](#)

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.5.2.10, “Communication Errors and Aborted Connections”](#).

- [Aborted_connects](#)

The number of failed attempts to connect to the MySQL server. See [Section B.5.2.10, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the [Connection_errors_xxx](#) status variables and the [host_cache](#) table.

- [Binlog_cache_disk_use](#)

The number of transactions that used the temporary binary log cache but that exceeded the value of [binlog_cache_size](#) and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the [Binlog_stmt_cache_disk_use](#) status variable.

- [Acl_cache_items_count](#)

The number of cached privilege objects. Each object is the privilege combination of a user and its active roles.

- [Binlog_cache_use](#)

The number of transactions that used the binary log cache.

- [Binlog_stmt_cache_disk_use](#)

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of [binlog_stmt_cache_size](#) and used a temporary file to store those statements.

- [Binlog_stmt_cache_use](#)

The number of nontransactional statements that used the binary log statement cache.

- [Bytes_received](#)

The number of bytes received from all clients.

- [Bytes_sent](#)

The number of bytes sent to all clients.

- [Caching_sha2_password_rsa_public_key](#)

The public key used by the [caching_sha2_password](#) authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the [caching_sha2_password_private_key_path](#) and [caching_sha2_password_public_key_path](#) system variables. The value of [Caching_sha2_password_rsa_public_key](#) comes from the latter file.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

The discussion at the beginning of this section indicates how to relate these statement-counting status variables to other such variables.

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

`Com_explain_other` indicates the number of `EXPLAIN FOR CONNECTION` statements executed. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).

`Com_change_repl_filter` indicates the number of `CHANGE REPLICATION FILTER` statements executed.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

- `Connection_errors_xxx`

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 8.12.4.2, “DNS Lookup](#)

Optimization and the Host Cache”), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

- `Connection_errors_accept`

The number of errors that occurred during calls to `accept()` on the listening port.

- `Connection_errors_internal`

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- `Connection_errors_max_connections`

The number of connections refused because the server `max_connections` limit was reached.

- `Connection_errors_peer_address`

The number of errors that occurred while searching for connecting client IP addresses.

- `Connection_errors_select`

The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- `Connection_errors_tcpwrap`

The number of connections refused by the `libwrap` library.

- `Connections`

The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `Created_tmp_files`

How many temporary files `mysqld` has created.

- `Created_tmp_tables`

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Delayed_errors`

This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `Delayed_insert_threads`

This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `Delayed_writes`

This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `dragnet.Status`

The result of the most recent assignment to the `dragnet.log_error_filter_rules` system variable, empty if no such assignment has occurred.

This variable was added in MySQL 8.0.12.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `group_replication_primary_member`

Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_external_lock`

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among

storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT coll FROM foo`, assuming that `coll` is indexed.

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `Innodb_available_undo_logs`

`Innodb_available_undo_logs` was removed in MySQL 8.0.2. The number of available rollback segments per tablespace may be retrieved using `SHOW VARIABLES LIKE 'innodb_rollback_segments';`

- `Innodb_buffer_pool_dump_status`

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

For related information and examples, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `Innodb_buffer_pool_load_status`

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.

For related information and examples, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `Innodb_buffer_pool_bytes_data`

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_flushed](#)

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_free](#)

The number of free [pages](#) in the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_latched](#)

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the [UNIV_DEBUG](#) system is defined at server build time.

- [Innodb_buffer_pool_pages_misc](#)

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as [Innodb_buffer_pool_pages_total](#) - [Innodb_buffer_pool_pages_free](#) - [Innodb_buffer_pool_pages_data](#). When using [compressed tables](#), [Innodb_buffer_pool_pages_misc](#) may report an out-of-bounds value (Bug #59550).

- [Innodb_buffer_pool_pages_total](#)

The total size of the [InnoDB buffer pool](#), in [pages](#). When using [compressed tables](#), the reported [Innodb_buffer_pool_pages_data](#) value may be larger than [Innodb_buffer_pool_pages_total](#) (Bug #59550)

- [Innodb_buffer_pool_read_ahead](#)

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread.

- [Innodb_buffer_pool_read_ahead_evicted](#)

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread that were subsequently [evicted](#) without having been accessed by queries.

