- On a region map, a [MultiPolygon](#) could represent a system of lakes.

MultiPolygon Assertions

- A [MultiPolygon](#) has no two [Polygon](#) elements with interiors that intersect.

- A [MultiPolygon](#) has no two [Polygon](#) elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A [MultiPolygon](#) may not have cut lines, spikes, or punctures. A [MultiPolygon](#) is a regular, closed point set.
- A [MultiPolygon](#) that has more than one [Polygon](#) has an interior that is not connected. The number of connected components of the interior of a [MultiPolygon](#) is equal to the number of [Polygon](#) values in the [MultiPolygon](#).

MultiPolygon Properties

- A [MultiPolygon](#) is a two-dimensional geometry.
- A [MultiPolygon](#) boundary is a set of closed curves ([LineString](#) values) corresponding to the boundaries of its [Polygon](#) elements.
- Each [Curve](#) in the boundary of the [MultiPolygon](#) is in the boundary of exactly one [Polygon](#) element.
- Every [Curve](#) in the boundary of an [Polygon](#) element is in the boundary of the [MultiPolygon](#).

11.5.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see [Section 12.15.6, “Geometry Format Conversion Functions”](#).

The following sections describe the spatial data formats MySQL uses:

- [Well-Known Text \(WKT\) Format](#)
- [Well-Known Binary \(WKB\) Format](#)
- [Internal Geometry Storage Format](#)

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see [Section 11.5, “Spatial Data Types”](#)).

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL [Point\(\)](#) function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both

use `ST_X()` to extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `ST_GeomFromText()`.

```
mysql> SELECT ST_X(Point(15, 20));
+-----+
| ST_X(POINT(15, 20)) |
+-----+
| 15 |
+-----+

mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
+-----+
| ST_X(ST_GeomFromText('POINT(15 20)')) |
+-----+
| 15 |
+-----+
```

- A `LineString` with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A `MultiPoint` with three `Point` values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

Spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

- A `MultiLineString` with two `LineString` values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A `MultiPolygon` with two `Polygon` values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by `BLOB` values containing geometric WKB information. This format is

defined by the OpenGIS specification (see [Section 11.5, “Spatial Data Types”](#)). It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 -1)` consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
010100000000000000000000F03F000000000000F0BF
```

The sequence consists of the components shown in the following table.

Table 11.2 WKB Components Example

Component	Size	Value
Byte order	1 byte	01
WKB type	4 bytes	01000000
X coordinate	8 bytes	000000000000F03F
Y coordinate	8 bytes	000000000000F0BF

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-ending values.
- MySQL supports geometry types of `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`. Other geometry types are not supported.
- Only `GeometryCollection` can be empty. Such a value is stored with 0 elements.
- Polygon rings can be specified both clockwise and counterclockwise. MySQL flips the rings automatically when reading data.

Cartesian coordinates are stored in the length unit of the spatial reference system, with X values in the X coordinates and Y values in the Y coordinates. Axis directions are those specified by the spatial reference system.

Geographic coordinates are stored in the angle unit of the spatial reference system, with longitudes in the X coordinates and latitudes in the Y coordinates. Axis directions and the meridian are those specified by the spatial reference system.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+-----+
| LENGTH(@g) |
+-----+
|          25 |
+-----+
mysql> SELECT HEX(@g);
+-----+
| HEX(@g) |
+-----+
| 00000000010100000000000000000000F03F000000000000F0BF |
+-----+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = `Point`)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (-1)

11.5.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except `GeometryCollection`)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically valid geometries should check them using the `ST_IsValid()` function.

11.5.5 Spatial Reference System Support

A spatial reference system (SRS) for spatial data is a coordinate-based system for geographic locations.

There are different types of spatial reference systems:

- A projected SRS is a projection of a globe onto a flat surface; that is, a flat map. For example, a light bulb inside a globe that shines on a paper cylinder surrounding the globe projects a map onto the paper. The result is georeferenced: Each point maps to a place on the globe. The coordinate system on that plane is Cartesian using a length unit (meters, feet, and so forth), rather than degrees of longitude and latitude.

The globes in this case are ellipsoids; that is, flattened spheres. Earth is a bit shorter in its North-South axis than its East-West axis, so a slightly flattened sphere is more correct, but perfect spheres permit faster calculations.

- A geographic SRS is a nonprojected SRS representing longitude-latitude (or latitude-longitude) coordinates on an ellipsoid, in any angular unit.
- The SRS denoted in MySQL by SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything. SRID 0 is the default SRID for spatial data in MySQL.

MySQL maintains information about available spatial reference systems for spatial data in the data dictionary `mysql.st_spatial_reference_systems` table, which can store entries for projected and geographic SRSs. This data dictionary table is invisible, but SRS entry contents are available through the `INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS` table, implemented as a view on `mysql.st_spatial_reference_systems` (see [Section 24.26](#), “The `INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS` Table”).

The following example shows what an SRS entry looks like:

```
mysql> SELECT *
      FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS
      WHERE SRS_ID = 4326\G
***** 1. row *****
      SRS_NAME: WGS 84
      SRS_ID: 4326
  ORGANIZATION: EPSG
ORGANIZATION_COORDSYS_ID: 4326
  DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984",
      SPHEROID["WGS 84",6378137,298.257223563,
      AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]],
      PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
      UNIT["degree",0.017453292519943278,
      AUTHORITY["EPSG","9122"]],
      AXIS["Lat",NORTH],AXIS["Long",EAST],
      AUTHORITY["EPSG","4326"]]
  DESCRIPTION:
```

This entry describes the SRS used for GPS systems. It has a name (`SRS_NAME`) of WGS 84 and an ID (`SRS_ID`) of 4326, which is the ID used by the [European Petroleum Survey Group](#) (EPSG).

SRS definitions in the `DEFINITION` column are WKT values, represented as specified in the [Open Geospatial Consortium](#) document [OGC 12-063r5](#).

`SRS_ID` values represent the same kind of values passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are cached in the data dictionary cache so that parsing overhead is not incurred for every statement that needs SRS information.

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

- `CREATE SPATIAL REFERENCE SYSTEM`: See [Section 13.1.17, “CREATE SPATIAL REFERENCE SYSTEM Syntax”](#). The description for this statement includes additional information about SRS components.
- `DROP SPATIAL REFERENCE SYSTEM`: See [Section 13.1.28, “DROP SPATIAL REFERENCE SYSTEM Syntax”](#).

11.5.6 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the notes about spatial indexes under [Section 11.5.10, “Creating Spatial Indexes”](#).

Columns with a spatial data type can have an SRID attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For implications of an SRID-restricted column, see [Section 11.5.1, “Spatial Data Types”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

11.5.7 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = ST_GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
INSERT INTO geom VALUES
(ST_GeomFromWKB(X'010100000000000000000000F03F000000000000F03F'));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See [Section 27.7.7.56](#), “`mysql_real_escape_string_quote()`”.

11.5.8 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```
SELECT ST_AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```
SELECT ST_AsBinary(g) FROM geom;
```

11.5.9 Optimizing Spatial Analysis

For `MyISAM` and `InnoDB` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` and `InnoDB` support both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 13.1.14, “CREATE INDEX Syntax”](#).

11.5.10 Creating Spatial Indexes

For `InnoDB` and `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
CREATE SPATIAL INDEX g ON geom (g);
```

SPATIAL INDEX creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

The optimizer can use spatial indexes defined on columns that are SRID-restricted. For more information, see [Section 11.5.1, “Spatial Data Types”](#), and [Section 8.3.3, “SPATIAL Index Optimization”](#).

For more information on indexing spatial columns, see [Section 13.1.14, “CREATE INDEX Syntax”](#).

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- With **ALTER TABLE**:

```
ALTER TABLE geom DROP INDEX g;
```

- With **DROP INDEX**:

```
DROP INDEX g ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra           |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                 |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
| 32376    |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

11.5.11 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
```

fid	ST_AsText(g)
21	LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ...
22	LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
23	LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
24	LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
25	LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26	LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...
249	LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2	LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ...
3	LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4	LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5	LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6	LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7	LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...
10	LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ...
11	LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ...
13	LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ...
154	LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155	LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157	LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...

```
20 rows in set (0.00 sec)
```

Use [EXPLAIN](#) to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
         key: g
        key_len: 32
         ref: NULL
         rows: 50
      Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';
```

```
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: geom
      type: ALL
possible_keys: NULL
      key: NULL
     key_len: NULL
       ref: NULL
      rows: 32376
    Extra: Using where
1 row in set (0.00 sec)
```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
+-----+-----+
| fid | ST_AsText(g) |
+-----+-----+

11.6 The JSON Data Type

- [Creating JSON Values](#)
- [Normalization, Merging, and Autowrapping of JSON Values](#)
- [Searching and Modifying JSON Values](#)
- [Comparison and Ordering of JSON Values](#)
- [Converting between JSON and non-JSON values](#)

- [Aggregation of JSON Values](#)

MySQL supports a native `JSON` data type defined by [RFC 7159](#) that enables efficient access to data in JSON (JavaScript Object Notation) documents. The `JSON` data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in `JSON` columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in `JSON` columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

MySQL 8.0 also supports the *JSON Merge Patch* format defined in [RFC 7396](#), using the `JSON_MERGE_PATCH()` function. See the description of this function, as well as [Normalization, Merging, and Autowrapping of JSON Values](#), for examples and further information.

**Note**

This discussion uses `JSON` in monospace to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a `JSON` document is roughly the same as for `LONGBLOB` or `LONGTEXT`; see [Section 11.8, “Data Type Storage Requirements”](#), for more information. It is important to keep in mind that the size of any JSON document stored in a `JSON` column is limited to the value of the `max_allowed_packet` system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.) You can obtain the amount of space required to store a JSON document using the `JSON_STORAGE_SIZE()` function; note that for a `JSON` column, the storage size—and thus the value returned by this function—is that used by the column prior to any partial updates that may have been performed on it (see the discussion of the JSON partial update optimization later in this section).

A `JSON` column cannot have a default value.

Along with the `JSON` data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see [Section 12.16, “JSON Functions”](#).

A set of spatial functions for operating on GeoJSON values is also available. See [Section 12.15.11, “Spatial GeoJSON Functions”](#).

`JSON` columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

Partial Updates of JSON Values

In MySQL 8.0, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update that meets the following conditions:

- The column being updated was declared as `JSON`.

- The `UPDATE` statement uses any of the three functions `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` to update the column. A direct assignment of the column value (for example, `UPDATE mytable SET jcol = '{"a": 10, "b": 25}'`) cannot be performed as a partial update.

Updates of multiple `JSON` columns in a single `UPDATE` statement can be optimized in this fashion; MySQL can perform partial updates of only those columns whose values are updated using the three functions just listed.

- The input column and the target column must be the same column; a statement such as `UPDATE mytable SET jcol1 = JSON_SET(jcol2, '$.a', 100)` cannot be performed as a partial update.

The update can use nested calls to any of the functions listed in the previous item, in any combination, as long as the input and target columns are the same.

- All changes replace existing array or object values with new ones, and do not add any new elements to the parent object or array.
- The value being replaced must be at least as large as the replacement value. In other words, the new value cannot be any larger than the old one.

A possible exception to this requirement occurs when a previous partial update has left sufficient space for the larger value. You can use the function `JSON_STORAGE_FREE()` see how much space has been freed by any partial updates of a `JSON` column.

Such partial updates can be written to the binary log using a compact format that saves space; this can be enabled by setting the `binlog_row_value_options` system variable to `PARTIAL_JSON`. See the description of this variable for more information.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within `[` and `]` characters:

```
[ "abc", 10, null, true, false ]
```

A JSON object contains a set of key-value pairs separated by commas and enclosed within `{` and `}` characters:

```
{ "k1": "value", "k2": 10 }
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```
[ "12:18:29.000000", "2015-07-29", "2015-07-29 12:18:29.000000" ]
```

Nesting is permitted within JSON array elements and JSON object key values:

```
[ 99, { "id": "HK500", "cost": 75.99 }, [ "hot", "cold" ] ]
{ "k1": "value", "k2": [ 10, 20 ] }
```

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see [Section 12.16.2, “Functions That Create JSON Values”](#)) as well as by casting values of other types to the

JSON type using `CAST(value AS JSON)` (see [Converting between JSON and non-JSON values](#)). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value into a column that has the `JSON` data type and passing an argument to a function that expects a JSON value (usually shown as `json_doc` or `json_val` in the documentation for MySQL JSON functions), as the following examples demonstrate:

- Attempting to insert a value into a `JSON` column succeeds if the value is a valid JSON value, but fails if it is not:

```
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)

mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.
```

Positions for “at position *N*” in such error messages are 0-based, but should be considered rough indications of where the problem in a value actually occurs.

- The `JSON_TYPE()` function expects a JSON argument and attempts to parse it into a JSON value. It returns the value's JSON type if it is valid and produces an error otherwise:

```
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+-----+
| JSON_TYPE('["a", "b", 1]') |
+-----+
| ARRAY                        |
+-----+

mysql> SELECT JSON_TYPE('hello');
+-----+
| JSON_TYPE('hello')          |
+-----+
| STRING                      |
+-----+

mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

MySQL handles strings used in JSON context using the `utf8mb4` character set and `utf8mb4_bin` collation. Strings in other character sets are converted to `utf8mb4` as necessary. (For strings in the `ascii` or `utf8` character sets, no conversion is needed because `ascii` and `utf8` are subsets of `utf8mb4`.)

As an alternative to writing JSON values using literal strings, functions exist for composing JSON values from component elements. `JSON_ARRAY()` takes a (possibly empty) list of values and returns a JSON array containing those values:

```
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+-----+
| JSON_ARRAY('a', 1, NOW()) |
+-----+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+-----+
```

`JSON_OBJECT()` takes a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+-----+
| {"key1": 1, "key2": "abc"}           |
+-----+
```

`JSON_MERGE_PRESERVE()` takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}');
+-----+
| JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}') |
+-----+
| ["a", 1, {"key": "value"}]                          |
+-----+
1 row in set (0.00 sec)
```

For information about the merging rules, see [Normalization, Merging, and Autowrapping of JSON Values](#).

(MySQL 8.0.3 and later also support `JSON_MERGE_PATCH()`, which has somewhat different behavior. See [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#), for information about the differences between these two functions.)

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+-----+
| @j      |
+-----+
| {"key": "value"} |
+-----+
```

However, user-defined variables cannot be of `JSON` data type, so although `@j` in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does *not* have the `JSON` data type. Instead, the result from `JSON_OBJECT()` is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of `utf8mb4` and a collation of `utf8mb4_bin`:

```
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-----+-----+
| CHARSET(@j) | COLLATION(@j) |
+-----+-----+
| utf8mb4     | utf8mb4_bin   |
+-----+-----+
```

Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive.

```
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
+-----+
| 0 |
+-----+
```

Case sensitivity also applies to the JSON `null`, `true`, and `false` literals, which always must be written in lowercase:

```
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+-----+-----+-----+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+-----+-----+-----+
| 1 | 0 | 0 |
+-----+-----+-----+

mysql> SELECT CAST('null' AS JSON);
+-----+
| CAST('null' AS JSON) |
+-----+
| null |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.
```

Case sensitivity of the JSON literals differs from that of the SQL `NULL`, `TRUE`, and `FALSE` literals, which can be written in any lettercase:

```
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+-----+-----+-----+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
```

Sometimes it may be necessary or desirable to insert quote characters (" or ') into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

```
mascot: The MySQL mascot is a dolphin named "Sakila".
```

One way to insert this as a JSON object into the `facts` table is to use the MySQL `JSON_OBJECT()` function. In this case, you must escape each quote character using a backslash, as shown here:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\"."));
```

This does not work in the same way if you insert the value as a JSON object literal, in which case, you must use the double backslash escape sequence, like this:

```
mysql> INSERT INTO facts VALUES
```

```
> ('{"mascot": "Our mascot is a dolphin named \\"Sakila\\"."}');
```

Using the double backslash keeps MySQL from performing escape sequence processing, and instead causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in either of the ways just shown, you can see that the backslashes are present in the JSON column value by doing a simple `SELECT`, like this:

```
mysql> SELECT sentence FROM facts;
+-----+
| sentence |
+-----+
| {"mascot": "Our mascot is a dolphin named \"Sakila\".\"} |
+-----+
```

To look up this particular sentence employing `mascot` as the key, you can use the column-path operator `->`, as shown here:

```
mysql> SELECT col->"$.mascot" FROM qtest;
+-----+
| col->"$.mascot" |
+-----+
| "Our mascot is a dolphin named \"Sakila\".\" |
+-----+
1 row in set (0.00 sec)
```

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value using `mascot` as the key, but without including the surrounding quote marks or any escapes, use the inline path operator `->>`, like this:

```
mysql> SELECT sentence->>"$.mascot" FROM facts;
+-----+
| sentence->>"$.mascot" |
+-----+
| Our mascot is a dolphin named "Sakila". |
+-----+
```

Note

The previous example does not work as shown if the `NO_BACKSLASH_ESCAPES` server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the `JSON_OBJECT()` function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
```

See the description of the `JSON_UNQUOTE()` function for more information about the effects of this mode on escaped characters in JSON values.

Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized. This means that members with keys that duplicate a key found later in the document, reading from left to right, are discarded. The object value produced by the following `JSON_OBJECT()` call includes only the second `key1` element because that key name occurs earlier in the value, as shown here:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": "def", "key2": "abc"} |
+-----+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
>     ('{"x": 17, "x": "red"}'),
>     ('{"x": 17, "x": "red", "x": [3, 5, 7]}');

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| {"x": "red"} |
| {"x": [3, 5, 7]} |
+-----+
```

This “last duplicate key wins” behavior is suggested by [RFC 7159](#) and is implemented by most JavaScript parsers. (Bug #86866, Bug #26369555)

In versions of MySQL prior to 8.0.3, members with keys that duplicated a key found earlier in the document were discarded. The object value produced by the following `JSON_OBJECT()` call does not include the second `key1` element because that key name occurs earlier in the value:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": 1, "key2": "abc"} |
+-----+
```

Prior to MySQL 8.0.3, this “first duplicate key wins” normalization was also performed when inserting values into JSON columns.

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
>     ('{"x": 17, "x": "red"}'),
>     ('{"x": 17, "x": "red", "x": [3, 5, 7]}');

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| {"x": 17} |
| {"x": 17} |
+-----+
```

MySQL also discards extra whitespace between keys, values, or elements in the original JSON document. To make lookups more efficient, it also sorts the keys of a JSON object. *You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.*

MySQL functions that produce JSON values (see [Section 12.16.2, “Functions That Create JSON Values”](#)) always return normalized values.

Merging JSON Values

Two merging algorithms are supported in MySQL 8.0.3 (and later), implemented by the functions `JSON_MERGE_PRESERVE()` and `JSON_MERGE_PATCH()`. These differ in how they handle duplicate keys: `JSON_MERGE_PRESERVE()` retains values for duplicate keys, while `JSON_MERGE_PATCH()` discards all but the last value. The next few paragraphs explain how each of these two functions handles the merging of different combinations of JSON documents (that is, of objects and arrays).

Note

`JSON_MERGE_PRESERVE()` is the same as the `JSON_MERGE()` function found in previous versions of MySQL (renamed in MySQL 8.0.3). `JSON_MERGE()` is still supported as an alias for `JSON_MERGE_PRESERVE()` in MySQL 8.0, but is deprecated and subject to removal in a future release.

Merging arrays. In contexts that combine multiple arrays, the arrays are merged into a single array. `JSON_MERGE_PRESERVE()` does this by concatenating arrays named later to the end of the first array. `JSON_MERGE_PATCH()` considers each argument as an array consisting of a single element (thus having 0 as its index) and then applies “last duplicate key wins” logic to select only the last argument. You can compare the results shown by this query:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Preserve,
->   JSON_MERGE_PATCH('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Patch\G
***** 1. row *****
Preserve: [1, 2, "a", "b", "c", true, false]
Patch: [true, false]
```

Multiple objects when merged produce a single object. `JSON_MERGE_PRESERVE()` handles multiple objects having the same key by combining all unique values for that key in an array; this array is then used as the value for that key in the result. `JSON_MERGE_PATCH()` discards values for which duplicate keys are found, working from left to right, so that the result contains only the last value for that key. The following query illustrates the difference in the results for the duplicate key `a`:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('{ "a": 1, "b": 2}', '{ "c": 3, "a": 4}', '{ "c": 5, "d": 3}') AS Preserve,
->   JSON_MERGE_PATCH('{ "a": 3, "b": 2}', '{ "c": 3, "a": 4}', '{ "c": 5, "d": 3}') AS Patch\G
***** 1. row *****
Preserve: { "a": [1, 4], "b": 2, "c": [3, 5], "d": 3}
Patch: { "a": 4, "b": 2, "c": 5, "d": 3}
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by `[` and `]` characters to convert it to an array. In the following statement, each argument is autowrapped as an array (`[1]`, `[2]`). These are then merged to produce a single result array; as in the previous two cases, `JSON_MERGE_PRESERVE()` combines values having the same key while `JSON_MERGE_PATCH()` discards values for all duplicate keys except the last, as shown here:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('1', '2') AS Preserve,
->   JSON_MERGE_PATCH('1', '2') AS Patch\G
***** 1. row *****
Preserve: [1, 2]
Patch: 2
```

Array and object values are merged by autowrapping the object as an array and merging the arrays by combining values or by “last duplicate key wins” according to the choice of merging function (`JSON_MERGE_PRESERVE()` or `JSON_MERGE_PATCH()`, respectively), as can be seen in this example:

```
mysql> SELECT
->     JSON_MERGE_PRESERVE('[10, 20]', '{"a": "x", "b": "y"}') AS Preserve,
->     JSON_MERGE_PATCH('[10, 20]', '{"a": "x", "b": "y"}') AS Patch\G
***** 1. row *****
Preserve: [10, 20, {"a": "x", "b": "y"}]
Patch: {"a": "x", "b": "y"}
```

Searching and Modifying JSON Values

A JSON path expression selects a value within a JSON document.

Path expressions are useful with functions that extract parts of or modify a JSON document, to specify where within that document to operate. For example, the following query extracts from a JSON document the value of the member with the `name` key:

```
mysql> SELECT JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name');
+-----+
| JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name') |
+-----+
| "Aztalan" |
+-----+
```

Path syntax uses a leading `$` character to represent the JSON document under consideration, optionally followed by selectors that indicate successively more specific parts of the document:

- A period followed by a key name names the member in an object with the given key. The key name must be specified within double quotation marks if the name without quotes is not legal within path expressions (for example, if it contains a space).
- `[N]` appended to a `path` that selects an array names the value at position `N` within the array. Array positions are integers beginning with zero. If `path` does not select an array value, `path[0]` evaluates to the same value as `path`:

```
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+-----+
| JSON_SET('"x"', '$[0]', 'a') |
+-----+
| "a" |
+-----+
1 row in set (0.00 sec)
```

- `[M to N]` specifies a subset or range of array values starting with the value at position `M`, and ending with the value at position `N`.

`last` is supported as a synonym for the index of the rightmost array element. Relative addressing of array elements is also supported. If `path` does not select an array value, `path[last]` evaluates to the same value as `path`, as shown later in this section (see [Rightmost array element](#)).

- Paths can contain `*` or `**` wildcards:
 - `[*]` evaluates to the values of all members in a JSON object.
 - `[*]` evaluates to the values of all elements in a JSON array.
 - `prefix**suffix` evaluates to all paths that begin with the named prefix and end with the named suffix.
- A path that does not exist in the document (evaluates to nonexistent data) evaluates to `NULL`.

Let `$` refer to this JSON array with three elements:

```
[3, {"a": [5, 6], "b": 10}, [99, 100]]
```

Then:

- `$.[0]` evaluates to `3`.
- `$.[1]` evaluates to `{"a": [5, 6], "b": 10}`.
- `$.[2]` evaluates to `[99, 100]`.
- `$.[3]` evaluates to `NULL` (it refers to the fourth array element, which does not exist).

Because `$.[1]` and `$.[2]` evaluate to nonscalar values, they can be used as the basis for more-specific path expressions that select nested values. Examples:

- `$.[1].a` evaluates to `[5, 6]`.
- `$.[1].a[1]` evaluates to `6`.
- `$.[1].b` evaluates to `10`.
- `$.[2][0]` evaluates to `99`.

As mentioned previously, path components that name keys must be quoted if the unquoted key name is not legal in path expressions. Let `$` refer to this value:

```
{"a fish": "shark", "a bird": "sparrow"}
```

The keys both contain a space and must be quoted:

- `$. "a fish"` evaluates to `shark`.
- `$. "a bird"` evaluates to `sparrow`.

Paths that use wildcards evaluate to an array that can contain multiple values:

```
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*') |
+-----+
| [1, 2, [3, 4, 5]] |
+-----+
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.c[*]');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.c[*]') |
+-----+
| [3, 4, 5] |
+-----+
```

In the following example, the path `$.**.b` evaluates to multiple paths (`$.a.b` and `$.c.b`) and produces an array of the matching path values:

```
mysql> SELECT JSON_EXTRACT('{ "a": { "b": 1 }, "c": { "b": 2 } }', '$**.b');
+-----+
| JSON_EXTRACT('{ "a": { "b": 1 }, "c": { "b": 2 } }', '$**.b') |
+-----+
```

```
| [1, 2] |
+-----+
```

Ranges from arrays. You can use ranges with the `to` keyword to specify subsets of JSON arrays. For example, `$$[1 to 3]` includes the second, third, and fourth elements of an array, as shown here:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.00 sec)
```

The syntax is `M to N`, where `M` and `N` are, respectively, the first and last indexes of a range of elements from a JSON array. `N` must be greater than `M`; `M` must be greater than or equal to 0. Array elements are indexed beginning with 0.

You can use ranges in contexts where wildcards are supported.

Rightmost array element. The `last` keyword is supported as a synonym for the index of the last element in an array. Expressions of the form `last - N` can be used for relative addressing, and within range definitions, like this:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.01 sec)
```

If the path is evaluated against a value that is not an array, the result of the evaluation is the same as if the value had been wrapped in a single-element array:

```
mysql> SELECT JSON_REPLACE('"Sakila"', '$[last]', 10);
+-----+
| JSON_REPLACE('"Sakila"', '$[last]', 10) |
+-----+
| 10 |
+-----+
1 row in set (0.00 sec)
```

You can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See [Section 12.16.3, “Functions That Search JSON Values”](#), for more information. See also [Indexing a Generated Column to Provide a JSON Column Index](#).

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path-value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexistent values within the document.

Consider this document:

```
mysql> SET @j = '{"a", {"b": [true, false]}, [10, 20]}';
```

`JSON_SET()` replaces values for paths that exist and adds values for paths that do not exist.

```
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a": {"b": [1, false]}, [10, 20, 2]}] |
+-----+
```

In this case, the path `$(1).b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (`1`). The path `$(2)[2]` does not exist, so the corresponding value (`2`) is added to the value selected by `$(2)`.

`JSON_INSERT()` adds new values but does not replace existing values:

```
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a": {"b": [true, false]}, [10, 20, 2]}] |
+-----+
```

`JSON_REPLACE()` replaces existing values and ignores new values:

```
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a": {"b": [1, false]}, [10, 20]}] |
+-----+
```

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

`JSON_REMOVE()` takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
+-----+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+-----+
| [{"a": {"b": [true]}]} |
+-----+
```

The paths have these effects:

- `$(2)` matches `[10, 20]` and removes it.
- The first instance of `$(1).b[1]` matches `false` in the `b` element and removes it.
- The second instance of `$(1).b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

Comparison and Ordering of JSON Values

JSON values can be compared using the `=`, `<`, `<=`, `>`, `>=`, `<>`, `!=`, and `<=>` operators.

The following comparison operators and functions are not yet supported with JSON values:

- `BETWEEN`
- `IN()`
- `GREATEST()`
- `LEAST()`

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the `JSON_TYPE()` function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

```
BLOB
BIT
OPAQUE
DATETIME
TIME
DATE
BOOLEAN
ARRAY
OBJECT
STRING
INTEGER, DOUBLE
NULL
```

For JSON values of the same precedence, the comparison rules are type specific:

- `BLOB`

The first `N` bytes of the two values are compared, where `N` is the number of bytes in the shorter value. If the first `N` bytes of the two values are identical, the shorter value is ordered before the longer value.

- `BIT`

Same rules as for `BLOB`.

- `OPAQUE`

Same rules as for `BLOB`. `OPAQUE` values are values that are not classified as one of the other types.

- `DATETIME`

A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL `DATETIME` and `TIMESTAMP` types, respectively, they are equal if they represent the same point in time.

- `TIME`

The smaller of two time values is ordered before the larger one.

- `DATE`

The earlier date is ordered before the more recent date.

- [ARRAY](#)

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

```
[ ] < [ "a" ] < [ "ab" ] < [ "ab", "cd", "ef" ] < [ "ab", "ef" ]
```

- [BOOLEAN](#)

The JSON false literal is less than the JSON true literal.

- [OBJECT](#)

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

```
{ "a": 1, "b": 2 } = { "b": 2, "a": 1 }
```

The order of two objects that are not equal is unspecified but deterministic.

- [STRING](#)

Strings are ordered lexically on the first *N* bytes of the [utf8mb4](#) representation of the two strings being compared, where *N* is the length of the shorter string. If the first *N* bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

```
"a" < "ab" < "b" < "bc"
```

This ordering is equivalent to the ordering of SQL strings with collation [utf8mb4_bin](#). Because [utf8mb4_bin](#) is a binary collation, comparison of JSON values is case-sensitive:

```
"A" < "a"
```

- [INTEGER](#), [DOUBLE](#)

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see [Section 9.1.2, “Numeric Literals”](#).

The rules for comparing native MySQL numeric types are discussed in [Section 12.2, “Type Conversion in Expression Evaluation”](#), but the rules for comparing numbers within JSON values differ somewhat:

- In a comparison between two columns that use the native MySQL [INT](#) and [DOUBLE](#) numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is

converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.

- On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers will be integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
< 9.223372036854776e18 = 9223372036854776000 < 9223372036854776001
```

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
```

(not defined for 9.223372036854776e18)

- Double comparison:

```
9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
```

For comparison of any JSON value to SQL `NULL`, the result is `UNKNOWN`.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

Table 11.3 JSON Conversion Rules

other type	CAST(other type AS JSON)	CAST(JSON AS other type)
JSON	No change	No change
utf8 character type (<code>utf8mb4</code> , <code>utf8</code> , <code>ascii</code>)	The string is parsed into a JSON value.	The JSON value is serialized into a <code>utf8mb4</code> string.
Other character types	Other character encodings are implicitly converted to <code>utf8mb4</code> and treated as described for utf8 character type.	The JSON value is serialized into a <code>utf8mb4</code> string, then cast to the other character encoding. The result may not be meaningful.
<code>NULL</code>	Results in a <code>NULL</code> value of type JSON.	Not applicable.
Geometry types	The geometry value is converted into a JSON document by calling <code>ST_AsGeoJSON()</code> .	Illegal operation. Workaround: Pass the result of <code>CAST(json_val AS CHAR)</code> to <code>ST_GeomFromGeoJSON()</code> .
All other types	Results in a JSON document consisting of a single scalar value.	Succeeds if the JSON document consists of a single scalar value of the target type

other type	CAST(other type AS JSON)	CAST(JSON AS other type)
		and that scalar value can be cast to the target type. Otherwise, returns <code>NULL</code> and produces a warning.

`ORDER BY` and `GROUP BY` for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL `NULL` orders before all JSON values, including the JSON null literal; for descending sorts, SQL `NULL` orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the `max_sort_length` system variable, so keys that differ only after the first `max_sort_length` bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the `ORDER BY`, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See [Section 8.3.11, “Optimizer Use of Generated Column Indexes”](#).

Aggregation of JSON Values

For aggregation of JSON values, SQL `NULL` values are ignored as for other data types. Non-`NULL` values are converted to a numeric type and aggregated, except for `MIN()`, `MAX()`, and `GROUP_CONCAT()`.

The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

11.7 Data Type Default Values

Data type specifications can have explicit or implicit default values.

A `DEFAULT value` clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 (
  i      INT DEFAULT -1,
  c      VARCHAR(10) DEFAULT '',
  price DOUBLE(16,2) DEFAULT 0.00
);
```

`SERIAL DEFAULT VALUE` is a special case. In the definition of an integer column, it is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Some aspects of explicit `DEFAULT` clause handling are version dependent, as described following.

- [Handling of Explicit Defaults as of MySQL 8.0.13](#)
- [Handling of Explicit Defaults Prior to MySQL 8.0.13](#)

- [Handling of Implicit Defaults](#)

Handling of Explicit Defaults as of MySQL 8.0.13

The default value specified in a [DEFAULT](#) clause can be a literal constant or an expression. With one exception, enclose expression default values within parentheses to distinguish them from literal constant default values. Examples:

```
CREATE TABLE t1 (
  -- literal defaults
  i INT          DEFAULT 0,
  c VARCHAR(10) DEFAULT '',
  -- expression defaults
  f FLOAT        DEFAULT (RAND() * RAND()),
  b BINARY(16)   DEFAULT (UUID_TO_BIN(UUID())),
  d DATE         DEFAULT (CURRENT_DATE + INTERVAL 1 YEAR),
  p POINT        DEFAULT (Point(0,0)),
  j JSON         DEFAULT (JSON_ARRAY())
);
```

The exception is that, for [TIMESTAMP](#) and [DATETIME](#) columns, you can specify the [CURRENT_TIMESTAMP](#) function as the default, without enclosing parentheses. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

The [BLOB](#), [TEXT](#), [GEOMETRY](#), and [JSON](#) data types can be assigned a default value only if the value is written as an expression, even if the expression value is a literal:

- This is permitted (literal default specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT ('abc'));
```

- This produces an error (literal default not specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT 'abc');
```

Expression default values must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, built-in functions (both deterministic and nondeterministic), and operators are permitted.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- An expression default value cannot depend on a column that has the [AUTO_INCREMENT](#) attribute.
- An expression default value for one column can refer to other table columns, with the exception that references to generated columns or columns with expression default values must be to columns that occur earlier in the table definition. That is, expression default values cannot contain forward references to generated columns or columns with expression default values.

The ordering constraint also applies to the use of [ALTER TABLE](#) to reorder table columns. If the resulting table would have an expression default value that contains a forward reference to a generated column or column with an expression default value, the statement fails.

Note

If any component of an expression default value depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE` and `CREATE TABLE ... SELECT`, the destination table preserves expression default values from the original table.

If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT`, `UPDATE`, and `ALTER TABLE`.

When inserting a new row, the default value for a column with an expression default can be inserted either by omitting the column name or by specifying the column as `DEFAULT` (just as for columns with literal defaults):

```
mysql> CREATE TABLE t4 (uid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())));
mysql> INSERT INTO t4 () VALUES();
mysql> INSERT INTO t4 () VALUES(DEFAULT);
mysql> SELECT BIN_TO_UUID(uid) AS uid FROM t4;
+-----+
| uid                                     |
+-----+
| f1109174-94c9-11e8-971d-3bf1095aa633 |
| f110cf9a-94c9-11e8-971d-3bf1095aa633 |
+-----+
```

However, the use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

Not all storage engines permit expression default values. For those that do not, an `ER_UNSUPPORTED_ACTION_ON_DEFAULT_VAL_GENERATED` error occurs.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

Handling of Explicit Defaults Prior to MySQL 8.0.13

With one exception, the default value specified in a `DEFAULT` clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify `CURRENT_TIMESTAMP` as the default. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types cannot be assigned a default value.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

Handling of Implicit Defaults

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause. Exception: If the column is defined as part of a `PRIMARY KEY` but not explicitly as `NOT NULL`, MySQL creates it as a `NOT NULL` column (because `PRIMARY KEY` columns must be `NOT NULL`).

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();  
INSERT INTO t VALUES(DEFAULT);  
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 5.1.10, “Server SQL Modes”](#).

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see [Section 5.1.7, “Server System Variables”](#)). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 11.3, “Date and Time Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

11.8 Data Type Storage Requirements

- [InnoDB Table Storage Requirements](#)
- [Numeric Type Storage Requirements](#)
- [Date and Time Type Storage Requirements](#)
- [String Type Storage Requirements](#)
- [Spatial Type Storage Requirements](#)
- [JSON Storage Requirements](#)

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes [BLOB](#) or [TEXT](#) columns, which contribute only 9 to 12 bytes toward this size. For [BLOB](#) and [TEXT](#) data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see [Chapter 16, *Alternative Storage Engines*](#), and [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

InnoDB Table Storage Requirements

See [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#) for information about storage requirements for [InnoDB](#) tables.

Numeric Type Storage Requirements

Data Type	Storage Required
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT , INTEGER	4 bytes
BIGINT	8 bytes
FLOAT(<i>p</i>)	4 bytes if $0 \leq p \leq 24$, 8 bytes if $25 \leq p \leq 53$
FLOAT	4 bytes
DOUBLE [PRECISION] , REAL	8 bytes
DECIMAL(<i>M</i>,<i>D</i>) , NUMERIC(<i>M</i>,<i>D</i>)	Varies; see following discussion
BIT(<i>M</i>)	approximately $(M+7)/8$ bytes

Values for [DECIMAL](#) (and [NUMERIC](#)) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2

Leftover Digits	Number of Bytes
4	2
5	3
6	3
7	4
8	4

Date and Time Type Storage Requirements

For [TIME](#), [DATETIME](#), and [TIMESTAMP](#) columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

Data Type	Storage Required Before MySQL 5.6.4	Storage Required as of MySQL 5.6.4
YEAR	1 byte	1 byte
DATE	3 bytes	3 bytes
TIME	3 bytes	3 bytes + fractional seconds storage
DATETIME	8 bytes	5 bytes + fractional seconds storage
TIMESTAMP	4 bytes	4 bytes + fractional seconds storage

As of MySQL 5.6.4, storage for [YEAR](#) and [DATE](#) remains unchanged. However, [TIME](#), [DATETIME](#), and [TIMESTAMP](#) are represented differently. [DATETIME](#) is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

Fractional Seconds Precision	Storage Required
0	0 bytes
1, 2	1 byte
3, 4	2 bytes
5, 6	3 bytes

For example, [TIME\(0\)](#), [TIME\(2\)](#), [TIME\(4\)](#), and [TIME\(6\)](#) use 3, 4, 5, and 6 bytes, respectively. [TIME](#) and [TIME\(0\)](#) are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

String Type Storage Requirements

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
CHAR(M)	The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Characteristics . Otherwise, $M \times w$ bytes, $\leq M \leq 255$, where <i>w</i> is the number of bytes required for the maximum-length character in the character set.

Data Type	Storage Required
<code>BINARY(M)</code>	M bytes, $0 \leq M \leq 255$
<code>VARCHAR(M)</code> , <code>VARBINARY(M)</code>	$L + 1$ bytes if column values require 0 – 255 bytes, $L + 2$ bytes if values may require more than 255 bytes
<code>TINYBLOB</code> , <code>TINYTEXT</code>	$L + 1$ bytes, where $L < 2^8$
<code>BLOB</code> , <code>TEXT</code>	$L + 2$ bytes, where $L < 2^{16}$
<code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>	$L + 3$ bytes, where $L < 2^{24}$
<code>LONGBLOB</code> , <code>LONGTEXT</code>	$L + 4$ bytes, where $L < 2^{32}$
<code>ENUM('value1', 'value2', ...)</code>	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
<code>SET('value1', 'value2', ...)</code>	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is L (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires L bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a `utf8` Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see [Section 10.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (L), plus one byte to record the length of the string. For the string `'abcd'`, L is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of *characters* is less. For example, `utf8mb4` characters can require up to four bytes per character, so a `VARCHAR` column that uses the `utf8mb4` character set can be declared to be a maximum of 16,383 characters. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The size of an [ENUM](#) object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 11.4.4, “The ENUM Type”](#).

The size of a [SET](#) object is determined by the number of different set members. If the set size is N , the object occupies $(N+7)/8$ bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A [SET](#) can have a maximum of 64 members. See [Section 11.4.5, “The SET Type”](#).

Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The [LENGTH\(\)](#) function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see [Section 11.5.3, “Supported Spatial Data Formats”](#).

JSON Storage Requirements

In general, the storage requirement for a [JSON](#) column is approximately the same as for a [LONGBLOB](#) or [LONGTEXT](#) column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a [JSON](#) column such that it cannot be any larger than the value of [max_allowed_packet](#).

11.9 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, [MEDIUMINT UNSIGNED](#) is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, −, *, and /) with [DECIMAL](#) columns are done with precision of 65 decimal (base 10) digits. See [Section 11.1.1, “Numeric Type Overview”](#).

If accuracy is not too important or if speed is the highest priority, the [DOUBLE](#) type may be good enough. For high precision, you can always convert to a fixed-point type stored in a [BIGINT](#). This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

11.10 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
BOOL	TINYINT
BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR(M)

Other Vendor Type	MySQL Type
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	tinyint(1)	YES		NULL	
b	double	YES		NULL	
c	mediumtext	YES		NULL	
d	decimal(10,0)	YES		NULL	

```
4 rows in set (0.01 sec)
```

Chapter 12 Functions and Operators

Table of Contents

12.1 Function and Operator Reference	1711
12.2 Type Conversion in Expression Evaluation	1723
12.3 Operators	1726
12.3.1 Operator Precedence	1727
12.3.2 Comparison Functions and Operators	1728
12.3.3 Logical Operators	1735
12.3.4 Assignment Operators	1737
12.4 Control Flow Functions	1738
12.5 String Functions	1741
12.5.1 String Comparison Functions	1757
12.5.2 Regular Expressions	1760
12.5.3 Character Set and Collation of Function Results	1770
12.6 Numeric Functions and Operators	1771
12.6.1 Arithmetic Operators	1772
12.6.2 Mathematical Functions	1774
12.7 Date and Time Functions	1783
12.8 What Calendar Is Used By MySQL?	1807
12.9 Full-Text Search Functions	1807
12.9.1 Natural Language Full-Text Searches	1808
12.9.2 Boolean Full-Text Searches	1812
12.9.3 Full-Text Searches with Query Expansion	1817
12.9.4 Full-Text Stopwords	1818
12.9.5 Full-Text Restrictions	1823
12.9.6 Fine-Tuning MySQL Full-Text Search	1824
12.9.7 Adding a Collation for Full-Text Indexing	1827
12.9.8 ngram Full-Text Parser	1828
12.9.9 MeCab Full-Text Parser Plugin	1831
12.10 Cast Functions and Operators	1835
12.11 XML Functions	1841
12.12 Bit Functions and Operators	1853
12.13 Encryption and Compression Functions	1865
12.14 Information Functions	1872
12.15 Spatial Analysis Functions	1883
12.15.1 Spatial Function Reference	1883
12.15.2 Argument Handling by Spatial Functions	1886
12.15.3 Functions That Create Geometry Values from WKT Values	1886
12.15.4 Functions That Create Geometry Values from WKB Values	1889
12.15.5 MySQL-Specific Functions That Create Geometry Values	1890
12.15.6 Geometry Format Conversion Functions	1892
12.15.7 Geometry Property Functions	1894
12.15.8 Spatial Operator Functions	1906
12.15.9 Functions That Test Spatial Relations Between Geometry Objects	1910
12.15.10 Spatial Geohash Functions	1916
12.15.11 Spatial GeoJSON Functions	1918
12.15.12 Spatial Convenience Functions	1920
12.16 JSON Functions	1924
12.16.1 JSON Function Reference	1924
12.16.2 Functions That Create JSON Values	1925

12.16.3 Functions That Search JSON Values	1926
12.16.4 Functions That Modify JSON Values	1936
12.16.5 Functions That Return JSON Value Attributes	1945
12.16.6 JSON Table Functions	1948
12.16.7 JSON Utility Functions	1952
12.16.8 JSON Path Syntax	1958
12.17 Functions Used with Global Transaction Identifiers (GTIDs)	1959
12.18 MySQL Enterprise Encryption Functions	1962
12.18.1 MySQL Enterprise Encryption Installation	1962
12.18.2 MySQL Enterprise Encryption Usage and Examples	1963
12.18.3 MySQL Enterprise Encryption Function Reference	1965
12.18.4 MySQL Enterprise Encryption Function Descriptions	1965
12.19 Aggregate (GROUP BY) Functions	1969
12.19.1 Aggregate (GROUP BY) Function Descriptions	1969
12.19.2 GROUP BY Modifiers	1978
12.19.3 MySQL Handling of GROUP BY	1985
12.19.4 Detection of Functional Dependence	1988
12.20 Window Functions	1991
12.20.1 Window Function Descriptions	1991
12.20.2 Window Function Concepts and Syntax	1997
12.20.3 Window Function Frame Specification	2001
12.20.4 Named Windows	2005
12.20.5 Window Function Restrictions	2006
12.21 Internal Functions	2006
12.22 Miscellaneous Functions	2008
12.23 Precision Math	2025
12.23.1 Types of Numeric Values	2026
12.23.2 DECIMAL Data Type Characteristics	2026
12.23.3 Expression Handling	2027
12.23.4 Rounding Behavior	2029
12.23.5 Precision Math Examples	2030

Expressions can be used at several points in [SQL](#) statements, such as in the [ORDER BY](#) or [HAVING](#) clauses of [SELECT](#) statements, in the [WHERE](#) clause of a [SELECT](#), [DELETE](#), or [UPDATE](#) statement, or in [SET](#) statements. Expressions can be written using literal values, column values, [NULL](#), built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 23.2](#), “Using Stored Routines (Procedures and Functions)”, and [Section 28.4](#), “Adding New Functions to MySQL”. See [Section 9.2.4](#), “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains [NULL](#) always produces a [NULL](#) value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See [Section 5.1.10](#), “Server SQL Modes”.) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|          2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

12.1 Function and Operator Reference

Table 12.1 Functions and Operators

Name	Description
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ADDDATE()</code>	Add time values (intervals) to a date value
<code>ADDTIME()</code>	Add time
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>AND, &&</code>	Logical AND
<code>ANY_VALUE()</code>	Suppress <code>ONLY_FULL_GROUP_BY</code> value rejection
<code>ASCII()</code>	Return numeric value of left-most character
<code>ASIN()</code>	Return the arc sine
<code>=</code>	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)
<code>:=</code>	Assign a value
<code>ASYMMETRIC_DECRYPT()</code>	Decrypt ciphertext using private or public key
<code>ASYMMETRIC_DERIVE()</code>	Derive symmetric key from asymmetric keys
<code>ASYMMETRIC_ENCRYPT()</code>	Encrypt cleartext using private or public key
<code>ASYMMETRIC_SIGN()</code>	Generate signature from digest
<code>ASYMMETRIC_VERIFY()</code>	Verify that signature matches digest
<code>ATAN()</code>	Return the arc tangent
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>AVG()</code>	Return the average value of the argument
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>BETWEEN ... AND ...</code>	Check whether a value is within a range of values
<code>BIN()</code>	Return a string containing binary representation of a number
<code>BIN_TO_UUID()</code>	Convert binary UUID to string

Name	Description
<code>BINARY</code>	Cast a string to a binary string
<code>BIT_AND()</code>	Return bitwise AND
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code>BIT_LENGTH()</code>	Return length of argument in bits
<code>BIT_OR()</code>	Return bitwise OR
<code>BIT_XOR()</code>	Return bitwise XOR
<code>&</code>	Bitwise AND
<code>~</code>	Bitwise inversion
<code> </code>	Bitwise OR
<code>^</code>	Bitwise XOR
<code>CAN_ACCESS_COLUMN()</code>	Internal use only
<code>CAN_ACCESS_DATABASE()</code>	Internal use only
<code>CAN_ACCESS_TABLE()</code>	Internal use only
<code>CAN_ACCESS_VIEW()</code>	Internal use only
<code>CASE</code>	Case operator
<code>CAST()</code>	Cast a value as a certain type
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CHAR()</code>	Return the character for each integer passed
<code>CHAR_LENGTH()</code>	Return number of characters in argument
<code>CHARACTER_LENGTH()</code>	Synonym for <code>CHAR_LENGTH()</code>
<code>CHARSET()</code>	Return the character set of the argument
<code>COALESCE()</code>	Return the first non-NULL argument
<code>COERCIBILITY()</code>	Return the collation coercibility value of the string argument
<code>COLLATION()</code>	Return the collation of the string argument
<code>COMPRESS()</code>	Return result as a binary string
<code>CONCAT()</code>	Return concatenated string
<code>CONCAT_WS()</code>	Return concatenate with separator
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CONV()</code>	Convert numbers between different number bases
<code>CONVERT()</code>	Cast a value as a certain type
<code>CONVERT_TZ()</code>	Convert from one time zone to another
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent
<code>COUNT()</code>	Return a count of the number of rows returned
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>CRC32()</code>	Compute a cyclic redundancy check value
<code>CREATEASYMMETRICPRIVKEY()</code>	Create private key

Name	Description
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	Create public key
<code>CREATE_DH_PARAMETERS()</code>	Generate shared DH secret
<code>CREATE_DIGEST()</code>	Generate digest from string
<code>CUME_DIST()</code>	Cumulative distribution value
<code>CURDATE()</code>	Return the current date
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_ROLE()</code>	Returns the current active roles
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name
<code>CURTIME()</code>	Return the current time
<code>DATABASE()</code>	Return the default (current) database name
<code>DATE()</code>	Extract the date part of a date or datetime expression
<code>DATE_ADD()</code>	Add time values (intervals) to a date value
<code>DATE_FORMAT()</code>	Format date as specified
<code>DATE_SUB()</code>	Subtract a time value (interval) from a date
<code>DATEDIFF()</code>	Subtract two dates
<code>DAY()</code>	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code>	Return the name of the weekday
<code>DAYOFMONTH()</code>	Return the day of the month (0-31)
<code>DAYOFWEEK()</code>	Return the weekday index of the argument
<code>DAYOFYEAR()</code>	Return the day of the year (1-366)
<code>DECODE()</code>	Decodes a string encrypted using <code>ENCODE()</code>
<code>DEFAULT()</code>	Return the default value for a table column
<code>DEGREES()</code>	Convert radians to degrees
<code>DENSE_RANK()</code>	Rank of current row within its partition, without gaps
<code>DES_DECRYPT()</code>	Decrypt a string
<code>DES_ENCRYPT()</code>	Encrypt a string
<code>DIV</code>	Integer division
<code>/</code>	Division operator
<code>ELT()</code>	Return string at index number
<code>ENCODE()</code>	Encode a string
<code>ENCRYPT()</code>	Encrypt a string
<code>=</code>	Equal operator
<code><=></code>	NULL-safe equal to operator
<code>EXP()</code>	Raise to the power of

Name	Description
<code>EXPORT_SET()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>EXTRACT()</code>	Extract part of a date
<code>ExtractValue()</code>	Extracts a value from an XML string using XPath notation
<code>FIELD()</code>	Return the index (position) of the first argument in the subsequent arguments
<code>FIND_IN_SET()</code>	Return the index position of the first argument within the second argument
<code>FIRST_VALUE()</code>	Value of argument from first row of window frame
<code>FLOOR()</code>	Return the largest integer value not greater than the argument
<code>FORMAT()</code>	Return a number formatted to specified number of decimal places
<code>FOUND_ROWS()</code>	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
<code>FROM_BASE64()</code>	Decode base64 encoded string and return result
<code>FROM_DAYS()</code>	Convert a day number to a date
<code>FROM_UNIXTIME()</code>	Format Unix timestamp as a date
<code>GeomCollection()</code>	Construct geometry collection from geometries
<code>GeometryCollection()</code>	Construct geometry collection from geometries
<code>GET_DD_COLUMN_PRIVILEGES()</code>	Internal use only
<code>GET_DD_CREATE_OPTIONS()</code>	Internal use only
<code>GET_DD_INDEX_SUB_PART_LENGTH()</code>	Internal use only
<code>GET_FORMAT()</code>	Return a date format string
<code>GET_LOCK()</code>	Get a named lock
<code>></code>	Greater than operator
<code>>=</code>	Greater than or equal operator
<code>GREATEST()</code>	Return the largest argument
<code>GROUP_CONCAT()</code>	Return a concatenated string
<code>GROUPING()</code>	Distinguish super-aggregate ROLLUP rows from regular rows
<code>GTID_SUBSET()</code>	Return true if all GTIDs in subset are also in set; otherwise false.
<code>GTID_SUBTRACT()</code>	Return all GTIDs in set that are not in subset.
<code>HEX()</code>	Return a hexadecimal representation of a decimal or string value
<code>HOUR()</code>	Extract the hour
<code>ICU_VERSION()</code>	ICU library version
<code>IF()</code>	If/else construct
<code>IFNULL()</code>	Null if/else construct
<code>IN()</code>	Check whether a value is within a set of values
<code>INET_ATON()</code>	Return the numeric value of an IP address

Name	Description
INET_NTOA()	Return the IP address from a numeric value
INET6_ATON()	Return the numeric value of an IPv6 address
INET6_NTOA()	Return the IPv6 address from a numeric value
INSERT()	Insert a substring at the specified position up to the specified number of characters
INSTR()	Return the index of the first occurrence of substring
INTERNAL_AUTO_INCREMENT()	Internal use only
INTERNAL_AVG_ROW_LENGTH()	Internal use only
INTERNAL_CHECK_TIME()	Internal use only
INTERNAL_CHECKSUM()	Internal use only
INTERNAL_DATA_FREE()	Internal use only
INTERNAL_DATA_LENGTH()	Internal use only
INTERNAL_DD_CHAR_LENGTH()	Internal use only
INTERNAL_GET_COMMENT_OR_ERROR()	Internal use only
INTERNAL_GET_VIEW_WARNING_OR_ERROR()	Internal use only
INTERNAL_INDEX_COLUMN_CARDINALITY()	Internal use only
INTERNAL_INDEX_LENGTH()	Internal use only
INTERNAL_KEYS_DISABLED()	Internal use only
INTERNAL_MAX_DATA_LENGTH()	Internal use only
INTERNAL_TABLE_ROWS()	Internal use only
INTERNAL_UPDATE_TIME()	Internal use only
INTERVAL()	Return the index of the argument that is less than the first argument
IS	Test a value against a boolean
IS_FREE_LOCK()	Whether the named lock is free
IS_IPV4()	Whether argument is an IPv4 address
IS_IPV4_COMPAT()	Whether argument is an IPv4-compatible address
IS_IPV4_MAPPED()	Whether argument is an IPv4-mapped address
IS_IPV6()	Whether argument is an IPv6 address
IS NOT	Test a value against a boolean
IS NOT NULL	NOT NULL value test
IS NULL	NULL value test
IS_USED_LOCK()	Whether the named lock is in use; return connection identifier if true
IS_UUID()	Whether argument is a valid UUID
ISNULL()	Test whether the argument is NULL
JSON_ARRAY()	Create JSON array
JSON_ARRAY_APPEND()	Append data to JSON document
JSON_ARRAY_INSERT()	Insert into JSON array

Name	Description
JSON_ARRAYAGG()	Return result set as a single JSON array
->	Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT() .
JSON_CONTAINS()	Whether JSON document contains specific object at path
JSON_CONTAINS_PATH()	Whether JSON document contains any data at path
JSON_DEPTH()	Maximum depth of JSON document
JSON_EXTRACT()	Return data from JSON document
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()) .
JSON_INSERT()	Insert data into JSON document
JSON_KEYS()	Array of keys from JSON document
JSON_LENGTH()	Number of elements in JSON document
JSON_MERGE() (deprecated 8.0.3)	Merge JSON documents, preserving duplicate keys. Deprecated synonym for JSON_MERGE_PRESERVE()
JSON_MERGE_PATCH()	Merge JSON documents, replacing values of duplicate keys
JSON_MERGE_PRESERVE()	Merge JSON documents, preserving duplicate keys
JSON_OBJECT()	Create JSON object
JSON_OBJECTAGG()	Return result set as a single JSON object
JSON_PRETTY()	Prints a JSON document in human-readable format, with each array element or object member printed on a new line, indented two spaces with respect to its parent.
JSON_QUOTE()	Quote JSON document
JSON_REMOVE()	Remove data from JSON document
JSON_REPLACE()	Replace values in JSON document
JSON_SEARCH()	Path to value within JSON document
JSON_SET()	Insert data into JSON document
JSON_STORAGE_FREE()	Freed space within binary representation of a JSON column value following a partial update
JSON_STORAGE_SIZE()	Space used for storage of binary representation of a JSON document; for a JSON column, the space used when the document was inserted, prior to any partial updates
JSON_TABLE()	Returns data from a JSON expression as a relational table
JSON_TYPE()	Type of JSON value
JSON_UNQUOTE()	Unquote JSON value
JSON_VALID()	Whether JSON value is valid
LAG()	Value of argument from row lagging current row within partition
LAST_DAY	Return the last day of the month for the argument
LAST_INSERT_ID()	Value of the AUTOINCREMENT column for the last INSERT
LAST_VALUE()	Value of argument from last row of window frame

Name	Description
<code>LCASE()</code>	Synonym for <code>LOWER()</code>
<code>LEAD()</code>	Value of argument from row leading current row within partition
<code>LEAST()</code>	Return the smallest argument
<code>LEFT()</code>	Return the leftmost number of characters as specified
<code><<</code>	Left shift
<code>LENGTH()</code>	Return the length of a string in bytes
<code><</code>	Less than operator
<code><=</code>	Less than or equal operator
<code>LIKE</code>	Simple pattern matching
<code>LineString()</code>	Construct <code>LineString</code> from <code>Point</code> values
<code>LN()</code>	Return the natural logarithm of the argument
<code>LOAD_FILE()</code>	Load the named file
<code>LOCALTIME()</code> , <code>LOCALTIME</code>	Synonym for <code>NOW()</code>
<code>LOCALTIMESTAMP()</code> , <code>LOCALTIMESTAMP()</code>	Synonym for <code>NOW()</code>
<code>LOCATE()</code>	Return the position of the first occurrence of substring
<code>LOG()</code>	Return the natural logarithm of the first argument
<code>LOG10()</code>	Return the base-10 logarithm of the argument
<code>LOG2()</code>	Return the base-2 logarithm of the argument
<code>LOWER()</code>	Return the argument in lowercase
<code>LPAD()</code>	Return the string argument, left-padded with the specified string
<code>LTRIM()</code>	Remove leading spaces
<code>MAKE_SET()</code>	Return a set of comma-separated strings that have the corresponding bit in bits set
<code>MAKEDATE()</code>	Create a date from the year and day of year
<code>MAKETIME()</code>	Create time from hour, minute, second
<code>MASTER_POS_WAIT()</code>	Block until the slave has read and applied all updates up to the specified position
<code>MATCH</code>	Perform full-text search
<code>MAX()</code>	Return the maximum value
<code>MBRContains()</code>	Whether MBR of one geometry contains MBR of another
<code>MBRCoveredBy()</code>	Whether one MBR is covered by another
<code>MBRCovers()</code>	Whether one MBR covers another
<code>MBRDisjoint()</code>	Whether MBRs of two geometries are disjoint
<code>MBREquals()</code>	Whether MBRs of two geometries are equal
<code>MBRIntersects()</code>	Whether MBRs of two geometries intersect
<code>MBROverlaps()</code>	Whether MBRs of two geometries overlap
<code>MBRTouches()</code>	Whether MBRs of two geometries touch

Name	Description
<code>MBRWithin()</code>	Whether MBR of one geometry is within MBR of another
<code>MD5()</code>	Calculate MD5 checksum
<code>MICROSECOND()</code>	Return the microseconds from argument
<code>MID()</code>	Return a substring starting from the specified position
<code>MIN()</code>	Return the minimum value
<code>-</code>	Minus operator
<code>MINUTE()</code>	Return the minute from the argument
<code>MOD()</code>	Return the remainder
<code>%, MOD</code>	Modulo operator
<code>MONTH()</code>	Return the month from the date passed
<code>MONTHNAME()</code>	Return the name of the month
<code>MultiLineString()</code>	Construct MultiLineString from LineString values
<code>MultiPoint()</code>	Construct MultiPoint from Point values
<code>MultiPolygon()</code>	Construct MultiPolygon from Polygon values
<code>NAME_CONST()</code>	Causes the column to have the given name
<code>NOT, !</code>	Negates value
<code>NOT BETWEEN ... AND ...</code>	Check whether a value is not within a range of values
<code>!=, <></code>	Not equal operator
<code>NOT IN()</code>	Check whether a value is not within a set of values
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of REGEXP
<code>NOW()</code>	Return the current date and time
<code>NTH_VALUE()</code>	Value of argument from N-th row of window frame
<code>N_TILE()</code>	Bucket number of current row within its partition.
<code>NULLIF()</code>	Return NULL if expr1 = expr2
<code>OCT()</code>	Return a string containing octal representation of a number
<code>OCTET_LENGTH()</code>	Synonym for LENGTH()
<code> , OR</code>	Logical OR
<code>ORD()</code>	Return character code for leftmost character of the argument
<code>PASSWORD()</code>	Calculate and return a password string
<code>PERCENT_RANK()</code>	Percentage rank value
<code>PERIOD_ADD()</code>	Add a period to a year-month
<code>PERIOD_DIFF()</code>	Return the number of months between periods
<code>PI()</code>	Return the value of pi
<code>+</code>	Addition operator
<code>Point()</code>	Construct Point from coordinates
<code>Polygon()</code>	Construct Polygon from LineString arguments
<code>POSITION()</code>	Synonym for LOCATE()

Name	Description
POW()	Return the argument raised to the specified power
POWER()	Return the argument raised to the specified power
QUARTER()	Return the quarter from a date argument
QUOTE()	Escape the argument for use in an SQL statement
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value
RANDOM_BYTES()	Return a random byte vector
RANK()	Rank of current row within its partition, with gaps
REGEXP	Whether string matches regular expression
REGEXP_INSTR()	Starting index of substring matching regular expression
REGEXP_LIKE()	Whether string matches regular expression
REGEXP_REPLACE()	Replace substrings matching regular expression
REGEXP_SUBSTR()	Return substring matching regular expression
RELEASE_ALL_LOCKS()	Releases all current named locks
RELEASE_LOCK()	Releases the named lock
REPEAT()	Repeat a string the specified number of times
REPLACE()	Replace occurrences of a specified string
REVERSE()	Reverse the characters in a string
RIGHT()	Return the specified rightmost number of characters
>>	Right shift
RLIKE	Whether string matches regular expression
ROLES_GRAPHML()	Returns a GraphML document representing memory role subgraphs
ROUND()	Round the argument
ROW_COUNT()	The number of rows updated
ROW_NUMBER()	Number of current row within its partition
RPAD()	Append string the specified number of times
RTRIM()	Remove trailing spaces
SCHEMA()	Synonym for DATABASE()
SEC_TO_TIME()	Converts seconds to 'HH:MM:SS' format
SECOND()	Return the second (0-59)
SESSION_USER()	Synonym for USER()
SHA1(), SHA()	Calculate an SHA-1 160-bit checksum
SHA2()	Calculate an SHA-2 checksum
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SLEEP()	Sleep for a number of seconds
SOUNDEX()	Return a soundex string

Name	Description
<code>SOUNDS LIKE</code>	Compare sounds
<code>SPACE()</code>	Return a string of the specified number of spaces
<code>SQRT()</code>	Return the square root of the argument
<code>ST_Area()</code>	Return Polygon or MultiPolygon area
<code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>	Convert from internal geometry format to WKB
<code>ST_AsGeoJSON()</code>	Generate GeoJSON object from geometry
<code>ST_AsText()</code> , <code>ST_AsWKT()</code>	Convert from internal geometry format to WKT
<code>ST_Buffer()</code>	Return geometry of points within given distance from geometry
<code>ST_Buffer_Strategy()</code>	Produce strategy option for <code>ST_Buffer()</code>
<code>ST_Centroid()</code>	Return centroid as a point
<code>ST_Contains()</code>	Whether one geometry contains another
<code>ST_ConvexHull()</code>	Return convex hull of geometry
<code>ST_Crosses()</code>	Whether one geometry crosses another
<code>ST_Difference()</code>	Return point set difference of two geometries
<code>ST_Dimension()</code>	Dimension of geometry
<code>ST_Disjoint()</code>	Whether one geometry is disjoint from another
<code>ST_Distance()</code>	The distance of one geometry from another
<code>ST_Distance_Sphere()</code>	Minimum distance on earth between two geometries
<code>ST_EndPoint()</code>	End Point of LineString
<code>ST_Envelope()</code>	Return MBR of geometry
<code>ST_Equals()</code>	Whether one geometry is equal to another
<code>ST_ExteriorRing()</code>	Return exterior ring of Polygon
<code>ST_GeoHash()</code>	Produce a geohash value
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromTxt()</code>	Return geometry collection from WKT
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection
<code>ST_GeometryType()</code>	Return name of geometry type
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon
<code>ST_Intersection()</code>	Return point set intersection of two geometries
<code>ST_Intersects()</code>	Whether one geometry intersects another
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple

Name	Description
<code>ST_IsEmpty()</code>	Placeholder function
<code>ST_IsSimple()</code>	Whether a geometry is simple
<code>ST_IsValid()</code>	Whether a geometry is valid
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value
<code>ST_Latitude()</code>	Return latitude of Point
<code>ST_Length()</code>	Return length of LineString
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value
<code>ST_Longitude()</code>	Return longitude of Point
<code>ST_MakeEnvelope()</code>	Rectangle around two points
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon
<code>ST_NumPoints()</code>	Return number of points in LineString
<code>ST_Overlaps()</code>	Whether one geometry overlaps another
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value
<code>ST_PointFromText()</code>	Construct Point from WKT
<code>ST_PointFromWKB()</code>	Construct Point from WKB
<code>ST_PointN()</code>	Return N-th point from LineString
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB
<code>ST_Simplify()</code>	Return simplified geometry
<code>ST_SRID()</code>	Return spatial reference system ID for geometry
<code>ST_StartPoint()</code>	Start Point of LineString

Name	Description
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries
<code>ST_Touches()</code>	Whether one geometry touches another
<code>ST_Transform()</code>	Transform coordinates of geometry
<code>ST_Union()</code>	Return point set union of two geometries
<code>ST_Validate()</code>	Return validated geometry
<code>ST_Within()</code>	Whether one geometry is within another
<code>ST_X()</code>	Return X coordinate of Point
<code>ST_Y()</code>	Return Y coordinate of Point
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest
<code>STD()</code>	Return the population standard deviation
<code>STDDEV()</code>	Return the population standard deviation
<code>STDDEV_POP()</code>	Return the population standard deviation
<code>STDDEV_SAMP()</code>	Return the sample standard deviation
<code>STR_TO_DATE()</code>	Convert a string to a date
<code>STRCMP()</code>	Compare two strings
<code>SUBDATE()</code>	Synonym for <code>DATE_SUB()</code> when invoked with three arguments
<code>SUBSTR()</code>	Return the substring as specified
<code>SUBSTRING()</code>	Return the substring as specified
<code>SUBSTRING_INDEX()</code>	Return a substring from a string before the specified number of occurrences of the delimiter
<code>SUBTIME()</code>	Subtract times
<code>SUM()</code>	Return the sum
<code>SYSDATE()</code>	Return the time at which the function executes
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>TAN()</code>	Return the tangent of the argument
<code>TIME()</code>	Extract the time portion of the expression passed
<code>TIME_FORMAT()</code>	Format as time
<code>TIME_TO_SEC()</code>	Return the argument converted to seconds
<code>TIMEDIFF()</code>	Subtract time
<code>*</code>	Multiplication operator
<code>TIMESTAMP()</code>	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
<code>TIMESTAMPADD()</code>	Add an interval to a datetime expression
<code>TIMESTAMPDIFF()</code>	Subtract an interval from a datetime expression
<code>TO_BASE64()</code>	Return the argument converted to a base-64 string
<code>TO_DAYS()</code>	Return the date argument converted to days

Name	Description
<code>TO_SECONDS()</code>	Return the date or datetime argument converted to seconds since Year 0
<code>TRIM()</code>	Remove leading and trailing spaces
<code>TRUNCATE()</code>	Truncate to specified number of decimal places
<code>UCASE()</code>	Synonym for <code>UPPER()</code>
<code>-</code>	Change the sign of the argument
<code>UNCOMPRESS()</code>	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code>	Return the length of a string before compression
<code>UNHEX()</code>	Return a string containing hex representation of a number
<code>UNIX_TIMESTAMP()</code>	Return a Unix timestamp
<code>UpdateXML()</code>	Return replaced XML fragment
<code>UPPER()</code>	Convert to uppercase
<code>USER()</code>	The user name and host name provided by the client
<code>UTC_DATE()</code>	Return the current UTC date
<code>UTC_TIME()</code>	Return the current UTC time
<code>UTC_TIMESTAMP()</code>	Return the current UTC date and time
<code>UUID()</code>	Return a Universal Unique Identifier (UUID)
<code>UUID_SHORT()</code>	Return an integer-valued universal identifier
<code>UUID_TO_BIN()</code>	Convert string UUID to binary
<code>VALIDATE_PASSWORD_STRENGTH()</code>	Determine strength of password
<code>VALUES()</code>	Defines the values to be used during an <code>INSERT</code>
<code>VAR_POP()</code>	Return the population standard variance
<code>VAR_SAMP()</code>	Return the sample variance
<code>VARIANCE()</code>	Return the population standard variance
<code>VERSION()</code>	Return a string that indicates the MySQL server version
<code>WAIT_FOR_EXECUTED_GTID_SET()</code>	Wait until the given GTIDs have executed on slave.
<code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</code>	Wait until the given GTIDs have executed on slave.
<code>WEEK()</code>	Return the week number
<code>WEEKDAY()</code>	Return the weekday index
<code>WEEKOFYEAR()</code>	Return the calendar week of the date (1-53)
<code>WEIGHT_STRING()</code>	Return the weight string for a string
<code>XOR</code>	Logical XOR
<code>YEAR()</code>	Return the year
<code>YEARWEEK()</code>	Return the year and week

12.2 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```
mysql> SELECT 1+'1';
      -> 2
mysql> SELECT CONCAT(2,' test');
      -> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
      -> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
      -> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see [Section 11.3.7, “Conversion Between Date and Time Types”](#).

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see [Comparison and Ordering of JSON Values](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
```

```

-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1

```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *str_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `1`, or `'1a'`.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```

mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0

```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```

mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16

```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```

mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1

```

For more information about floating-point comparisons, see [Section B.5.4.8, “Problems with Floating-Point Values”](#).

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- These properties imply that `F -> D -> F` conversions are lossless unless `F` is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see [Section 10.4, “Connection Character Sets and Collations”](#).)

For integer expressions, the preceding remarks about expression *evaluation* apply somewhat differently for expression *assignment*; for example, in a statement such as this:

In this case, the table in the column resulting from the expression has type `INT` or `BIGINT` depending on the length of the integer expression. If the maximum length of the expression does not fit in an `INT`, `BIGINT` is used instead. The length is taken from the `max_length` value of the `SELECT` result set metadata (see [Section 27.7.5, “C API Data Structures”](#)). This means that you can force a `BIGINT` rather than `INT` by use of a sufficiently long expression:

Operators

Table 12.2 Operators

Name	Description
AND, &&	Logical AND
=	Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)
:=	Assign a value
BETWEEN ... AND ...	Check whether a value is within a range of values
BINARY	Cast a string to a binary string
&	Bitwise AND
~	Bitwise inversion
	Bitwise OR

Name	Description
<code>^</code>	Bitwise XOR
<code>CASE</code>	Case operator
<code>DIV</code>	Integer division
<code>/</code>	Division operator
<code>=</code>	Equal operator
<code><=></code>	NULL-safe equal to operator
<code>></code>	Greater than operator
<code>>=</code>	Greater than or equal operator
<code>IS</code>	Test a value against a boolean
<code>IS NOT</code>	Test a value against a boolean
<code>IS NOT NULL</code>	NOT NULL value test
<code>IS NULL</code>	NULL value test
<code>-></code>	Return value from JSON column after evaluating path; equivalent to <code>JSON_EXTRACT()</code> .
<code>->></code>	Return value from JSON column after evaluating path and unquoting the result; equivalent to <code>JSON_UNQUOTE(JSON_EXTRACT())</code> .
<code><<</code>	Left shift
<code><</code>	Less than operator
<code><=</code>	Less than or equal operator
<code>LIKE</code>	Simple pattern matching
<code>-</code>	Minus operator
<code>%, MOD</code>	Modulo operator
<code>NOT, !</code>	Negates value
<code>NOT BETWEEN ... AND ...</code>	Check whether a value is not within a range of values
<code>!=, <></code>	Not equal operator
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of REGEXP
<code> , OR</code>	Logical OR
<code>+</code>	Addition operator
<code>REGEXP</code>	Whether string matches regular expression
<code>>></code>	Right shift
<code>RLIKE</code>	Whether string matches regular expression
<code>SOUNDS LIKE</code>	Compare sounds
<code>*</code>	Multiplication operator
<code>-</code>	Change the sign of the argument
<code>XOR</code>	Logical XOR

12.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=

```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>`, `>=`, `>`, `<=`, `<`, `<>`, `!=`, `IS`, `LIKE`, `REGEXP`, and `IN`. When used as an assignment operator, it has the same precedence as `:=`. [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#), and [Section 9.4, “User-Defined Variables”](#), explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 5.1.10, “Server SQL Modes”](#).

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
      -> 7
mysql> SELECT (1+2)*3;
      -> 9

```

12.3.2 Comparison Functions and Operators

Table 12.3 Comparison Operators

Name	Description
<code>BETWEEN ... AND ...</code>	Check whether a value is within a range of values
<code>COALESCE()</code>	Return the first non-NULL argument
<code>=</code>	Equal operator
<code><=></code>	NULL-safe equal to operator

Name	Description
>	Greater than operator
>=	Greater than or equal operator
<code>GREATEST()</code>	Return the largest argument
<code>IN()</code>	Check whether a value is within a set of values
<code>INTERVAL()</code>	Return the index of the argument that is less than the first argument
<code>IS</code>	Test a value against a boolean
<code>IS NOT</code>	Test a value against a boolean
<code>IS NOT NULL</code>	NOT NULL value test
<code>IS NULL</code>	NULL value test
<code>ISNULL()</code>	Test whether the argument is NULL
<code>LEAST()</code>	Return the smallest argument
<	Less than operator
<=	Less than or equal operator
<code>LIKE</code>	Simple pattern matching
<code>NOT BETWEEN ... AND ...</code>	Check whether a value is not within a range of values
<code>!=, <></code>	Not equal operator
<code>NOT IN()</code>	Check whether a value is not within a set of values
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

Comparison operations result in a value of 1 (`TRUE`), 0 (`FALSE`), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see [Section 13.2.11.5, “Row Subqueries”](#).

Some of the functions in this section return values other than 1 (`TRUE`), 0 (`FALSE`), or `NULL`. `LEAST()` and `GREATEST()` are examples of such functions; [Section 12.2, “Type Conversion in Expression Evaluation”](#), describes the rules for comparison operations performed by these and similar functions for determining their return values.

Note

In previous versions of MySQL, when evaluating an expression containing `LEAST()` or `GREATEST()`, the server attempted to guess the context in which the function was used, and to coerce the function's arguments to the data type of the expression as a whole. For example, the arguments to `LEAST("11", "45", "2")` are evaluated and sorted as strings, so that this expression returns

"11". In MySQL 8.0.3 and earlier, when evaluating the expression `LEAST("11", "45", "2") + 0`, the server converted the arguments to integers (anticipating the addition of integer 0 to the result) before sorting them, thus returning 2.

Beginning with MySQL 8.0.4, the server no longer attempts to infer context in this fashion. Instead, the function is executed using the arguments as provided, performing data type conversions to one or more of the arguments if and only if they are not all of the same type. Any type coercion mandated by an expression that makes use of the return value is now performed following function execution. This means that, in MySQL 8.0.4 and later, `LEAST("11", "45", "2") + 0` evaluates to `"11" + 0` and thus to integer 11. (Bug #83895, Bug #25123839)

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See [Section 12.10, "Cast Functions and Operators"](#).

By default, string comparisons are not case-sensitive and use the current character set. The default is `utf8mb4`.

- `=`

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

For row comparisons, `(a, b) = (x, y)` is equivalent to:

```
(a = x) AND (b = y)
```

- `<=>`

`NULL`-safe equal. This operator performs an equality comparison like the `=` operator, but returns 1 rather than `NULL` if both operands are `NULL`, and 0 rather than `NULL` if one operand is `NULL`.

The `<=>` operator is equivalent to the standard SQL `IS NOT DISTINCT FROM` operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

For row comparisons, `(a, b) <=> (x, y)` is equivalent to:

```
(a <=> x) AND (b <=> y)
```

- `<>, !=`

Not equal:

```
mysql> SELECT '.01' <> '0.01';
      -> 1
mysql> SELECT .01 <> '0.01';
      -> 0
mysql> SELECT 'zapp' <> 'zappp';
      -> 1
```

For row comparisons, $(a, b) <> (x, y)$ and $(a, b) \neq (x, y)$ are equivalent to:

```
(a <> x) OR (b <> y)
```

- **<=**

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
      -> 1
```

For row comparisons, $(a, b) <= (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b <= y))
```

- **<**

Less than:

```
mysql> SELECT 2 < 2;
      -> 0
```

For row comparisons, $(a, b) < (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b < y))
```

- **>=**

Greater than or equal:

```
mysql> SELECT 2 >= 2;
      -> 1
```

For row comparisons, $(a, b) >= (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b >= y))
```

- **>**

Greater than:

```
mysql> SELECT 2 > 2;
      -> 0
```

For row comparisons, $(a, b) > (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b > y))
```

```
(a > x) OR ((a = x) AND (b > y))
```

- `IS boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- `IS NOT boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL`

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See [Section 5.1.7, “Server System Variables”](#).

The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

See [Obtaining Auto-Increment Values](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Connector/ODBC Connection Parameters](#).

- `IS NOT NULL`

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `expr BETWEEN min AND max`

If `expr` is greater than or equal to `min` and `expr` is less than or equal to `max`, `BETWEEN` returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 AND 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max`

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)`

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

The return type of `COALESCE()` is the aggregated type of the argument types.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`

Returns `1` if `expr` is equal to any of the values in the `IN` list, else returns `0`. If all values are constants, they are evaluated according to the type of `expr` and sorted. The search for the item then is done using a binary search. This means `IN` is very quick if the `IN` value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#), but applied to all the arguments.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

`IN` can be used to compare row constructors:

```
mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0
```

You should never mix quoted and unquoted values in an `IN` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

The number of values in the `IN` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 13.2.11.3, “Subqueries with ANY, IN, or SOME”](#).

- `expr NOT IN (value,...)`

This is the same as `NOT (expr IN (value,...))`.

- `ISNULL(expr)`

If `expr` is `NULL`, `ISNULL()` returns `1`, otherwise it returns `0`.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `INTERVAL(N,N1,N2,N3,...)`

Returns 0 if $N < N1$, 1 if $N < N2$ and so on or -1 if N is `NULL`. All arguments are treated as integers. It is required that $N1 < N2 < N3 < \dots < Nn$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `LEAST(value1,value2,...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a `DECIMAL` value, they are compared as `DECIMAL` values.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of `LEAST()` is the aggregated type of the comparison argument types.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

12.3.3 Logical Operators

Table 12.4 Logical Operators

Name	Description
<code>AND</code> , <code>&&</code>	Logical AND
<code>NOT</code> , <code>!</code>	Negates value
<code> </code> , <code> </code> , <code>OR</code>	Logical OR
<code>XOR</code>	Logical XOR

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- NOT, !

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and NOT NULL returns NULL.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as (!1)+1.

- AND, &&

Logical AND. Evaluates to 1 if all operands are nonzero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

```
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0
```

- OR, ||

Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

```
mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1
```

- XOR

Logical XOR. Returns `NULL` if either operand is `NULL`. For non-`NULL` operands, evaluates to `1` if an odd number of operands is nonzero, otherwise `0` is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

`a XOR b` is mathematically equal to `(a AND (NOT b)) OR ((NOT a) and b)`.

12.3.4 Assignment Operators

Table 12.5 Assignment Operators

Name	Description
<code>=</code>	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)
<code>:=</code>	Assign a value

- `:=`

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement. You can perform multiple assignments in the same statement.

Unlike `=`, the `:=` operator is never interpreted as a comparison operator. This means you can use `:=` in any valid SQL statement (not just in `SET` statements) to assign a value to a variable.