- [Innodb_buffer_pool_read_ahead_rnd](#)

The number of “random” read-aheads initiated by [InnoDB](#). This happens when a query scans a large portion of a table but in random order.

- [Innodb_buffer_pool_read_requests](#)

The number of logical read requests.

- [Innodb_buffer_pool_reads](#)

The number of logical reads that [InnoDB](#) could not satisfy from the [buffer pool](#), and had to read directly from disk.

- [Innodb_buffer_pool_resize_status](#)

The status of an operation to resize the [InnoDB buffer pool](#) dynamically, triggered by setting the [innodb_buffer_pool_size](#) parameter dynamically. The [innodb_buffer_pool_size](#) parameter

is dynamic, which allows you to resize the buffer pool without restarting the server. See [Configuring InnoDB Buffer Pool Size Online](#) for related information.

- `Innodb_buffer_pool_wait_free`

Normally, writes to the [InnoDB buffer pool](#) happen in the background. When [InnoDB](#) needs to read or create a [page](#) and no clean pages are available, [InnoDB](#) flushes some [dirty pages](#) first and waits for that operation to finish. This counter counts instances of these waits. If `innodb_buffer_pool_size` has been set properly, this value should be small.

- `Innodb_buffer_pool_write_requests`

The number of writes done to the [InnoDB buffer pool](#).

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_reads`

The current number of pending reads.

- `Innodb_data_pending_writes`

The current number of pending writes.

- `Innodb_data_read`

The amount of data read since the server was started (in bytes).

- `Innodb_data_reads`

The total number of data reads (OS file reads).

- `Innodb_data_writes`

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of [pages](#) that have been written to the [doublewrite buffer](#). See [Section 15.11.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See [Section 15.11.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with [atomic instructions](#).

- [Innodb_log_waits](#)

The number of times that the [log buffer](#) was too small and a [wait](#) was required for it to be [flushed](#) before continuing.

- [Innodb_log_write_requests](#)

The number of write requests for the [InnoDB redo log](#).

- [Innodb_log_writes](#)

The number of physical writes to the [InnoDB redo log](#) file.

- [Innodb_num_open_files](#)

The number of files [InnoDB](#) currently holds open.

- [Innodb_os_log_fsyncs](#)

The number of `fsync()` writes done to the [InnoDB redo log](#) files.

- [Innodb_os_log_pending_fsyncs](#)

The number of pending `fsync()` operations for the [InnoDB redo log](#) files.

- [Innodb_os_log_pending_writes](#)

The number of pending writes to the [InnoDB redo log](#) files.

- [Innodb_os_log_written](#)

The number of bytes written to the [InnoDB redo log](#) files.

- [Innodb_page_size](#)

[InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- [Innodb_pages_created](#)

The number of pages created by operations on [InnoDB](#) tables.

- [Innodb_pages_read](#)

The number of pages read from the [InnoDB](#) buffer pool by operations on [InnoDB](#) tables.

- [Innodb_pages_written](#)

The number of pages written by operations on [InnoDB](#) tables.

- [Innodb_row_lock_current_waits](#)

The number of [row locks](#) currently being waited for by operations on [InnoDB](#) tables.

- [Innodb_row_lock_time](#)

The total time spent in acquiring [row locks](#) for [InnoDB](#) tables, in milliseconds.

- `Innodb_row_lock_time_avg`
The average time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.
- `Innodb_row_lock_time_max`
The maximum time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.
- `Innodb_row_lock_waits`
The number of times operations on [InnoDB](#) tables had to wait for a [row lock](#).
- `Innodb_rows_deleted`
The number of rows deleted from [InnoDB](#) tables.
- `Innodb_rows_inserted`
The number of rows inserted into [InnoDB](#) tables.
- `Innodb_rows_read`
The number of rows read from [InnoDB](#) tables.
- `Innodb_rows_updated`
The number of rows updated in [InnoDB](#) tables.
- `Innodb_truncated_status_writes`
The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.
- `Key_blocks_not_flushed`
The number of key blocks in the [MyISAM](#) key cache that have changed but have not yet been flushed to disk.
- `Key_blocks_unused`
The number of unused blocks in the [MyISAM](#) key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in [Section 5.1.7, “Server System Variables”](#).
- `Key_blocks_used`
The number of used blocks in the [MyISAM](#) key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.
- `Key_read_requests`
The number of requests to read a key block from the [MyISAM](#) key cache.
- `Key_reads`
The number of physical reads of a key block from disk into the [MyISAM](#) key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.
- `Key_write_requests`

The number of requests to write a key block to the [MyISAM](#) key cache.