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1

mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

You can make value assignments using `:=` in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```
mysql> SELECT @var1;
-> 4
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7
```

```
mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT @var1;
-> 1
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` operator, this is not recommended. [Section 9.4, “User-Defined Variables”](#), explains why you should avoid doing this.

- `=`

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#).

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

For more information, see [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#), [Section 13.2.12, “UPDATE Syntax”](#), and [Section 13.2.11, “Subquery Syntax”](#).

12.4 Control Flow Functions

Table 12.6 Flow Control Operators

Name	Description
<code>CASE</code>	Case operator
<code>IF()</code>	If/else construct
<code>IFNULL()</code>	Null if/else construct
<code>NULLIF()</code>	Return NULL if <code>expr1 = expr2</code>

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END`

```
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

The first `CASE` syntax returns the `result` for the first `value=compare_value` comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

Note

The syntax of the `CASE` expression described here differs slightly from that of the SQL `CASE` statement described in [Section 13.6.5.1, “CASE Syntax”](#), for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

The return type of a `CASE` expression result is the aggregated type of all result values:

- If all types are numeric, the aggregated type is also numeric:
 - If at least one argument is double precision, the result is double precision.
 - Otherwise, if at least one argument is `DECIMAL`, the result is `DECIMAL`.
 - Otherwise, the result is an integer type (with one exception):
 - If all integer types are all signed or all unsigned, the result is the same sign and the precision is the highest of all specified integer types (that is, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, or `BIGINT`).
 - If there is a combination of signed and unsigned integer types, the result is signed and the precision may be higher. For example, if the types are signed `INT` and unsigned `INT`, the result is signed `BIGINT`.
 - The exception is unsigned `BIGINT` combined with any signed integer type. The result is `DECIMAL` with sufficient precision and scale 0.
- If all types are `BIT`, the result is `BIT`. Otherwise, `BIT` arguments are treated similar to `BIGINT`.
- If all types are `YEAR`, the result is `YEAR`. Otherwise, `YEAR` arguments are treated similar to `INT`.
- If all types are character string (`CHAR` or `VARCHAR`), the result is `VARCHAR` with maximum length determined by the longest character length of the operands.
- If all types are character or binary string, the result is `VARBINARY`.
- `SET` and `ENUM` are treated similar to `VARCHAR`; the result is `VARCHAR`.
- If all types are `JSON`, the result is `JSON`.
- If all types are temporal, the result is temporal:
 - If all temporal types are `DATE`, `TIME`, or `TIMESTAMP`, the result is `DATE`, `TIME`, or `TIMESTAMP`, respectively.
 - Otherwise, for a mix of temporal types, the result is `DATETIME`.
- If all types are `GEOMETRY`, the result is `GEOMETRY`.

- If any type is `BLOB`, the result is `BLOB`.
- For all other type combinations, the result is `VARCHAR`.
- Literal `NULL` operands are ignored for type aggregation.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- `IF(expr1,expr2,expr3)`

If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`), `IF()` returns `expr2`. Otherwise, it returns `expr3`.

Note

There is also an `IF statement`, which differs from the `IF()` function described here. See [Section 13.6.5.2, “IF Syntax”](#).

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows:

- If `expr2` or `expr3` produce a string, the result is a string.
If `expr2` and `expr3` are both strings, the result is case-sensitive if either string is case sensitive.
- If `expr2` or `expr3` produce a floating-point value, the result is a floating-point value.
- If `expr2` or `expr3` produce an integer, the result is an integer.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

- `IFNULL(expr1,expr2)`

If `expr1` is not `NULL`, `IFNULL()` returns `expr1`; otherwise it returns `expr2`.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default return type of `IFNULL(expr1,expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | varbinary(4)  | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `VARBINARY(4)` (a string type).

- `NULLIF(expr1,expr2)`

Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

The return value has the same type as the first argument.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note

MySQL evaluates `expr1` twice if the arguments are not equal.

12.5 String Functions

Table 12.7 String Operators

Name	Description
<code>ASCII()</code>	Return numeric value of left-most character
<code>BIN()</code>	Return a string containing binary representation of a number
<code>BIT_LENGTH()</code>	Return length of argument in bits
<code>CHAR()</code>	Return the character for each integer passed
<code>CHAR_LENGTH()</code>	Return number of characters in argument
<code>CHARACTER_LENGTH()</code>	Synonym for <code>CHAR_LENGTH()</code>
<code>CONCAT()</code>	Return concatenated string
<code>CONCAT_WS()</code>	Return concatenate with separator
<code>ELT()</code>	Return string at index number
<code>EXPORT_SET()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>FIELD()</code>	Return the index (position) of the first argument in the subsequent arguments
<code>FIND_IN_SET()</code>	Return the index position of the first argument within the second argument

String Functions

Name	Description
<code>FORMAT()</code>	Return a number formatted to specified number of decimal places
<code>FROM_BASE64()</code>	Decode base64 encoded string and return result
<code>HEX()</code>	Return a hexadecimal representation of a decimal or string value
<code>INSERT()</code>	Insert a substring at the specified position up to the specified number of characters
<code>INSTR()</code>	Return the index of the first occurrence of substring
<code>LCASE()</code>	Synonym for LOWER()
<code>LEFT()</code>	Return the leftmost number of characters as specified
<code>LENGTH()</code>	Return the length of a string in bytes
<code>LIKE</code>	Simple pattern matching
<code>LOAD_FILE()</code>	Load the named file
<code>LOCATE()</code>	Return the position of the first occurrence of substring
<code>LOWER()</code>	Return the argument in lowercase
<code>LPAD()</code>	Return the string argument, left-padded with the specified string
<code>LTRIM()</code>	Remove leading spaces
<code>MAKE_SET()</code>	Return a set of comma-separated strings that have the corresponding bit in bits set
<code>MATCH</code>	Perform full-text search
<code>MID()</code>	Return a substring starting from the specified position
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of REGEXP
<code>OCT()</code>	Return a string containing octal representation of a number
<code>OCTET_LENGTH()</code>	Synonym for LENGTH()
<code>ORD()</code>	Return character code for leftmost character of the argument
<code>POSITION()</code>	Synonym for LOCATE()
<code>QUOTE()</code>	Escape the argument for use in an SQL statement
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>REPEAT()</code>	Repeat a string the specified number of times
<code>REPLACE()</code>	Replace occurrences of a specified string
<code>REVERSE()</code>	Reverse the characters in a string
<code>RIGHT()</code>	Return the specified rightmost number of characters
<code>RLIKE</code>	Whether string matches regular expression

Name	Description
RPAD()	Append string the specified number of times
RTRIM()	Remove trailing spaces
SOUNDEX()	Return a soundex string
SOUNDS LIKE	Compare sounds
SPACE()	Return a string of the specified number of spaces
STRCMP()	Compare two strings
SUBSTR()	Return the substring as specified
SUBSTRING()	Return the substring as specified
SUBSTRING_INDEX()	Return a substring from a string before the specified number of occurrences of the delimiter
TO_BASE64()	Return the argument converted to a base-64 string
TRIM()	Remove leading and trailing spaces
UCASE()	Synonym for UPPER()
UNHEX()	Return a string containing hex representation of a number
UPPER()	Convert to uppercase
WEIGHT_STRING()	Return the weight string for a string

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 5.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- [ASCII\(*str*\)](#)

Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns `NULL` if *str* is `NULL`. [ASCII\(\)](#) works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the [ORD\(\)](#) function.

- [BIN\(*N*\)](#)

Returns a string representation of the binary value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 2)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT BIN(12);
-> '1100'
```

- [BIT_LENGTH\(*str*\)](#)

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- `CHAR(N,... [USING charset_name])`

`CHAR()` interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
```

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000         | 010000         |
+-----+-----+
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));
+-----+-----+
| CHARSET(CHAR(X'65')) | CHARSET(CHAR(X'65' USING utf8)) |
+-----+-----+
| binary              | utf8                             |
+-----+-----+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

- `CHAR_LENGTH(str)`

Returns the length of the string *str*, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

- `CHARACTER_LENGTH(str)`

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- `CONCAT(str1,str2,...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary

strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
      -> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
      -> NULL
mysql> SELECT CONCAT(14.3);
      -> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
      -> 'MySQL'
```

- `CONCAT_WS(separator, str1, str2, ...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
      -> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
      -> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N, str1, str2, str3, ...)`

`ELT()` returns the *N*th element of the list of strings: *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns `NULL` if *N* is less than 1 or greater than the number of arguments. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
      -> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
      -> 'Dd'
```

- `EXPORT_SET(bits, on, off[, separator[, number_of_bits]])`

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every bit not set in the value, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ,). The number of bits examined is given by *number_of_bits*, which has a default of 64 if not specified. *number_of_bits* is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
      -> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
      -> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str, str1, str2, str3, ...)`

Returns the index (position) of *str* in the *str1*, *str2*, *str3*, ... list. Returns 0 if *str* is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If *str* is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to *N* if the string *str* is in the string list *strlist* consisting of *N* substrings. A string list is a string composed of substrings separated by , characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (,) character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
-> 2
```

- `FORMAT(X, D[, locale])`

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. If *D* is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see [Section 10.15, "MySQL Server Locale Support"](#)). If no locale is specified, the default is 'en_US'.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
-> '12,332'
mysql> SELECT FORMAT(12332.2, 2, 'de_DE');
-> '12.332,20'
```

- `FROM_BASE64(str)`

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

- `HEX(str), HEX(N)`

For a string argument *str*, `HEX()` returns a hexadecimal string representation of *str* where each byte of each character in *str* is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument *N*, `HEX()` returns a hexadecimal string representation of the value of *N* treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

```
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
      -> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
      -> 'FF', 255
```

- `INSERT(str,pos,len,newstr)`

Returns the string *str*, with the substring beginning at position *pos* and *len* characters long replaced by the string *newstr*. Returns the original string if *pos* is not within the length of the string. Replaces the rest of the string from position *pos* if *len* is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
      -> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
      -> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
      -> 'QuWhat '
```

This function is multibyte safe.

- `INSTR(str,substr)`

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
      -> 4
mysql> SELECT INSTR('xbar', 'foobar');
      -> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

`LCASE()` used in a view is rewritten as `LOWER()` when storing the view's definition. (Bug #12844279)

- `LEFT(str,len)`

Returns the leftmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
      -> 'fooba'
```

This function is multibyte safe.

- `LENGTH(str)`

Returns the length of the string *str*, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
-> 4
```

Note

The `Length()` OpenGIS spatial function is named `ST_Length()` in MySQL.

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string *str* with all characters changed to lowercase according to the current character set mapping. The default is `utf8mb4`.

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

For collations of Unicode character sets, `LOWER()` and `UPPER()` work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, `utf8mb4_0900_ai_ci` and `utf8_unicode_520_ci` work according to UCA 9.0.0 and 5.2.0, respectively, whereas `utf8_unicode_ci` works according to UCA 4.0.0. See [Section 10.10.1, “Unicode Character Sets”](#).

This function is multibyte safe.

`LCASE()` used within views is rewritten as `LOWER()`.

- `LPAD(str, len, padstr)`

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT LPAD('hi',4,'?');
-> '??hi'
mysql> SELECT LPAD('hi',1,'?');
-> 'h'
```

- `LTRIM(str)`

Returns the string `str` with leading space characters removed.

```
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
```

This function is multibyte safe.

- `MAKE_SET(bits, str1, str2, ...)`

Returns a set value (a string containing substrings separated by `,` characters) consisting of the strings that have the corresponding bit in `bits` set. `str1` corresponds to bit 0, `str2` to bit 1, and so on. `NULL` values in `str1, str2, ...` are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
-> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
-> ''
```

- `MID(str, pos, len)`

`MID(str, pos, len)` is a synonym for `SUBSTRING(str, pos, len)`.

- `OCT(N)`

Returns a string representation of the octal value of *N*, where *N* is a longlong (**BIGINT**) number. This is equivalent to `CONV(N,10,8)`. Returns **NULL** if *N* is **NULL**.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 256^2) ...
```

If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr,str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (`\`), single quote (`'`), ASCII **NUL**, and Control+Z preceded by a backslash. If the argument is **NULL**, the return value is the word “NULL” without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 9.1.1, “String Literals”](#), and [Section 27.7.7.56, “mysql_real_escape_string_quote\(\)”](#).

- `REPEAT(str,count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns **NULL** if *str* or *count* are **NULL**.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str,from_str,to_str)`

Returns the string *str* with all occurrences of the string *from_str* replaced by the string *to_str*. `REPLACE()` performs a case-sensitive match when searching for *from_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- `REVERSE(str)`

Returns the string *str* with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str, len)`

Returns the rightmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- `RPAD(str, len, padstr)`

Returns the string *str*, right-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multibyte safe.

- `RTRIM(str)`

Returns the string *str* with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multibyte safe.

- `SOUNDEX(str)`

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All nonalphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

**Important**

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including `utf-8`. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

**Note**

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of *N* space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str,pos)`, `SUBSTR(str FROM pos)`, `SUBSTR(str,pos,len)`, `SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str,pos)`, `SUBSTRING(str FROM pos)`, `SUBSTRING(str,pos,len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
-> 'ratica'
```

```
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multibyte safe.

If *len* is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)`

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned.

`SUBSTRING_INDEX()` performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multibyte safe.

- `TO_BASE64(str)`

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the `FROM_BASE64()` function.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is '+'.
- The encoding for alphabet value 63 is '/'.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.
- `TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)`

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'
```

This function is multibyte safe.

- `UCASE(str)`

`UCASE()` is a synonym for `UPPER()`.

`UCASE()` used within views is rewritten as `UPPER()`.

- `UNHEX(str)`

For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'
```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

```
mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+
```

A `NULL` result can occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a `CHAR(3)` column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` for the column value returns 'A'. By contrast '41' is stored into a `BINARY(3)` column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`.

For a numeric argument `N`, the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N), 16, 10)` instead. See the description of `HEX()`.

- `UPPER(str)`

Returns the string `str` with all characters changed to uppercase according to the current character set mapping. The default is `utf8mb4`.

```
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

See the description of `LOWER()` for information that also applies to `UPPER()`. This included information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

`UCASE()` used within views is rewritten as `UPPER()`.

- `WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [flags])`

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

- If `WEIGHT_STRING(str1) = WEIGHT_STRING(str2)`, then `str1 = str2` (`str1` and `str2` are considered equal)
- If `WEIGHT_STRING(str1) < WEIGHT_STRING(str2)`, then `str1 < str2` (`str1` sorts before `str2`)

`WEIGHT_STRING()` is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See [Section 10.13, “Adding a Collation to a Character Set”](#).

This list briefly summarizes the arguments. More details are given in the discussion following the list.

- `str`: The input string expression.
- `AS` clause: Optional; cast the input string to a given type and length.
- `flags`: Optional; unused.

The input string, `str`, is a string expression. If the input is a nonbinary (character) string such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is `NULL`, `WEIGHT_STRING()` returns `NULL`.

Examples:

```
mysql> SET @s = _utf8mb4 'AB' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 1C471C60                |
+-----+-----+-----+
```

```
mysql> SET @s = _utf8mb4 'ab' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 1C471C60                |
+-----+-----+-----+
```

```
mysql> SET @s = CAST('AB' AS BINARY);
```

```
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 4142                    |
+-----+-----+-----+
```

```
mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 6162                    |
+-----+-----+-----+
```

The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```
mysql> SET @s = CONVERT(X'C39F' USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-----+
| HEX(WEIGHT_STRING(@s)) |
+-----+
| 0FEA0FEA                |
+-----+
```

For non-`NULL` return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of *N* characters. *N* must be at least 1. If *N* is less than the length of the input string, the string is truncated to *N* characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, *N* is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```
mysql> SET NAMES 'latin1';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 41422020                            |
+-----+
mysql> SET NAMES 'utf8';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 0041004200200020                    |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
+-----+
| 61620000                            |
+-----+
```

The *flags* clause currently is unused.

12.5.1 String Comparison Functions

Table 12.8 String Comparison Operators

Name	Description
<code>LIKE</code>	Simple pattern matching
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either *expr* or *pat* is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
|                                         0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                         1 |
+-----+
```

In particular, trailing spaces are significant, which is not true for `CHAR` or `VARCHAR` comparisons performed with the `=` operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-----+-----+
| 'a' = 'a ' | 'a' LIKE 'a ' |
+-----+-----+
|          1 |              0 |
+-----+-----+
1 row in set (0.00 sec)
```

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.

- `_` matches exactly one character.

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed.

- `\%` matches one `%` character.
- `_` matches one `_` character.

```
mysql> SELECT 'David!' LIKE 'David\_%';
-> 0
mysql> SELECT 'David_' LIKE 'David\_%';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_0900_as_cs;
-> 0
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

Note

Because MySQL uses C escape syntax in strings (for example, `\n` to represent a newline character), you must double any `\` that you use in `LIKE` strings. For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+-----+
| filename |
+-----+
| C:       |
| C:\      |
| C:\Programs |
| C:\Programs\ |
+-----+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
| 0 | -1 |
+-----+-----+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 10.8.4, “Collation Coercibility in Expressions”](#).

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
-->
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (utf8mb4_0900_ai_ci,IMPLICIT)
and (utf8mb4_0900_as_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci);
+-----+
| STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci) |
+-----+
| 0 |
+-----+
```

12.5.2 Regular Expressions

Table 12.9 Regular Expression Functions and Operators

Name	Description
<code>NOT REGEXP</code>	Negation of REGEXP
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression

Name	Description
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>RLIKE</code>	Whether string matches regular expression

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the functions and operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also [Section 3.3.4.7, “Pattern Matching”](#).

MySQL implements regular expression support using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe. (Prior to MySQL 8.0.4, MySQL used Henry Spencer's implementation of regular expressions, which operates in byte-wise fashion and is not multibyte safe. For information about ways in which applications that use regular expressions may be affected by the implementation change, see [Regular Expression Compatibility Considerations](#).)

- [Regular Expression Functions and Operators](#)
- [Regular Expression Syntax](#)
- [Regular Expression Resource Control](#)
- [Regular Expression Compatibility Considerations](#)

Regular Expression Functions and Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is `NULL`, the return value is `NULL`.

`REGEXP` and `RLIKE` are synonyms for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT 'Michael!' REGEXP '.*';
+-----+
| 'Michael!' REGEXP '.*' |
+-----+
| 1 |
+-----+
mysql> SELECT 'new*\n*line' REGEXP 'new\\*\\.\\*line';
+-----+
| 'new*\n*line' REGEXP 'new\\*\\.\\*line' |
+-----+
| 0 |
+-----+
mysql> SELECT 'a' REGEXP '^[a-d]';
+-----+
| 'a' REGEXP '^[a-d]' |
+-----+
| 1 |
+-----+
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+-----+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
```

1	0
---	---

- `REGEXP_INSTR(expr, pat[, pos[, occurrence[, return_option[, match_type]]])`

Returns the starting index of the substring of the string `expr` that matches the regular expression specified by the pattern `pat`, 0 if there is no match. If `expr` or `pat` is `NULL`, the return value is `NULL`. Character indexes begin at 1.

`REGEXP_INSTR()` takes these optional arguments:

- `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.
- `occurrence`: Which occurrence of a match to search for. If omitted, the default is 1.
- `return_option`: Which type of position to return. If this value is 0, `REGEXP_INSTR()` returns the position of the matched substring's first character. If this value is 1, `REGEXP_INSTR()` returns the position following the matched substring. If omitted, the default is 0.
- `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog');
+-----+
| REGEXP_INSTR('dog cat dog', 'dog') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog', 2);
+-----+
| REGEXP_INSTR('dog cat dog', 'dog', 2) |
+-----+
| 9 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{2}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{2}') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{4}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{4}') |
+-----+
| 8 |
+-----+
```

- `REGEXP_LIKE(expr, pat[, match_type])`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is `NULL`, the return value is `NULL`.

The pattern can be an extended regular expression, the syntax for which is discussed in [Regular Expression Syntax](#). The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

The optional `match_type` argument is a string that may contain any or all the following characters specifying how to perform matching:

- **c**: Case sensitive matching.
- **i**: Case insensitive matching.
- **m**: Multiple-line mode. Recognize line terminators within the string. The default behavior is to match line terminators only at the start and end of the string expression.
- **n**: The `.` character matches line terminators. The default is for `.` matching to stop at the end of a line.
- **u**: Unix-only line endings. Only the newline character is recognized as a line ending by the `.`, `^`, and `$` match operators.

If characters specifying contradictory options are specified within *match_type*, the rightmost one takes precedence.

By default, regular expression operations use the character set and collation of the *expr* and *pat* arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 10.8.4, “Collation Coercibility in Expressions”](#). Arguments may be specified with explicit collation indicators to change comparison behavior.

```
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE');
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs);
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs) |
+-----+
| 0 |
+-----+
```

match_type may be specified with the **c** or **i** characters to override the default case sensitivity. Exception: If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings, even if *match_type* contains the **i** character.

Note

Because MySQL uses the C escape syntax in strings (for example, `\n` to represent the newline character), you must double any `\` that you use in your *expr* and *pat* arguments.

```
mysql> SELECT REGEXP_LIKE('Michael!', '.*');
+-----+
| REGEXP_LIKE('Michael!', '.*') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('new*\n*line', 'new\\*.*\\*line');
+-----+
| REGEXP_LIKE('new*\n*line', 'new\\*.*\\*line') |
+-----+
| 0 |
+-----+
mysql> SELECT REGEXP_LIKE('a', '^[a-d]');
+-----+
```

```
| REGEXP_LIKE('a', '^[a-d]') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('a', 'A'), REGEXP_LIKE('a', BINARY 'A');
+-----+-----+
| REGEXP_LIKE('a', 'A') | REGEXP_LIKE('a', BINARY 'A') |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

```
mysql> SELECT REGEXP_LIKE('abc', 'ABC');
+-----+
| REGEXP_LIKE('abc', 'ABC') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('abc', 'ABC', 'c');
+-----+
| REGEXP_LIKE('abc', 'ABC', 'c') |
+-----+
| 0 |
+-----+
```

- `REGEXP_REPLACE(expr, pat, repl[, pos[, occurrence[, match_type]])`

Replaces occurrences in the string *expr* that match the regular expression specified by the pattern *pat* with the replacement string *repl*, and returns the resulting string. If *expr*, *pat*, or *repl* is `NULL`, the return value is `NULL`.

`REGEXP_REPLACE()` takes these optional arguments:

- *pos*: The position in *expr* at which to start the search. If omitted, the default is 1.
- *occurrence*: Which occurrence of a match to replace. If omitted, the default is 0 (which means “replace all occurrences”).
- *match_type*: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_REPLACE('a b c', 'b', 'X');
+-----+
| REGEXP_REPLACE('a b c', 'b', 'X') |
+-----+
| a X c |
+-----+
mysql> SELECT REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3);
+-----+
| REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3) |
+-----+
| abc def X |
+-----+
```

- `REGEXP_SUBSTR(expr, pat[, pos[, occurrence[, match_type]])`

Returns the substring of the string *expr* that matches the regular expression specified by the pattern *pat*, `NULL` if there is no match. If *expr* or *pat* is `NULL`, the return value is `NULL`.

`REGEXP_SUBSTR()` takes these optional arguments:

- *pos*: The position in *expr* at which to start the search. If omitted, the default is 1.
- *occurrence*: Which occurrence of a match to search for. If omitted, the default is 1.
- *match_type*: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+');
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+') |
+-----+
| abc                                     |
+-----+
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3);
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3) |
+-----+
| ghi                                         |
+-----+
```

Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the `|` alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

The following list covers some of the basic special characters and constructs that can be used in regular expressions. For information about the full regular expression syntax supported by the ICU library used to implement regular expression support, visit the [International Components for Unicode website](#).

- `^`

Match the beginning of a string.

```
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo$');      -> 0
mysql> SELECT REGEXP_LIKE('fofo', '^fo$');      -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo\ngo$');  -> 1
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo$');      -> 0
```

- `.`

Match any character (including carriage return and newline, although to match these in the middle of a string, the `m` (multiple line) match-control character or the `(?m)` within-pattern modifier must be given).

```
mysql> SELECT REGEXP_LIKE('fofo', '^f.*$');          -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$');      -> 0
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$', 'm');  -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '(?m)^f.*$');  -> 1
```

- `a*`

Match any sequence of zero or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba*n');          -> 1
mysql> SELECT REGEXP_LIKE('Baaan', '^Ba*n');        -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba*n');            -> 1
```

- `a+`

Match any sequence of one or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba+n');          -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba+n');           -> 0
```

- `a?`

Match either zero or one `a` character.

```
mysql> SELECT REGEXP_LIKE('Bn', '^Ba?n');           -> 1
mysql> SELECT REGEXP_LIKE('Ban', '^Ba?n');          -> 1
mysql> SELECT REGEXP_LIKE('Baan', '^Ba?n');         -> 0
```

- `de|abc`

Alternation; match either of the sequences `de` or `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', 'pi|apa');          -> 1
mysql> SELECT REGEXP_LIKE('axe', 'pi|apa');          -> 0
mysql> SELECT REGEXP_LIKE('apa', 'pi|apa');          -> 1
mysql> SELECT REGEXP_LIKE('apa', '^(pi|apa)$');      -> 1
mysql> SELECT REGEXP_LIKE('pi', '^(pi|apa)$');       -> 1
mysql> SELECT REGEXP_LIKE('pix', '^(pi|apa)$');      -> 0
```

- `(abc)*`

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', '^(pi)*$');          -> 1
mysql> SELECT REGEXP_LIKE('pip', '^(pi)*$');         -> 0
mysql> SELECT REGEXP_LIKE('pipi', '^(pi)*$');        -> 1
```

- `{1}, {2,3}`

Repetition; `{n}` and `{m,n}` notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- `a*`

Can be written as `a{0,}`.

- `a+`

Can be written as `a{1,}`.

- `a?`

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly *n* instances of *a*. `a{n,}` matches *n* or more instances of *a*. `a{m,n}` matches *m* through *n* instances of *a*, inclusive. If both *m* and *n* are given, *m* must be less than or equal to *n*.

```
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{2}e');          -> 0
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{3}e');          -> 1
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{1,10}e');        -> 1
```

- `[a-dX]`, `^[a-dX]`

Matches any character that is (or is not, if `^` is used) either *a*, *b*, *c*, *d* or *X*. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[]` pair matches only itself.

```
mysql> SELECT REGEXP_LIKE('aXbc', '[a-dXYZ]');            -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '^[a-dXYZ]$');          -> 0
mysql> SELECT REGEXP_LIKE('aXbc', '^[a-dXYZ]+$');         -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '^^[a-dXYZ]+$');        -> 0
mysql> SELECT REGEXP_LIKE('gheis', '^[^a-dXYZ]+$');       -> 1
mysql> SELECT REGEXP_LIKE('gheisa', '^[^a-dXYZ]+$');      -> 0
```

- `[=character_class=]`

Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, `[[=o=]]`, `[[= (+)=]]`, and `[o (+)]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[:character_class:]`

Within a bracket expression (written using `[` and `]`), `[:character_class:]` represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

Character Class Name	Meaning
<code>alnum</code>	Alphanumeric characters
<code>alpha</code>	Alphabetic characters
<code>blank</code>	Whitespace characters
<code>cntrl</code>	Control characters
<code>digit</code>	Digit characters

Character Class Name	Meaning
<code>graph</code>	Graphic characters
<code>lower</code>	Lowercase alphabetic characters
<code>print</code>	Graphic or space characters
<code>punct</code>	Punctuation characters
<code>space</code>	Space, tab, newline, and carriage return
<code>upper</code>	Uppercase alphabetic characters
<code>xdigit</code>	Hexadecimal digit characters

```
mysql> SELECT REGEXP_LIKE('justalnums', '[:alnum:]+');      -> 1
mysql> SELECT REGEXP_LIKE('!!!', '[:alnum:]+');            -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT REGEXP_LIKE('1+2', '1+2');                    -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\+2');                    -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\\+2');                    -> 1
```

Regular Expression Resource Control

`REGEXP_LIKE()` and similar functions use resources that can be controlled by setting system variables:

- The match engine uses memory for its internal stack. To control the maximum available memory for the stack in bytes, set the `regexp_stack_limit` system variable.
- The match engine operates in steps. To control the maximum number of steps performed by the engine (and thus indirectly the execution time), set the `regexp_time_limit` system variable. Because this limit is expressed as number of steps, it affects execution time only indirectly. Typically, it is on the order of milliseconds.

Regular Expression Compatibility Considerations

Prior to MySQL 8.0.4, MySQL used the Henry Spencer regular expression library to support regular expression operations, rather than International Components for Unicode (ICU). The following discussion describes differences between the Spencer and ICU libraries that may affect applications:

- With the Spencer library, the `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

ICU has full Unicode support and is multibyte safe. Its regular expression functions treat all strings as as `UTF-16`. You should keep in mind that positional indexes are based on 16-bit chunks and not on code points. This means that, when passed to such functions, characters using more than one chunk may produce unanticipated results, such as those shown here:

```
mysql> SELECT REGEXP_INSTR('####b', 'b');
+-----+
| REGEXP_INSTR('??b', 'b') |
```

```

+-----+
|                    5 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('####bxxx', 'b', 4);
+-----+
| REGEXP_INSTR('???bxxx', 'b', 4) |
+-----+
|                    5 |
+-----+
1 row in set (0.00 sec)

```

Characters within the Unicode Basic Multilingual Plane, which includes characters used by most modern languages, are safe in this regard:

```

mysql> SELECT REGEXP_INSTR('ᄇᄃᄂ', 'b');
+-----+
| REGEXP_INSTR('ᄇᄃᄂ', 'b') |
+-----+
|                    3 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('עבד', 'b');
+-----+
| REGEXP_INSTR('עבד', 'b') |
+-----+
|                    3 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('ᄇᄃᄂᄃᄂ', '周');
+-----+
| REGEXP_INSTR('ᄇᄃᄂᄃᄂ', '周') |
+-----+
|                    3 |
+-----+
1 row in set (0.00 sec)

```

Emoji, such as the “sushi” character **##** (U+1F363) used in the first two examples, are not included in the Basic Multilingual Plane, but rather in Unicode's Supplementary Multilingual Plane. Another issue can arise with emoji and other 4-byte characters when `REGEXP_SUBSTR()` or a similar function begins searching in the middle of a character. Each of the two statements in the following example starts from the second 2-byte position in the first argument. The first statement works on a string consisting solely of 2-byte (BMP) characters. The second statement contains 4-byte characters which are incorrectly interpreted in the result because the first two bytes are stripped off and so the remainder of the character data is misaligned.

```

mysql> SELECT REGEXP_SUBSTR('周周周周', '.*', 2);
+-----+
| REGEXP_SUBSTR('周周周周', '.*', 2) |
+-----+
| 周周周 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_SUBSTR('#####', '.*', 2);
+-----+
| REGEXP_SUBSTR('????', '.*', 2) |
+-----+

```

```
| ?#遑#遑#遑 |
+-----+
1 row in set (0.00 sec)
```

- For the `.` operator, the Spencer library matches line-terminator characters (carriage return, newline) anywhere in string expressions, including in the middle. To match line terminator characters in the middle of strings with ICU, specify the `m` match-control character.
- The Spencer library supports word-beginning and word-end boundary markers (`[[:<:]]` and `[[:>:]]` notation). ICU does not.
- The Spencer library supports collating element bracket expressions (`[.characters.]` notation). ICU does not.
- For repetition counts (`{n}` and `{m,n}` notation), the Spencer library has a maximum of 255. ICU has no such limit, although the maximum number of match engine steps can be limited by setting the `regexp_time_limit` system variable.
- ICU interprets parentheses as metacharacters. To specify a literal open parenthesis `(` in a regular expression, it must be escaped:

```
mysql> SELECT REGEXP_LIKE('(', '(');
ERROR 3692 (HY000): Mismatched parenthesis in regular expression.
mysql> SELECT REGEXP_LIKE('(', '\\(');
+-----+
| REGEXP_LIKE('(', '\\(') |
+-----+
| 1 |
+-----+
```

12.5.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 10.4, “Connection Character Sets and Collations”](#)). This applies only to `BIN_TO_UUID()`, `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

An exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `BIN_TO_UUID()`, `CONV()`, or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost | utf8            | utf8_general_ci   |
+-----+-----+-----+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+-----+-----+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+-----+-----+
| binary                   | binary                     |
+-----+-----+
```

12.6 Numeric Functions and Operators

Table 12.10 Numeric Functions and Operators

Name	Description
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ASIN()</code>	Return the arc sine
<code>ATAN()</code>	Return the arc tangent
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CONV()</code>	Convert numbers between different number bases
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent

Name	Description
<code>CRC32()</code>	Compute a cyclic redundancy check value
<code>DEGREES()</code>	Convert radians to degrees
<code>DIV</code>	Integer division
<code>/</code>	Division operator
<code>EXP()</code>	Raise to the power of
<code>FLOOR()</code>	Return the largest integer value not greater than the argument
<code>LN()</code>	Return the natural logarithm of the argument
<code>LOG()</code>	Return the natural logarithm of the first argument
<code>LOG10()</code>	Return the base-10 logarithm of the argument
<code>LOG2()</code>	Return the base-2 logarithm of the argument
<code>-</code>	Minus operator
<code>MOD()</code>	Return the remainder
<code>%, MOD</code>	Modulo operator
<code>PI()</code>	Return the value of pi
<code>+</code>	Addition operator
<code>POW()</code>	Return the argument raised to the specified power
<code>POWER()</code>	Return the argument raised to the specified power
<code>RADIANS()</code>	Return argument converted to radians
<code>RAND()</code>	Return a random floating-point value
<code>ROUND()</code>	Round the argument
<code>SIGN()</code>	Return the sign of the argument
<code>SIN()</code>	Return the sine of the argument
<code>SQRT()</code>	Return the square root of the argument
<code>TAN()</code>	Return the tangent of the argument
<code>*</code>	Multiplication operator
<code>TRUNCATE()</code>	Truncate to specified number of decimal places
<code>-</code>	Change the sign of the argument

12.6.1 Arithmetic Operators

Table 12.11 Arithmetic Operators

Name	Description
<code>DIV</code>	Integer division
<code>/</code>	Division operator
<code>-</code>	Minus operator
<code>%, MOD</code>	Modulo operator
<code>+</code>	Addition operator
<code>*</code>	Multiplication operator
<code>-</code>	Change the sign of the argument

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 12.10, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see [Section 12.7, “Date and Time Functions”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of -2^{63} .

- [*](#)

Multiplication:

```
mysql> SELECT 3*5;
      -> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
      -> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
      -> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of [BIGINT](#) calculations. (See [Section 11.2, “Numeric Types”](#).)

- [/](#)

Division:

```
mysql> SELECT 3/5;
      -> 0.60
```

Division by zero produces a [NULL](#) result:

```
mysql> SELECT 102/(1-1);
      -> NULL
```

A division is calculated with [BIGINT](#) arithmetic only if performed in a context where its result is converted to an integer.

- [DIV](#)

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to [DECIMAL](#) and divided using [DECIMAL](#) arithmetic before converting the result to [BIGINT](#). If the result exceeds [BIGINT](#) range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
      -> 2, -2, -2, 2
```

- [N % M](#), [N MOD M](#)

Modulo operation. Returns the remainder of [N](#) divided by [M](#). For more information, see the description for the [MOD\(\)](#) function in [Section 12.6.2, “Mathematical Functions”](#).

12.6.2 Mathematical Functions

Table 12.12 Mathematical Functions

Name	Description
ABS()	Return the absolute value
ACOS()	Return the arc cosine
ASIN()	Return the arc sine
ATAN()	Return the arc tangent

Name	Description
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CONV()</code>	Convert numbers between different number bases
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent
<code>CRC32()</code>	Compute a cyclic redundancy check value
<code>DEGREES()</code>	Convert radians to degrees
<code>EXP()</code>	Raise to the power of
<code>FLOOR()</code>	Return the largest integer value not greater than the argument
<code>LN()</code>	Return the natural logarithm of the argument
<code>LOG()</code>	Return the natural logarithm of the first argument
<code>LOG10()</code>	Return the base-10 logarithm of the argument
<code>LOG2()</code>	Return the base-2 logarithm of the argument
<code>MOD()</code>	Return the remainder
<code>PI()</code>	Return the value of pi
<code>POW()</code>	Return the argument raised to the specified power
<code>POWER()</code>	Return the argument raised to the specified power
<code>RADIANS()</code>	Return argument converted to radians
<code>RAND()</code>	Return a random floating-point value
<code>ROUND()</code>	Round the argument
<code>SIGN()</code>	Return the sign of the argument
<code>SIN()</code>	Return the sine of the argument
<code>SQRT()</code>	Return the square root of the argument
<code>TAN()</code>	Return the tangent of the argument
<code>TRUNCATE()</code>	Truncate to specified number of decimal places

All mathematical functions return `NULL` in the event of an error.

- `ABS(X)`

Returns the absolute value of `X`.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

```
mysql> SELECT ACOS(1);
-> 0
mysql> SELECT ACOS(1.0001);
-> NULL
mysql> SELECT ACOS(0);
-> 1.5707963267949
```

- **ASIN(X)**

Returns the arc sine of *X*, that is, the value whose sine is *X*. Returns **NULL** if *X* is not in the range **-1** to **1**.

```
mysql> SELECT ASIN(0.2);
-> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
|          0 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+-----+
```

- **ATAN(X)**

Returns the arc tangent of *X*, that is, the value whose tangent is *X*.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- **ATAN(Y,X), ATAN2(Y,X)**

Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of Y / X , except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

- **CEIL(X)**

CEIL() is a synonym for **CEILING()**.

- **CEILING(X)**

Returns the smallest integer value not less than *X*.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
```

```
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `CONV(N,from_base,to_base)`

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from_base* to base *to_base*. Returns `NULL` if any argument is `NULL`. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *from_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. `CONV()` works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+'10'+X'0a',10,10);
-> '40'
```

- `COS(X)`

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- `COT(X)`

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- `DEGREES(X)`

Returns the argument *X*, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- `EXP(X)`

Returns the value of e (the base of natural logarithms) raised to the power of X . The inverse of this function is [LOG\(\)](#) (using a single argument only) or [LN\(\)](#).

```
mysql> SELECT EXP(2);
      -> 7.3890560989307
mysql> SELECT EXP(-2);
      -> 0.13533528323661
mysql> SELECT EXP(0);
      -> 1
```

- [FLOOR\(X\)](#)

Returns the largest integer value not greater than X .

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
      -> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- [FORMAT\(X,D\)](#)

Formats the number X to a format like ' $\#,###,###.##$ ', rounded to D decimal places, and returns the result as a string. For details, see [Section 12.5, “String Functions”](#).

- [HEX\(N_or_S\)](#)

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 12.5, “String Functions”](#), for details.

- [LN\(X\)](#)

Returns the natural logarithm of X ; that is, the base- e logarithm of X . If X is less than or equal to 0.0E0, the function returns [NULL](#) and a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LN(2);
      -> 0.69314718055995
mysql> SELECT LN(-2);
      -> NULL
```

This function is synonymous with [LOG\(X\)](#). The inverse of this function is the [EXP\(\)](#) function.

- [LOG\(X\), LOG\(B,X\)](#)

If called with one parameter, this function returns the natural logarithm of X . If X is less than or equal to 0.0E0, the function returns [NULL](#) and a warning “Invalid argument for logarithm” is reported.

The inverse of this function (when called with a single argument) is the [EXP\(\)](#) function.

```
mysql> SELECT LOG(2);
      -> 0.69314718055995
mysql> SELECT LOG(-2);
      -> NULL
```

If called with two parameters, this function returns the logarithm of X to the base B . If X is less than or equal to 0, or if B is less than or equal to 1, then [NULL](#) is returned.

```
mysql> SELECT LOG(2,65536);
-> 16
mysql> SELECT LOG(10,100);
-> 2
mysql> SELECT LOG(1,100);
-> NULL
```

$\text{LOG}(B,X)$ is equivalent to $\text{LOG}(X) / \text{LOG}(B)$.

- $\text{LOG2}(X)$

Returns the base-2 logarithm of X . If X is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
-> NULL
```

$\text{LOG2}()$ is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression $\text{LOG}(X) / \text{LOG}(2)$.

- $\text{LOG10}(X)$

Returns the base-10 logarithm of X . If X is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG10(2);
-> 0.30102999566398
mysql> SELECT LOG10(100);
-> 2
mysql> SELECT LOG10(-100);
-> NULL
```

$\text{LOG10}(X)$ is equivalent to $\text{LOG}(10,X)$.

- $\text{MOD}(N,M), N \% M, N \text{ MOD } M$

Modulo operation. Returns the remainder of N divided by M .

```
mysql> SELECT MOD(234, 10);
-> 4
mysql> SELECT 253 \% 7;
-> 1
mysql> SELECT MOD(29,9);
-> 2
mysql> SELECT 29 MOD 9;
-> 2
```

This function is safe to use with `BIGINT` values.

$\text{MOD}()$ also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

$\text{MOD}(N,0)$ returns `NULL`.

- `PI()`

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.000000000000000000;
-> 3.141592653589793116
```

- `POW(X,Y)`

Returns the value of X raised to the power of Y .

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- `POWER(X,Y)`

This is a synonym for `POW()`.

- `RADIANS(X)`

Returns the argument X , converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- `RAND([N])`

Returns a random floating-point value v in the range $0 \leq v < 1.0$. To obtain a random integer R in the range $i \leq R < j$, use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range $7 \leq R < 12$, use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument N is specified, it is used as the seed value:

- With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.
- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND()`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i      | RAND() |
+-----+-----+
| 1      | 0.61914388706828 |
| 2      | 0.93845168309142 |
| 3      | 0.83482678498591 |
+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i      | RAND(3) |
+-----+-----+
| 1      | 0.90576975597606 |
| 2      | 0.37307905813035 |
| 3      | 0.14808605345719 |
+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i      | RAND() |
+-----+-----+
| 1      | 0.35877890638893 |
| 2      | 0.28941420772058 |
| 3      | 0.37073435016976 |
+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i      | RAND(3) |
+-----+-----+
| 1      | 0.90576975597606 |
| 2      | 0.37307905813035 |
| 3      | 0.14808605345719 |
+-----+-----+
3 rows in set (0.01 sec)
```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see [Section 8.2.1.18, “Function Call Optimization”](#).

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #49222)

- `ROUND(X)`, `ROUND(X,D)`

Rounds the argument *X* to *D* decimal places. The rounding algorithm depends on the data type of *X*. *D* defaults to 0 if not specified. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
|          150.00 |          150 |
+-----+-----+
```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
|          3 |             2 |
+-----+-----+
```

For more information, see [Section 12.23, “Precision Math”](#).

- `SIGN(X)`

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether *X* is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)`

Returns the sine of `X`, where `X` is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)`

Returns the square root of a nonnegative number `X`.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- `TAN(X)`

Returns the tangent of `X`, where `X` is given in radians.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- `TRUNCATE(X,D)`

Returns the number `X`, truncated to `D` decimal places. If `D` is `0`, the result has no decimal point or fractional part. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

12.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 11.3, “Date and Time Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Table 12.13 Date and Time Functions

Name	Description
<code>ADDDATE ()</code>	Add time values (intervals) to a date value
<code>ADDTIME ()</code>	Add time
<code>CONVERT_TZ ()</code>	Convert from one time zone to another
<code>CURDATE ()</code>	Return the current date
<code>CURRENT_DATE ()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_TIME ()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP ()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURTIME ()</code>	Return the current time
<code>DATE ()</code>	Extract the date part of a date or datetime expression
<code>DATE_ADD ()</code>	Add time values (intervals) to a date value
<code>DATE_FORMAT ()</code>	Format date as specified
<code>DATE_SUB ()</code>	Subtract a time value (interval) from a date
<code>DATEDIFF ()</code>	Subtract two dates
<code>DAY ()</code>	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME ()</code>	Return the name of the weekday
<code>DAYOFMONTH ()</code>	Return the day of the month (0-31)
<code>DAYOFWEEK ()</code>	Return the weekday index of the argument
<code>DAYOFYEAR ()</code>	Return the day of the year (1-366)
<code>EXTRACT ()</code>	Extract part of a date
<code>FROM_DAYS ()</code>	Convert a day number to a date
<code>FROM_UNIXTIME ()</code>	Format Unix timestamp as a date
<code>GET_FORMAT ()</code>	Return a date format string
<code>HOUR ()</code>	Extract the hour
<code>LAST_DAY</code>	Return the last day of the month for the argument
<code>LOCALTIME ()</code> , <code>LOCALTIME</code>	Synonym for <code>NOW()</code>
<code>LOCALTIMESTAMP</code> , <code>LOCALTIMESTAMP ()</code>	Synonym for <code>NOW()</code>
<code>MAKEDATE ()</code>	Create a date from the year and day of year
<code>MAKETIME ()</code>	Create time from hour, minute, second
<code>MICROSECOND ()</code>	Return the microseconds from argument
<code>MINUTE ()</code>	Return the minute from the argument
<code>MONTH ()</code>	Return the month from the date passed
<code>MONTHNAME ()</code>	Return the name of the month

Name	Description
<code>NOW()</code>	Return the current date and time
<code>PERIOD_ADD()</code>	Add a period to a year-month
<code>PERIOD_DIFF()</code>	Return the number of months between periods
<code>QUARTER()</code>	Return the quarter from a date argument
<code>SEC_TO_TIME()</code>	Converts seconds to 'HH:MM:SS' format
<code>SECOND()</code>	Return the second (0-59)
<code>STR_TO_DATE()</code>	Convert a string to a date
<code>SUBDATE()</code>	Synonym for <code>DATE_SUB()</code> when invoked with three arguments
<code>SUBTIME()</code>	Subtract times
<code>SYSDATE()</code>	Return the time at which the function executes
<code>TIME()</code>	Extract the time portion of the expression passed
<code>TIME_FORMAT()</code>	Format as time
<code>TIME_TO_SEC()</code>	Return the argument converted to seconds
<code>TIMEDIFF()</code>	Subtract time
<code>TIMESTAMP()</code>	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
<code>TIMESTAMPADD()</code>	Add an interval to a datetime expression
<code>TIMESTAMPDIFF()</code>	Subtract an interval from a datetime expression
<code>TO_DAYS()</code>	Return the date argument converted to days
<code>TO_SECONDS()</code>	Return the date or datetime argument converted to seconds since Year 0
<code>UNIX_TIMESTAMP()</code>	Return a Unix timestamp
<code>UTC_DATE()</code>	Return the current UTC date
<code>UTC_TIME()</code>	Return the current UTC time
<code>UTC_TIMESTAMP()</code>	Return the current UTC date and time
<code>WEEK()</code>	Return the week number
<code>WEEKDAY()</code>	Return the weekday index
<code>WEEKOFYEAR()</code>	Return the calendar week of the date (1-53)
<code>YEAR()</code>	Return the year
<code>YEARWEEK()</code>	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
      -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the connection's current time zone, which is available as the value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the current time zone. See [Section 5.1.12, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

Several functions are more strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero. These functions are affected: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `LAST_DAY()` (permits a day part of zero), `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- `ADDDATE(date,INTERVAL expr unit), ADDDATE(expr,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'
```

- `ADDTIME(expr1,expr2)`

`ADDTIME()` adds *expr2* to *expr1* and returns the result. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt, from_tz, to_tz)`

`CONVERT_TZ()` converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value. Time zones are specified as described in [Section 5.1.12, “MySQL Server Time Zone Support”](#). This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from *from_tz* to UTC, no conversion occurs. The `TIMESTAMP` range is described in [Section 11.1.2, “Date and Time Type Overview”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'
```

Note

To use named time zones such as `'MET'` or `'Europe/Moscow'`, the time zone tables must be properly set up. See [Section 5.1.12, “MySQL Server Time Zone Support”](#), for instructions.

- `CURDATE()`

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE`, `CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURRENT_TIME`, `CURRENT_TIME([fsp])`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP([fsp])`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `CURTIME([fsp])`

Returns the current time as a value in `'HH:MM:SS'` or `HHMMSS` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)`

`DATEDIFF()` returns *expr1* - *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- `DATE_ADD(date,INTERVAL expr unit),DATE_SUB(date,INTERVAL expr unit)`

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a - for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

The `INTERVAL` keyword and the *unit* specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

<i>unit</i> Value	Expected <i>expr</i> Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOURL	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECONDS.MICROSECONDS'
MINUTE_MICROSECOND	'MINUTES:SECONDS.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'

<i>unit</i> Value	Expected <i>expr</i> Format
HOUR_MICROSECOND	'HOURS:MINUTES:SECONDS.MICROSECONDS'
HOUR_SECOND	'HOURS:MINUTES:SECONDS'
HOUR_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEARS-MONTHS'

The return value depends on the arguments:

- **DATETIME** if the first argument is a **DATETIME** (or **TIMESTAMP**) value, or if the first argument is a **DATE** and the *unit* value uses **HOURS**, **MINUTES**, or **SECONDS**.
- String otherwise.

To ensure that the result is **DATETIME**, you can use **CAST()** to convert the first argument to **DATETIME**.

MySQL permits any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters. If the *date* argument is a **DATE** value and your calculations involve only **YEAR**, **MONTH**, and **DAY** parts (that is, no time parts), the result is a **DATE** value. Otherwise, the result is a **DATETIME** value.

Date arithmetic also can be performed using **INTERVAL** together with the **+** or **-** operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

INTERVAL *expr unit* is permitted on either side of the **+** operator if the expression on the other side is a date or datetime value. For the **-** operator, **INTERVAL *expr unit*** is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2009-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2008-12-31';
-> '2009-01-01'
mysql> SELECT '2005-01-01' - INTERVAL 1 SECOND;
-> '2004-12-31 23:59:59'
mysql> SELECT DATE_ADD('2000-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2001-01-01 00:00:00'
mysql> SELECT DATE_ADD('2010-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2011-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2005-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2004-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
```

```
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
->          INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

Because `expr` is treated as a string, be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOURL_MINUTE`, `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```
mysql> SELECT 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2009-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2009-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
->          INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 DAY);
-> '2013-01-02'
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 HOUR);
-> '2013-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2009-01-30', INTERVAL 1 MONTH);
-> '2009-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2006-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The `%` character is required before format specifier characters.

Specifier	Description
<code>%a</code>	Abbreviated weekday name (<i>Sun..Sat</i>)
<code>%b</code>	Abbreviated month name (<i>Jan..Dec</i>)
<code>%c</code>	Month, numeric (<i>0..12</i>)
<code>%D</code>	Day of the month with English suffix (<i>0th, 1st, 2nd, 3rd, ...</i>)
<code>%d</code>	Day of the month, numeric (<i>00..31</i>)
<code>%e</code>	Day of the month, numeric (<i>0..31</i>)
<code>%f</code>	Microseconds (<i>000000..999999</i>)
<code>%H</code>	Hour (<i>00..23</i>)
<code>%h</code>	Hour (<i>01..12</i>)
<code>%I</code>	Hour (<i>01..12</i>)
<code>%i</code>	Minutes, numeric (<i>00..59</i>)
<code>%j</code>	Day of year (<i>001..366</i>)
<code>%k</code>	Hour (<i>0..23</i>)
<code>%l</code>	Hour (<i>1..12</i>)
<code>%M</code>	Month name (<i>January..December</i>)
<code>%m</code>	Month, numeric (<i>00..12</i>)
<code>%p</code>	<i>AM</i> or <i>PM</i>
<code>%r</code>	Time, 12-hour (<i>hh:mm:ss</i> followed by <i>AM</i> or <i>PM</i>)
<code>%S</code>	Seconds (<i>00..59</i>)
<code>%s</code>	Seconds (<i>00..59</i>)
<code>%T</code>	Time, 24-hour (<i>hh:mm:ss</i>)
<code>%U</code>	Week (<i>00..53</i>), where Sunday is the first day of the week; <code>WEEK()</code> mode 0
<code>%u</code>	Week (<i>00..53</i>), where Monday is the first day of the week; <code>WEEK()</code> mode 1
<code>%V</code>	Week (<i>01..53</i>), where Sunday is the first day of the week; <code>WEEK()</code> mode 2; used with <code>%X</code>
<code>%v</code>	Week (<i>01..53</i>), where Monday is the first day of the week; <code>WEEK()</code> mode 3; used with <code>%x</code>
<code>%W</code>	Weekday name (<i>Sunday..Saturday</i>)
<code>%w</code>	Day of the week (<i>0=Sunday..6=Saturday</i>)
<code>%X</code>	Year for the week where Sunday is the first day of the week, numeric, four digits; used with <code>%V</code>
<code>%x</code>	Year for the week, where Monday is the first day of the week, numeric, four digits; used with <code>%v</code>

Specifier	Description
<code>%Y</code>	Year, numeric, four digits
<code>%y</code>	Year, numeric (two digits)
<code>%%</code>	A literal <code>%</code> character
<code>%x</code>	<code>x</code> , for any “ <code>x</code> ” not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as `'2014-00-00'`.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable ([Section 10.15, “MySQL Server Locale Support”](#)).

For the `%U`, `%u`, `%V`, and `%v` specifiers, see the description of the `WEEK()` function for information about the mode values. The mode affects how week numbering occurs.

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
      -> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
      -> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
      ->          '%D %y %a %d %m %b %j');
      -> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
      ->          '%H %k %I %r %T %S %w');
      -> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
      -> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
      -> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable ([Section 10.15, “MySQL Server Locale Support”](#)).

```
mysql> SELECT DAYNAME('2007-02-03');
      -> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as `'0000-00-00'` or `'2008-00-00'` that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
```

```
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of unit specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '2009-07-02');
-> 2009
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
-> 200907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 12.8, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp, format)`

Returns a representation of the *unix_timestamp* argument as a value in '`YYYY-MM-DD HH:MM:SS`' or `YYYYMMDDHHMMSS` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. *unix_timestamp* is an internal timestamp value such as is produced by the `UNIX_TIMESTAMP()` function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
-> '%Y %D %M %h:%i:%s %x');
-> '2015 11 13 10:08:01 AM'
```

```
-> '2015 13th November 10:08:01 2015'
```

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
<code>GET_FORMAT(DATE, 'USA')</code>	<code>'%m.%d.%Y'</code>
<code>GET_FORMAT(DATE, 'JIS')</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT(DATE, 'ISO')</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT(DATE, 'EUR')</code>	<code>'%d.%m.%Y'</code>
<code>GET_FORMAT(DATE, 'INTERNAL')</code>	<code>'%Y%m%d'</code>
<code>GET_FORMAT(DATETIME, 'USA')</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT(DATETIME, 'JIS')</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT(DATETIME, 'ISO')</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT(DATETIME, 'EUR')</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT(DATETIME, 'INTERNAL')</code>	<code>'%Y%m%d%H%i%s'</code>
<code>GET_FORMAT(TIME, 'USA')</code>	<code>'%h:%i:%s %p'</code>
<code>GET_FORMAT(TIME, 'JIS')</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT(TIME, 'ISO')</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT(TIME, 'EUR')</code>	<code>'%H.%i.%s'</code>
<code>GET_FORMAT(TIME, 'INTERNAL')</code>	<code>'%H%i%s'</code>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOUR(time)`

Returns the hour for `time`. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- `LAST_DAY(date)`

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
      -> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
      -> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
      -> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
      -> NULL
```

- `LOCALTIME, LOCALTIME([fsp])`

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- `LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])`

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- `MAKEDATE(year,dayofyear)`

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
      -> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
      -> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
      -> NULL
```

- `MAKETIME(hour,minute,second)`

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

The *second* argument can have a fractional part.

```
mysql> SELECT MAKETIME(12,15,30);
      -> '12:15:30'
```

- `MICROSECOND(expr)`

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
      -> 123456
mysql> SELECT MICROSECOND('2009-12-31 23:59:59.000010');
      -> 10
```

- `MINUTE(time)`

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
```

```
-> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable ([Section 10.15, “MySQL Server Locale Support”](#)).

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW([fsp])`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1,P2)`

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format `YYMM` or `YYYYMM`. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)`

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 11.3.1, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004','%m/%d/%Y');
-> '2004-04-31'
```

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled, zero dates or part of dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('15:35:00','%H:%i:%s');
+-----+
| STR_TO_DATE('15:35:00','%H:%i:%s') |
+-----+
| 15:35:00                           |
+-----+
mysql> SET sql_mode = 'NO_ZERO_IN_DATE';
mysql> SELECT STR_TO_DATE('15:35:00','%h:%i:%s');
+-----+
| STR_TO_DATE('15:35:00','%h:%i:%s') |
+-----+
| NULL                               |
+-----+
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1411
Message: Incorrect datetime value: '15:35:00' for function str_to_date
```

**Note**

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
      -> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
      -> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
      -> '2007-12-02'
```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
      -> '2007-12-02 12:00:00'
```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
      -> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
      -> '-00:59:59.999999'
```

- `SYSDATE([fsp])`

Returns the current date and time as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYMMDDHHMMSS` format, depending on whether the function is used in a string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
```

SYSDATE()	SLEEP(2)	SYSDATE()
2006-04-12 13:47:44	0	2006-04-12 13:47:46

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the master and the slave.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)`

Adds the integer expression *interval* to the date or datetime expression *datetime_expr*. The unit for *interval* is given by the *unit* argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns *datetime_expr2* - *datetime_expr1*, where *datetime_expr1* and *datetime_expr2* are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or 0.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 11.3, “Date and Time Types”](#). For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `TO_SECONDS(expr)`

Given a date or datetime *expr*, returns the number of seconds since the year 0. If *expr* is not a valid date or datetime value, returns `NULL`.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
```

```
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS( NOW() );
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 11.3, “Date and Time Types”](#).

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
| 86400 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP()`, `UNIX_TIMESTAMP(date)`

If called with no argument, returns a Unix timestamp (seconds since `'1970-01-01 00:00:00'` UTC). The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or `DECIMAL` if an argument is given that includes a fractional seconds part.

If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since `'1970-01-01 00:00:00'` UTC. The *date* argument may be a `DATE`, `DATETIME`, or `TIMESTAMP` string, or a number in `YYMMDD`, `YYMMDDHHMMSS`, `YYYYMMDD`, or `YYYYMMDDHHMMSS` format. If the argument includes a time part, it may optionally include a fractional seconds part. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in [Section 5.1.12, “MySQL Server Time Zone Support”](#).

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
```

```

-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012

```

When `UNIX_TIMESTAMP()` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0. The valid range of values is the same as for the `TIMESTAMP` data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC.

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the CET time zone:

```

mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+

```

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See [Section 12.10, “Cast Functions and Operators”](#).

- `UTC_DATE, UTC_DATE()`

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```

mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814

```

- `UTC_TIME, UTC_TIME([fsp])`

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```

mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000

```

- `UTC_TIMESTAMP, UTC_TIMESTAMP([fsp])`

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[,mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See [Section 5.1.7, “Server System Variables”](#).

The following table describes how the *mode* argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with 4 or more days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with 4 or more days this year
4	Sunday	0-53	with 4 or more days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with 4 or more days this year
7	Monday	1-53	with a Monday in this year

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date,3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date,mode)`

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

The *mode* argument works exactly like the *mode* argument to `WEEK()`. For the single-argument syntax, a *mode* value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

Note that the week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

12.8 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.9 Full-Text Search Functions

`MATCH (col1,col2,...) AGAINST (expr [search_modifier])`

```
search_modifier:
{
    IN NATURAL LANGUAGE MODE
    | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
    | IN BOOLEAN MODE
    | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in [Section 12.9.8, “ngram Full-Text Parser”](#), and [Section 12.9.9, “MeCab Full-Text Parser Plugin”](#).
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.

- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (") characters. The stopwords list applies. For more information about stopwords lists, see [Section 12.9.4, “Full-Text Stopwords”](#).

Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 12.9.1, “Natural Language Full-Text Searches”](#).

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 12.9.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 12.9.3, “Full-Text Searches with Query Expansion”](#).

For information about `FULLTEXT` query performance, see [Section 8.3.5, “Column Indexes”](#).

For more information about `InnoDB FULLTEXT` indexes, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#).

Constraints on full-text searching are listed in [Section 12.9.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility dumps the contents of a `MyISAM` full-text index. This may be helpful for debugging full-text queries. See [Section 4.6.3, “myisam_ftdump — Display Full-Text Index information”](#).

12.9.1 Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
```

```

) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)

mysql> INSERT INTO articles (title,body) VALUES
      ('MySQL Tutorial','DBMS stands for DataBase ...'),
      ('How To Use MySQL Well','After you went through a ...'),
      ('Optimizing MySQL','In this tutorial we will show ...'),
      ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
      ('MySQL vs. YourSQL','In the following database comparison ...'),
      ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.01 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title                | body                                |
+-----+-----+-----+
| 1  | MySQL Tutorial       | DBMS stands for DataBase ...      |
| 5  | MySQL vs. YourSQL    | In the following database comparison ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a case-sensitive or binary collation for the indexed columns. For example, a column that uses the `utf8mb4` character set of can be assigned a collation of `utf8mb4_0900_as_cs` or `utf8mb4_bin` to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

Note

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```

mysql> SELECT COUNT(*) FROM articles
      WHERE MATCH (title,body)
      AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)

```

You might find it quicker to rewrite the query as follows:

```

mysql> SELECT
      COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
      AS count
      FROM articles;
+-----+
| count |
+-----+

```

```
|      2 |
+-----+
1 row in set (0.03 sec)
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in [Section 12.9.2, “Boolean Full-Text Searches”](#), and [Section 12.9.3, “Full-Text Searches with Query Expansion”](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
        AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
        FROM articles;
+-----+-----+
| id | score |
+-----+-----+
| 1 | 0.22764469683170319 |
| 2 | 0 |
| 3 | 0.22764469683170319 |
| 4 | 0 |
| 5 | 0 |
| 6 | 0 |
+-----+-----+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
        ('Security implications of running MySQL as root'
         IN NATURAL LANGUAGE MODE) AS score
        FROM articles WHERE MATCH (title,body) AGAINST
        ('Security implications of running MySQL as root'
         IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | body | score |
+-----+-----+-----+
| 4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
| 6 | When configured properly, MySQL ... | 1.3114095926285 |
+-----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`. If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ('), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa' 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The built-in `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index that uses the built-in `FULLTEXT` parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create `FULLTEXT` indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 28.2, “The MySQL Plugin API”](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for `InnoDB` search indexes, or four characters for `MyISAM`. You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` configuration option for `InnoDB` search indexes, or `ft_min_word_len` for `MyISAM`.

Note

This behavior does not apply to `FULLTEXT` indexes that use the ngram parser. For the ngram parser, token length is defined by the `ngram_token_size` option.

- Words in the stopwords list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopwords list, but it can be overridden by a user-defined list. The stopwords lists and related configuration options are different for `InnoDB` search indexes and `MyISAM` ones. Stopword processing is controlled by the configuration options `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for `InnoDB` search indexes, and `ft_stopword_file` for `MyISAM` ones.

See [Section 12.9.4, “Full-Text Stopwords”](#) to view default stopwords lists and how to change them. The default minimum word length can be changed as described in [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on [MyISAM](#) tables. For example, although the word “MySQL” is present in every row of the [articles](#) table shown earlier, a search for the word in a [MyISAM](#) search index produces no results:

```
mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopwords. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes [InnoDB](#) tables more suited to experimentation with full-text searches. If you create a [MyISAM](#) table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on [InnoDB](#) tables, or use the boolean search mode explained in [Section 12.9.2, “Boolean Full-Text Searches”](#).

12.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `-` operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
      AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
+-----+-----+-----+
| id | title                | body                                |
+-----+-----+-----+
| 1 | MySQL Tutorial        | DBMS stands for DataBase ...      |
| 2 | How To Use MySQL Well | After you went through a ...      |
| 3 | Optimizing MySQL      | In this tutorial we will show ...  |
| 4 | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ... |
| 6 | MySQL Security        | When configured properly, MySQL ... |
+-----+-----+-----+
```

Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- `+` stands for [AND](#)
- `-` stands for [NOT](#)
- `[no operator]` implies [OR](#)

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.
- **InnoDB** tables require a **FULLTEXT** index on all columns of the **MATCH()** expression to perform boolean queries. Boolean queries against a **MyISAM** search index can work even without a **FULLTEXT** index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply to **FULLTEXT** indexes created using the built-in **FULLTEXT** parser and MeCab parser plugin. **innodb_ft_min_token_size** and **innodb_ft_max_token_size** are used for **InnoDB** search indexes. **ft_min_word_len** and **ft_max_word_len** are used for **MyISAM** search indexes.

Minimum and maximum word length full-text parameters do not apply to **FULLTEXT** indexes created using the ngram parser. ngram token size is defined by the **ngram_token_size** option.

- The stopword list applies, controlled by **innodb_ft_enable_stopword**, **innodb_ft_server_stopword_table**, and **innodb_ft_user_stopword_table** for **InnoDB** search indexes, and **ft_stopword_file** for **MyISAM** ones.
- **InnoDB** full-text search does not support the use of multiple operators on a single search word, as in this example: **'++apple'**. Use of multiple operators on a single search word returns a syntax error to standard out. **MyISAM** full-text search will successfully process the same search ignoring all operators except for the operator immediately adjacent to the search word.
- **InnoDB** full-text search only supports leading plus or minus signs. For example, **InnoDB** supports **'+apple'** but does not support **'apple+'**. Specifying a trailing plus or minus sign causes **InnoDB** to report a syntax error.
- **InnoDB** full-text search does not support the use of a leading plus sign with wildcard (**'+*'**), a plus and minus sign combination (**'+-'**), or leading a plus and minus sign combination (**'+-apple'**). These invalid queries return a syntax error.
- **InnoDB** full-text search does not support the use of the **@** symbol in boolean full-text searches. The **@** symbol is reserved for use by the **@distance** proximity search operator.
- They do not use the 50% threshold that applies to **MyISAM** search indexes.

The boolean full-text search capability supports the following operators:

- **+**

A leading or trailing plus sign indicates that this word *must* be present in each row that is returned. **InnoDB** only supports leading plus signs.

- **-**

A leading or trailing minus sign indicates that this word must *not* be present in any of the rows that are returned. **InnoDB** only supports leading minus signs.

Note: The **-** operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by **-** returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither **+** nor **-** is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of **MATCH() ... AGAINST()** without the **IN BOOLEAN MODE** modifier.

- `@distance`

This operator works on `InnoDB` tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the `@distance` operator, for example, `MATCH(col1) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)`

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `()`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the `innodb_ft_min_token_size` setting for `InnoDB` tables, or `ft_min_word_len` for `MyISAM` tables. These options are not applicable to `FULLTEXT` indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `'+word +the*'` could return fewer rows than a search for `'+word +the'`, because the second query ignores the too-short search term `the`.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the `"` characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

Relevancy Rankings for InnoDB Boolean Mode Search

[InnoDB](#) full-text search is modeled on the [Sphinx](#) full-text search engine, and the algorithms used are based on [BM25](#) and [TF-IDF](#) ranking algorithms. For these reasons, relevancy rankings for [InnoDB](#) boolean full-text search may differ from [MyISAM](#) relevancy rankings.

[InnoDB](#) uses a variation of the “term frequency-inverse document frequency” ([TF-IDF](#)) weighting system to rank a document's relevance for a given full-text search query. The [TF-IDF](#) weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

How Relevancy Ranking is Calculated

The term frequency ([TF](#)) value is the number of times that a word appears in a document. The inverse document frequency ([IDF](#)) value of a word is calculated using the following formula, where [total_records](#) is the number of records in the collection, and [matching_records](#) is the number of records that the search term appears in.

```
${IDF} = log10( ${total_records} / ${matching_records} )
```

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

```
${TF} * ${IDF}
```

Using the [TF](#) and [IDF](#) values, the relevancy ranking for a document is calculated using this formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

The formula is demonstrated in the following examples.

Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```
mysql> CREATE TABLE articles (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
title VARCHAR(200),
body TEXT,
FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','This database tutorial ...'),
('How To Use MySQL','After you went through a ...'),
('Optimizing Your Database','In this database tutorial ...'),
('MySQL vs. YourSQL','When comparing databases ...'),
('MySQL Security','When configured properly, MySQL ...'),
('Database, Database, Database','database database database'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL Full-Text Indexes','MySQL fulltext indexes use a ..');
Query OK, 8 rows affected (0.06 sec)
Records: 8 Duplicates: 0 Warnings: 0

mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('database' IN BOOLEAN MODE)
AS score FROM articles ORDER BY score DESC;
```

id	title	body	score
6	Database, Database, Database	database database database	1.0886961221694946
3	Optimizing Your Database	In this database tutorial ...	0.36289870738983154
1	MySQL Tutorial	This database tutorial ...	0.18144935369491577
2	How To Use MySQL	After you went through a ...	0
4	MySQL vs. YourSQL	When comparing databases ...	0
5	MySQL Security	When configured properly, MySQL ...	0
7	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...	0
8	MySQL Full-Text Indexes	MySQL fulltext indexes use a ..	0

```
8 rows in set (0.00 sec)
```

There are 8 records in total, with 3 that match the “database” search term. The first record ([id 6](#)) contains the search term 6 times and has a relevancy ranking of [1.0886961221694946](#). This ranking value is calculated using a [TF](#) value of 6 (the “database” search term appears 6 times in record [id 6](#)) and an [IDF](#) value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

```
${IDF} = log10( 8 / 3 ) = 0.42596873216370745
```

The [TF](#) and [IDF](#) values are then entered into the ranking formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

Performing the calculation in the MySQL command-line client returns a ranking value of [1.088696164686938](#).

```
mysql> SELECT 6*log10(8/3)*log10(8/3);
+-----+
| 6*log10(8/3)*log10(8/3) |
+-----+
| 1.088696164686938 |
+-----+
1 row in set (0.00 sec)
```

**Note**

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client (1.0886961221694946 versus 1.088696164686938). The difference is due to how the casts between integers and floats/doubles are performed internally by `InnoDB` (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

$$\${rank} = \${TF} * \${IDF} * \${IDF} + \${TF} * \${IDF} * \${IDF}$$

Performing a search on two terms ('mysql tutorial') returns the following results:

```
mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('mysql tutorial' IN BOOLEAN MODE)
      AS score FROM articles ORDER BY score DESC;
```

id	title	body	score
1	MySQL Tutorial	This database tutorial ...	0.7405621409416199
3	Optimizing Your Database	In this database tutorial ...	0.3624762296676636
5	MySQL Security	When configured properly, MySQL ...	0.031219376251101494
8	MySQL Full-Text Indexes	MySQL fulltext indexes use a ..	0.031219376251101494
2	How To Use MySQL	After you went through a ...	0.015609688125550747
4	MySQL vs. YourSQL	When comparing databases ...	0.015609688125550747
7	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...	0.015609688125550747
6	Database, Database, Database	database database database	0

8 rows in set (0.00 sec)

In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
```

(1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2))
0.7405621541938003

1 row in set (0.00 sec)

**Note**

The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really

mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
  WHERE MATCH (title,body)
  AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

id	title	body
1	MySQL Tutorial	DBMS stands for DataBase ...
5	MySQL vs. YourSQL	In the following database comparison ...

```
2 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM articles
  WHERE MATCH (title,body)
  AGAINST ('database' WITH QUERY EXPANSION);
```

id	title	body
5	MySQL vs. YourSQL	In the following database comparison ...
1	MySQL Tutorial	DBMS stands for DataBase ...
3	Optimizing MySQL	In this tutorial we will show ...
6	MySQL Security	When configured properly, MySQL ...
2	How To Use MySQL Well	After you went through a ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...

```
6 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

12.9.4 Full-Text Stopwords

The stopwords list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopwords lookups if the stopwords file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopwords lookups depends on the server collation. For example, lookups are case insensitive if the collation is `utf8mb4_0900_ai_ci`, whereas lookups are case-sensitive if the collation is `utf8mb4_0900_as_cs` or `utf8mb4_bin`.

- [Stopwords for InnoDB Search Indexes](#)

- [Stopwords for MyISAM Search Indexes](#)

Stopwords for InnoDB Search Indexes

[InnoDB](#) has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default [InnoDB](#) stopwords list, query the [INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD](#) table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a      |
| about  |
| an     |
| are    |
| as     |
| at     |
| be     |
| by     |
| com    |
| de     |
| en     |
| for    |
| from   |
| how    |
| i      |
| in     |
| is     |
| it     |
| la     |
| of     |
| on     |
| or     |
| that   |
| the    |
| this   |
| to     |
| was    |
| what   |
| when   |
| where  |
| who    |
| will   |
| with   |
| und    |
| the    |
| www    |
+-----+
36 rows in set (0.00 sec)
```

To define your own stopwords list for all [InnoDB](#) tables, define a table with the same structure as the [INNODB_FT_DEFAULT_STOPWORD](#) table, populate it with stopwords, and set the value of the [innodb_ft_server_stopword_table](#) option to a value in the form *db_name/table_name* before creating the full-text index. The stopwords table must have a single [VARCHAR](#) column named *value*. The following example demonstrates creating and configuring a new global stopwords table for [InnoDB](#).

```
-- Create a new stopwords table

mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)
```

```
-- Insert stopwords (for simplicity, a single stopwords is used in this example)

mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table

mysql> CREATE TABLE opening_lines (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
opening_line TEXT(500),
author VARCHAR(200),
title VARCHAR(200)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopwords table

mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 1
```

Verify that the specified stopwords ('Ishmael') does not appear by querying the words in `INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE`.

Note

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an `InnoDB` full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.

```
mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----+
| word |
+-----+
| across |
| all |
| burn |
| buy |
| call |
| comes |
```

```

| dalloway |
| first    |
| flowers  |
| happened |
| herself  |
| invisible|
| less     |
| love     |
| man      |
+-----+
15 rows in set (0.00 sec)

```

To create stopwords lists on a table-by-table basis, create other stopwords tables and use the `innodb_ft_user_stopword_table` option to specify the stopwords table that you want to use before you create the full-text index.

Stopwords for MyISAM Search Indexes

The stopwords file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`.

To override the default stopwords list for MyISAM tables, set the `ft_stopword_file` system variable. (See [Section 5.1.7, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopwords list, or the empty string to disable stopwords filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopwords file, restart the server and rebuild your `FULLTEXT` indexes.

The stopwords list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopwords list is the server's default character set; see [Section 10.3.2, “Server Character Set and Collation”](#).

The following list shows the default stopwords for `MyISAM` search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

12.9.5 Full-Text Restrictions

- Full-text searches are supported for [InnoDB](#) and [MyISAM](#) tables only.
- Full-text searches are not supported for partitioned tables. See [Section 22.6, “Restrictions and Limitations on Partitioning”](#).
- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the [utf8](#) character set can be used, but not the [ucs2](#) character set. Although [FULLTEXT](#) indexes on [ucs2](#) columns cannot be used, you can perform [IN BOOLEAN MODE](#) searches on a [ucs2](#) column that has no such index.

The remarks for [utf8](#) also apply to [utf8mb4](#), and the remarks for [ucs2](#) also apply to [utf16](#), [utf16le](#), and [utf32](#).

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser *cannot determine where words begin and end in these and other such languages*.

A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with [InnoDB](#) and [MyISAM](#) tables.

- Although the use of multiple character sets within a single table is supported, all columns in a [FULLTEXT](#) index must use the same character set and collation.
- The [MATCH\(\)](#) column list must match exactly the column list in some [FULLTEXT](#) index definition for the table, unless this [MATCH\(\)](#) is [IN BOOLEAN MODE](#) on a [MyISAM](#) table. For [MyISAM](#) tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to [AGAINST\(\)](#) must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.
- Index hints are more limited for [FULLTEXT](#) searches than for non-[FULLTEXT](#) searches. See [Section 8.9.4, “Index Hints”](#).
- For [InnoDB](#), all DML operations ([INSERT](#), [UPDATE](#), [DELETE](#)) involving columns with full-text indexes are processed at transaction commit time. For example, for an [INSERT](#) operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.
- The '%' character is not a supported wildcard character for full-text searches.

12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “Installing MySQL from Source”](#).

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- [Configuring Minimum and Maximum Word Length](#)
- [Configuring the Natural Language Search Threshold](#)
- [Modifying Boolean Full-Text Search Operators](#)
- [Character Set Modifications](#)
- [Rebuilding InnoDB Full-Text Indexes](#)
- [Optimizing InnoDB Full-Text Indexes](#)
- [Rebuilding MyISAM Full-Text Indexes](#)

Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` and `innodb_ft_max_token_size` for InnoDB search indexes, and `ft_min_word_len` and `ft_max_word_len` for MyISAM ones.

Note

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your `FULLTEXT` indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your `FULLTEXT` indexes. For MyISAM tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding MyISAM full-text indexes.

Configuring the Natural Language Search Threshold

For MyISAM search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on `MyISAM` tables, set the `ft_boolean_syntax` system variable. (`InnoDB` does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)). No rebuilding of indexes is necessary in this case.

Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:

- Modify the MySQL source: In `storage/innobase/handler/ha_innodb.cc` (for `InnoDB`), or in `storage/myisam/ftdefs.h` (for `MyISAM`), see the `true_word_char()` and `misc_word_char()` macros. Add '-' to one of those macros and recompile MySQL.
- Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. . You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 10.12.1, “Character Definition Arrays”](#).
- Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 10.13, “Adding a Collation to a Character Set”](#). For an example specific to full-text indexing, see [Section 12.9.7, “Adding a Collation for Full-Text Indexing”](#).

Rebuilding InnoDB Full-Text Indexes

If you modify full-text variables that affect indexing (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `innodb_ft_server_stopword_table`, `innodb_ft_user_stopword_table`, `innodb_ft_enable_stopword`, `ngram_token_size`) you must rebuild your `FULLTEXT` indexes after making the changes. Modifying the `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` variables, which cannot be set dynamically, require restarting the server and rebuilding the indexes.

To rebuild the `FULLTEXT` indexes for an `InnoDB` table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)

mysql> OPTIMIZE TABLE opening_lines;
+-----+-----+-----+-----+
| Table           | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.opening_lines | optimize | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server.

To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for MyISAM table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.9.7 Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `'-'` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 10.13, “Adding a Collation to a Character Set”](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in [Section 10.13, “Adding a Collation to a Character Set”](#), can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The collation ID must be unused, so choose a value different from 1000 if that ID is already taken on your system.

```
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1000"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
```

```
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the '-' character) from 10 (punctuation) to 01 (small letter). In the following array, this is the element in the fourth row down, third value from the end.

```
<ctype>
<map>
00
20 20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
84 84 84 84 84 84 84 84 84 84 10 10 10 10 10 10
10 81 81 81 81 81 81 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 10 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 10 10 10 10 20
10 00 10 02 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02
</map>
</ctype>
```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
  a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
  FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)
```

6. Test the collation to verify that hyphen is considered as a word character:

```
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a      |
+-----+
| ----  |
+-----+
1 row in set (0.00 sec)
```

12.9.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with [InnoDB](#) and [MyISAM](#).

**Note**

MySQL also provides a MeCab full-text parser plugin for Japanese, which tokenizes documents into meaningful words. For more information, see [Section 12.9.9, “MeCab Full-Text Parser Plugin”](#).

An ngram is a contiguous sequence of *n* characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of *n* characters. For example, you can tokenize “abcd” for different values of *n* using the ngram full-text parser.