- [Key_writes](#)

The number of physical writes of a key block from the [MyISAM](#) key cache to disk.

- [Last_query_cost](#)

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. [Last_query_cost](#) has session scope.

The [Last_query_cost](#) value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or [UNION](#). For the latter, the value is set to 0.

- [Last_query_partial_plans](#)

The number of iterations the query optimizer made in execution plan construction for the previous query. [Last_query_cost](#) has session scope.

- [Locked_connects](#)

The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see [Section 6.3.12, “User Account Locking”](#).

- [Max_execution_time_exceeded](#)

The number of [SELECT](#) statements for which the execution timeout was exceeded.

- [Max_execution_time_set](#)

The number of [SELECT](#) statements for which a nonzero execution timeout was set. This includes statements that include a nonzero [MAX_EXECUTION_TIME](#) optimizer hint, and statements that include no such hint but execute while the timeout indicated by the [max_execution_time](#) system variable is nonzero.

- [Max_execution_time_set_failed](#)

The number of [SELECT](#) statements for which the attempt to set an execution timeout failed.

- [Max_used_connections](#)

The maximum number of connections that have been in use simultaneously since the server started.

- [Max_used_connections_time](#)

The time at which [Max_used_connections](#) reached its current value.

- [Not_flushed_delayed_rows](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [mecab_charset](#)

The character set currently used by the MeCab full-text parser plugin. For related information, see [Section 12.9.9, “MeCab Full-Text Parser Plugin”](#).

- `Ongoing_anonymous_transaction_count`

Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- `Ongoing_anonymous_gtid_violating_transaction_count`

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=ANONYMOUS` and that violate GTID consistency.

- `Ongoing_automatic_gtid_violating_transaction_count`

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=AUTOMATIC` and that violate GTID consistency.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached table definitions.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of table definitions that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 25.15, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

This status variable was removed in MySQL 8.0.3.

- `Qcache_free_memory`

This status variable was removed in MySQL 8.0.3.

- `Qcache_hits`

This status variable was removed in MySQL 8.0.3.

- `Qcache_inserts`

This status variable was removed in MySQL 8.0.3.

- `Qcache_lowmem_prunes`

This status variable was removed in MySQL 8.0.3.

- `Qcache_not_cached`

This status variable was removed in MySQL 8.0.3.

- `Qcache_queries_in_cache`

This status variable was removed in MySQL 8.0.3.

- `Qcache_total_blocks`

This status variable was removed in MySQL 8.0.3.

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Questions`

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

The average time in microseconds the master waited for a slave reply. This variable is always 0, is deprecated and it will be removed in a future version.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

The total time in microseconds the master waited for slave replies. This variable is always 0, is deprecated and it will be removed in a future version.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

The total number of times the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

The number of times the master turned off semisynchronous replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

The number of times the master failed when calling time functions such as `gettimeofday()`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

The average time in microseconds the master waited for each transaction.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

The total time in microseconds the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

The total number of times the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

The number of sessions currently waiting for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is `ON` if the plugin has been enabled and the slave I/O thread is running, `OFF` otherwise.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `Rsa_public_key`

This variable is available if MySQL was compiled using OpenSSL (see [Section 6.4.4, “OpenSSL Versus wolfSSL”](#)). Its value is the public key used by the `sha256_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

For information about `sha256_password`, see [Section 6.5.1.2, “SHA-256 Pluggable Authentication”](#).

- `Secondary_engine_execution_count`

For future use. This variable was added in MySQL 8.0.13.

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- [Select_scan](#)

The number of joins that did a full scan of the first table.

- [Slave_heartbeat_period](#)

This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the [HEARTBEAT_INTERVAL](#) column of the [replication_connection_configuration](#) table.