```
n=1: 'a', 'b', 'c', 'd'
n=2: 'ab', 'bc', 'cd'
n=3: 'abc', 'bcd'
n=4: 'abcd'
```

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in [Section 12.9, “Full-Text Search Functions”](#) applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, `ft_max_word_len`) are also applicable.

Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the `ngram_token_size` configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, `ngram_token_size` is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set `ngram_token_size` to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set `ngram_token_size` accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set `ngram_token_size` to a value of 2 or higher.

As a read-only variable, `ngram_token_size` may only be set as part of a startup string or in a configuration file:

- Startup string:

```
mysqld --ngram_token_size=2
```

- Configuration file:

```
[mysqld]
ngram_token_size=2
```

**Note**

The following minimum and maximum word length configuration options are ignored for `FULLTEXT` indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

Creating a FULLTEXT Index that Uses the ngram Parser

To create a `FULLTEXT` index that uses the ngram parser, specify `WITH PARSE` `ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an [ngram FULLTEXT](#) index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the [INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE](#) table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body) WITH PARSE ngram
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

INSERT INTO articles (title,body) VALUES
('数据库管理','在本教程中我将向你展示如何管理数据库'),
('数据库应用开发','学习开发数据库应用程序');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a [FULLTEXT](#) index to an existing table, you can use [ALTER TABLE](#) or [CREATE INDEX](#). For example:

```
CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSE ngram;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSE ngram;
```

ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopwords list. If a word is equal to an entry in the stopwords list, the word is excluded from the index. For the ngram parser, stopwords handling is performed differently. Instead of excluding tokens that are equal to entries in the stopwords list, the ngram parser excludes tokens that *contain* stopwords. For example, assuming [ngram_token_size=2](#), a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (“,”) is defined as a stopwords, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopwords list, which contains a list of English stopwords. For a stopwords list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopwords list, see [Section 12.9.4, “Full-Text Stopwords”](#).

Stopwords greater in length than [ngram_token_size](#) are ignored.

ngram Parser Term Search

For *natural language mode* search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For *boolean mode* search, the search term is converted to an ngram phrase search. For example, the string 'abc' (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing 'ab' and the other containing 'abc', the search phrase “ab bc” only matches the document containing 'abc'.

ngram Parser Wildcard Search

Because an ngram `FULLTEXT` index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram `FULLTEXT` search indexes:

- If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on “a*” returns all rows starting with “a”.
- If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an “abc*” wildcard search is converted to “ab bc”.

ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

12.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with `InnoDB` and `MyISAM`.

Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see [Section 12.9.8, “ngram Full-Text Parser”](#).

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes “データベース管理” (“Database Management”) into “データベース” (“Database”) and “管理” (“Management”). By comparison, the `ngram` full-text parser tokenizes text into a contiguous sequence of `n` characters, where `n` represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in [Section 12.9, “Full-Text Search Functions”](#) applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the [MeCab: Yet Another Part-of-Speech and Morphological Analyzer](#) project on Github.

Installing the MeCab Parser Plugin

The MeCab parser plugin requires `mecab` and `mecab-ipadic`.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system `mecab` version is too old), MySQL dynamically links to the system `mecab` installation if it is installed to the default location. On other supported Unix-like platforms, `libmecab.so` is statically linked in `libpluginmecab.so`, which is located in the MySQL plugin directory. `mecab-ipadic` is included in MySQL binaries and is located in `MYSQL_HOME/lib/mecab`.

You can install `mecab` and `mecab-ipadic` using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build `mecab` and `mecab-ipadic` from source. For information about installing `mecab` and `mecab-ipadic` using a native package management utility, see [Installing MeCab From a Binary Distribution \(Optional\)](#). If you want to build `mecab` and `mecab-ipadic` from source, see [Building MeCab From Source \(Optional\)](#).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

```
[mysqld]
loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
```

The `loose` prefix is an [option modifier](#). The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

For information about the MySQL configuration file and its location, see [Section 4.2.7, “Using Option Files”](#).

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For `InnoDB` tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For `MyISAM` tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

```
[mysqld]
innodb_ft_min_token_size=1
```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

```
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
```

To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

```
dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
```

If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file will differ, as will the dictionaries and their location.

Note

After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpm`s character sets.
- The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.
- The `ipadic_utf-8` dictionary supports the `utf8` and `utf8mb4` character sets.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.
5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

```
INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
```

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

```
mysql> SHOW PLUGINS;
```

A `mecab` plugin should appear in the list of plugins.

Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSE`r `ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a `mecab FULLTEXT` index, inserting sample data, and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table:

```
mysql> USE test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
```

```

        body TEXT,
        FULLTEXT (title,body) WITH PARSEER mecab
    ) ENGINE=InnoDB CHARACTER SET utf8;

mysql> SET NAMES utf8;

mysql> INSERT INTO articles (title,body) VALUES
    ('データベース管理','このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
    ('データベースアプリケーション開発','データベースアプリケーションを開発することを学ぶ');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;

```

To add a [FULLTEXT](#) index to an existing table, you can use [ALTER TABLE](#) or [CREATE INDEX](#). For example:

```

CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSEER mecab;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSEER mecab;

```

MeCab Parser Space Handling

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

MeCab Parser Stopword Handling

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see [Section 12.9.4, “Full-Text Stopwords”](#).

MeCab Parser Term Search

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

MeCab Parser Wildcard Search

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース*' IN BOOLEAN MODE);
```

MeCab Parser Phrase Search

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

Installing MeCab From a Binary Distribution (Optional)

This section describes how to install `mecab` and `mecab-ipadic` from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

Installing MeCab From Source (Optional)

If you want to build `mecab` and `mecab-ipadic` from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for `mecab` and `mecab-ipadic` from <http://taku910.github.io/mecab/#download>. As of February, 2016, the latest available packages are `mecab-0.996.tar.gz` and `mecab-ipadic-2.7.0-20070801.tar.gz`.

2. Install `mecab`:

```
tar zxvf mecab-0.996.tar
cd mecab-0.996
./configure
make
make check
su
make install
```

3. Install `mecab-ipadic`:

```
tar zxvf mecab-ipadic-2.7.0-20070801.tar
cd mecab-ipadic-2.7.0-20070801
./configure
make
su
make install
```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

12.10 Cast Functions and Operators

Table 12.14 Cast Functions and Operators

Name	Description
<code>BINARY</code>	Cast a string to a binary string
<code>CAST()</code>	Cast a value as a certain type
<code>CONVERT()</code>	Cast a value as a certain type

Cast functions and operators enable conversion of values from one data type to another.

`CONVERT()` with a `USING` clause provides a way to convert data between different character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8_table (utf8_column)
  SELECT CONVERT(latin1_column USING utf8) FROM latin1_table;
```

You can also use `CONVERT()` without `USING` or `CAST()` to convert strings between different character sets:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);
```

If you specify `CHARACTER SET charset_name` as just shown, the resulting character set and collation are `charset_name` and the default collation of `charset_name`. If you omit `CHARACTER SET charset_name`, the resulting character set and collation are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 10.4, “Connection Character Sets and Collations”](#)).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, this is legal:

```
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

But this is illegal:

```
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8_bin);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result character set has a case-insensitive collation, a `LIKE` operation is not case-sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1)
FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
```

```
FROM tbl_name;
```

`CONVERT()` and `CAST()` can be used more generally for comparing strings that are represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (latin2_general_ci,IMPLICIT) for operation '='

```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-----+
| @s1 = CONVERT(@s2 USING latin1) |
+-----+
| 1 |
+-----+
```

For string literals, another way to specify the character set is to use a character set introducer (`_latin1` and `_latin2` in the preceding example are instances of introducers). Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see [Section 10.3.8, “Character Set Introducers”](#).

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York    | new york                            |
+-----+-----+
```

If you convert an indexed column using `BINARY`, `CAST()`, or `CONVERT()`, MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
***** 1. row *****
      Table: new_table
Create Table: CREATE TABLE `new_table` (
  `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4

```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ', CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See [Section 12.7, “Date and Time Functions”](#).

To cast a string to a number, you normally need do nothing other than use the string value in numeric context:

```
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see [Section 12.2, “Type Conversion in Expression Evaluation”](#).

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see [Section 12.6.1, “Arithmetic Operators”](#)). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see [Section 5.1.10, “Server SQL Modes”](#)). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.

- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- `BINARY expr`

The `BINARY` operator converts the expression to a binary string. A common use for `BINARY` is to force a character string comparison to be done byte by byte rather than character by character, in effect becoming case-sensitive. The `BINARY` operator also causes trailing spaces in comparisons to be significant.

```
mysql> SELECT 'a' = 'A';
      -> 1
mysql> SELECT BINARY 'a' = 'A';
      -> 0
mysql> SELECT 'a' = 'a ';
      -> 1
mysql> SELECT BINARY 'a' = 'a ';
      -> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

For purposes of converting a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a string literal, it can be designated as a binary string without performing any conversion by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
      -> 1
mysql> SELECT _binary 'a' = 'A';
      -> 0
```

For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. A character column defined with the `BINARY` attribute is assigned table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, the binary collation for the `utf8` character set is `utf8_bin`, so if the table default character set is `utf8`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)
```

```

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB

```

- `CAST(expr AS type)`

The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

`CAST()` is standard SQL syntax.

- `CONVERT(expr,type), CONVERT(expr USING transcoding_name)`

The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

Discussion of `CONVERT(expr, type)` syntax here also applies to `CAST(expr AS type)`, which is equivalent.

`CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT()` with `USING` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

`CONVERT()` without `USING` and `CAST()` take an expression and a `type` value specifying the result type. These `type` values are permitted:

- `BINARY[(N)]`

Produces a string with the `BINARY` data type. See [Section 11.4.2, “The BINARY and VARBINARY Types”](#) for a description of how this affects comparisons. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`.

- `CHAR[(N)] [charset_info]`

Produces a string with the `CHAR` data type. If the optional length `N` is given, `CHAR(N)` causes the cast to use no more than `N` characters of the argument. No padding occurs for values shorter than `N` characters.

With no `charset_info` clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these `charset_info` values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.
- `UNICODE`: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the default collation for the character set.

- `DATE`

Produces a `DATE` value.

- `DATETIME`

Produces a `DATETIME` value.

- `DECIMAL[(M[,D])]`

Produces a `DECIMAL` value. If the optional `M` and `D` values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

- `JSON`

Produces a `JSON` value. For details on the rules for conversion of values between `JSON` and other types, see [Comparison and Ordering of JSON Values](#).

- `NCHAR[(N)]`

Like `CHAR`, but produces a string with the national character set. See [Section 10.3.7, “The National Character Set”](#).

Unlike `CHAR`, `NCHAR` does not permit trailing character set information to be specified.

- `SIGNED [INTEGER]`

Produces a signed integer value.

- `TIME`

Produces a `TIME` value.

- `UNSIGNED [INTEGER]`

Produces an unsigned integer value.

12.11 XML Functions

Table 12.15 XML Functions

Name	Description
<code>ExtractValue()</code>	Extracts a value from an XML string using XPath notation
<code>UpdateXML()</code>	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-

depth discussion of these topics is beyond the scope of this manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 8.0 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax ``${variable_name}`` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) ``${myvariable}`` is used where ``${myvariable}`` was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[${@i}]');
+-----+-----+
| @i | ExtractValue(@xml, '//b[${@i}]') |
+-----+-----+
| 1 | X |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[${@j}]');

- **Variables in stored programs (strong checking).** Variables using the syntax ``${variable_name}`` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
->   DECLARE i INT DEFAULT 1;
->   DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
->
->   WHILE i < 4 DO
->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
->     SET i = i+1;
->   END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();

+-----+-----+-----+
| xml                                     | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a>                | 1 | X                             |
+-----+-----+-----+
1 row in set (0.00 sec)

+-----+-----+-----+
| xml                                     | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a>                | 2 | Y                             |
+-----+-----+-----+
1 row in set (0.01 sec)

+-----+-----+-----+
| xml                                     | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a>                | 3 | Z                             |
+-----+-----+-----+
1 row in set (0.01 sec)
```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup *xml_frag* and an XPath expression *xpath_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the *xpath_expr* after appending `/text()`. In other words, `ExtractValue('<a>Sakila', '/a/b')` and `ExtractValue('<a>Sakila', '/a/b/text()')` produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as `xpath_expr` is valid, and `xml_frag` consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in `xml_frag` or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-----+
| ExtractValue('<a><b/></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-----+
| ExtractValue('<a><c/></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-----+
| 1                                           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-----+
| 0                                           |
+-----+
1 row in set (0.01 sec)
```

Important

`ExtractValue()` returns only `CDATA`, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
-> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
+-----+-----+-----+-----+-----+
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 10.8.4, “Collation Coercibility in Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL                                     |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                                           |
+-----+
1 row in set (0.00 sec)
```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```
mysql> SELECT
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
->   UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

**Note**

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<a/>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a>` because it is a child of the root element `a`. It does not have a match in `<a/>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c></c>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><c/>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><c/>`; `<c><a>`; `<c><a/></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a>` or `<c><a></c>`.

**Note**

`//tag` is the equivalent of `/descendant-or-self::*/*tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @xml;
```

```
+-----+
| @xml                                     |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a>      |
+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT ExtractValue(@xml, '//b[1]');
```

```
+-----+
| ExtractValue(@xml, '//b[1]')           |
+-----+
```

```

+-----+
| x z   |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]') |
+-----+
|                               |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z   |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
|                               |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z   |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x   |
+-----+
1 row in set (0.00 sec)

```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `*/b` matches the `b` element in either of the XML fragments `<a>` or `<c></c>`. However, the expression does not produce a match in the fragment `<a/>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `*/b/*` will match any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
-> ' <a><b c="1">X</b><b c="2">Y</b></a>',
-> 'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[d[../@c="1"]]/d`:

```
mysql> SELECT ExtractValue(
-> ' <a>
->   <b c="1"><d>X</d></b>
->   <b c="2"><d>X</d></b>
->   </a>',
-> 'a/b/d[../@c="1"]'
-> ) AS result;
+-----+
| result |
+-----+
| X      |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
 - `axis::comment()`
 - `axis::text()`

- `axis::processing-instructions()`
- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
+-----+
| x |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
 - `id()`
 - `lang()`
 - `local-name()`
 - `name()`
 - `namespace-uri()`
 - `normalize-space()`
 - `starts-with()`
 - `string()`
 - `substring-after()`
 - `substring-before()`
 - `translate()`
- The following axes are not supported:
 - `following-sibling`
 - `following`
 - `preceding-sibling`

- `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444                          |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h></a>                  |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

Error handling. For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL                                |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                                |
+-----+
```

```
+-----+
1 row in set (0.00 sec)
```

Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

XPath Injection. *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='lc3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='lc3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php

$file      = "users.xml";

$login     = $_POST["login"];
$password  = $_POST["password"];

$xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

if( file_exists($file) )
{
    $xml = simplexml_load_file($file);

    if($result = $xml->xpath($xpath))
        echo "You are now logged in as user $result[0].";
    else
        echo "Invalid login name or password.";
}
else
    exit("Failed to open $file.");

?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()='<code>$login' and password/text()='<code>$password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id'
-> ) AS id;
+-----+
| id                |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)
```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```
mysql> SELECT @id = ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->     INSTR(@id, ' ') = 0,
->     @id,
->     'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID                |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

12.12 Bit Functions and Operators

Table 12.16 Bit Functions and Operators

Name	Description
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code>&</code>	Bitwise AND
<code>~</code>	Bitwise inversion
<code> </code>	Bitwise OR
<code>^</code>	Bitwise XOR
<code><<</code>	Left shift
<code>>></code>	Right shift

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions are described in [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).) Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. Nonbinary string arguments are converted to `BIGINT` and processed as such, as before.

An implication of this change in behavior is that bit operations on binary string arguments might produce a different result in MySQL 8.0 than in 5.7. For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see [Bit Functions and Operators](#), in [MySQL 5.7 Reference Manual](#).

Bit Operations Prior to MySQL 8.0

Bit operations prior to MySQL 8.0 handle only unsigned 64-bit integer argument and result values (that is, unsigned `BIGINT` values). Conversion of arguments of other types to `BIGINT` occurs as necessary. Examples:

- This statement operates on numeric literals, treated as unsigned 64-bit integers:

```
mysql> SELECT 127 | 128, 128 << 2, BIT_COUNT(15);
+-----+-----+-----+
| 127 | 128 | 128 << 2 | BIT_COUNT(15) |
+-----+-----+-----+
|      255 |      512 |          4 |
+-----+-----+-----+
```

- This statement performs to-number conversions on the string arguments ('127' to 127, and so forth) before performing the same operations as the first statement and producing the same results:

```
mysql> SELECT '127' | '128', '128' << 2, BIT_COUNT('15');
+-----+-----+-----+
| '127' | '128' | '128' << 2 | BIT_COUNT('15') |
+-----+-----+-----+
|      255 |      512 |          4 |
+-----+-----+-----+
```

- This statement uses hexadecimal literals for the bit-operation arguments. MySQL by default treats hexadecimal literals as binary strings, but in numeric context evaluates them as numbers (see [Section 9.1.4, "Hexadecimal Literals"](#)). Prior to MySQL 8.0, numeric context includes bit operations. Examples:

```
mysql> SELECT X'7F' | X'80', X'80' << 2, BIT_COUNT(X'0F');
+-----+-----+-----+
| X'7F' | X'80' | X'80' << 2 | BIT_COUNT(X'0F') |
+-----+-----+-----+
|      255 |      512 |          4 |
+-----+-----+-----+
```

Handling of bit-value literals in bit operations is similar to hexadecimal literals (that is, as numbers).

Bit Operations in MySQL 8.0

MySQL 8.0 extends bit operations to handle binary string arguments directly (without conversion) and produce binary string results. (Arguments that are not integers or binary strings are still converted to integers, as before.) This extension enhances bit operations in the following ways:

- Bit operations become possible on values longer than 64 bits.
- It is easier to perform bit operations on values that are more naturally represented as binary strings than as integers.

For example, consider UUID values and IPv6 addresses, which have human-readable text formats like this:

```
UUID: 6ccd780c-baba-1026-9564-5b8c656024db
```

```
IPv6: fe80::219:d1ff:fe91:1a72
```

It is cumbersome to operate on text strings in those formats. An alternative is convert them to fixed-length binary strings without delimiters. `UUID_TO_BIN()` and `INET6_ATON()` each produce a value of data type `BINARY(16)`, a binary string 16 bytes (128 bits) long. The following statements illustrate this (`HEX()` is used to produce displayable values):

```
mysql> SELECT HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db'));
+-----+
| HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db')) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72'));
+-----+
| HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72')) |
+-----+
| FE80000000000000000219D1FFFE911A72 |
+-----+
```

Those binary values are easily manipulable with bit operations to perform actions such as extracting the timestamp from UUID values, or extracting the network and host parts of IPv6 addresses. (For examples, see later in this discussion.)

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: `BINARY`, `VARBINARY`, or one of the `BLOB` types.

What about hexadecimal literals and bit literals? Recall that those are binary strings by default in MySQL, but numbers in numeric context. How are they handled for bit operations in MySQL 8.0? Does MySQL continue to evaluate them in numeric context, as is done prior to MySQL 8.0? Or do bit operations evaluate them as binary strings, now that binary strings can be handled “natively” without conversion?

Answer: It has been common to specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers, so MySQL continues to evaluate bit operations in numeric context when all bit arguments are hexadecimal or bit literals, for backward compatibility. If you require evaluation as binary strings instead, that is easily accomplished: Use the `_binary` introducer for at least one literal.

- These bit operations evaluate the hexadecimal literals and bit literals as integers:

```
mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
+-----+
| X'40' | X'01' | b'11110001' & b'01001111' |
+-----+
|          65 |          65 |
+-----+
```

- These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the `_binary` introducer:

```
mysql> SELECT _binary X'40' | X'01', b'11110001' & _binary b'01001111';
+-----+
| _binary X'40' | X'01' | b'11110001' & _binary b'01001111' |
+-----+
| A | A |
+-----+
```

Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII `A`.

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
+-----+
| _binary X'4040404040404040' | X'0102030405060708' |
+-----+
| ABCDEFGH |
+-----+
```

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

```
_binary literal
BINARY literal
CAST(literal AS BINARY)
```

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
+-----+
| @v1 | @v2 | @v3 & @v4 |
+-----+
| A | A |
+-----+
```

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
ERROR 3513 (HY000): Binary operands of bitwise
operators must be of equal length
```

To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```
mysql> SELECT _binary X'0040' | X'0001';
+-----+
| _binary X'0040' | X'0001' |
+-----+
| A |
+-----+
mysql> SELECT _binary X'40' | X'01';
+-----+
| _binary X'40' | X'01' |
+-----+
| A |
+-----+
```

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:

```
mysql> SELECT LPAD(X'40', 2, X'00') | X'0001';
+-----+
```

```

+-----+
| LPAD(X'40', 2, X'00') | X'0001' |
+-----+
| A |
+-----+
mysql> SELECT X'40' | SUBSTR(X'0001', 2, 1);
+-----+
| X'40' | SUBSTR(X'0001', 2, 1) |
+-----+
| A |
+-----+

```

Binary String Bit-Operation Examples

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit operations in binary-string context:

```

mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
+-----+
| HEX(@uuid) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+

```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```

mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16)) >> 80;
mysql> SELECT HEX(@ts_mask);
+-----+
| HEX(@ts_mask) |
+-----+
| FFFFFFFFFFFFFFFF0000000000000000 |
+-----+
mysql> SELECT HEX(@node_mask);
+-----+
| HEX(@node_mask) |
+-----+
| 000000000000000000000000FFFFFFFF |
+-----+

```

The `CAST(... AS BINARY(16))` function is used here because the masks must be the same length as the UUID value against which they are applied. The same result can be produced using other functions to pad the masks to the required length:

```

SET @ts_mask= RPAD(X'FFFFFFFFFFFFFFFF' , 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFFFFFF', 16, X'00') ;

```

Use the masks to extract the timestamp and node number parts:

```

mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
+-----+
| timestamp part |
+-----+
| 6CCD780CBABA10260000000000000000 |
+-----+

```

```
mysql> SELECT HEX(@uuid & @node_mask) AS 'node part';
+-----+
| node part |
+-----+
| 000000000000000000000005B8C656024DB |
+-----+
```

The preceding example uses these bit operations: right shift (\gg) and bitwise AND ($\&$).

Note

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of $128 - 80 = 48$ bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address `::`, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
+-----+
| all zeros |
+-----+
| 00000000000000000000000000000000 |
+-----+
```

To produce the complementary value (all ones), use the `~` operator to invert the bits:

```
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
+-----+
| all ones |
+-----+
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+-----+
```

Shift the all-ones value left or right to produce the network and host masks:

```
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```

Display the masks to verify that they cover the correct parts of the address:

```
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
+-----+
| network mask |
+-----+
```

```

| ffff:ffff:ffff:ffff:ffff:: |
+-----+
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
+-----+
| host mask |
+-----+
| ::ffff:255.255.255.255 |
+-----+

```

Extract and display the network and host parts of the address:

```

mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----+
| network part |
+-----+
| fe80::219:0:0:0 |
+-----+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+-----+
| host part |
+-----+
| ::d1ff:fe91:1a72 |
+-----+

```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, more information about literal-value handling in bit operations, and potential incompatibilities between MySQL 8.0 and older MySQL versions.

Bitwise AND, OR, and XOR Operations

For &, |, and ^ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```

mysql> SELECT 64 | 1, X'40' | X'01';
+-----+
| 64 | 1 | X'40' | X'01' |
+-----+
| 65 | 65 |
+-----+

```

Examples of binary-string evaluation:

```

mysql> SELECT _binary X'40' | X'01';
+-----+
| _binary X'40' | X'01' |
+-----+

```

```

| A |
+-----+
mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+-----+
| @var1 | @var2 |
+-----+
| A |
+-----+

```

Bitwise Complement and Shift Operations

For `~`, `<<`, and `>>` bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```

mysql> SELECT ~0, 64 << 2, X'40' << 2;
+-----+-----+-----+
| ~0 | 64 << 2 | X'40' << 2 |
+-----+-----+-----+
| 18446744073709551615 | 256 | 256 |
+-----+-----+-----+

```

Examples of binary-string evaluation:

```

mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+-----+
| HEX(_binary X'1111000022220000' >> 16) |
+-----+
| 0000111100002222 |
+-----+
mysql> SELECT HEX(_binary X'1111000022220000' << 16);
+-----+
| HEX(_binary X'1111000022220000' << 16) |
+-----+
| 0000222200000000 |
+-----+
mysql> SET @var1 = X'F0F0F0F0';
mysql> SELECT HEX(~@var1);
+-----+
| HEX(~@var1) |
+-----+
| 0F0F0F0F |
+-----+

```

BIT_COUNT() Operations

The `BIT_COUNT()` function always returns an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```
mysql> SELECT BIT_COUNT(127);
+-----+
| BIT_COUNT(127) |
+-----+
| 7 |
+-----+
mysql> SELECT BIT_COUNT(b'010101'), BIT_COUNT(_binary b'010101');
+-----+-----+
| BIT_COUNT(b'010101') | BIT_COUNT(_binary b'010101') |
+-----+-----+
| 3 | 3 |
+-----+-----+
```

BIT_AND(), BIT_OR(), and BIT_XOR() Operations

For the `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`, all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:

```
mysql> CREATE TABLE t (group_id INT, a VARBINARY(6));
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (2, NULL);
mysql> INSERT INTO t VALUES (2, X'1234');
mysql> INSERT INTO t VALUES (2, X'FF34');
mysql> SELECT HEX(BIT_AND(a)), HEX(BIT_OR(a)), HEX(BIT_XOR(a))
FROM t GROUP BY group_id;
+-----+-----+-----+
| HEX(BIT_AND(a)) | HEX(BIT_OR(a)) | HEX(BIT_XOR(a)) |
+-----+-----+-----+
| FFFFFFFF | 000000000000 | 000000000000 |
| 1234 | FF34 | ED00 |
+-----+-----+-----+
```

Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

For backward compatibility, MySQL 8.0 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or `NULL` literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or `NULL` literals. (This does not apply to such literals if they are written with a `_binary` introducer, `BINARY` operator, or other way of specifying them explicitly as binary strings.)

The literal handling just described is the same as prior to MySQL 8.0. Examples:

- These bit operations evaluate the literals in numeric context and produce a `BIGINT` result:

```
b'0001' | b'0010'
X'0008' << 8
```

- These bit operations evaluate `NULL` in numeric context and produce a `BIGINT` result that has a `NULL` value:

```
NULL & NULL
NULL >> 4
```

In MySQL 8.0, you can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```
_binary b'0001' | b'0010'
_binary X'0008' << 8
BINARY NULL & NULL
BINARY NULL >> 4
```

The result of the last two expressions is `NULL`, just as without the `BINARY` operator, but the data type of the result is a binary string type rather than an integer type.

Bit-Operation Incompatibilities with MySQL 5.7

Because bit operations can handle binary string arguments natively in MySQL 8.0, some expressions produce a different result in MySQL 8.0 than in 5.7. The five problematic expression types to watch out for are:

```
nonliteral_binary { & | ^ } binary
binary { & | ^ } nonliteral_binary
nonliteral_binary { << >> } anything
~ nonliteral_binary
AGGR_BIT_FUNC(nonliteral_binary)
```

Those expressions return `BIGINT` in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- `{ op1 op2 ... }`: List of operators that apply to the given expression type.
- `binary`: Any kind of binary string argument, including a hexadecimal literal, bit literal, or `NULL` literal.
- `nonliteral_binary`: An argument that is a binary string value other than a hexadecimal literal, bit literal, or `NULL` literal.
- `AGGR_BIT_FUNC`: An aggregate function that takes bit-value arguments: `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`.

For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see [Bit Functions and Operators](#), in [MySQL 5.7 Reference Manual](#).

The following list describes available bit functions and operators:

- |
Bitwise OR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 | 15;
-> 31
mysql> SELECT _binary X'40404040' | X'01020304';
-> 'ABCD'
```

• `&`

Bitwise AND.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 & 15;
-> 13
mysql> SELECT HEX(_binary X'FF' & b'11110000');
-> 'F0'
```

• `^`

Bitwise XOR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 ^ 1;
-> 0
```

```
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFCD'
```

- <<

Shifts a longlong (**BIGINT**) number or binary string to the left.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or **NULL** literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
-> 'FF00FF00FF00'
```

- >>

Shifts a longlong (**BIGINT**) number or binary string to the right.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or **NULL** literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
-> '0000FF00FF00'
```

- ~

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 5 & ~1;
-> 4
mysql> SELECT HEX(~X'0000FFFF1111EEEE');
-> 'FFFF0000EEEE1111'
```

- `BIT_COUNT(N)`

Returns the number of bits that are set in the argument `N` as an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```
mysql> SELECT BIT_COUNT(64), BIT_COUNT(BINARY 64);
-> 1, 7
mysql> SELECT BIT_COUNT('64'), BIT_COUNT(_binary '64');
-> 1, 7
mysql> SELECT BIT_COUNT(X'40'), BIT_COUNT(_binary X'40');
-> 1, 1
```

12.13 Encryption and Compression Functions

Table 12.17 Encryption Functions

Name	Description
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>ASYMMETRIC_DECRYPT()</code>	Decrypt ciphertext using private or public key
<code>ASYMMETRIC_DERIVE()</code>	Derive symmetric key from asymmetric keys
<code>ASYMMETRIC_ENCRYPT()</code>	Encrypt cleartext using private or public key
<code>ASYMMETRIC_SIGN()</code>	Generate signature from digest
<code>ASYMMETRIC_VERIFY()</code>	Verify that signature matches digest
<code>COMPRESS()</code>	Return result as a binary string
<code>CREATE_ASYMMETRIC_PRIV_KEY()</code>	Create private key
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	Create public key
<code>CREATE_DH_PARAMETERS()</code>	Generate shared DH secret
<code>CREATE_DIGEST()</code>	Generate digest from string
<code>DECODE()</code>	Decodes a string encrypted using <code>ENCODE()</code>
<code>DES_DECRYPT()</code>	Decrypt a string
<code>DES_ENCRYPT()</code>	Encrypt a string

Name	Description
<code>ENCODE()</code>	Encode a string
<code>ENCRYPT()</code>	Encrypt a string
<code>MD5()</code>	Calculate MD5 checksum
<code>PASSWORD()</code>	Calculate and return a password string
<code>RANDOM_BYTES()</code>	Return a random byte vector
<code>SHA1()</code> , <code>SHA()</code>	Calculate an SHA-1 160-bit checksum
<code>SHA2()</code>	Calculate an SHA-2 checksum
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest
<code>UNCOMPRESS()</code>	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code>	Return the length of a string before compression
<code>VALIDATE_PASSWORD_STRENGTH()</code>	Determine strength of password

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `SHA()`, `SHA1()`, `SHA2()`, `STATEMENT_DIGEST()`, `STATEMENT_DIGEST_TEXT()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as `SHA2()`.

**Caution**

Passwords or other sensitive values supplied as arguments to encryption functions are sent in cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str,key_str[,init_vector])`

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

The optional initialization vector argument, *init_vector*. Statements that use `AES_DECRYPT()` are unsafe for statement-based replication.

- `AES_ENCRYPT(str,key_str[,init_vector])`

`AES_ENCRYPT()` and `AES_DECRYPT()` implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

`AES_ENCRYPT()` encrypts the string *str* using the key string *key_str* and returns a binary string containing the encrypted output. `AES_DECRYPT()` decrypts the encrypted string *crypt_str* using the key string *key_str* and returns the original cleartext string. If either function argument is `NULL`, the function returns `NULL`.

The *str* and *crypt_str* arguments can be any length, and padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the `AES_DECRYPT()` function. The length of *crypt_str* can be calculated using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

For a key length of 128 bits, the most secure way to pass a key to the *key_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

Do not pass a password or passphrase directly to `crypt_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

`AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see [Section 5.1.7, “Server System Variables”](#).
- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
+-----+
| AES_DECRYPT(@crypt_str,@key_str,@init_vector) |
+-----+
| text                                         |
+-----+
```

The following table lists each permitted block encryption mode, the SSL libraries that support it, and whether the initialization vector argument is required.

Block Encryption Mode	SSL Libraries that Support Mode	Initialization Vector Required
ECB	OpenSSL, wolfSSL	No
CBC	OpenSSL, wolfSSL	Yes
CFB1	OpenSSL	Yes
CFB8	OpenSSL	Yes
CFB128	OpenSSL	Yes
OFB	OpenSSL	Yes

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as [zlib](#). Otherwise, the return value is always [NULL](#). The compressed string can be uncompressed with [UNCOMPRESS\(\)](#).

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `.` character is added to avoid problems with endspace trimming should the result be stored in a [CHAR](#) or [VARCHAR](#) column. (However, use of nonbinary string data types such as [CHAR](#) or [VARCHAR](#) to store compressed strings is not recommended anyway because character set conversion may occur. Use a [VARBINARY](#) or [BLOB](#) binary string column instead.)
- [DECODE\(*crypt_str*,*pass_str*\)](#)

This function was removed in MySQL 8.0.3.

Consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#) instead.

- [DES_DECRYPT\(*crypt_str*\[,*key_str*\]\)](#)

This function was removed in MySQL 8.0.3.

Consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#) instead.

- [DES_ENCRYPT\(*str*\[,*{key_num|key_str}*\]\)](#)

This function was removed in MySQL 8.0.3.

Consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#) instead.

- [ENCODE\(*str*,*pass_str*\)](#)

This function was removed in MySQL 8.0.3.

Consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#) instead.

- [ENCRYPT\(*str*\[,*salt*\]\)](#)

This function was removed in MySQL 8.0.3. For one-way hashing, consider using [SHA2\(\)](#) instead.

- [MD5\(*str*\)](#)

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or [NULL](#) if the argument was [NULL](#). The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

If FIPS mode is enabled, `MD5()` returns `NULL`. See [Section 6.6, “FIPS Support”](#).

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `PASSWORD(str)`

This function was removed in MySQL 8.0.11.

- `RANDOM_BYTES(len)`

This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library. Permitted values of `len` range from 1 to 1024. For values outside that range, `RANDOM_BYTES()` generates a warning and returns `NULL`.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

- `SHA1(str)`, `SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. `SHA()` is synonymous with `SHA1()`.

The return value is a string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the cleartext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is `NULL` or the hash length is not one of the permitted values, the return value is `NULL`. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
```

```
-> '23097d223405d8228642a477bda255b32aadbce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See [Section 6.4, “Using Encrypted Connections”](#).

`SHA2()` can be considered cryptographically more secure than `MD5()` or `SHA1()`.

- `STATEMENT_DIGEST(statement)`

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or `NULL` if the argument is `NULL`. The related `STATEMENT_DIGEST_TEXT()` function returns the normalized statement digest. For information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests and Sampling”](#).

Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The `max_digest_length` system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+-----+
| STATEMENT_DIGEST(@stmt) |
+-----+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492cbd78387 |
+-----+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+-----+
| STATEMENT_DIGEST_TEXT(@stmt) |
+-----+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ? |
+-----+
```

- `STATEMENT_DIGEST_TEXT(statement)`

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or `NULL` if the argument is `NULL`. For additional discussion and examples, see the description of the related `STATEMENT_DIGEST()` function.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- `VALIDATE_PASSWORD_STRENGTH(str)`

Given an argument representing a cleartext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` component. If that component is not installed, the function always returns 0. For information about installing `validate_password`, see [Section 6.5.3, “The Password Validation Component”](#). To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password`. See [Section 6.5.3.2, “Password Validation Options and Variables”](#).

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password.check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

Password Test	Return Value
Length < 4	0
Length \geq 4 and < <code>validate_password.length</code>	25
Satisfies policy 1 (<code>LOW</code>)	50
Satisfies policy 2 (<code>MEDIUM</code>)	75
Satisfies policy 3 (<code>STRONG</code>)	100

12.14 Information Functions

Table 12.18 Information Functions

Name	Description
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>CHARSET()</code>	Return the character set of the argument
<code>COERCIBILITY()</code>	Return the collation coercibility value of the string argument
<code>COLLATION()</code>	Return the collation of the string argument
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_ROLE()</code>	Returns the current active roles
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name
<code>DATABASE()</code>	Return the default (current) database name
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>ICU_VERSION()</code>	ICU library version
<code>LAST_INSERT_ID()</code>	Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>
<code>ROLES_GRAPHML()</code>	Returns a GraphML document representing memory role subgraphs
<code>ROW_COUNT()</code>	The number of rows updated
<code>SCHEMA()</code>	Synonym for <code>DATABASE()</code>
<code>SESSION_USER()</code>	Synonym for <code>USER()</code>
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>

Name	Description
<code>USER()</code>	The user name and host name provided by the client
<code>VERSION()</code>	Return a string that indicates the MySQL server version

- `BENCHMARK(count,expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye'));
+-----+
| BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye')) |
+-----+
|                                                    0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'utf8'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE utf8_swedish_ci);
-> 0
```

```
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	<code>USER()</code> return value
4	Coercible	Literal string
5	Numeric	Numeric or temporal value
5	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

For more information, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'utf8_general_ci'
mysql> SELECT COLLATION(_utf8mb4'abc');
-> 'utf8mb4_0900_ai_ci'
mysql> SELECT COLLATION(_latin1'abc');
-> 'latin1_swedish_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

- `CURRENT_ROLE()`

Returns a `utf8` string containing the current active roles for the current session, separated by commas, or `NONE` if there are none. The value reflects the setting of the `sql_quote_show_create` system variable.

Suppose that an account is granted roles as follows:

```
GRANT 'r1', 'r2' TO 'u1'@'localhost';
SET DEFAULT ROLE ALL TO 'u1'@'localhost';
```

In sessions for `u1`, the initial `CURRENT_ROLE()` value names the default account roles. Using `SET ROLE` changes that:

```
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%`,`r2`@`%` |
+-----+
mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%` |
+-----+
```

- `CURRENT_USER`, `CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`

- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see [Section 17.4.1.8, “Replication of CURRENT_USER\(\)”](#).

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see [Section 12.5.2, “Regular Expressions”](#)). This function is primarily intended for use in test cases.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;

mysql> CREATE TABLE t (
    id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
    name VARCHAR(10) NOT NULL
);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
```

```

+----+-----+
mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

mysql> INSERT INTO t VALUES
      (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
| 1 | Bob |
| 2 | Mary |
| 3 | Jane |
| 4 | Lisa |
+----+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 2 |
+-----+

```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For `InnoDB` tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:

```

mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+-----+
| @@innodb_autoinc_lock_mode |
+-----+
| 1 |
+-----+

mysql> CREATE TABLE `t` (
      `id` INT(11) NOT NULL AUTO_INCREMENT,
      `val` INT(11) DEFAULT NULL,
      PRIMARY KEY (`id`),
      UNIQUE KEY `i1` (`val`)
      ) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);

# With auto_increment_offset=1, the inserted rows
# result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t\G
***** 1. row *****

```

```

Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

# LAST_INSERT_ID() returns the first automatically generated
# value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

# The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2 Duplicates: 2 Warnings: 0

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

```

For more information, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```

mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);

```

2. Use the table to generate sequence numbers like this:

```

mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();

```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 27.7.7.38](#), “`mysql_insert_id()`”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROLES_GRAPHML()`

Returns a `utf8` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` or `SUPER` privilege is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:

```
mysql> SELECT ROLES_GRAPHML();
+-----+
| ROLES_GRAPHML() |
+-----+
| <?xml version="1.0" encoding="UTF-8"?><graphml /> |
+-----+
```

- `ROW_COUNT()`

`ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA INFILE`.
- `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

- `USER()`

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'davida@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in [Section 5.1.7, “Server System Variables”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '8.0.15-standard'
```

12.15 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see [Section 11.5, “Spatial Data Types”](#).

12.15.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

Table 12.19 Spatial Functions

Name	Description
<code>GeomCollection()</code>	Construct geometry collection from geometries
<code>GeometryCollection()</code>	Construct geometry collection from geometries
<code>LineString()</code>	Construct LineString from Point values
<code>MBRContains()</code>	Whether MBR of one geometry contains MBR of another
<code>MBRCoveredBy()</code>	Whether one MBR is covered by another
<code>MBRCovers()</code>	Whether one MBR covers another
<code>MBRDisjoint()</code>	Whether MBRs of two geometries are disjoint
<code>MBREquals()</code>	Whether MBRs of two geometries are equal
<code>MBRIntersects()</code>	Whether MBRs of two geometries intersect
<code>MBROverlaps()</code>	Whether MBRs of two geometries overlap
<code>MBRTouches()</code>	Whether MBRs of two geometries touch
<code>MBRWithin()</code>	Whether MBR of one geometry is within MBR of another
<code>MultiLineString()</code>	Construct MultiLineString from LineString values
<code>MultiPoint()</code>	Construct MultiPoint from Point values
<code>MultiPolygon()</code>	Construct MultiPolygon from Polygon values
<code>Point()</code>	Construct Point from coordinates
<code>Polygon()</code>	Construct Polygon from LineString arguments
<code>ST_Area()</code>	Return Polygon or MultiPolygon area

Name	Description
<code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>	Convert from internal geometry format to WKB
<code>ST_AsGeoJSON()</code>	Generate GeoJSON object from geometry
<code>ST_AsText()</code> , <code>ST_AsWKT()</code>	Convert from internal geometry format to WKT
<code>ST_Buffer()</code>	Return geometry of points within given distance from geometry
<code>ST_Buffer_Strategy()</code>	Produce strategy option for <code>ST_Buffer()</code>
<code>ST_Centroid()</code>	Return centroid as a point
<code>ST_Contains()</code>	Whether one geometry contains another
<code>ST_ConvexHull()</code>	Return convex hull of geometry
<code>ST_Crosses()</code>	Whether one geometry crosses another
<code>ST_Difference()</code>	Return point set difference of two geometries
<code>ST_Dimension()</code>	Dimension of geometry
<code>ST_Disjoint()</code>	Whether one geometry is disjoint from another
<code>ST_Distance()</code>	The distance of one geometry from another
<code>ST_Distance_Sphere()</code>	Minimum distance on earth between two geometries
<code>ST_EndPoint()</code>	End Point of LineString
<code>ST_Envelope()</code>	Return MBR of geometry
<code>ST_Equals()</code>	Whether one geometry is equal to another
<code>ST_ExteriorRing()</code>	Return exterior ring of Polygon
<code>ST_GeoHash()</code>	Produce a geohash value
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromTxt()</code>	Return geometry collection from WKT
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection
<code>ST_GeometryType()</code>	Return name of geometry type
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon
<code>ST_Intersection()</code>	Return point set intersection of two geometries
<code>ST_Intersects()</code>	Whether one geometry intersects another
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple
<code>ST_IsEmpty()</code>	Placeholder function
<code>ST_IsSimple()</code>	Whether a geometry is simple
<code>ST_IsValid()</code>	Whether a geometry is valid
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value

Name	Description
<code>ST_Latitude()</code>	Return latitude of Point
<code>ST_Length()</code>	Return length of LineString
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value
<code>ST_Longitude()</code>	Return longitude of Point
<code>ST_MakeEnvelope()</code>	Rectangle around two points
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon
<code>ST_NumPoints()</code>	Return number of points in LineString
<code>ST_Overlaps()</code>	Whether one geometry overlaps another
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value
<code>ST_PointFromText()</code>	Construct Point from WKT
<code>ST_PointFromWKB()</code>	Construct Point from WKB
<code>ST_PointN()</code>	Return N-th point from LineString
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB
<code>ST_Simplify()</code>	Return simplified geometry
<code>ST_SRID()</code>	Return spatial reference system ID for geometry
<code>ST_StartPoint()</code>	Start Point of LineString
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries
<code>ST_Touches()</code>	Whether one geometry touches another
<code>ST_Transform()</code>	Transform coordinates of geometry

Name	Description
<code>ST_Union()</code>	Return point set union of two geometries
<code>ST_Validate()</code>	Return validated geometry
<code>ST_Within()</code>	Whether one geometry is within another
<code>ST_X()</code>	Return X coordinate of Point
<code>ST_Y()</code>	Return Y coordinate of Point

12.15.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described at [Section 11.5.2.2, “Geometry Class”](#). The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional argument-handling characteristics, as discussed in the sections where those function descriptions occur.

Spatial functions are defined only for valid geometry values.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32}-1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

Spatial functions that take multiple geometry arguments require those arguments to have the same SRID value (that is, same value in the lower 32 bits). Assuming equal SRIDs, spatial functions do nothing with them after performing the equality check; geometry values are implicitly handled using Cartesian coordinates (SRID 0). If a spatial function returns `ER_GIS_DIFFERENT_SRIDS`, it means that the geometry arguments did not all have the same SRID. You must modify them to have the same SRID.

The [Open Geospatial Consortium](#) guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

Empty geometry-collection handling is as follows: An empty WKT input geometry collection may be specified as `'GEOMETRYCOLLECTION()'`. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

12.15.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see [Well-Known Text \(WKT\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

`ST_GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'` nonstandard syntax. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1) | ST_AsWKT(@s2) |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
```

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any geometry argument is `NULL` or is not a syntactically well-formed geometry, or if the SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range `(-180, 180]`, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range `[-90, 90]`, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- `ST_GeomCollFromText(wkt[, srid [, options]])`,
`ST_GeometryCollectionFromText(wkt[, srid [, options]])`,
`ST_GeomCollFromText(wkt[, srid [, options]])`

Constructs a `GeometryCollection` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

```
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10));"
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+-----+
| ST_AsText(ST_GeomCollFromText(@g)) |
+-----+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+-----+
```

- `ST_GeomFromText(wkt[, srid[, options]]), ST_GeometryFromText(wkt[, srid[, options]])`

Constructs a geometry value of any type using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromText(wkt[, srid[, options]]), ST_LineStringFromText(wkt[, srid[, options]])`

Constructs a `LineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromText(wkt[, srid[, options]]), ST_MultiLineStringFromText(wkt[, srid[, options]])`

Constructs a `MultiLineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromText(wkt[, srid[, options]]), ST_MultiPointFromText(wkt[, srid[, options]])`

Constructs a `MultiPoint` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromText(wkt[, srid[, options]]), ST_MultiPolygonFromText(wkt[, srid[, options]])`

Constructs a `MultiPolygon` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromText(wkt[, srid[, options]])`

Constructs a `Point` value using its WKT representation and SRID.

`ST_PointFromText()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromText(wkt[, srid[, options]]), ST_PolygonFromText(wkt[, srid[, options]])`

Constructs a `Polygon` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

12.15.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a [BLOB](#) containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

`ST_GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.0, these functions also accepted geometry objects as returned by the functions in [Section 12.15.5, “MySQL-Specific Functions That Create Geometry Values”](#). Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_SRID(Point(0, 0), 4326)` or `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If the WKB or SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

- `ST_GeomCollFromWKB(wkb[, srid[, options]])`,
`ST_GeometryCollectionFromWKB(wkb[, srid[, options]])`

Constructs a `GeometryCollection` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_GeomFromWKB(wkb[, srid [, options]]), ST_GeometryFromWKB(wkb[, srid [, options]])`

Constructs a geometry value of any type using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromWKB(wkb[, srid [, options]]), ST_LineStringFromWKB(wkb[, srid [, options]])`

Constructs a `LineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromWKB(wkb[, srid [, options]]), ST_MultiLineStringFromWKB(wkb[, srid [, options]])`

Constructs a `MultiLineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromWKB(wkb[, srid [, options]]), ST_MultiPointFromWKB(wkb[, srid [, options]])`

Constructs a `MultiPoint` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromWKB(wkb[, srid [, options]]), ST_MultiPolygonFromWKB(wkb[, srid [, options]])`

Constructs a `MultiPolygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromWKB(wkb[, srid [, options]])`

Constructs a `Point` value using its WKB representation and SRID.

`ST_PointFromWKB()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromWKB(wkb[, srid [, options]]), ST_PolygonFromWKB(wkb[, srid [, options]])`

Constructs a `Polygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

12.15.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeomCollection(g [, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeomCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeomCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `GeometryCollection(g [, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeometryCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeometryCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `LineString(pt [, pt] ...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls [, ls] ...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls [, ls] ...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

12.15.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See [Section 12.15.3, “Functions That Create Geometry Values from WKT Values”](#), and [Section 12.15.4, “Functions That Create Geometry Values from WKB Values”](#).

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'` nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1)          | ST_AsWKT(@s2)          |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
mysql> SELECT ST_AsWKT(GeomCollection());
+-----+
| ST_AsWKT(GeomCollection()) |
+-----+
| GEOMETRYCOLLECTION EMPTY    |
+-----+
```

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an `ER_WARN_SRS_NOT_FOUND_AXIS_ORDER` warning occurs.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-`NULL`.

These functions are available for format conversions or coordinate swapping:

- `ST_AsBinary(g [, options]), ST_AsWKB(g [, options])`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

`ST_AsBinary()` and `ST_AsWKB()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

- `ST_AsText(g [, options]), ST_AsWKT(g [, options])`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional *options* argument may be given to override the default axis order.

`ST_AsText()` and `ST_AsWKT()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+-----+
| ST_AsText(ST_GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

Output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
| MULTIPOINT((1 1),(2 2),(3 3)) |
+-----+
```

- `ST_SwapXY(g)`

Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

`ST_SwapXY()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
```

```
mysql> SELECT ST_AsText(@g);
+-----+
| ST_AsText(@g) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_SwapXY(@g));
+-----+
| ST_AsText(ST_SwapXY(@g)) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

12.15.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, the `ST_Area()` polygon function returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

12.15.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If any SRID argument refers to an undefined SRS, an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining geometry properties:

- `ST_Dimension(g)`

Returns the inherent dimension of the geometry value `g`. The dimension can be -1, 0, 1, or 2. The meaning of these values is given in [Section 11.5.2.2, "Geometry Class"](#).

`ST_Dimension()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+-----+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `ST_Envelope(g)`

Returns the minimum bounding rectangle (MBR) for the geometry value `g`. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

If the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')) |
+-----+
| LINESTRING(1 1,1 2) |
+-----+
```

`ST_Envelope()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
- `ST_GeometryType(g)`

Returns a binary string indicating the name of the geometry type of which the geometry instance `g` is a member. The name corresponds to one of the instantiable [Geometry](#) subclasses.

`ST_GeometryType()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
+-----+
| ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `ST_IsEmpty(g)`

This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.

The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsEmpty()` handles its arguments as described in the introduction to this section.

- `ST_IsSimple(g)`

Returns 1 if the geometry value `g` is simple according to the ISO *SQL/MM Part 3: Spatial* standard. `ST_IsSimple()` returns 0 if the argument is not simple.

The descriptions of the instantiable geometric classes given under [Section 11.5.2, “The OpenGIS Geometry Model”](#) include the specific conditions that cause class instances to be classified as not simple.

`ST_IsSimple()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- `ST_SRID(g, srid)`

With a single argument representing a valid geometry object *g*, `ST_SRID()` returns an integer indicating the ID of the spatial reference system (SRS) associated with *g*.

With the optional second argument representing a valid SRID value, `ST_SRID()` returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

`ST_SRID()` handles its arguments as described in the introduction to this section, with this exception:

- For the single-argument syntax, `ST_SRID()` returns the geometry SRID even if it refers to an undefined SRS. An `ER_SRS_NOT_FOUND` error does not occur.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
|          0 |
+-----+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
|         4326 |
+-----+
```

It is possible to create a geometry in a particular SRID by passing to `ST_SRID()` the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

12.15.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the `Point` object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For `Point` objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the `Point` object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a `Point` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If a longitude or latitude argument is out of range, an error occurs:
 - If any longitude argument is not in the range `(-180, 180]`, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range `[-90, 90]`, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.

With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a `Point` object like the first argument with its latitude equal to the second argument.

`ST_Latitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+-----+
| ST_Latitude(@pt) |
+-----+
| 45 |
+-----+
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+-----+
| ST_AsText(ST_Latitude(@pt, 10)) |
+-----+
| POINT(10 90) |
+-----+
```

This function was added in MySQL 8.0.12.

- `ST_Longitude(p [, new_longitude_val])`

With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Longitude()` returns the longitude value of `p` as a double-precision number.

With the optional second argument representing a valid longitude value, `ST_Longitude()` returns a `Point` object like the first argument with its longitude equal to the second argument.

`ST_Longitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-----+
| ST_Longitude(@pt) |
+-----+
| 90 |
+-----+
mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+-----+
| ST_AsText(ST_Longitude(@pt, 10)) |
+-----+
| POINT(45 10) |
+-----+
```

This function was added in MySQL 8.0.12.

- `ST_X(p[, new_x_val])`

With a single argument representing a valid `Point` object `p`, `ST_X()` returns the X-coordinate value of `p` as a double-precision number. As of MySQL 8.0.12, the X coordinate is considered to refer to the axis that appears first in the `Point` spatial reference system (SRS) definition.

With the optional second argument, `ST_X()` returns a `Point` object like the first argument with its X coordinate equal to the second argument. As of MySQL 8.0.12, if the `Point` object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_X()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_X(Point(56.7, 53.34));
+-----+
| ST_X(Point(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
mysql> SELECT ST_AsText(ST_X(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_X(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(10.5 53.34) |
+-----+
```

- `ST_Y(p[, new_y_val])`

With a single argument representing a valid `Point` object `p`, `ST_Y()` returns the Y-coordinate value of `p` as a double-precision number. As of MySQL 8.0.12, the Y coordinate is considered to refer to the axis that appears second in the `Point` spatial reference system (SRS) definition.

With the optional second argument, `ST_Y()` returns a `Point` object like the first argument with its Y coordinate equal to the second argument. As of MySQL 8.0.12, if the `Point` object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_Y()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Y(Point(56.7, 53.34));
+-----+
| ST_Y(Point(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
mysql> SELECT ST_AsText(ST_Y(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_Y(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(56.7 10.5) |
+-----+
```

12.15.7.3 LineString and MultiLineString Property Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

Some functions in this section also work for `MultiLineString` values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining linestring properties:

- `ST_EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

`ST_EndPoint()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+-----+
| ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `ST_IsClosed(ls)`

For a `LineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same).

For a `MultiLineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each `LineString` in `ls`).

`ST_IsClosed()` returns 0 if `ls` is not closed, and `NULL` if `ls` is `NULL`.

`ST_IsClosed()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls1)) |
+-----+
| 0 |
+-----+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls2)) |
+-----+
| 1 |
+-----+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls3)) |
+-----+
| 0 |
+-----+
```

- `ST_Length(ls)`

Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

`ST_Length()` computes a result as follows:

- If the geometry is a valid `LineString` in a Cartesian SRS, the return value is the Cartesian length of the geometry.
- If the geometry is a valid `MultiLineString` in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.
- If the geometry is a valid `LineString` in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.
- If the geometry is a valid `MultiLineString` in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

`ST_Length()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not a `LineString` or `MultiLineString`, the return value is `NULL`.
- If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.
- If the length computation result is `+inf`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range `(-180, 180]`, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range `[-90, 90]`, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_Length(ST_GeomFromText(@ls));
+-----+
| ST_Length(ST_GeomFromText(@ls)) |
+-----+
| 2.8284271247461903 |
+-----+

mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_Length(ST_GeomFromText(@mls));
+-----+
| ST_Length(ST_GeomFromText(@mls)) |
+-----+
| 4.242640687119286 |
+-----+
```

- `ST_NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`.

`ST_NumPoints()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
```

```
+-----+
| ST_NumPoints(ST_GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

- `ST_PointN(ls, N)`

Returns the *N*-th [Point](#) in the [LineString](#) value *ls*. Points are numbered beginning with 1.

`ST_PointN()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
+-----+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `ST_StartPoint(ls)`

Returns the [Point](#) that is the start point of the [LineString](#) value *ls*.

`ST_StartPoint()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
+-----+
| ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

12.15.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of [Polygon](#) or [MultiPolygon](#) values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is [NULL](#) or any geometry argument is an empty geometry, the return value is [NULL](#).
- If any geometry argument is not a syntactically well-formed geometry, an [ER_GIS_INVALID_DATA](#) error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an [ER_SRS_NOT_FOUND](#) error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an [ER_GIS_DIFFERENT_SRIDS](#) error occurs.
- Otherwise, the return value is non-[NULL](#).

These functions are available for obtaining polygon properties:

- `ST_Area({poly|mpoly})`

Returns a double-precision number indicating the area of the [Polygon](#) or [MultiPolygon](#) argument, as measured in its spatial reference system.

As of MySQL 8.0.13, `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
- If the geometry is valid but is not a `Polygon` or `MultiPolygon` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If the geometry is a valid `Polygon` in a Cartesian SRS, the result is the Cartesian area of the polygon.
- If the geometry is a valid `MultiPolygon` in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
- If the geometry is a valid `Polygon` in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
- If the geometry is a valid `MultiPolygon` in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
- If an area computation results in `+inf`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

- For arguments of dimension 0 or 1, the result is 0.
- If a geometry is empty, the return value is 0 rather than `NULL`.
- For a geometry collection, the result is the sum of the area values of all components. If the geometry collection is empty, its area is returned as 0.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+-----+
| ST_Area(ST_GeomFromText(@poly)) |
+-----+
| 4 |
+-----+

mysql> SET @mpoly =
      'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
```

```
+-----+
| ST_Area(ST_GeomFromText(@mpoly)) |
+-----+
|                                     8 |
+-----+
```

- `ST_Centroid({poly|mpoly})`

Returns the mathematical centroid for the [Polygon](#) or [MultiPolygon](#) argument as a [Point](#). The result is not guaranteed to be on the [MultiPolygon](#).

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single [MultiPolygon](#), [MultiLineString](#), or [MultiPoint](#) for centroid computation.

`ST_Centroid()` handles its arguments as described in the introduction to this section, with these exceptions:

- The return value is [NULL](#) for the additional condition that the argument is an empty geometry collection.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an [ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS](#) error occurs.

```
mysql> SET @poly =
        ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+-----+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly)) |
+-----+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+-----+
```

- `ST_ExteriorRing(poly)`

Returns the exterior ring of the [Polygon](#) value *poly* as a [LineString](#).

`ST_ExteriorRing()` handles its arguments as described in the introduction to this section.

```
mysql> SET @poly =
        'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,1 1 1))';
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+-----+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- `ST_InteriorRingN(poly, N)`

Returns the *N*-th interior ring for the [Polygon](#) value *poly* as a [LineString](#). Rings are numbered beginning with 1.

`ST_InteriorRingN()` handles its arguments as described in the introduction to this section.

```
mysql> SET @poly =
        'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,1 1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-----+
```

```
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- `ST_NumInteriorRing(poly)`, `ST_NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value *poly*.

`ST_NumInteriorRing()` and `ST_NumInteriorRings()` handle their arguments as described in the introduction to this section.

```
mysql> SET @poly =
'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+-----+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

12.15.7.5 GeometryCollection Property Functions

These functions return properties of `GeometryCollection` values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining geometry collection properties:

- `ST_GeometryN(gc, N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

`ST_GeometryN()` handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-----+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- `ST_NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value *gc*.

`ST_NumGeometries()` handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
+-----+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

12.15.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

These functions support all argument type combinations except those that are inapplicable according to the [Open Geospatial Consortium](#) specification.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any geometry argument has an SRID value for a geographic SRS, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
- Otherwise, the return value is non-`NULL`.

These spatial operator functions are available:

- `ST_Buffer(g, d[, strategy1[, strategy2[, strategy3]])`

Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.

If the geometry argument is empty, `ST_Buffer()` returns an empty geometry.

If the distance is 0, `ST_Buffer()` returns the geometry argument unchanged:

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
+-----+
| ST_AsText(ST_Buffer(@pt, 0)) |
+-----+
| POINT(0 0) |
+-----+
```

`ST_Buffer()` supports negative distances for `Polygon` and `MultiPolygon` values, and for geometry collections containing `Polygon` or `MultiPolygon` values. The result may be an empty geometry.

`ST_Buffer()` permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the `ST_Buffer_Strategy()` function, to be used for point, join, and end strategies:

- Point strategies apply to `Point` and `MultiPoint` geometries. If no point strategy is specified, the default is `ST_Buffer_Strategy('point_circle', 32)`.
- Join strategies apply to `LineString`, `MultiLineString`, `Polygon`, and `MultiPolygon` geometries. If no join strategy is specified, the default is `ST_Buffer_Strategy('join_round', 32)`.
- End strategies apply to `LineString` and `MultiLineString` geometries. If no end strategy is specified, the default is `ST_Buffer_Strategy('end_round', 32)`.

Up to one strategy of each type may be specified, and they may be given in any order.

`ST_Buffer()` handles its arguments as described in the introduction to this section, with these exceptions:

- For a negative distance for `Point`, `MultiPoint`, `LineString`, and `MultiLineString` values, and for geometry collections not containing any `Polygon` or `MultiPolygon` values, an `ER_WRONG_ARGUMENTS` error occurs.
- If multiple strategies of a given type are specified, an `ER_WRONG_ARGUMENTS` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+-----+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
+-----+
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))      |
+-----+
```

```
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+-----+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy)) |
+-----+
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5))                                     |
+-----+
```

- `ST_Buffer_Strategy(strategy[, points_per_circle])`

This function returns a strategy byte string for use with `ST_Buffer()` to influence buffer computation.

Information about strategies is available at Boost.org.

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are `'point_circle'` and `'point_square'`.
- For join strategies, permitted values are `'join_round'` and `'join_miter'`.
- For end strategies, permitted values are `'end_round'` and `'end_flat'`.

If the first argument is `'point_circle'`, `'join_round'`, `'join_miter'`, or `'end_round'`, the `points_per_circle` argument must be given as a positive numeric value. The maximum `points_per_circle` value is the value of the `max_points_in_geometry` system variable.

For examples, see the description of `ST_Buffer()`.

`ST_Buffer_Strategy()` handles its arguments as described in the introduction to this section, with these exceptions:

- If any argument is invalid, an `ER_WRONG_ARGUMENTS` error occurs.
- If the first argument is 'point_square' or 'end_flat', the `points_per_circle` argument must not be given or an `ER_WRONG_ARGUMENTS` error occurs.
- `ST_ConvexHull(g)`

Returns a geometry that represents the convex hull of the geometry value `g`.

This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull.

`ST_ConvexHull()` handles its arguments as described in the introduction to this section, with this exception:

- The return value is `NULL` for the additional condition that the argument is an empty geometry collection.

```
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----+
| POLYGON((5 0,25 0,15 25,5 0))                |
+-----+
```

- `ST_Difference(g1, g2)`

Returns a geometry that represents the point set difference of the geometry values `g1` and `g2`.

`ST_Difference()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----+
| POINT(1 1)                        |
+-----+
```

- `ST_Intersection(g1, g2)`

Returns a geometry that represents the point set intersection of the geometry values `g1` and `g2`.

`ST_Intersection()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+-----+
```

```
| ST_AsText(ST_Intersection(@g1, @g2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `ST_SymDifference(g1, g2)`

Returns a geometry that represents the point set symmetric difference of the geometry values *g1* and *g2*, which is defined as:

```
g1 symdifference g2 := (g1 union g2) difference (g1 intersection g2)
```

Or, in function call notation:

```
ST_SymDifference(g1, g2) = ST_Difference(ST_Union(g1, g2), ST_Intersection(g1, g2))
```

`ST_SymDifference()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+-----+
| ST_AsText(ST_SymDifference(@g1, @g2)) |
+-----+
| MULTIPOINT((1 1),(2 2)) |
+-----+
```

- `ST_Transform(g, target_srid)`

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, *target_srid*. Transformation support is limited to geographic SRSs, unless the SRID of the geometry argument is the same as the target SRID value, in which case the return value is the input geometry for any valid SRS.

`ST_Transform()` handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the geometry is in an SRS that `ST_Transform()` cannot transform from, an `ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED` error occurs.
- If the target SRID is in an SRS that `ST_Transform()` cannot transform to, an `ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED` error occurs.
- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84` error occurs.
- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84` error occurs.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.

- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+-----+
| ST_AsText(@p) |
+-----+
| POINT(52.381389 13.064444) |
+-----+
mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+-----+
| ST_AsText(@p) |
+-----+
| POINT(52.38208611407426 13.065520672345304) |
+-----+
```

- `ST_Union(g1, g2)`

Returns a geometry that represents the point set union of the geometry values `g1` and `g2`.

`ST_Union()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+-----+
| ST_AsText(ST_Union(@g1, @g2)) |
+-----+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
+-----+
```

In addition, [Section 12.15.7, “Geometry Property Functions”](#), discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `ST_Envelope(g)`
- `ST_StartPoint(ls)`
- `ST_EndPoint(ls)`
- `ST_PointN(ls, N)`
- `ST_ExteriorRing(poly)`
- `ST_InteriorRingN(poly, N)`
- `ST_GeometryN(gc, N)`

12.15.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

12.15.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values `g1` and `g2`, using precise object shapes. Except for `ST_Distance()`, the return values 1 and 0 indicate true and false, respectively. `ST_Distance()` returns distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These object-shape functions are available for testing geometry relationships:

- `ST_Contains(g1, g2)`

Returns 1 or 0 to indicate whether `g1` completely contains `g2`. This tests the opposite relationship as `ST_Within()`.

`ST_Contains()` handles its arguments as described in the introduction to this section.

- `ST_Crosses(g1, g2)`

Two geometries *spatially cross* if their spatial relation has the following properties:

- Unless `g1` and `g2` are both of dimension 1: `g1` crosses `g2` if the interior of `g2` has points in common with the interior of `g1`, but `g2` does not cover the entire interior of `g1`.
- If both `g1` and `g2` are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).

This function returns 1 or 0 to indicate whether `g1` spatially crosses `g2`.

`ST_Crosses()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for these additional conditions:

- `g1` is of dimension 2 (`Polygon` or `MultiPolygon`).
- `g2` is of dimension 1 (`Point` or `MultiPoint`).
- `ST_Disjoint(g1, g2)`

Returns 1 or 0 to indicate whether `g1` is spatially disjoint from (does not intersect) `g2`.

`ST_Disjoint()` handles its arguments as described in the introduction to this section.

- `ST_Distance(g1, g2)`

Returns the distance between `g1` and `g2`, measured in the length unit of the spatial reference system (SRS).

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

`ST_Distance()` handles its arguments as described in the introduction to this section, with these exceptions:

- `ST_Distance()` detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. The only permitted geographic argument types are `Point` and `Point`, or `Point` and `MultiPoint` (in any argument order). If called with other geometry type argument combinations in a geographic SRS, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
- If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.
- If an intermediate or final result produces `NaN` or a negative number, an `ER_GIS_INVALID_DATA` error occurs.

```
mysql> SET @g1 = Point(1,1);
mysql> SET @g2 = Point(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----+
| ST_Distance(@g1, @g2) |
+-----+
| 1.4142135623730951 |
+-----+

mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326);
mysql> SELECT ST_Distance(@g1, @g2);
+-----+
| ST_Distance(@g1, @g2) |
+-----+
| 156874.3859490455 |
+-----+
```

For the special case of distance calculations on a sphere, see the `ST_Distance_Sphere()` function.

- `ST_Equals(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

`ST_Equals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+-----+-----+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

- `ST_Intersects(g1, g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

`ST_Intersects()` handles its arguments as described in the introduction to this section.

- `ST_Overlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*.

`ST_Overlaps()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for the additional condition that the dimensions of the two geometries are not equal.

- `ST_Touches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether *g1* spatially touches *g2*.

`ST_Touches()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for the additional condition that both geometries are of dimension 0 (`Point` or `MultiPoint`).

- `ST_Within(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `ST_Contains()`.

`ST_Within()` handles its arguments as described in the introduction to this section.

12.15.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.

The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These MBR functions are available for testing geometry relationships:

- `MBRContains(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* contains the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRWithin()`.

`MBRContains()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 1 |
+-----+-----+
```

- `MBRCoveredBy(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is covered by the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRCovers()`.

`MBRCoveredBy()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContainsBy(@g1,@g2);
+-----+-----+
| MBRContains(@g1,@g2) | MBRContainsBy(@g1,@g2) |
+-----+-----+
| 1 | 0 |
+-----+-----+
mysql> SELECT MBRContains(@g2,@g1), MBRContainsBy(@g2,@g1);
+-----+-----+
| MBRContains(@g2,@g1) | MBRContainsBy(@g2,@g1) |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

- `MBRContains(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* covers the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRContainsBy()`. See the description of `MBRContainsBy()` for examples.

`MBRContains()` handles its arguments as described in the introduction to this section.

- `MBRDisjoint(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

`MBRDisjoint()` handles its arguments as described in the introduction to this section.

- `MBREquals(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are the same.

`MBREquals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

- `MBRIntersects(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* intersect.

`MBRIntersects()` handles its arguments as described in the introduction to this section.

- `MBROverlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* overlap.

`MBROverlaps()` handles its arguments as described in the introduction to this section.

- `MBRTouches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* touch.

`MBRTouches()` handles its arguments as described in the introduction to this section.

- `MBRWithin(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is within the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

`MBRWithin()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

12.15.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any argument is invalid, an error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- If any point argument does not have SRID 0 or 4326, an `ER_SRS_NOT_FOUND` error occurs. *point* argument SRID validity is not checked.
- If any SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an `ER_DATA_OUT_OF_RANGE` error occurs.
- Otherwise, the return value is non-`NULL`.

These geohash functions are available:

- `ST_GeoHash(longitude, latitude, max_length), ST_GeoHash(point, max_length)`

Returns a geohash string in the connection character set and collation.

For the first syntax, the `longitude` must be a number in the range $[-180, 180]$, and the `latitude` must be a number in the range $[-90, 90]$. For the second syntax, a `POINT` value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than `max_length` characters, which has an upper limit of 100. The string might be shorter than `max_length` characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or `max_length` characters, whichever comes first.

`ST_GeoHash()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
+-----+-----+
| ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
+-----+-----+
| xbpbbpbpbpb         | 0000000000000000         |
+-----+-----+
```

- `ST_LatFromGeoHash(geohash_str)`

Returns the latitude from a geohash string value, as a double-precision number in the range $[-90, 90]$.

The `ST_LatFromGeoHash()` decoding function reads no more than 433 characters from the `geohash_str` argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

`ST_LatFromGeoHash()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
+-----+
| ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
| -20 |
+-----+
```

- `ST_LongFromGeoHash(geohash_str)`

Returns the longitude from a geohash string value, as a double-precision number in the range $[-180, 180]$.

The remarks in the description of `ST_LatFromGeoHash()` regarding the maximum number of characters processed from the `geohash_str` argument also apply to `ST_LongFromGeoHash()`.

`ST_LongFromGeoHash()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
+-----+
| ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
| 45 |
+-----+
```

- `ST_PointFromGeoHash(geohash_str, srid)`

Returns a [POINT](#) value containing the decoded geohash value, given a geohash string value.

The X and Y coordinates of the point are the longitude in the range [−180, 180] and the latitude in the range [−90, 90], respectively.

The *srid* argument is an 32-bit unsigned integer.

The remarks in the description of [ST_LatFromGeoHash\(\)](#) regarding the maximum number of characters processed from the *geohash_str* argument also apply to [ST_PointFromGeoHash\(\)](#).

[ST_PointFromGeoHash\(\)](#) handles its arguments as described in the introduction to this section.

```
mysql> SET @gh = ST_GeoHash(45,-20,10);
mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
+-----+
| ST_AsText(ST_PointFromGeoHash(@gh,0)) |
+-----+
| POINT(45 -20) |
+-----+
```

12.15.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see <http://geojson.org>. The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native [JSON](#) data type and a set of SQL functions to enable operations on JSON values. For more information, see [Section 11.6, “The JSON Data Type”](#), and [Section 12.16, “JSON Functions”](#).

- [ST_AsGeoJSON\(*g* \[, *max_dec_digits* \[, *options*\]\]\)](#)

Generates a GeoJSON object from the geometry *g*. The object string has the connection character set and collation.

If any argument is [NULL](#), the return value is [NULL](#). If any non-[NULL](#) argument is invalid, an error occurs.

max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of $2^{32} - 1$. The minimum is 0.

options, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

Flag Value	Meaning
0	No options. This is the default if <i>options</i> is not specified.
1	Add a bounding box to the output.
2	Add a short-format CRS URN to the output. The default format is a short format (EPSG:srid).

Flag Value	Meaning
4	Add a long-format CRS URN (<code>urn:ogc:def:crs:EPSG::srid</code>). This flag overrides flag 2. For example, option values of 5 and 7 mean the same (add a bounding box and a long-format CRS URN).

```
mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2);
+-----+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2) |
+-----+
| {"type": "Point", "coordinates": [11.11, 12.22]}           |
+-----+
```

- `ST_GeomFromGeoJSON(str [, options [, srid]])`

Parses a string *str* representing a GeoJSON object and returns a geometry.

If any argument is `NULL`, the return value is `NULL`. If any non-`NULL` argument is invalid, an error occurs.

options, if given, describes how to handle GeoJSON documents that contain geometries with coordinate dimensions higher than 2. The following table shows the permitted *options* values.

Option Value	Meaning
1	Reject the document and produce an error. This is the default if <i>options</i> is not specified.
2, 3, 4	Accept the document and strip off the coordinates for higher coordinate dimensions.

options values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, these values will produce different effects.

The *srid* argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If *srid* refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a *crs* property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional *srid* argument is given, any CRS is ignored even if it is invalid.

If a *crs* member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an `ER_INVALID_GEOJSON_CRIS_NOT_TOP_LEVEL` error occurs.

As specified in the GeoJSON specification, parsing is case sensitive for the `type` member of the GeoJSON input (`Point`, `LineString`, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object:

```
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0] }';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+-----+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+-----+
| POINT(102 0) |
+-----+
```

12.15.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- Otherwise, the return value is non-`NULL`.

These convenience functions are available:

- `ST_Distance_Sphere(g1, g2 [, radius])`

Returns the minimum spherical distance between `Point` or `MultiPoint` arguments on a sphere, in meters. (For general-purpose distance calculations, see the `ST_Distance()` function.) The optional `radius` argument should be given in meters.

If both geometry parameters are valid Cartesian `Point` or `MultiPoint` values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

If both geometry parameters are valid `Point` or `MultiPoint` values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as $(2a+b)/3$, where a is the semi-major axis and b is the semi-minor axis of the SRS.

`ST_Distance_Sphere()` handles its arguments as described in the introduction to this section, with these exceptions:

- Supported geometry argument combinations are `Point` and `Point`, or `Point` and `MultiPoint` (in any argument order). If at least one of the geometries is neither `Point` nor `MultiPoint`, and its SRID is 0, an `ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS` error occurs. If at least one of

the geometries is neither `Point` nor `MultiPoint`, and its SRID refers to a geographic SRS, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs. If any geometry refers to a projected SRS, an `ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRS` error occurs.

- If any argument has a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- If the `radius` argument is present but not positive, an `ER_NONPOSITIVE_RADIUS` error occurs.
- If the distance exceeds the range of a double-precision number, an `ER_STD_OVERFLOW_ERROR` error occurs.

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+-----+
| ST_Distance_Sphere(@pt1, @pt2) |
+-----+
| 20015042.813723423 |
+-----+
```

- `ST_IsValid(g)`

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid. Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_IsValid()` returns 1 in this case. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsValid()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,-0.00 0,0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+-----+
| ST_IsValid(@ls1) |
+-----+
```

```

|          0 |
+-----+
mysql> SELECT ST_IsValid(@ls2);
+-----+
| ST_IsValid(@ls2) |
+-----+
|          1 |
+-----+
    
```

- `ST_MakeEnvelope(pt1, pt2)`

Returns the rectangle that forms the envelope around two points, as a [Point](#), [LineString](#), or [Polygon](#).

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points *pt1* and *pt2*, `ST_MakeEnvelope()` creates the result geometry on an abstract plane like this:

- If *pt1* and *pt2* are equal, the result is the point *pt1*.
- Otherwise, if (*pt1*, *pt2*) is a vertical or horizontal line segment, the result is the line segment (*pt1*, *pt2*).
- Otherwise, the result is a polygon using *pt1* and *pt2* as diagonal points.

The result geometry has an SRID of 0.

`ST_MakeEnvelope()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the arguments are not [Point](#) values, an [ER_WRONG_ARGUMENTS](#) error occurs.
- An [ER_GIS_INVALID_DATA](#) error occurs for the additional condition that any coordinate value of the two points is infinite or NaN.
- If any geometry has an SRID value for a geographic spatial reference system (SRS), an [ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS](#) error occurs.

```

mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+-----+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+-----+
| POLYGON((0 0,1 0,1 1,0 1,0 0)) |
+-----+
    
```

- `ST_Simplify(g, max_distance)`

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The `max_distance` argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to `ST_IsValid()`.

`ST_Simplify()` handles its arguments as described in the introduction to this section, with this exception:

- If the `max_distance` argument is not positive, or is NaN, an `ER_WRONG_ARGUMENTS` error occurs.

```
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
+-----+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+-----+
| LINESTRING(0 0,0 1,1 1,2 3,3 3) |
+-----+
mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
+-----+
| ST_AsText(ST_Simplify(@g, 1.0)) |
+-----+
| LINESTRING(0 0,3 3)              |
+-----+
```

- `ST_Validate(g)`

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid: `POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))`

`ST_Validate()` returns the geometry if it is syntactically well-formed and is geometrically valid, `NULL` if the argument is not syntactically well-formed or is not geometrically valid or is `NULL`.

`ST_Validate()` can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input `Polygon` or `MultiPolygon` has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_Validate()` returns it directly without further checks in this case.

As of MySQL 8.0.13, `ST_Validate()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If any longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If any latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, `ST_Validate()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not syntactically well-formed, the return value is `NULL`. An `ER_GIS_INVALID_DATA` error does not occur.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+-----+
| ST_AsText(ST_Validate(@ls1)) |
+-----+
| NULL                          |
+-----+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-----+
| ST_AsText(ST_Validate(@ls2)) |
+-----+
| LINESTRING(0 0,1 1)         |
+-----+
```

12.16 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the `JSON` data type and additional examples showing how to use these functions, see [Section 11.6, “The JSON Data Type”](#).

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

A set of spatial functions for operating on GeoJSON values is also available. See [Section 12.15.11, “Spatial GeoJSON Functions”](#).

12.16.1 JSON Function Reference

Table 12.20 JSON Functions

Name	Description
<code>JSON_ARRAY()</code>	Create JSON array
<code>JSON_ARRAY_APPEND()</code>	Append data to JSON document
<code>JSON_ARRAY_INSERT()</code>	Insert into JSON array
<code>-></code>	Return value from JSON column after evaluating path; equivalent to <code>JSON_EXTRACT()</code> .
<code>JSON_CONTAINS()</code>	Whether JSON document contains specific object at path
<code>JSON_CONTAINS_PATH()</code>	Whether JSON document contains any data at path
<code>JSON_DEPTH()</code>	Maximum depth of JSON document
<code>JSON_EXTRACT()</code>	Return data from JSON document
<code>->></code>	Return value from JSON column after evaluating path and unquoting the result; equivalent to <code>JSON_UNQUOTE(JSON_EXTRACT())</code> .

Name	Description
JSON_INSERT()	Insert data into JSON document
JSON_KEYS()	Array of keys from JSON document
JSON_LENGTH()	Number of elements in JSON document
JSON_MERGE() (deprecated 8.0.3)	Merge JSON documents, preserving duplicate keys. Deprecated synonym for JSON_MERGE_PRESERVE()
JSON_MERGE_PATCH()	Merge JSON documents, replacing values of duplicate keys
JSON_MERGE_PRESERVE()	Merge JSON documents, preserving duplicate keys
JSON_OBJECT()	Create JSON object
JSON_PRETTY()	Prints a JSON document in human-readable format, with each array element or object member printed on a new line, indented two spaces with respect to its parent.
JSON_QUOTE()	Quote JSON document
JSON_REMOVE()	Remove data from JSON document
JSON_REPLACE()	Replace values in JSON document
JSON_SEARCH()	Path to value within JSON document
JSON_SET()	Insert data into JSON document
JSON_STORAGE_FREE()	Freed space within binary representation of a JSON column value following a partial update
JSON_STORAGE_SIZE()	Space used for storage of binary representation of a JSON document; for a JSON column, the space used when the document was inserted, prior to any partial updates
JSON_TABLE()	Returns data from a JSON expression as a relational table
JSON_TYPE()	Type of JSON value
JSON_UNQUOTE()	Unquote JSON value
JSON_VALID()	Whether JSON value is valid

MySQL supports two aggregate JSON functions [JSON_ARRAYAGG\(\)](#) and [JSON_OBJECTAGG\(\)](#). See [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#), for descriptions of these.

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the [JSON_PRETTY\(\)](#) function. You can see how much storage space a given JSON value takes up, and how much space remains for additional storage, using [JSON_STORAGE_SIZE\(\)](#) and [JSON_STORAGE_FREE\(\)](#), respectively. For complete descriptions of these functions, see [Section 12.16.7, “JSON Utility Functions”](#).

12.16.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

- [JSON_ARRAY\(\[val\[, val\] ...\]\)](#)

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+-----+
| JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
+-----+
| [1, "abc", null, true, "11:30:24.000000"] |
```

- `JSON_OBJECT([key, val[, key, val] ...])`

Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is `NULL` or the number of arguments is odd.

```
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----+
| {"id": 87, "name": "carrot"}           |
+-----+
```

- `JSON_QUOTE(string)`

Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in [Table 12.21, “JSON_UNQUOTE\(\) Special Character Escape Sequences”](#).

```
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+-----+-----+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+-----+-----+
| "null"             | "\"null\""           |
+-----+-----+
mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-----+
| JSON_QUOTE('[1, 2, 3]') |
+-----+
| "[1, 2, 3]"           |
+-----+
```

You can also obtain JSON values by casting values of other types to the `JSON` type using `CAST(value AS JSON)`; see [Converting between JSON and non-JSON values](#), for more information.