- [Slave_last_heartbeat](#)

This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the [LAST_HEARTBEAT_TIMESTAMP](#) column of the [replication_connection_status](#) table.

- [Slave_open_temp_tables](#)

The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 17.4.1.31, “Replication and Temporary Tables”](#). This variable reports the total count of open temporary tables for *all* replication channels.

- [Slave_received_heartbeats](#)

This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the [COUNT_RECEIVED_HEARTBEATS](#) column of the [replication_connection_status](#) table.

- [Slave_retried_transactions](#)

This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the [COUNT_TRANSACTIONS_RETRIES](#) column of the [replication_applier_status](#) table.

- [Slave_rows_last_search_algorithm_used](#)

The search algorithm that was most recently used by this slave to locate rows for row-based replication. The result shows whether the slave used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

The method used depends on the setting for the [slave_rows_search_algorithms](#) system variable, and the keys that are available on the relevant table.

This variable is available only for debug builds of MySQL.

- [Slave_running](#)

This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the [SERVICE_STATE](#) column of the [replication_connection_status](#) and [replication_applier_status](#) tables.

- [Slow_launch_threads](#)

The number of threads that have taken more than [slow_launch_time](#) seconds to create.

- [Slow_queries](#)

The number of queries that have taken more than [long_query_time](#) seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 5.4.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful slave connections to an SSL-enabled master.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
```

Variable_name	Value
Ssl_server_not_after	Apr 28 14:16:39 2025 GMT
Ssl_server_not_before	May 1 14:16:39 2015 GMT

- `Ssl_server_not_before`

The first date for which the SSL certificate is valid.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- `Ssl_session_cache_size`

The SSL session cache size.

- `Ssl_session_cache_timeouts`

The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

How many SSL session cache entries were used.

- `Ssl_verify_depth`

The verification depth for replication SSL connections.

- `Ssl_verify_mode`

The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