Two aggregate functions generating JSON values are available. `JSON_ARRAYAGG()` returns a result set as a single JSON array, and `JSON_OBJECTAGG()` returns a result set as a single JSON object. For more information, see [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#).

12.16.3 Functions That Search JSON Values

The functions in this section perform search operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them.

- `JSON_CONTAINS(target, candidate[, path])`

Indicates by returning 1 or 0 whether a given *candidate* JSON document is contained within a *target* JSON document, or—if a *path* argument was supplied—whether the candidate is found at a specific path within the target. Returns `NULL` if any argument is `NULL`, or if the path argument does not identify a section of the target document. An error occurs if *target* or *candidate* is not a valid JSON document, or if the *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.
- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.
- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.
- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SET @j2 = '1';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.b');
+-----+
| JSON_CONTAINS(@j, @j2, '$.b') |
+-----+
| 0 |
+-----+

mysql> SET @j2 = '{"d": 4}';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 0 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.c');
+-----+
| JSON_CONTAINS(@j, @j2, '$.c') |
+-----+
| 1 |
+-----+
```

- `JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)`

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, or `one_or_all` is not `'one'` or `'all'`.

To check for a specific value at a path, use `JSON_CONTAINS()` instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the `one_or_all` argument:

- `'one'`: 1 if at least one path exists within the document, 0 otherwise.
- `'all'`: 1 if all paths exist within the document, 0 otherwise.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e');
+-----+
| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') |
+-----+
| 0 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') |
+-----+
| 0 |
+-----+
```

- `JSON_EXTRACT(json_doc, path[, path] ...)`

Returns data from a JSON document, selected from the parts of the document matched by the *path* arguments. Returns `NULL` if any argument is `NULL` or no paths locate a value in the document. An error occurs if the *json_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression.

The return value consists of all values matched by the *path* arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

```
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') |
+-----+
| 20 |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') |
+-----+
| [20, 10] |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') |
+-----+
| [30, 40] |
+-----+
```

MySQL supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a [JSON](#) column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- `column->path`

The `->` operator serves as an alias for the [JSON_EXTRACT\(\)](#) function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two [SELECT](#) statements shown here produce the same output:

```
mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY JSON_EXTRACT(c, "$.name");
```

c	c->"\$.id"	g
{"id": "3", "name": "Barney"}	"3"	3
{"id": "4", "name": "Betty"}	"4"	4
{"id": "2", "name": "Wilma"}	"2"	2

3 rows in set (0.00 sec)

```
mysql> SELECT c, c->"$.id", g
> FROM jemp
> WHERE c->"$.id" > 1
> ORDER BY c->"$.name";
```

c	c->"\$.id"	g
{"id": "3", "name": "Barney"}	"3"	3
{"id": "4", "name": "Betty"}	"4"	4
{"id": "2", "name": "Wilma"}	"2"	2

3 rows in set (0.00 sec)

This functionality is not limited to [SELECT](#), as shown here:

```
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
```

c	c->"\$.id"	g	n
{"id": "3", "name": "Barney"}	"3"	3	NULL
{"id": "4", "name": "Betty"}	"4"	4	1
{"id": "2", "name": "Wilma"}	"2"	2	NULL

3 rows in set (0.00 sec)

```
mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
  > FROM jemp
  > WHERE JSON_EXTRACT(c, "$.id") > 1
  > ORDER BY c->"$.name";
+-----+-----+-----+-----+
| c          | c->"$.id" | g    | n    |
+-----+-----+-----+-----+
| {"id": "3", "name": "Barney"} | "3"      | 3    | NULL |
| {"id": "2", "name": "Wilma"} | "2"      | 2    | NULL |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

(See [Indexing a Generated Column to Provide a JSON Column Index](#), for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
  > VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
+-----+
| a->"$[4]" |
+-----+
| 44        |
| [22, 44, 66] |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
+-----+-----+
| a          | b    |
+-----+-----+
| [3, 10, 5, 17, 44] | 33   |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+-----+-----+
2 rows in set (0.00 sec)
```

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
+-----+-----+
| a          | b    |
+-----+-----+
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+-----+-----+

mysql> SELECT a->"$[4][1]" FROM tj10;
+-----+
| a->"$[4][1]" |
+-----+
| NULL         |
| 44           |
+-----+
2 rows in set (0.00 sec)
```

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+-----+
| JSON_EXTRACT(a, "$[4][1]") |
+-----+
| NULL                        |
| 44                         |
+-----+
2 rows in set (0.00 sec)
```

- `column->>path`

This is an improved, unquoting extraction operator. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a `JSON` column value `column` and a path expression `path`, the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column -> path)`
- `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```
mysql> SELECT * FROM jemp WHERE g > 2;
+-----+-----+
| c                                           | g |
+-----+-----+
| {"id": "3", "name": "Barney"}              | 3 |
| {"id": "4", "name": "Betty"}              | 4 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> SELECT c->'$.name' AS name
->      FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| "Barney" |
| "Betty" |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
->      FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT c->>'$.name' AS name
->      FROM jemp WHERE g > 2;
```

```
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)
```

See [Indexing a Generated Column to Provide a JSON Column Index](#), for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10 VALUES
->      ('[3,10,5,"x",44]', 33),
->      ('[3,10,5,17,[22,"y",66]]', 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----+-----+
| a->"$[3]" | a->"$[4][1]" |
+-----+-----+
| "x"      | NULL        |
| 17       | "y"         |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT a->>"$[3]", a->>"$[4][1]" FROM tj10;
+-----+-----+
| a->>"$[3]" | a->>"$[4][1]" |
+-----+-----+
| x         | NULL         |
| 17        | y            |
+-----+-----+
2 rows in set (0.00 sec)
```

As with `->`, the `->>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```
mysql> EXPLAIN SELECT c->>'$.name' AS name
->      FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: jemp
    partitions: NULL
         type: range
possible_keys: i
         key: i
        key_len: 5
         ref: NULL
         rows: 2
   filtered: 100.00
    Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
        Code: 1003
```

```
Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`, '$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

This is similar to how MySQL expands the `->` operator in the same circumstances.

- `JSON_KEYS(json_doc[, path])`

Returns the keys from the top-level value of a JSON object as a JSON array, or, if a `path` argument is given, the top-level keys from the selected path. Returns `NULL` if any argument is `NULL`, the `json_doc` argument is not an object, or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.

```
mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }') |
+-----+
| [ "a", "b" ]                               |
+-----+
mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b') |
+-----+
| [ "c" ]                                           |
+-----+
```

- `JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])`

Returns the path to the given string within a JSON document. Returns `NULL` if any of the `json_doc`, `search_str`, or `path` arguments are `NULL`; no `path` exists within the document; or `search_str` is not found. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, `one_or_all` is not `'one'` or `'all'`, or `escape_char` is not a constant expression.

The `one_or_all` argument affects the search as follows:

- `'one'`: The search terminates after the first match and returns one path string. It is undefined which match is considered first.
- `'all'`: The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the `%` and `_` characters work as for the `LIKE` operator: `%` matches any number of characters (including zero characters), and `_` matches exactly one character.

To specify a literal `%` or `_` character in the search string, precede it by the escape character. The default is `\` if the `escape_char` argument is missing or `NULL`. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of `LIKE` in [Section 12.5.1, “String Comparison Functions”](#). For escape character handling, a difference from the `LIKE` behavior is that the escape character for `JSON_SEARCH()` must evaluate to a constant at compile time, not just at execution time. For example, if `JSON_SEARCH()` is used in a prepared statement and

the *escape_char* argument is supplied using a *?* parameter, the parameter value might be constant at execution time, but is not at compile time.

```
mysql> SET @j = '{"abc", [{"k": "10"}, "def"], {"x": "abc"}, {"y": "bcd"}}';

mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-----+
| JSON_SEARCH(@j, 'one', 'abc') |
+-----+
| "$[0]"                        |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-----+
| JSON_SEARCH(@j, 'all', 'abc') |
+-----+
| ["$[0]", "$[2].x"]           |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-----+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-----+
| NULL                          |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10');

+-----+
```

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators `*` and `**`, see [Section 12.16.8, “JSON Path Syntax”](#).

12.16.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- `JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)`

Appends values to the end of the indicated arrays within a JSON document and returns the result.

Returns `NULL` if any argument is `NULL`. An error occurs if the *json_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.

```
mysql> SET @j = '['a', ['b', 'c'], 'd'];
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1]', 1);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1]', 1) |
+-----+
| ["a", ["b", "c", 1], "d"]        |
+-----+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[0]', 2);
+-----+
| JSON_ARRAY_APPEND(@j, '$[0]', 2) |
+-----+
| [{"a", 2}, ["b", "c"], "d"]      |
+-----+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1][0]', 3);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1][0]', 3) |
+-----+
| ["a", [{"b", 3}, "c"], "d"]        |
+-----+

mysql> SET @j = '{"a": 1, "b": [2, 3], "c": 4}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.b', 'x');
+-----+
| JSON_ARRAY_APPEND(@j, '$.b', 'x') |
+-----+
| {"a": 1, "b": [2, 3, "x"], "c": 4} |
+-----+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.c', 'y');
+-----+
| JSON_ARRAY_APPEND(@j, '$.c', 'y') |
+-----+
| {"a": 1, "b": [2, 3], "c": [4, "y"]} |
+-----+

mysql> SET @j = '{"a": 1}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$', 'z');
+-----+
| JSON_ARRAY_APPEND(@j, '$', 'z') |
+-----+
| [{"a": 1}, "z"]                 |
+-----+
```

In MySQL 5.7, this function was named `JSON_APPEND()`. That name is no longer supported in MySQL 8.0.

- `JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)`

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.

```
mysql> SET @j = '["a", {"b": [1, 2]}, [3, 4]]';
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1]', 'x') |
+-----+
| ["a", "x", {"b": [1, 2]}, [3, 4]] |
+-----+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[100]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[100]', 'x') |
+-----+
| ["a", {"b": [1, 2]}, [3, 4], "x"] |
+-----+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x') |
+-----+
| ["a", {"b": ["x", 1, 2]}, [3, 4]] |
+-----+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[2][1]', 'y');
+-----+
| JSON_ARRAY_INSERT(@j, '$[2][1]', 'y') |
+-----+
| ["a", {"b": [1, 2]}, [3, "y", 4]] |
+-----+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y');
+-----+
| JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y') |
+-----+
| ["x", "a", {"b": [1, 2]}, [3, 4]] |
+-----+
```

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- `JSON_INSERT(json_doc, path, val[, path, val] ...)`

Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexistent path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexistent path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| { "a": 1, "b": [2, 3], "c": "[true, false]" }      |
+-----+
```

The third and final value listed in the result is a quoted string and not an array like the second one (which is not quoted in the output); no casting of values to the JSON type is performed. To insert the array as an array, you must perform such casts explicitly, as shown here:

```
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON));
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON)) |
+-----+
| { "a": 1, "b": [2, 3], "c": [true, false] }                      |
+-----+
1 row in set (0.00 sec)
```

- `JSON_MERGE(json_doc, json_doc[, json_doc] ...)`

Merges two or more JSON documents. Synonym for `JSON_MERGE_PRESERVE()`; deprecated in MySQL 8.0.3 and subject to removal in a future release.

```
mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE('[1, 2]', '[true, false]') |
+-----+
| [1, 2, true, false]                  |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'JSON_MERGE' is deprecated and will be removed in a future release. \
Please use JSON_MERGE_PRESERVE/JSON_MERGE_PATCH instead
1 row in set (0.00 sec)
```

For additional examples, see the entry for [JSON_MERGE_PRESERVE\(\)](#).

- [JSON_MERGE_PATCH\(*json_doc*, *json_doc*\[, *json_doc*\] ...\)](#)

Performs an [RFC 7396](#) compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

Note

For an explanation and example of the differences between this function and [JSON_MERGE_PRESERVE\(\)](#), see [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#).

[JSON_MERGE_PATCH\(\)](#) performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.
2. If the second argument is not an object, the result of the merge is the second argument.
3. If both arguments are objects, the result of the merge is an object with the following members:
 - All members of the first object which do not have a corresponding member with the same key in the second object.
 - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON `null` literal.
 - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON `null` literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see [Normalization, Merging, and Autowrapping of JSON Values](#).

```
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE_PATCH('[1, 2]', '[true, false]') |
+-----+
| [true, false]                               |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{\"name\": \"x\"}', '{\"id\": 47}');
+-----+
| JSON_MERGE_PATCH('{\"name\": \"x\"}', '{\"id\": 47}') |
+-----+
| {\"id\": 47, \"name\": \"x\"}                       |
+-----+

mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-----+
| JSON_MERGE_PATCH('1', 'true') |
+-----+
| true                           |
+-----+

mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{\"id\": 47}');
+-----+
| JSON_MERGE_PATCH('[1, 2]', '{\"id\": 47}') |
```

```
+-----+
| { "id": 47 } |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>      '{ "a": 3, "c":4 }');
+-----+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }') |
+-----+
| { "a": 3, "b": 2, "c": 4 } |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }',
>      '{ "a": 5, "d":6 }');
+-----+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }', '{ "a": 5, "d":6 }') |
+-----+
| { "a": 5, "b": 2, "c": 4, "d": 6 } |
+-----+
```

You can use this function to remove a member by specifying `null` as the value of the same member in the second argument, as shown here:

```
mysql> SELECT JSON_MERGE_PATCH('{ "a":1, "b":2 }', '{ "b":null }');
+-----+
| JSON_MERGE_PATCH('{ "a":1, "b":2 }', '{ "b":null }') |
+-----+
| { "a": 1 } |
+-----+
```

This example shows that the function operates in a recursive fashion; that is, values of members are not limited to scalars, but rather can themselves be JSON documents:

```
mysql> SELECT JSON_MERGE_PATCH('{ "a":{"x":1} }', '{ "a":{"y":2} }');
+-----+
| JSON_MERGE_PATCH('{ "a":{"x":1} }', '{ "a":{"y":2} }') |
+-----+
| { "a": { "x": 1, "y": 2 } } |
+-----+
```

`JSON_MERGE_PATCH()` is supported in MySQL 8.0.3 and later.

JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(). The behavior of `JSON_MERGE_PATCH()` is the same as that of `JSON_MERGE_PRESERVE()`, with the following two exceptions:

- `JSON_MERGE_PATCH()` removes any member in the first object with a matching key in the second object, provided that the value associated with the key in the second object is not JSON `null`.
- If the second object has a member with a key matching a member in the first object, `JSON_MERGE_PATCH()` *replaces* the value in the first object with the value in the second object, whereas `JSON_MERGE_PRESERVE()` *appends* the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key "a", with each of these two functions:

```
mysql> SET @x = '{ "a": 1, "b": 2 }',
>      @y = '{ "a": 3, "c": 4 }',
>      @z = '{ "a": 5, "d": 6 }';
```

```
mysql> SELECT JSON_MERGE_PATCH(@x, @y, @z) AS Patch,
-> JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve\G
***** 1. row *****
Patch: {"a": 5, "b": 2, "c": 4, "d": 6}
Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}
```

- `JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)`

Merges two or more JSON documents and returns the merged result. Returns `NULL` if any argument is `NULL`. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see [Normalization, Merging, and Autowrapping of JSON Values](#).

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```
mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE_PRESERVE('[1, 2]', '[true, false]') |
+-----+
| [1, 2, true, false] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{"name": "x"}', '{"id": 47}');
+-----+
| JSON_MERGE_PRESERVE('{"name": "x"}', '{"id": 47}') |
+-----+
| {"id": 47, "name": "x"} |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('1', 'true');
+-----+
| JSON_MERGE_PRESERVE('1', 'true') |
+-----+
| [1, true] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '{"id": 47}');
+-----+
| JSON_MERGE_PRESERVE('[1, 2]', '{"id": 47}') |
+-----+
| [1, 2, {"id": 47}] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }',
> '{ "a": 3, "c": 4 }');
+-----+
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }') |
+-----+
| {"a": [1, 3], "b": 2, "c": 4} |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }',
> '{ "a": 5, "d": 6 }');
+-----+
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }', '{ "a": 5, "d": 6 }') |
+-----+
```

```
+-----+
| { "a": [1, 3, 5], "b": 2, "c": 4, "d": 6} |
+-----+
```

This function was added in MySQL 8.0.3 as a synonym for `JSON_MERGE()`. The `JSON_MERGE()` function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from `JSON_MERGE_PATCH()` in significant respects; see [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#), for more information.

- `JSON_REMOVE(json_doc, path[, path] ...)`

Removes data from a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or is `$` or contains a `*` or `**` wildcard.

The `path` arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

```
mysql> SET @j = '{"a", ["b", "c"], "d"}';
mysql> SELECT JSON_REMOVE(@j, '$[1]');
+-----+
| JSON_REMOVE(@j, '$[1]') |
+-----+
| ["a", "d"]              |
+-----+
```

- `JSON_REPLACE(json_doc, path, val[, path, val] ...)`

Replaces existing values in a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexistent path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_REPLACE()` function and meets the conditions outlined in [Partial Updates of JSON Values](#).

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| { "a": 10, "b": [2, 3]}                             |
+-----+
```

- `JSON_SET(json_doc, path, val[, path, val] ...)`

Inserts or updates data in a JSON document and returns the result. Returns `NULL` if any argument is `NULL` or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_SET()` function and meets the conditions outlined in [Partial Updates of JSON Values](#).

The `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions are related:

- `JSON_SET()` replaces existing values and adds nonexisting values.
- `JSON_INSERT()` inserts values without replacing existing values.
- `JSON_REPLACE()` replaces *only* existing values.

The following examples illustrate these differences, using one path that does exist in the document (`$.a`) and another that does not exist (`$.c`):

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3], "c": "[true, false]"}      |
+-----+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 1, "b": [2, 3], "c": "[true, false]"}        |
+-----+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3]}                             |
+-----+
```

- `JSON_UNQUOTE(json_val)`

Unquotes JSON value and returns the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in Table 12.21, “`JSON_UNQUOTE()` Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`.

Table 12.21 `JSON_UNQUOTE()` Special Character Escape Sequences

Escape Sequence	Character Represented by Sequence
<code>\"</code>	A double quote (<code>"</code>) character
<code>\b</code>	A backspace character
<code>\f</code>	A formfeed character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character
<code>\\</code>	A backslash (<code>\</code>) character
<code>\uXXXX</code>	UTF-8 bytes for Unicode value <code>XXXX</code>

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| "abc"   | abc               |
+-----+-----+
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| [1, 2, 3] | [1, 2, 3]        |
+-----+-----+
```

The following set of examples shows how `JSON_UNQUOTE` handles escapes with `NO_BACKSLASH_ESCAPES` disabled and enabled:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+

mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
```

```

+-----+
|      2      |
+-----+

mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+-----+
| JSON_UNQUOTE('"\t\u0032"') |
+-----+
| \t\u0032                  |
+-----+

mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+-----+
| JSON_UNQUOTE('"\t\u0032"') |
+-----+
|      2                      |
+-----+

```

12.16.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- `JSON_DEPTH(json_doc)`

Returns the maximum depth of a JSON document. Returns `NULL` if the argument is `NULL`. An error occurs if the argument is not a valid JSON document.

An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

```

mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
+-----+-----+-----+
| JSON_DEPTH('{}') | JSON_DEPTH('[]') | JSON_DEPTH('true') |
+-----+-----+-----+
|      1          |      1          |      1          |
+-----+-----+-----+

mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[], {}]');
+-----+-----+
| JSON_DEPTH('[10, 20]') | JSON_DEPTH('[[], {}]') |
+-----+-----+
|      2                |      2                |
+-----+-----+

mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-----+
| JSON_DEPTH('[10, {"a": 20}]') |
+-----+
|      3                        |
+-----+

```

- `JSON_LENGTH(json_doc[, path])`

Returns the length of a JSON document, or, if a `path` argument is given, the length of the value within the document identified by the path. Returns `NULL` if any argument is `NULL` or the `path` argument does not identify a value in the document. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The length of a document is determined as follows:

- The length of a scalar is 1.

- The length of an array is the number of array elements.
- The length of an object is the number of object members.
- The length does not count the length of nested arrays or objects.

```
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+-----+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
+-----+
| 3 |
+-----+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+-----+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
+-----+
| 2 |
+-----+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
+-----+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b') |
+-----+
| 1 |
+-----+
```

- `JSON_TYPE(json_val)`

Returns a `utf8mb4` string indicating the type of a JSON value. This can be an object, an array, or a scalar type, as shown here:

```
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+-----+
| JSON_TYPE(@j) |
+-----+
| OBJECT        |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+-----+
| ARRAY          |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+-----+
| INTEGER        |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+-----+
| BOOLEAN        |
+-----+
```

`JSON_TYPE()` returns `NULL` if the argument is `NULL`:

```
mysql> SELECT JSON_TYPE(NULL);
+-----+
| JSON_TYPE(NULL) |
+-----+
```

```
+-----+
| NULL |
+-----+
```

An error occurs if the argument is not a valid JSON value:

```
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

For a non-`NULL`, non-error result, the following list describes the possible `JSON_TYPE()` return values:

- Purely JSON types:
 - `OBJECT`: JSON objects
 - `ARRAY`: JSON arrays
 - `BOOLEAN`: The JSON true and false literals
 - `NULL`: The JSON null literal
- Numeric types:
 - `INTEGER`: MySQL `TINYINT`, `SMALLINT`, `MEDIUMINT` and `INT` and `BIGINT` scalars
 - `DOUBLE`: MySQL `DOUBLE` `FLOAT` scalars
 - `DECIMAL`: MySQL `DECIMAL` and `NUMERIC` scalars
- Temporal types:
 - `DATETIME`: MySQL `DATETIME` and `TIMESTAMP` scalars
 - `DATE`: MySQL `DATE` scalars
 - `TIME`: MySQL `TIME` scalars
- String types:
 - `STRING`: MySQL `utf8` character type scalars: `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET`
- Binary types:
 - `BLOB`: MySQL binary type scalars including `BINARY`, `VARBINARY`, `BLOB`, and `BIT`
- All other types:
 - `OPAQUE` (raw bits)
- `JSON_VALID(val)`

Returns 0 or 1 to indicate whether a value is valid JSON. Returns `NULL` if the argument is `NULL`.

```
mysql> SELECT JSON_VALID('{\"a\": 1}');
+-----+
| JSON_VALID('{\"a\": 1}') |
+-----+
```

```

|          1 |
+-----+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('"hello"');
+-----+-----+
| JSON_VALID('hello') | JSON_VALID('"hello"') |
+-----+-----+
|          0 |          1 |
+-----+-----+

```

12.16.6 JSON Table Functions

This section contains information about JSON functions that convert JSON data to tabular data. In MySQL 8.0.4 and later, one such function—`JSON_TABLE()`—is supported.

- `JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)`

Extracts data from a JSON document and returns it as a relational table having the specified columns. The complete syntax for this function is shown here:

```

JSON_TABLE(
    expr,
    path COLUMNS (column_list)
) [AS] alias

column_list:
    column[, column][, ...]

column:
    name FOR ORDINALITY
    | name type PATH string path [on_error] [on_empty]
    | name type EXISTS PATH string path
    | NESTED [PATH] path COLUMNS (column_list)

on_error:
    {NULL | ERROR | DEFAULT json_string} ON ERROR

on_empty:
    {NULL | ERROR | DEFAULT json_string} ON EMPTY

```

***expr*:** This is an expression that returns JSON data. This can be a constant (`'{"a":1}'`), a column (`t1.json_data`, given table `t1` specified prior to `JSON_TABLE()` in the `FROM` clause), or a function call (`JSON_EXTRACT(t1,json_data,'$.post.comments')`).

***path*:** A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the *row source*; this is used to generate a row of relational data. The `COLUMNS` clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The *alias* is required. The usual rules for table aliases apply (see [Section 9.2, “Schema Object Names”](#)).

`JSON_TABLE()` supports four types of columns, described in the following list:

1. ***name* FOR ORDINALITY:** This type enumerates rows in the `COLUMNS` clause; the column named *name* is a counter whose type is `UNSIGNED INT`, and whose initial value is 1. This is equivalent to specifying a column as `AUTO_INCREMENT` in a `CREATE TABLE` statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a `NESTED [PATH]` clause.

2. *name type PATH string_path [on_error] [on_empty]*: Columns of this type are used to extract values specified by *string_path*. *type* is a MySQL data type. `JSON_TABLE()` extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. The exact behavior depends on the column type: If the column type is an SQL type, then only a scalar value can be saved in the column. Saving an object or array triggers the *on_error* clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string `'asd'` to an integer column. A missing value triggers the *on_empty* clause.

The optional *on_error* clause determines what `JSON_TABLE()` does when saving an object or array:

- **NULL ON ERROR**: The column is set to `NULL`; this is the default behavior. If an error occurs during type coercion, a warning is thrown.
- **ERROR ON ERROR**: An error is thrown.
- **DEFAULT json_string ON ERROR**: The *json_string* is parsed as JSON (provided that it is valid) and stored instead of the object or array. A warning is thrown if the error is caused by type coercion. Column type rules also apply to the default value.

When a value saved to a column is truncated, such as saving 3.14159 in a `DECIMAL(10,1)` column, a warning is issued independently of any **ON ERROR** option. When multiple values are truncated in a single statement, the warning is issued only once.

The optional *on_empty* clause determines what `JSON_TABLE()` does in the event that data is missing (depending on type). This clause is also triggered on a column in a **NESTED PATH** clause when the latter has no match and a `NULL` complemented row is produced for it. *on_empty* takes one of the following values:

- **NULL ON EMPTY**: The column is set to `NULL`; this is the default behavior.
- **ERROR ON EMPTY**: An error is thrown.
- **DEFAULT json_string ON EMPTY**: the provided *json_string* is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.

This query demonstrates the use of the **ON ERROR** and **ON EMPTY** options. The row corresponding to `{"b":1}` is empty for the path `"$.a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"a": "3"}, {"a": 2}, {"b": 1}, {"a": 0}, {"a": [1,2]} ]',
->     "$[*]"
->     COLUMNS(
->       rowid FOR ORDINALITY,
->       ac VARCHAR(100) PATH "$.a" DEFAULT '999' ON ERROR DEFAULT '111' ON EMPTY,
->       aj JSON PATH "$.a" DEFAULT '{"x": 333}' ON EMPTY,
->       bx INT EXISTS PATH "$.b"
->     )
->   ) AS tt;
```

rowid	ac	aj	bx
1	3		
2	2		
3			1
4	0		
5	[1,2]		

```

+-----+-----+-----+
| 1 | 3 | "3" | 0 |
| 2 | 2 | 2 | 0 |
| 3 | 111 | {"x": 333} | 1 |
| 4 | 0 | 0 | 0 |
| 5 | 999 | [1, 2] | 0 |
+-----+-----+-----+
5 rows in set (0.00 sec)

```

3. `name type EXISTS PATH path`: This column returns 1 if any data is present at the location specified by `path`, and 0 otherwise. `type` can be any valid MySQL data type, but should normally be specified as some variety of `INT`.
4. `NESTED [PATH] path COLUMNS (column_list)`: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple `PATH` options allows projection of JSON values from multiple levels of nesting into a single row.

The `path` is relative to the parent path row path of `JSON_TABLE()`, or the path of the parent `NESTED [PATH]` clause in the event of nested paths.

Column names are subject to the usual rules and limitations governing table column names. See [Section 9.2, "Schema Object Names"](#).

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the `path` preceding the `COLUMNS` keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"x":2,"y":8},{x":3,"y":7},{x":4,"y":6}] ',
->     "$[*]" COLUMNS(
->       xval VARCHAR(100) PATH "$.x",
->       yval VARCHAR(100) PATH "$.y"
->     )
-> ) AS jt1;

```

```

+-----+-----+
| xval | yval |
+-----+-----+
| 2    | 8    |
| 3    | 7    |
| 4    | 6    |
+-----+-----+

```

The expression `"$[*]"` matches each element of the array. You can filter the rows in the result by modifying the path; for example, using `"$[1]"` limits extraction to the second element of the JSON array used as the source, as shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"x":2,"y":8},{x":3,"y":7},{x":4,"y":6}] ',
->     "$[1]" COLUMNS(
->       xval VARCHAR(100) PATH "$.x",
->       yval VARCHAR(100) PATH "$.y"
->     )

```

```
-> ) AS jt1;
```

xval	yval
3	7

Within a column definition, "\$" passes the entire match to the column; "\$.x" and "\$.y" pass only the values corresponding to the keys *x* and *y*, respectively, within that match. For more information, see [Section 12.16.8, "JSON Path Syntax"](#).

NESTED PATH (or simply **NESTED**; **PATH** is optional) produces a set of records for each match in the **COLUMNS** clause to which it belongs. If there is no match, all columns of the nested path are set to **NULL**. This implements an outer join between the topmost clause and **NESTED [PATH]**. An inner join can be emulated by applying a suitable condition in the **WHERE** clause, as shown here:

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '[{"a": 1, "b": [11,111]}, {"a": 2, "b": [22,222]}, {"a":3}]',
->     '$[*]' COLUMNS(
->       a INT PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (b INT PATH '$')
->     )
-> ) AS jt
-> WHERE b IS NOT NULL;
```

a	b
1	11
1	111
2	22
2	222

Sibling nested paths—that is, two or more instances of **NESTED [PATH]** in the same **COLUMNS** clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to **NULL**. This means that the total number of records for a single match within a single containing **COLUMNS** clause is the sum and not the product of all records produced by **NESTED [PATH]** modifiers, as shown here:

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '[{"a": 1, "b": [11,111]}, {"a": 2, "b": [22,222]}]',
->     '$[*]' COLUMNS(
->       a INT PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (b1 INT PATH '$'),
->       NESTED PATH '$.b[*]' COLUMNS (b2 INT PATH '$')
->     )
-> ) AS jt;
```

a	b1	b2
1	11	NULL
1	111	NULL
1	NULL	11
1	NULL	111
2	22	NULL

2	222	NULL
2	NULL	22
2	NULL	222

A `FOR ORDINALITY` column enumerates records produced by the `COLUMNS` clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '["a": "a_val",
->       "b": [{"c": "c_val", "l": [1,2]}]},
->     {"a": "a_val",
->       "b": [{"c": "c_val", "l": [11]}, {"c": "c_val", "l": [22]}]}]',
->     '$[*]' COLUMNS(
->       top_ord FOR ORDINALITY,
->       apath VARCHAR(10) PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (
->         bpath VARCHAR(10) PATH '$.c',
->         ord FOR ORDINALITY,
->         NESTED PATH '$.l[*]' COLUMNS (lpath varchar(10) PATH '$')
->       )
->     )
-> ) as jt;
```

top_ord	apath	bpath	ord	lpath
1	a_val	c_val	1	1
1	a_val	c_val	1	2
2	a_val	c_val	1	11
2	a_val	c_val	2	22

The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

12.16.7 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. `JSON_PRETTY()` prints out a JSON value in a format that is easy to read. `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()` show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a `JSON` column following a partial update.

- `JSON_PRETTY(json_val)`

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a `NULL` value, the function returns `NULL`. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

- Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.
- Each level of indentation adds two leading spaces.
- A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.
- The key and the value of an object member are separated by a colon followed by a space (': ').
- An empty object or array is printed on a single line. No space is printed between the opening and closing brace.
- Special characters in string scalars and key names are escaped employing the same rules used by the `JSON_QUOTE()` function.

```
mysql> SELECT JSON_PRETTY('123'); # scalar
+-----+
| JSON_PRETTY('123') |
+-----+
| 123                |
+-----+

mysql> SELECT JSON_PRETTY("[1,3,5]"); # array
+-----+
| JSON_PRETTY("[1,3,5]") |
+-----+
| [
|   1,
|   3,
|   5
| ] |
+-----+

mysql> SELECT JSON_PRETTY('{ "a": "10", "b": "15", "x": "25" }'); # object
+-----+
| JSON_PRETTY('{ "a": "10", "b": "15", "x": "25" }') |
+-----+
| {
|   "a": "10",
|   "b": "15",
|   "x": "25"
| } |
+-----+

mysql> SELECT JSON_PRETTY('["a",1,{"key1":
>   "value1"},"5",      "77" ,
>   {"key2":["value3","valueX",
>   "valueY"]},"j", "2"   ]')\G # nested arrays and objects
***** 1. row *****
JSON_PRETTY('["a",1,{"key1":
      "value1"},"5",      "77" ,
      {"key2":["value3","valueX",
      "valueY"]},"j", "2"   ]'): [
  "a",
  1,
  {
    "key1": "value1"
  },
  "5",
  "77",
  {
```

```

    "key2": [
      "value3",
      "valuex",
      "valuey"
    ]
  },
  "j",
  "2"
]

```

- `JSON_STORAGE_FREE(json_val)`

For a `JSON` column value, this function shows how much storage space was freed in its binary representation after it was updated in place using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a `JSON` column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a `JSON` column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns `NULL` if the argument is `NULL`.

If *json_val* is not `NULL`, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a `JSON` column, then insert a row containing a JSON object:

```

mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
->    ('{"a": 10, "b": "wxyz", "c": "[true, false]"}');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT * FROM jtable;
+-----+
| jcol                                     |
+-----+
| {"a": 10, "b": "wxyz", "c": "[true, false]"} |
+-----+
1 row in set (0.00 sec)

```

Now we update the column value using `JSON_SET()` such that a partial update can be performed; in this case, we replace the value pointed to by the `c` key (the array `[true, false]`) with one that takes up less space (the integer `1`):

```

mysql> UPDATE jtable
->    SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wxyz", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM jtable;
+-----+
| jcol                                     |
+-----+
| {"a": 10, "b": "wxyz", "c": 1} |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;

```

```

+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+
|                        14 |
+-----+
1 row in set (0.00 sec)

```

The effects of successive partial updates on this free space are cumulative, as shown in this example using `JSON_SET()` to reduce the space taken up by the value having key `b` (and making no other changes):

```

mysql> UPDATE jtable
      -> SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wx", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+
|                        16 |
+-----+
1 row in set (0.00 sec)

```

Updating the column without using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` means that the optimizer cannot perform the update in place; in this case, `JSON_STORAGE_FREE()` returns 0, as shown here:

```

mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+
|                        0 |
+-----+
1 row in set (0.00 sec)

```

Partial updates of JSON documents can be performed only on column values. For a user variable that stores a JSON value, the value is always completely replaced, even when the update is performed using `JSON_SET()`:

```

mysql> SET @j = '{"a": 10, "b": "wxyz", "c": "[true, false]}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$.a', 10, '$.b', 'wxyz', '$.c', '1');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+-----+-----+
| @j                        | Free |
+-----+-----+
| {"a": 10, "b": "wxyz", "c": "1"} |    0 |
+-----+-----+
1 row in set (0.00 sec)

```

For a JSON literal, this function always returns 0:

```
mysql> SELECT JSON_STORAGE_FREE('{ "a": 10, "b": "wxyz", "c": "1" }') AS Free;
+-----+
| Free |
+-----+
|    0 |
+-----+
1 row in set (0.00 sec)
```

- `JSON_STORAGE_SIZE(json_val)`

This function returns the number of bytes used to store the binary representation of a JSON document. When the argument is a `JSON` column, this is the space used to store the JSON document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. `json_val` must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns `NULL` if the argument is `NULL`.

An error results when `json_val` is not `NULL`, and is not—or cannot be successfully parsed as—a JSON document.

To illustrate this function's behavior when used with a `JSON` column as its argument, we create a table named `jtable` containing a `JSON` column `jcol`, insert a JSON value into the table, then obtain the storage space used by this column with `JSON_STORAGE_SIZE()`, as shown here:

```
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO jtable VALUES
->      ('{ "a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]" }');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT
->      jcol,
->      JSON_STORAGE_SIZE(jcol) AS Size,
->      JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
```

jcol	Size	Free
{ "a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]" }	47	0

```
1 row in set (0.00 sec)
```

According to the output of `JSON_STORAGE_SIZE()`, the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using `JSON_STORAGE_FREE()`; since no updates have yet been performed, this is 0, as expected.

Next we perform an `UPDATE` on the table that should result in a partial update of the document stored in `jcol`, and then test the result as shown here:

```
mysql> UPDATE jtable SET jcol =
->      JSON_SET(jcol, "$.b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT
->      jcol,
->      JSON_STORAGE_SIZE(jcol) AS Size,
->      JSON_STORAGE_FREE(jcol) AS Free
```

```
-> FROM jtable;
```

jcol	Size	Free
{ "a": 1000, "b": "a", "c": "[1, 3, 5, 7]" }	47	3

```
1 row in set (0.00 sec)
```

The value returned by `JSON_STORAGE_FREE()` in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by `JSON_STORAGE_SIZE()` is unchanged by the partial update.

Partial updates are supported for updates using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The direct assignment of a value to a JSON column cannot be partially updated; following such an update, `JSON_STORAGE_SIZE()` always shows the storage used for the newly-set value:

```
mysql> UPDATE jtable
mysql>     SET jcol = '{"a": 4.55, "b": "wxyz", "c": "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT
  ->     jcol,
  ->     JSON_STORAGE_SIZE(jcol) AS Size,
  ->     JSON_STORAGE_FREE(jcol) AS Free
  -> FROM jtable;
```

jcol	Size	Free
{ "a": 4.55, "b": "wxyz", "c": "[true, false]" }	56	0

```
1 row in set (0.00 sec)
```

A JSON user variable cannot be partially updated. This means that this function always shows the space currently used to store a JSON document in a user variable:

```
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+-----+-----+
| @j                | Size |
+-----+-----+
| [100, "sakila", [1, 3, 5], 425.05] | 45 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+-----+-----+
| @j                | Size |
+-----+-----+
| [100, "json", [1, 3, 5], 425.05] | 43 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[2][0]', JSON_ARRAY(10, 20, 30));
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+-----+-----+
```

```
| @j | Size |
+-----+-----+
| [100, "json", [[10, 20, 30], 3, 5], 425.05] | 56 |
+-----+-----+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns the current storage space used:

```
mysql> SELECT
->     JSON_STORAGE_SIZE('[100, "sakila", [1, 3, 5], 425.05]') AS A,
->     JSON_STORAGE_SIZE('{ "a": 1000, "b": "a", "c": "[1, 3, 5, 7]" }') AS B,
->     JSON_STORAGE_SIZE('{ "a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]" }') AS C,
->     JSON_STORAGE_SIZE('[100, "json", [[10, 20, 30], 3, 5], 425.05]') AS D;
+-----+-----+-----+-----+
| A | B | C | D |
+-----+-----+-----+-----+
| 45 | 44 | 47 | 56 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

12.16.8 JSON Path Syntax

Many of the functions described in previous sections require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading `$` character. Path legs are separated by period characters (`.`). Cells in arrays are represented by `[N]`, where `N` is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see <http://www.ecma-international.org/ecma-262/5.1/#sec-7.6>). Path expressions, like JSON text, should be encoded using the `ascii`, `utf8`, or `utf8mb4` character set. Other character encodings are implicitly coerced to `utf8mb4`. The complete syntax is shown here:

```
pathExpression:
    scope [ (pathLeg)* ]

pathLeg:
    member | arrayLocation | doubleAsterisk

member:
    period ( keyName | asterisk )

arrayLocation:
    leftBracket ( nonNegativeInteger | asterisk ) rightBracket

keyName:
    ESIdentifier | doubleQuotedString

doubleAsterisk:
    '**'

period:
    '.'

asterisk:
    '*'

leftBracket:
    '['

rightBracket:
    ']'
```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as `$`. You can use `'$'` as a synonym for the document in JSON path expressions.

Note

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard `*` and `**` tokens are used as follows:

- `.*` represents the values of all members in the object.
- `[*]` represents the values of all cells in the array.
- `[prefix]**suffix` represents all paths beginning with *prefix* and ending with *suffix*. *prefix* is optional, while *suffix* is required; in other words, a path may not end in `**`.

In addition, a path may not contain the sequence `***`.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as `JSON_CONTAINS_PATH()`, `JSON_SET()`, and `JSON_REPLACE()`. For examples which include the use of the `*` and `**` wildcards, see the description of the `JSON_SEARCH()` function.

12.17 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See [GTID Sets](#) for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
  RETURNS TEXT DETERMINISTIC
  RETURN CONCAT(g1, ',', g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

Table 12.22 GTID Functions

Name	Description
<code>GTID_SUBSET()</code>	Return true if all GTIDs in subset are also in set; otherwise false.
<code>GTID_SUBTRACT()</code>	Return all GTIDs in set that are not in subset.
<code>WAIT_FOR_EXECUTED_GTID_SET()</code>	Wait until the given GTIDs have executed on slave.
<code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</code>	Wait until the given GTIDs have executed on slave.

- `GTID_SUBSET(set1, set2)`

Given two sets of global transaction identifiers *set1* and *set2*, returns true if all GTIDs in *set1* are also in *set2*. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
1 row in set (0.00 sec)
```

- `GTID_SUBTRACT(set1,set2)`

Given two sets of global transaction identifiers *set1* and *set2*, returns only those GTIDs from *set1* that are not in *set2*.