```
# define SSL_VERIFY_NONE          0x00
# define SSL_VERIFY_PEER          0x01
# define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
# define SSL_VERIFY_CLIENT_ONCE  0x04
```

`SSL_VERIFY_PEER` indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. `SSL_VERIFY_CLIENT_ONCE` indicates that a request for the client certificate will be done only in the initial handshake.

- `Ssl_version`

The SSL protocol version of the connection; for example, TLSv1. If the connection is not encrypted, the value is empty.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Table_open_cache_hits`

The number of hits for open tables cache lookups.

- `Table_open_cache_misses`

The number of misses for open tables cache lookups.

- `Table_open_cache_overflows`

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache / table_open_cache_instances`.

- `tablespace_definition_cache`

Property	Value
Command-Line Format	<code>--tablespace-definition-cache=N</code>
System Variable	<code>tablespace_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of tablespace definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused tablespace definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by [tablespace_definition_cache](#).

A setting of 0 means that tablespace definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- [Tc_log_max_pages_used](#)

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of [Tc_log_max_pages_used](#) and [Tc_log_page_size](#) is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- [Tc_log_page_size](#)

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for [Tc_log_max_pages_used](#).

- [Tc_log_page_waits](#)

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- [Threads_cached](#)

The number of threads in the thread cache.

- [Threads_connected](#)

The number of currently open connections.

- [Threads_created](#)

The number of threads created to handle connections. If [Threads_created](#) is big, you may want to increase the [thread_cache_size](#) value. The cache miss rate can be calculated as [Threads_created/Connections](#).

- [Threads_running](#)

The number of threads that are not sleeping.

- [Uptime](#)

The number of seconds that the server has been up.

- `Uptime_since_flush_status`

The number of seconds since the most recent `FLUSH STATUS` statement.

5.1.10 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Combination SQL Modes](#)
- [Strict SQL Mode](#)
- [Comparison of the IGNORE Keyword and Strict SQL Mode](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 8.0 FAQ: Server SQL Mode”](#).

When working with `InnoDB` tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for `InnoDB` tables.

Setting the SQL Mode

The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
```

```
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

Important

SQL mode and user-defined partitioning. Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and slave.

For more information, see [Section 22.6, “Restrictions and Limitations on Partitioning”](#).

The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- `TRADITIONAL`

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

Note

With `TRADITIONAL` mode enabled, an `INSERT` or `UPDATE` aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

- `ALLOW_INVALID_DATES`

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

With `ALLOW_INVALID_DATES` enabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

Treat `"` as an identifier quote character (like the ``` quote character) and not as a string quote character. You can still use ``` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

- `ERROR_FOR_DIVISION_BY_ZERO`

The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes `MOD(N, 0)`. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If this mode is enabled, division by zero inserts `NULL` and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

`ERROR_FOR_DIVISION_BY_ZERO` is deprecated. `ERROR_FOR_DIVISION_BY_ZERO` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `ERROR_FOR_DIVISION_BY_ZERO` is enabled without also enabling strict mode or vice versa.

Because `ERROR_FOR_DIVISION_BY_ZERO` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `HIGH_NOT_PRECEDENCE`

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
```

```
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 9.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 9.2.4, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. For this reason, `mysqldump` automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (`\`) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

By default, `NO_ENGINE_SUBSTITUTION` is enabled.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_UNSIGNED_SUBTRACTION`

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21) unsigned | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21)          | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 12.10, “Cast Functions and Operators”](#).

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
- If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.

`NO_ZERO_DATE` is deprecated. `NO_ZERO_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `NO_ZERO_IN_DATE`

The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as `'2010-00-01'` or `'2010-01-00'`, but not `'0000-00-00'`. To control whether the server permits `'0000-00-00'`, use the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.

`NO_ZERO_IN_DATE` is deprecated. `NO_ZERO_IN_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_IN_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_IN_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `ONLY_FULL_GROUP_BY`

Reject queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on (uniquely determined by) `GROUP BY` columns.

A MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. The `HAVING` clause can refer to aliases regardless of whether `ONLY_FULL_GROUP_BY` is enabled.

For additional discussion and examples, see [Section 12.19.3, “MySQL Handling of GROUP BY”](#).

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from [CHAR](#) column values on retrieval. If [PAD_CHAR_TO_FULL_LENGTH](#) is enabled, trimming does not occur and retrieved [CHAR](#) values are padded to their full length. This mode does not apply to [VARCHAR](#) columns, for which trailing spaces are retained on retrieval.

Note

As of MySQL 8.0.13, [PAD_CHAR_TO_FULL_LENGTH](#) is deprecated. It will be removed in a future version of MySQL.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1    | CHAR_LENGTH(c1) |
+-----+-----+
| xy    |                2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1          | CHAR_LENGTH(c1) |
+-----+-----+
| xy          |                10 |
+-----+-----+
1 row in set (0.00 sec)
```

- [PIPES_AS_CONCAT](#)

Treat `||` as a string concatenation operator (same as [CONCAT\(\)](#)) rather than as a synonym for [OR](#).

- [REAL_AS_FLOAT](#)

Treat [REAL](#) as a synonym for [FLOAT](#). By default, MySQL treats [REAL](#) as a synonym for [DOUBLE](#).

- [STRICT_ALL_TABLES](#)

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see [Strict SQL Mode](#).

- [STRICT_TRANS_TABLES](#)

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see [Strict SQL Mode](#).

- [TIME_TRUNCATE_FRACTIONAL](#)

Control whether rounding or truncation occurs when inserting a [TIME](#), [DATE](#), or [TIMESTAMP](#) value with a fractional seconds part into a column having the same type but fewer fractional digits. The behavior is to use rounding. If this mode is enabled, truncation occurs instead. The following sequence of statements illustrates the difference:

```
CREATE TABLE t (id INT, tval TIME(1));
SET sql_mode='';
INSERT INTO t (id, tval) VALUES(1, 1.55);
SET sql_mode='TIME_TRUNCATE_FRACTIONAL';
INSERT INTO t (id, tval) VALUES(2, 1.55);
```

The resulting table contents look like this, where the first value has been subject to rounding and the second to truncation:

```
mysql> SELECT id, tval FROM t ORDER BY id;
+-----+-----+
| id | tval |
+-----+-----+
| 1 | 00:00:01.6 |
| 2 | 00:00:01.5 |
+-----+-----+
```

Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to [REAL_AS_FLOAT](#), [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), and [ONLY_FULL_GROUP_BY](#).

[ANSI](#) mode also causes the server to return an error for queries where a set function [S](#) with an outer reference [S\(outer_ref\)](#) cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, [MAX\(t1.b\)](#) cannot be aggregated in the outer query because it appears in the [WHERE](#) clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats [S\(outer_ref\)](#) in such queries the same way that it would interpret [S\(const\)](#).

See [Section 1.8, “MySQL Standards Compliance”](#).

- [TRADITIONAL](#)

[TRADITIONAL](#) is equivalent to [STRICT_TRANS_TABLES](#), [STRICT_ALL_TABLES](#), [NO_ZERO_IN_DATE](#), [NO_ZERO_DATE](#), [ERROR_FOR_DIVISION_BY_ZERO](#), and [NO_ENGINE_SUBSTITUTION](#).

Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as [INSERT](#) or [UPDATE](#). A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-[NULL](#) column that has no explicit [DEFAULT](#) clause in its definition. (For a [NULL](#)

column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#)). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See [Section 5.1.7, “Server System Variables”](#).)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
 - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
 - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 11.7, “Data Type Default Values”](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes `MOD(N, 0)`:

For data-change operations (`INSERT`, `UPDATE`):

- If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits `'0000-00-00'` as a valid date:
 - If strict mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.

- If strict mode is enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.
- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as '2010-00-01' or '2010-01-00'):
- If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes.

Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string 'abc' into an integer column).

Operational Mode	When Statement Default is Error	When Statement Default is Warning
Without <code>IGNORE</code> or strict SQL mode	Error	Warning
With <code>IGNORE</code>	Warning	Warning (same as without <code>IGNORE</code> or strict SQL mode)
With strict SQL mode	Error (same as without <code>IGNORE</code> or strict SQL mode)	Error
With <code>IGNORE</code> and strict SQL mode	Warning	Warning

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

The Effect of IGNORE on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting.

For example, if the table `t` has a primary key column `i`, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2  Duplicates: 1  Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1062 | Duplicate entry '1' for key 'PRIMARY' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

These statements support the `IGNORE` keyword:

- **CREATE TABLE ... SELECT:** `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.
- **DELETE:** `IGNORE` causes MySQL to ignore errors during the process of deleting rows.
- **INSERT:** With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- **LOAD DATA, LOAD XML:** With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- **UPDATE:** With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following errors:

```
ER_BAD_NULL_ERROR
ER_DUP_ENTRY
ER_DUP_ENTRY_WITH_KEY_NAME
ER_DUP_KEY
ER_NO_PARTITION_FOR_GIVEN_VALUE
ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT
ER_NO_REFERENCED_ROW_2
ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET
ER_ROW_IS_REFERENCED_2
ER_SUBQUERY_NO_1_ROW
ER_VIEW_CHECK_FAILED
```

The Effect of Strict SQL Mode on Statement Execution

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.

For example, in non-strict SQL mode, inserting the string 'abc' into an integer column results in conversion of the value to 0 and a warning:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see [Section 5.1.10, “Server SQL Modes”](#).

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP()`
- `UPDATE` (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a `NOT NULL` column that has no explicit `DEFAULT` clause in its definition.

```
ER_BAD_NULL_ERROR
```

```

ER_CUT_VALUE_GROUP_CONCAT
ER_DATA_TOO_LONG
ER_DATETIME_FUNCTION_OVERFLOW
ER_DIVISION_BY_ZERO
ER_INVALID_ARGUMENT_FOR_LOGARITHM

```

5.1.11 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 5.1.11.1, “Verifying System Support for IPv6”](#).
- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with an appropriate `--bind-address` option. See [Section 5.1.7, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 6.2.4, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```

mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';

```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 12.22, “Miscellaneous Functions”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

5.1.11.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```

shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...

```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [macOS](#)

5.1.11.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. For details, see the `--bind-address` description in [Section 5.1.6, “Server Command Options”](#).

5.1.11.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]  
bind-address = *
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `--bind-address` description in [Section 5.1.6, “Server Command Options”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 6.2.4, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:      ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1   | ::             |
+-----+-----+
```

5.1.11.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 5.1.11.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = *
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `--bind-address` description in [Section 5.1.6, “Server Command Options”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:      2001:db8:0:f101::1 via TCP/IP
...
```

```
mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteip6user@2001:db8:0:f101::2 | :: |
+-----+-----+
```

5.1.11.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `--bind-address` description in [Section 5.1.6, “Server Command Options”](#). In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the [gogoc](#) IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

5.1.12 MySQL Server Time Zone Support

MySQL Server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server's current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

Note

If set to `SYSTEM`, every MySQL function call that requires a timezone calculation makes a system library call to determine the current system timezone. This call may be protected by a global mutex, resulting in contention.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

```
mysql> SET GLOBAL time_zone = timezone;
```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
mysql> SET time_zone = timezone;
```

The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and

retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given in several formats, none of which are case-sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

Populating the Time Zone Tables

Several tables in the `mysql` system database exist to maintain time zone information (see [Section 5.3, “The mysql System Database”](#)). The MySQL installation procedure creates the time zone tables, but does not load them. You must do so manually using the following instructions.

Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Solaris, and macOS. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a `zoneinfo` database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no zoneinfo database (for example, Windows), you can use a package that is available for download at the MySQL Developer Zone:

```
https://dev.mysql.com/downloads/timezones.html
```

Download a time zone package that contains SQL statements and unpack it, then load the package file contents into the time zone tables:

```
shell> mysql -u root mysql < file_name
```

Then restart the server.

Warning

Do *not* use a downloadable package that contains [MyISAM](#) tables. MySQL uses [InnoDB](#) for the time zone tables. Trying to replace them with [MyISAM](#) tables will cause problems.

Warning

Do not use a downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see [Section 17.4.1, “Replication Features and Issues”](#).

5.1.12.1 Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to [SYSTEM](#). Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated. For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables. For instructions for both methods, see [Populating the Time Zone Tables](#). `mysqld` caches time zone information that it looks up, so after updating the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
|          0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 02:00:00 |
+-----+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
```

```
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+
```

5.1.12.2 Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the local time zone to UTC so there is no difference between internal values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
    a INT,
    ts TIMESTAMP DEFAULT NOW(),
    PRIMARY KEY (ts)
);
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+-----+
| a | ts | UNIX_TIMESTAMP(ts) |
+-----+
| 1 | 2008-12-31 23:59:59 | 1230767999 |
| 2 | 2008-12-31 23:59:59 | 1230768000 |
+-----+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+-----+
| a | ts |
+-----+
```

```
+-----+-----+
| 1 | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+-----+-----+
| a | ts |
+-----+-----+
| 2 | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)
```

5.1.13 Server Tracking of Client Session State Changes

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

One use for the tracker mechanism is to provide a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

Another use for the tracker mechanism is to permit applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:

- Immediately after `START TRANSACTION`
- After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

```
READ ONLY
READ WRITE
ISOLATION LEVEL
WITH CONSISTENT SNAPSHOT
```

To support the preceding session-switching activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
 - The default schema (database).
 - Session-specific values for system variables.
 - User-defined variables.
 - Temporary tables.
 - Prepared statements.

The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.
- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker.
- Available GTIDs. The `session_track_gtids` system variable controls this tracker.
- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see [Section 5.1.7, “Server System Variables”](#). Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected. To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:

- `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See [Section 27.7.7.69, “mysql_session_track_get_first\(\)”](#).
- `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See [Section 27.7.7.70, “mysql_session_track_get_next\(\)”](#).

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@session.session_track_schema=ON;
SET @@session.session_track_system_variables='*';
SET @@session.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@session.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(1, RAND());
```

```
COMMIT;
```

Run the script as follows to see the information provided by the enabled trackers. For a description of the [Tracker](#): information displayed by `mysqltest` for the various trackers, see [Section 27.7.7.69](#), “`mysql_session_track_get_first()`”.

```
shell> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
SET @@session.session_track_schema=ON;
SET @@session.session_track_system_variables='*';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES

```

5.1.14 Server-Side Help

MySQL Server supports a [HELP](#) statement that returns information from the MySQL Reference manual (see [Section 13.8.3, “HELP Syntax”](#)). Several tables in the `mysql` system database contain the information needed to support this statement (see [Section 5.3, “The mysql System Database”](#)). The proper operation of this statement requires that these help tables be initialized, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table content initialization occurs when you initialize the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, help table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <https://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Git and a MySQL development source tree, you must use a downloaded copy of the `fill_help_tables.sql` file because the source tree contains only a “stub” version.

Note

For a server that participates in replication, the help table content upgrade process involves multiple servers. For details, see [Section 17.4.1.27, “Replication of Server-Side Help Tables”](#).

5.1.15 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:      8388600
Block_size:       1024
Division_limit:   100
Age_limit:        300
blocks used:      0
not flushed:      0
w_requests:       0
writes:           0
r_requests:       0
reads:            0

handler status:
read_key:         0
read_next:        0
read_rnd          0
read_first:       1
write:            0
delete            0
update:           0

Table status:
Opened tables:    5
Open tables:      0
Open files:       7
Open streams:     0

Alarm status:
Active alarms:    1
Max used alarms:  2
Next alarm time:  67
```

5.1.16 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a

separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 13.7.7.4, “KILL Syntax”](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also [Section 13.4.2.7, “STOP SLAVE Syntax”](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

Note

To guarantee crash safety on the slave, you must run the slave with `--relay-log-recovery` enabled.

See also [Section 17.2.4, “Replication Relay and Status Logs”](#).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. `InnoDB` flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. `MyISAM` flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by `systemd` in response to the code, for platforms on which `systemd` is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
 - The `mysql` directory corresponds to the `mysql` system database, which contains information required by the MySQL server as it runs. This database contains data dictionary tables and system tables. See [Section 5.3, “The mysql System Database”](#).
 - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See [Chapter 25, MySQL Performance Schema](#).
 - The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See [Chapter 26, MySQL sys Schema](#).

Other subdirectories correspond to databases created by users or applications.

Note

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See [Section 5.4, “MySQL Server Logs”](#).
- `InnoDB` tablespace and log files. See [Chapter 15, The InnoDB Storage Engine](#).
- Default/autogenerated SSL and RSA certificate and key files. See [Section 6.4.3, “Creating SSL and RSA Certificates and Keys”](#).
- The server process ID file (while the server is running).
- The `mysqld-auto.cnf` file that stores persisted global system variable settings. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

5.3 The mysql System Database

The `mysql` database is the system database. It contains tables that store information required by the MySQL server as it runs. A broad categorization is that the `mysql` database contains data dictionary tables that store database object metadata, and system tables used for other operational purposes. The following discussion further subdivides the set of system tables into smaller categories.

- [Data Dictionary Tables](#)
- [Grant System Tables](#)
- [Object Information System Tables](#)
- [Log System Tables](#)
- [Server-Side Help System Tables](#)
- [Time Zone System Tables](#)
- [Replication System Tables](#)
- [Optimizer System Tables](#)
- [Miscellaneous System Tables](#)

The remainder of this section enumerates the tables in each category, with cross references for additional information. Data dictionary tables and system tables use the [InnoDB](#) storage engine unless otherwise indicated.

`mysql` system tables and data dictionary tables reside in a single [InnoDB](#) tablespace file named `mysql.ibd` in the MySQL data directory. Previously, these tables were created in individual tablespace files in the `mysql` database directory.

Data Dictionary Tables

These tables comprise the data dictionary, which contains metadata about database objects. For additional information, see [Chapter 14, MySQL Data Dictionary](#).

Important

The data dictionary is new in MySQL 8.0. A data dictionary-enabled server entails some general operational differences compared to previous MySQL releases. For details, see [Section 14.7, “Data Dictionary Usage Differences”](#). Also, for upgrades to MySQL 8.0 from MySQL 5.7, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see [Section 2.11.1, “Upgrading MySQL”](#), particularly [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#).

- `catalogs`: Catalog information.
- `character_sets`: Information about available character sets.
- `collations`: Information about collations for each character set.
- `column_statistics`: Histogram statistics for column values. See [Section 8.9.6, “Optimizer Statistics”](#).
- `column_type_elements`: Information about types used by columns.
- `columns`: Information about columns in tables.
- `dd_properties`: A table that identifies data dictionary properties, such as its version. The server uses this to determine whether the data dictionary must be upgraded to a newer version.