All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

```
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:26-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:21-22:25-57
1 row in set (0.01 sec)
```

- `WAIT_FOR_EXECUTED_GTID_SET(gtid_set [, timeout])`

Wait until the server has applied all of the transactions whose global transaction identifiers are contained in *gtid_set*; that is, until the condition `GTID_SUBSET(gtid_subset, @@global.gtid_executed)` holds. See [Section 17.1.3.1, “GTID Format and Storage”](#) for a definition of GTID sets.

If a timeout is specified, and *timeout* seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. *timeout* is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied.

`WAIT_FOR_EXECUTED_GTID_SET()` monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```
mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 0
```

For a syntax description for GTID sets, see [Section 17.1.3.1, “GTID Format and Storage”](#).

For `WAIT_FOR_EXECUTED_GTID_SET()`, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])`

`WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` is similar to `WAIT_FOR_EXECUTED_GTID_SET()` in that it waits until all of the transactions whose global transaction identifiers are contained in *gtid_set* have been applied, or until *timeout* seconds have elapsed, whichever occurs first. However, `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` applies to a specific replication channel, and stops only after the transactions have been applied on the specified channel, for which the applier must be running. In contrast, `WAIT_FOR_EXECUTED_GTID_SET()` stops after the transactions have been applied, regardless of where they were applied (on any replication channel or any user client), and whether or not any replication channels are running.

The *channel* option names which replication channel the function applies to. If no channel is named and no channels other than the default replication channel exist, the function applies to the default replication channel. If multiple replication channels exist, you must specify a channel as otherwise it is not known which replication channel the function applies to. See [Section 17.2.3, “Replication Channels”](#) for more information on replication channels.

Note

Because `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` applies to a specific replication channel, if an expected transaction arrives on a different replication channel or from a user client, for example in a failover or manual recovery situation, the function can hang indefinitely if no timeout is set. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead to ensure correct handling of transactions in these situations.

GTID sets used with `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` are represented as strings and must be quoted in the same way as for `WAIT_FOR_EXECUTED_GTID_SET()`. For `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`, the return value for the function is an arbitrary positive number. If GTID-based replication is not active (that is, if the value of the `gtid_mode` variable is OFF), then this value is undefined and `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` returns NULL. If the slave is not running then the function also returns NULL.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

12.18 MySQL Enterprise Encryption Functions

Note

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

MySQL Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

MySQL Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

12.18.1 MySQL Enterprise Encryption Installation

MySQL Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements (adjust the file name suffix as necessary):

```
CREATE FUNCTION asymmetric_decrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING
  SONAME 'openssl_udf.so';
```

Once installed, UDFs remain installed across server restarts. To unload UDFs, use the `DROP FUNCTION` statement. For example, to unload the key-generation functions, do this:

```
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
```

In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

12.18.2 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks:

- [Create a private/public key pair using RSA encryption](#)
- [Use the private key to encrypt data and the public key to decrypt it](#)
- [Generate a digest from a string](#)
- [Use the digest with a key pair](#)
- [Create a symmetric key](#)
- [Limit CPU usage by key-generation operations](#)

Create a private/public key pair using RSA encryption

```
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);
```

Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

Use the private key to encrypt data and the public key to decrypt it

This requires that the members of the key pair be RSA keys.

```
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @priv);
SET @cleartext = ASYMMETRIC_DECRYPT(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

Generate a digest from a string

```
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';

-- Generate digest string
```

```
SET @dig = CREATE_DIGEST(@dig_type, 'My text to digest');
```

Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest.

```
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

Create a symmetric key

This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `CREATE_DH_PARAMETERS()`, then pass the secret as the “key length” to `CREATE_ASYMMETRIC_PRIV_KEY()`.

```
-- Generate DH shared symmetric secret
SET @dhp = CREATE_DH_PARAMETERS(1024);
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv2);

-- Generate symmetric key using public key of first party,
-- private key of second party
SET @sym1 = ASYMMETRIC_DERIVE(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = ASYMMETRIC_DERIVE(@pub2, @priv1);
```

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`:

```
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SELECT CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege.

Digest and signature strings can be handled similarly.

Limit CPU usage by key-generation operations

The `CREATE_ASYMMETRIC_PRIV_KEY()` and `CREATE_DH_PARAMETERS()` encryption functions take a key-length parameter, and the amount of CPU resources required by these functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL imposes a minimum key length of 1,024 bits for all keys. OpenSSL also imposes a maximum key length of 10,000 bits and 16,384 bits for DSA and RSA keys, respectively, for `CREATE_ASYMMETRIC_PRIV_KEY()`, and a maximum key length of 10,000 bits for `CREATE_DH_PARAMETERS()`. If those maximum values are too high, three environment variables are

available to enable MySQL server administrators to set lower maximum lengths for key generation, and thereby to limit CPU usage:

- `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD`: Maximum DSA key length in bits for `CREATE_ASYMMETRIC_PRIV_KEY()`. The minimum and maximum values for this variable are 1,024 and 10,000.
- `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD`: Maximum RSA key length in bits for `CREATE_ASYMMETRIC_PRIV_KEY()`. The minimum and maximum values for this variable are 1,024 and 16,384.
- `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD`: Maximum key length in bits for `CREATE_DH_PARAMETERS()`. The minimum and maximum values for this variable are 1,024 and 10,000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4,096 bits for DSA and RSA keys for `CREATE_ASYMMETRIC_PRIV_KEY()`, set these variables:

```
export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096
```

The example uses Bourne shell syntax. The syntax for other shells may differ.

12.18.3 MySQL Enterprise Encryption Function Reference

Table 12.23 MySQL Enterprise Encryption Functions

Name	Description
<code>ASYMMETRIC_DECRYPT()</code>	Decrypt ciphertext using private or public key
<code>ASYMMETRIC_DERIVE()</code>	Derive symmetric key from asymmetric keys
<code>ASYMMETRIC_ENCRYPT()</code>	Encrypt cleartext using private or public key
<code>ASYMMETRIC_SIGN()</code>	Generate signature from digest
<code>ASYMMETRIC_VERIFY()</code>	Verify that signature matches digest
<code>CREATE_ASYMMETRIC_PRIV_KEY()</code>	Create private key
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	Create public key
<code>CREATE_DH_PARAMETERS()</code>	Generate shared DH secret
<code>CREATE_DIGEST()</code>	Generate digest from string

12.18.4 MySQL Enterprise Encryption Function Descriptions

MySQL Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.
- If the arguments are not suitable to permit a function to perform the requested operation, it returns `NULL` or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key. (OpenSSL imposes its own key-length limits, and server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples”](#).)
- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

Table 12.24 Supported Algorithms by Function

Function	Supported Algorithms
<code>ASYMMETRIC_DECRYPT()</code>	RSA
<code>ASYMMETRIC_DERIVE()</code>	DH
<code>ASYMMETRIC_ENCRYPT()</code>	RSA
<code>ASYMMETRIC_SIGN()</code>	RSA, DSA
<code>ASYMMETRIC_VERIFY()</code>	RSA, DSA
<code>CREATE_ASYMMETRIC_PRIV_KEY()</code>	RSA, DSA, DH
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	RSA, DSA, DH
<code>CREATE_DH_PARAMETERS()</code>	DH

Note

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, `ASYMMETRIC_ENCRYPT()` and `ASYMMETRIC_DECRYPT()` accept only RSA keys.

The following descriptions describe the calling sequences for MySQL Enterprise Encryption functions. For additional examples and discussion, see [Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples”](#).

- `ASYMMETRIC_DECRYPT(algorithm, crypt_str, key_str)`

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting cleartext as a binary string. If decryption fails, the result is `NULL`.

key_str must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with `ASYMMETRIC_ENCRYPT()` to produce the encrypted string. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA'

For a usage example, see the description of `ASYMMETRIC_ENCRYPT()`.

- `ASYMMETRIC_DERIVE(pub_key_str, priv_key_str)`

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is `NULL`.

pub_key_str and *priv_key_str* must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```
ASYMMETRIC_DERIVE(@pub1, @priv2) = ASYMMETRIC_DERIVE(@pub2, @priv1)
```

- `ASYMMETRIC_ENCRYPT(algorithm, str, key_str)`

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

The *str* length cannot be greater than the *key_str* length – 11, in bytes

key_str must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA'

To encrypt a string, pass a private or public key string to `ASYMMETRIC_ENCRYPT()`. To recover the original unencrypted string, pass the encrypted string to `ASYMMETRIC_DECRYPT()`, along with the public or private key string corresponding to the private or public key string used for encryption.

```
-- Generate private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @priv);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @pub);

-- Encrypt using public key, decrypt using private key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @priv), @pub) = @s
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @pub), @priv) = @s
```

- `ASYMMETRIC_SIGN(algorithm, digest_str, priv_key_str, digest_type)`

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is `NULL`.

digest_str is the digest string. It can be generated by calling `CREATE_DIGEST()`. *digest_type* indicates the digest algorithm used to generate the digest string.

priv_key_str is the private key string to use for signing the digest string. It must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA'

Supported *digest_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

For a usage example, see the description of [ASYMMETRIC_VERIFY\(\)](#).

- [ASYMMETRIC_VERIFY\(*algorithm*, *digest_str*, *sig_str*, *pub_key_str*, *digest_type*\)](#)

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

digest_str is the digest string. It can be generated by calling [CREATE_DIGEST\(\)](#). *digest_type* indicates the digest algorithm used to generate the digest string.

sig_str is the signature string. It can be generated by calling [ASYMMETRIC_SIGN\(\)](#).

pub_key_str is the public key string of the signer. It corresponds to the private key passed to [ASYMMETRIC_SIGN\(\)](#) to generate the signature string and must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA'

Supported *digest_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';

-- Create private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);

-- Generate digest from string
SET @dig = CREATE_DIGEST(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

- [CREATE_ASYMMETRIC_PRIV_KEY\(*algorithm*, {*key_len*|*dh_secret*}\)](#)

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is [NULL](#).

Supported *algorithm* values: 'RSA', 'DSA', 'DH'

Supported *key_len* values: The minimum key length in bits is 1,024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples”](#).

For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to [CREATE_DH_PARAMETERS\(\)](#).

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

```
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('DSA', 2048);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('DSA', @priv);
```

For an example showing DH key generation, see the description of [ASYMMETRIC_DERIVE\(\)](#).

Some general considerations in choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.
- Generation of DH keys takes much longer than RSA or RSA keys.
- Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#).
- [CREATE_ASYMMETRIC_PUB_KEY\(*algorithm*, *priv_key_str*\)](#)

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is [NULL](#).

priv_key_str must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA', 'DH'

For a usage example, see the description of [CREATE_ASYMMETRIC_PRIV_KEY\(\)](#).

- [CREATE_DH_PARAMETERS\(*key_len*\)](#)

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to [CREATE_ASYMMETRIC_PRIV_KEY\(\)](#). If secret generation fails, the result is null.

Supported *key_len* values: The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 12.18.2, “MySQL Enterprise Encryption Usage and Examples”](#).

For an example showing how to use the return value for generating symmetric keys, see the description of [ASYMMETRIC_DERIVE\(\)](#).

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
```

- [CREATE_DIGEST\(*digest_type*, *str*\)](#)

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is [NULL](#).

Supported *digest_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
SET @dig = CREATE_DIGEST('SHA512', The quick brown fox);
```

The resulting digest string is suitable for use with [ASYMMETRIC_SIGN\(\)](#) and [ASYMMETRIC_VERIFY\(\)](#).

12.19 Aggregate (GROUP BY) Functions

12.19.1 Aggregate (GROUP BY) Function Descriptions

This section describes group (aggregate) functions that operate on sets of values.

Table 12.25 Aggregate (GROUP BY) Functions

Name	Description
AVG()	Return the average value of the argument
BIT_AND()	Return bitwise AND
BIT_OR()	Return bitwise OR
BIT_XOR()	Return bitwise XOR
COUNT()	Return a count of the number of rows returned
COUNT(DISTINCT)	Return the count of a number of different values
GROUP_CONCAT()	Return a concatenated string
JSON_ARRAYAGG()	Return result set as a single JSON array
JSON_OBJECTAGG()	Return result set as a single JSON object
MAX()	Return the maximum value
MIN()	Return the minimum value
STD()	Return the population standard deviation
STDDEV()	Return the population standard deviation
STDDEV_POP()	Return the population standard deviation
STDDEV_SAMP()	Return the sample standard deviation
SUM()	Return the sum
VAR_POP()	Return the population standard variance
VAR_SAMP()	Return the sample variance
VARIANCE()	Return the population standard variance

Unless otherwise stated, group functions ignore [NULL](#) values.

If you use a group function in a statement containing no [GROUP BY](#) clause, it is equivalent to grouping on all rows. For more information, see [Section 12.19.3, “MySQL Handling of GROUP BY”](#).

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by [\[over_clause\]](#), representing an optional [OVER](#) clause. [over_clause](#) is described in [Section 12.20.2, “Window Function Concepts and Syntax”](#), which also includes other information about window function usage.

For numeric arguments, the variance and standard deviation functions return a [DOUBLE](#) value. The [SUM\(\)](#) and [AVG\(\)](#) functions return a [DECIMAL](#) value for exact-value arguments (integer or [DECIMAL](#)), and a [DOUBLE](#) value for approximate-value arguments ([FLOAT](#) or [DOUBLE](#)).

The [SUM\(\)](#) and [AVG\(\)](#) aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as [SUM\(\)](#) or [AVG\(\)](#) that expect a numeric argument cast the argument to a number if necessary. For [SET](#) or [ENUM](#) values, the cast operation causes the underlying numeric value to be used.

The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in [Section 12.12, “Bit Functions and Operators”](#).

- `AVG([DISTINCT] expr) [over_clause]`

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

If there are no matching rows, `AVG()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, AVG(test_score)
       FROM student
       GROUP BY student_name;
```

- `BIT_AND(expr) [over_clause]`

Returns the bitwise `AND` of all bits in *expr*.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.12, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `BIT_OR(expr) [over_clause]`

Returns the bitwise `OR` of all bits in *expr*.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.12, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `BIT_XOR(expr) [over_clause]`

Returns the bitwise `XOR` of all bits in `expr`.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_XOR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.12, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `COUNT(expr) [over_clause]`

Returns a count of the number of non-`NULL` values of `expr` in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

```
mysql> SELECT student.student_name,COUNT(*)
        FROM student,course
        WHERE student.student_id=course.student_id
        GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

For transactional storage engines such as `InnoDB`, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

`InnoDB` does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

As of MySQL 8.0.13, `SELECT COUNT(*) FROM tbl_name` query performance for `InnoDB` tables is optimized for single-threaded workloads if there are no extra clauses such as `WHERE` or `GROUP BY`.

`InnoDB` processes `SELECT COUNT(*)` statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, `InnoDB` processes `SELECT COUNT(*)` statements by scanning the clustered index.

Processing `SELECT COUNT(*)` statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

`InnoDB` handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For `MyISAM` tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to `MyISAM` tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- `COUNT(DISTINCT expr,[expr...])`

Returns a count of the number of rows with different non-`NULL` `expr` values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain [NULL](#) by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-[NULL](#) values from a group. It returns [NULL](#) if there are no non-[NULL](#) values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
               [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
           GROUP_CONCAT(test_score)
       FROM student
       GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
           GROUP_CONCAT(DISTINCT test_score
                        ORDER BY test_score DESC SEPARATOR ' ')
       FROM student
       GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the [DISTINCT](#) clause. To sort values in the result, use the [ORDER BY](#) clause. To sort in reverse order, add the [DESC](#) (descending) keyword to the name of the column you are sorting by in the [ORDER BY](#) clause. The default is ascending order; this may be specified explicitly using the [ASC](#) keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use [SEPARATOR](#) followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify [SEPARATOR ''](#).

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where *val* is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is [TEXT](#) or [BLOB](#) unless `group_concat_max_len` is less than or equal to 512, in which case the result type is [VARCHAR](#) or [VARBINARY](#).

See also [CONCAT\(\)](#) and [CONCAT_WS\(\)](#): [Section 12.5, “String Functions”](#).

- `JSON_ARRAYAGG(col_or_expr)`

Aggregates a result set as a single [JSON](#) array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns [NULL](#) if the result contains no rows, or in the event of an error.

```
mysql> SELECT o_id, attribute, value FROM t3;
+-----+-----+-----+
| o_id | attribute | value |
+-----+-----+-----+
| 2    | color    | red   |
| 2    | fabric   | silk  |
| 3    | color    | green |
| 3    | shape    | square|
+-----+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes
> FROM t3 GROUP BY o_id;
+-----+-----+
| o_id | attributes |
+-----+-----+
| 2    | ["color", "fabric"] |
| 3    | ["color", "shape"]  |
+-----+-----+
2 rows in set (0.00 sec)
```

- `JSON_OBJECTAGG(key, value)`

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns `NULL` if the result contains no rows, or in the event of an error. An error occurs if any key name is `NULL` or the number of arguments is not equal to 2.

```
mysql> SELECT o_id, attribute, value FROM t3;
+-----+-----+-----+
| o_id | attribute | value |
+-----+-----+-----+
| 2    | color    | red   |
| 2    | fabric   | silk  |
| 3    | color    | green |
| 3    | shape    | square|
+-----+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_OBJECTAGG(attribute, value) FROM t3 GROUP BY o_id;
+-----+-----+
| o_id | JSON_OBJECTAGG(attribute, name) |
+-----+-----+
| 2    | {"color": "red", "fabric": "silk"} |
| 3    | {"color": "green", "shape": "square"} |
+-----+-----+
1 row in set (0.00 sec)
```

Duplicate key handling

When the result of this function is normalized, values having duplicate keys are discarded, and only the last value encountered is used with that key in the returned object (“last duplicate key wins”). This means that the result of using this function on columns from a `SELECT` can depend on the order in which the rows are returned, which is not guaranteed. Consider the following:

```
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)
```

```
mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
```

```
Query OK, 3 rows affected (0.10 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+-----+-----+
| c     | i     |
+-----+-----+
| key   | 3     |
| key   | 4     |
| key   | 5     |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+-----+
| JSON_OBJECTAGG(c, i) |
+-----+
| {"key": 5}            |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+-----+-----+
| c     | i     |
+-----+-----+
| key   | 3     |
| key   | 5     |
| key   | 4     |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+-----+
| JSON_OBJECTAGG(c, i) |
+-----+
| {"key": 4}            |
+-----+
1 row in set (0.00 sec)
```

See [Normalization, Merging, and Autowrapping of JSON Values](#), for additional information and examples.

- `MAX([DISTINCT] expr) [over_clause]`

Returns the maximum value of *expr*. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MAX()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
```

```
GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `MIN([DISTINCT] expr) [over_clause]`

Returns the minimum value of *expr*. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
       FROM student
       GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `STD(expr) [over_clause]`

Returns the population standard deviation of *expr*. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

If there are no matching rows, `STD()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `STDDEV(expr) [over_clause]`

Returns the population standard deviation of *expr*. `STDDEV()` is a synonym for the standard SQL function `STDDEV_POP()`, provided for compatibility with Oracle.

If there are no matching rows, `STDDEV()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `STDDEV_POP(expr) [over_clause]`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

If there are no matching rows, `STDDEV_POP()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `STDDEV_SAMP(expr) [over_clause]`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `SUM([DISTINCT] expr) [over_clause]`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

If there are no matching rows, `SUM()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

- `VAR_POP(expr) [over_clause]`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

If there are no matching rows, `VAR_POP()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `VAR_SAMP(expr) [over_clause]`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

If there are no matching rows, `VAR_SAMP()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- `VARIANCE(expr) [over_clause]`

Returns the population standard variance of *expr*. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

If there are no matching rows, `VARIANCE()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

12.19.2 GROUP BY Modifiers

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. For example, `ROLLUP` can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a `sales` table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
```

```
(
  year      INT,
  country   VARCHAR(20),
  product   VARCHAR(32),
  profit    INT
);
```

To summarize table contents per year, use a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 |    4525 |
| 2001 |    3010 |
+-----+-----+
```

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 |    4525 |
| 2001 |    3010 |
| NULL |    7535 |
+-----+-----+
```

The `NULL` value in the `year` column identifies the grand total super-aggregate line.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary of the `sales` table based on `year`, `country`, and `product` might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
        FROM sales
        GROUP BY year, country, product;
+-----+-----+-----+-----+
| year | country | product | profit |
+-----+-----+-----+-----+
| 2000 | Finland | Computer |    1500 |
| 2000 | Finland | Phone   |     100 |
| 2000 | India   | Calculator |    150 |
| 2000 | India   | Computer |    1200 |
| 2000 | USA     | Calculator |     75 |
| 2000 | USA     | Computer |    1500 |
| 2001 | Finland | Phone   |     10 |
| 2001 | USA     | Calculator |     50 |
| 2001 | USA     | Computer |    2700 |
```

2001	USA	TV	250
+-----+	+-----+	+-----+	+-----+

With `ROLLUP` added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	profit
+-----+	+-----+	+-----+	+-----+
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535
+-----+	+-----+	+-----+	+-----+

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

Previously, MySQL did not allow the use of `DISTINCT` or `ORDER BY` in a query having a `WITH ROLLUP` option. This restriction is lifted in MySQL 8.0.12 and later. (Bug #87450, Bug #86311, Bug #26640100, Bug #26073513)

For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, `HAVING` clause, and (as of MySQL 8.0.12) `ORDER BY` clause. For example, `GROUPING(year)` returns 1 when `NULL` in the `year` column occurs in a super-aggregate row, and 0 otherwise. Similarly, `GROUPING(country)` and `GROUPING(product)` return 1 for super-aggregate `NULL` values in the `country` and `product` columns, respectively:

```
mysql> SELECT
    year, country, product, SUM(profit) AS profit,
    GROUPING(year) AS grp_year,
    GROUPING(country) AS grp_country,
    GROUPING(product) AS grp_product
FROM sales
```

GROUP BY year, country, product WITH ROLLUP;						
year	country	product	profit	grp_year	grp_country	grp_product
2000	Finland	Computer	1500	0	0	0
2000	Finland	Phone	100	0	0	0
2000	Finland	NULL	1600	0	0	1
2000	India	Calculator	150	0	0	0
2000	India	Computer	1200	0	0	0
2000	India	NULL	1350	0	0	1
2000	USA	Calculator	75	0	0	0
2000	USA	Computer	1500	0	0	0
2000	USA	NULL	1575	0	0	1
2000	NULL	NULL	4525	0	1	1
2001	Finland	Phone	10	0	0	0
2001	Finland	NULL	10	0	0	1
2001	USA	Calculator	50	0	0	0
2001	USA	Computer	2700	0	0	0
2001	USA	TV	250	0	0	0
2001	USA	NULL	3000	0	0	1
2001	NULL	NULL	3010	0	1	1
NULL	NULL	NULL	7535	1	1	1

Instead of displaying the `GROUPING()` results directly, you can use `GROUPING()` to substitute labels for super-aggregate `NULL` values:

```
mysql> SELECT
    IF(GROUPING(year), 'All years', year) AS year,
    IF(GROUPING(country), 'All countries', country) AS country,
    IF(GROUPING(product), 'All products', product) AS product,
    SUM(profit) AS profit
  FROM sales
  GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	All products	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	All products	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	All products	1575
2000	All countries	All products	4525
2001	Finland	Phone	10
2001	Finland	All products	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	All products	3000
2001	All countries	All products	3010
All years	All countries	All products	7535

With multiple expression arguments, `GROUPING()` returns a result representing a bitmask the combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, `GROUPING(year, country, product)` is evaluated like this:

```
result for GROUPING(product)
+ result for GROUPING(country) << 1
+ result for GROUPING(year) << 2
```

The result of such a `GROUPING()` is nonzero if any of the expressions represents a super-aggregate `NULL`, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP
HAVING GROUPING(year, country, product) <> 0;
```

year	country	product	profit
2000	Finland	NULL	1600
2000	India	NULL	1350
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	NULL	10
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of quantity values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```

name	size	quantity
ball	small	10
ball	large	20
ball	NULL	5
hoop	small	15
hoop	large	5
hoop	NULL	3

A simple `ROLLUP` operation produces these results, in which it is not so easy to distinguish `NULL` values in super-aggregate rows from `NULL` values in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	NULL	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	NULL	23
NULL	NULL	58

Using `GROUPING()` to substitute labels for the super-aggregate `NULL` values makes the result easier to interpret:

```
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
  FROM t1
  GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	All sizes	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	All sizes	23
All items	All sizes	58

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

Prior to MySQL 8.0.12, when you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` were mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using `ROLLUP` with `ORDER BY` and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:

```
mysql> SELECT * FROM
    (SELECT year, SUM(profit) AS profit
     FROM sales GROUP BY year WITH ROLLUP) AS dt
  ORDER BY year DESC;
```

year	profit
2001	3010
2000	4525
NULL	7535

As of MySQL 8.0.12, `ORDER BY` and `ROLLUP` can be used together, which enables the use of `ORDER BY` and `GROUPING()` to achieve a specific sort order of grouped results. For example:

```
mysql> SELECT year, SUM(profit) AS profit
  FROM sales
  GROUP BY year WITH ROLLUP
  ORDER BY GROUPING(year) DESC;
```

year	profit
NULL	7535
2000	4525
2001	3010

In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
        FROM sales
        GROUP BY year, country, product WITH ROLLUP
        LIMIT 5;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using [LIMIT](#) with [ROLLUP](#) may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

The [NULL](#) indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the [GROUP BY](#) clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to [NULL](#). (If you specify grouping columns by column position, the server identifies which columns to set to [NULL](#) by position.)

Because the [NULL](#) values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as [NULL](#) values only in the select list or [HAVING](#) clause. You cannot test them as [NULL](#) values in join conditions or the [WHERE](#) clause to determine which rows to select. For example, you cannot add [WHERE product IS NULL](#) to the query to eliminate from the output all but the super-aggregate rows.

The [NULL](#) values do appear as [NULL](#) on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a [NULL](#) represents a regular grouped value or a super-aggregate value.

A MySQL extension permits a column that does not appear in the [GROUP BY](#) list to be named in the select list. (For information about nonaggregated columns and [GROUP BY](#), see [Section 12.19.3, “MySQL Handling of GROUP BY”](#).) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by [WITH ROLLUP](#). For example, in the following query, [country](#) is a nonaggregated column that does not appear in the [GROUP BY](#) list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
```

year	country	profit
2000	India	4525
2001	USA	3010
NULL	USA	7535

This behavior is permitted when the [ONLY_FULL_GROUP_BY](#) SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because [country](#) is not listed in the [GROUP BY](#) clause. With [ONLY_FULL_GROUP_BY](#) enabled, you can still execute the query by using the [ANY_VALUE\(\)](#) function for nondeterministic-value columns:

```
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
```

year	country	profit
2000	India	4525
2001	USA	3010
NULL	USA	7535

12.19.3 MySQL Handling of GROUP BY

SQL92 and earlier does not permit queries for which the select list, [HAVING](#) condition, or [ORDER BY](#) list refer to nonaggregated columns that are not named in the [GROUP BY](#) clause. For example, this query is illegal in standard SQL92 because the nonaggregated [name](#) column in the select list does not appear in the [GROUP BY](#):

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL92, the [name](#) column must be omitted from the select list or named in the [GROUP BY](#) clause.

SQL99 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on [GROUP BY](#) columns: If such a relationship exists between [name](#) and [custid](#), the query is legal. This would be the case, for example, were [custid](#) a primary key of [customers](#).

MySQL implements detection of functional dependence. If the [ONLY_FULL_GROUP_BY](#) SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, [HAVING](#) condition, or [ORDER BY](#) list refer to nonaggregated columns that are neither named in the [GROUP BY](#) clause nor are functionally dependent on them.

If [ONLY_FULL_GROUP_BY](#) is disabled, a MySQL extension to the standard SQL use of [GROUP BY](#) permits the select list, [HAVING](#) condition, or [ORDER BY](#) list to refer to nonaggregated columns even if the columns are not functionally dependent on [GROUP BY](#) columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an [ORDER BY](#) clause. Result set sorting occurs after values have been chosen, and [ORDER BY](#) does not affect which value within each group the server chooses. Disabling [ONLY_FULL_GROUP_BY](#) is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the [GROUP BY](#) are the same for each group.

You can achieve the same effect without disabling [ONLY_FULL_GROUP_BY](#) by using [ANY_VALUE\(\)](#) to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with [ONLY_FULL_GROUP_BY](#) enabled because the nonaggregated [address](#) column in the select list is not named in the [GROUP BY](#) clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if [name](#) is a primary key of [t](#) or is a unique [NOT NULL](#) column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if [name](#)

is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique `NOT NULL` column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

If you know that, *for a given data set*, each `name` value in fact uniquely determines the `address` value, `address` is effectively functionally dependent on `name`. To tell MySQL to accept the query, you can use the `ANY_VALUE()` function:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable `ONLY_FULL_GROUP_BY`.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see [Section 12.19.4, “Detection of Functional Dependence”](#).

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. Here, too, `ANY_VALUE()` can be used, if it is immaterial which `name` value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

`ONLY_FULL_GROUP_BY` also affects handling of queries that use `DISTINCT` and `ORDER BY`. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

```
c1 c2 c3
1  2  A
3  4  B
1  2  C
```

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of `c3`, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the [HAVING](#) clause to aliased expressions in the select list. For example, the following query returns [name](#) values that occur only once in table [orders](#):

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the [HAVING](#) clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Standard SQL permits only column expressions in [GROUP BY](#) clauses, so a statement such as this is invalid because [FLOOR\(value/100\)](#) is a noncolumn expression:

```
SELECT id, FLOOR(value/100)
FROM tbl\_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in [GROUP BY](#) clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in [GROUP BY](#) clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl\_name
GROUP BY id, val;
```

The alias [val](#) is considered a column expression in the [GROUP BY](#) clause.

In the presence of a noncolumn expression in the [GROUP BY](#) clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with [ONLY_FULL_GROUP_BY](#) SQL mode enabled, the query containing [GROUP BY id, FLOOR\(value/100\)](#) is valid because that same [FLOOR\(\)](#) expression occurs in the select list. However, MySQL does not try to recognize functional dependence on [GROUP BY](#) noncolumn expressions, so the following query is invalid with [ONLY_FULL_GROUP_BY](#) enabled, even though the third selected expression is a simple formula of the [id](#) column and the [FLOOR\(\)](#) expression in the [GROUP BY](#) clause:

```
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl\_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```
SELECT id, F, id+F
FROM
  (SELECT id, FLOOR(value/100) AS F
   FROM tbl\_name)
```

```
GROUP BY id, FLOOR(value/100)) AS dt;
```

12.19.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

```
{X} -> {Y}
```

Understand this as “*X* uniquely determines *Y*,” which also means that *Y* is functionally dependent on *X*.

The examples use the `world` database, which can be downloaded from the [MySQL Documentation page](#). You can find details on how to install the database on the same page.

- [Functional Dependencies Derived from Keys](#)
- [Functional Dependencies Derived from Multiple-Column Keys and from Equalities](#)
- [Functional Dependency Special Cases](#)
- [Functional Dependencies and Views](#)
- [Combinations of Functional Dependencies](#)

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

```
{co.Code} -> {co.*}
```

Thus, `co.name` is functionally dependent on `GROUP BY` columns and the query is valid.

A `UNIQUE` index over a `NOT NULL` column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a `UNIQUE` index that permits `NULL` values because it permits multiple `NULL` values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

The pair (`cl.CountryCode`, `cl.Language`) is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

```
{cl.CountryCode, cl.Language} -> {cl.*}
```

Moreover, because of the equality in the `WHERE` clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

“Uniquely determines” relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

As with the previous example, a `UNIQUE` key over `NOT NULL` columns could be used instead of a primary key.

An `INNER JOIN` condition can be used instead of `WHERE`. The same functional dependencies apply:

```
SELECT co.Name, cl.Language,  
cl.Percentage * co.Population/100.0 AS SpokenBy  
FROM countrylanguage cl INNER JOIN country co  
ON cl.CountryCode = co.Code  
GROUP BY cl.CountryCode, cl.Language;
```

Functional Dependency Special Cases

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```
SELECT co.Name, cl.Language,  
cl.Percentage * co.Population/100.0 AS SpokenBy  
FROM countrylanguage cl LEFT JOIN country co  
ON cl.CountryCode = co.Code  
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

```
{cl.CountryCode} -> {co.Code}
```

`cl.CountryCode` is itself functionally dependent on `{cl.CountryCode, cl.Language}` which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

```
{co.Code} -> {co.Name}
```

Which yields:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```
SELECT co.Name, cl.Language,  
cl.Percentage * co.Population/100.0 AS SpokenBy  
FROM country co LEFT JOIN countrylanguage cl  
ON cl.CountryCode = co.Code  
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does *not* apply:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

Indeed, all **NULL**-complemented rows made for **cl** will be put into a single group (they have both **GROUP BY** columns equal to **NULL**), and inside this group the value of **co.Name** can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the **LEFT JOIN**. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW Country2 AS  
SELECT co.Code, UPPER(co.Name) AS UpperName,  
COUNT(cl.Language) AS OfficialLanguages  
FROM country AS co JOIN countrylanguage AS cl  
ON cl.CountryCode = co.Code  
WHERE cl.isOfficial = 'T'  
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is **co.Code**, which is also the group column and thus determines all other selected expressions:

```
{Country2.Code} -> {Country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the **city** table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,  
COUNT(*) AS Cities  
FROM country2 AS co2 JOIN city ci  
ON ci.CountryCode = co2.Code  
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table (or common table expression), as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
  FROM country AS co JOIN countrylanguage AS cl
  ON cl.CountryCode=co.Code
  WHERE cl.isOfficial='T'
  GROUP BY co.Code
) AS co2
JOIN city ci ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.20 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows related to that row. The following sections discuss how to use window functions, including descriptions of the `OVER` and `WINDOW` clauses. The first section provides descriptions of the nonaggregate window functions. For descriptions of the aggregate window functions, see [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).

For information about optimization and window functions, see [Section 8.2.1.19, “Window Function Optimization”](#).

12.20.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).

For window function usage information and examples, and definitions of terms such as the `OVER` clause, window, partition, frame, and peer, see [Section 12.20.2, “Window Function Concepts and Syntax”](#).

Table 12.26 Window Functions

Name	Description
<code>CUME_DIST()</code>	Cumulative distribution value
<code>DENSE_RANK()</code>	Rank of current row within its partition, without gaps
<code>FIRST_VALUE()</code>	Value of argument from first row of window frame
<code>LAG()</code>	Value of argument from row lagging current row within partition
<code>LAST_VALUE()</code>	Value of argument from last row of window frame

Name	Description
LEAD()	Value of argument from row leading current row within partition
NTH_VALUE()	Value of argument from N-th row of window frame
NTILE()	Bucket number of current row within its partition.
PERCENT_RANK()	Percentage rank value
RANK()	Rank of current row within its partition, with gaps
ROW_NUMBER()	Number of current row within its partition

In the following function descriptions, *over_clause* represents the [OVER](#) clause, described in [Section 12.20.2, “Window Function Concepts and Syntax”](#). Some window functions permit a *null_treatment* clause that specifies how to handle [NULL](#) values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only [RESPECT NULLS](#) (which is also the default). This means that [NULL](#) values are considered when calculating results. [IGNORE NULLS](#) is parsed, but produces an error.

- [CUME_DIST\(\)](#) *over_clause*

Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

This function should be used with [ORDER BY](#) to sort partition rows into the desired order. Without [ORDER BY](#), all rows are peers and have value $N/N = 1$, where N is the partition size.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

The following query shows, for the set of values in the [val](#) column, the [CUME_DIST\(\)](#) value for each row, as well as the percentage rank value returned by the similar [PERCENT_RANK\(\)](#) function. For reference, the query also displays row numbers using [ROW_NUMBER\(\)](#):

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    CUME_DIST() OVER w AS 'cume_dist',
    PERCENT_RANK() OVER w AS 'percent_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

val	row_number	cume_dist	percent_rank
1	1	0.2222222222222222	0
1	2	0.2222222222222222	0
2	3	0.3333333333333333	0.25
3	4	0.6666666666666666	0.375
3	5	0.6666666666666666	0.375
3	6	0.6666666666666666	0.375
4	7	0.8888888888888888	0.75
4	8	0.8888888888888888	0.75
5	9	1	1

- [DENSE_RANK\(\)](#) *over_clause*

Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups

of size greater than one do not produce noncontiguous rank numbers. For an example, see the [RANK \(\)](#) function description.

This function should be used with [ORDER BY](#) to sort partition rows into the desired order. Without [ORDER BY](#), all rows are peers.

[over_clause](#) is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

- [FIRST_VALUE\(expr\) \[null_treatment\] over_clause](#)

Returns the value of [expr](#) from the first row of the window frame.

[over_clause](#) is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

[null_treatment](#) is as described in the section introduction.

The following query demonstrates [FIRST_VALUE \(\)](#), [LAST_VALUE \(\)](#), and two instances of [NTH_VALUE \(\)](#):

```
mysql> SELECT
    time, subject, val,
    FIRST_VALUE(val) OVER w AS 'first',
    LAST_VALUE(val) OVER w AS 'last',
    NTH_VALUE(val, 2) OVER w AS 'second',
    NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
              ROWS UNBOUNDED PRECEDING);
```

time	subject	val	first	last	second	fourth
07:00:00	st113	10	10	10	NULL	NULL
07:15:00	st113	9	10	9	9	NULL
07:30:00	st113	25	10	25	9	NULL
07:45:00	st113	20	10	20	9	20
07:00:00	xh458	0	0	0	NULL	NULL
07:15:00	xh458	10	0	10	10	NULL
07:30:00	xh458	5	0	5	10	NULL
07:45:00	xh458	30	0	30	10	30
08:00:00	xh458	25	0	25	10	30

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the [NTH_VALUE \(\)](#) calls, the current frame does not always include the requested row; in such cases, the return value is [NULL](#).

- [LAG\(expr \[, N\[, default\]\]\) \[null_treatment\] over_clause](#)

Returns the value of [expr](#) from the row that lags (precedes) the current row by [N](#) rows within its partition. If there is no such row, the return value is [default](#). For example, if [N](#) is 3, the return value is [default](#) for the first two rows. If [N](#) or [default](#) are missing, the defaults are 1 and [NULL](#), respectively.

[N](#) must be a literal nonnegative integer. If [N](#) is 0, [expr](#) is evaluated for the current row.

[over_clause](#) is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

[null_treatment](#) is as described in the section introduction.

[LAG \(\)](#) (and the similar [LEAD \(\)](#) function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the [LAG \(\)](#) and [LEAD \(\)](#) values from the adjoining rows, as well as the differences between the current and adjoining rows:

```
mysql> SELECT
    t, val,
    LAG(val)          OVER w AS 'lag',
    LEAD(val)         OVER w AS 'lead',
    val - LAG(val)    OVER w AS 'lag diff',
    val - LEAD(val)   OVER w AS 'lead diff'
  FROM series
  WINDOW w AS (ORDER BY t);
```

t	val	lag	lead	lag diff	lead diff
12:00:00	100	NULL	125	NULL	-25
13:00:00	125	100	132	25	-7
14:00:00	132	125	145	7	-13
15:00:00	145	132	140	13	5
16:00:00	140	145	150	-5	-10
17:00:00	150	140	200	10	-50
18:00:00	200	150	NULL	50	NULL

In the example, the `LAG()` and `LEAD()` calls use the default `N` and `default` values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()`: The function returns the `default` value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```
mysql> SELECT n FROM fib ORDER BY n;
```

n
1
1
2
3
5
8

The following query shows the `LAG()` and `LEAD()` values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

```
mysql> SELECT
    n,
    LAG(n, 1, 0)      OVER w AS 'lag',
    LEAD(n, 1, 0)     OVER w AS 'lead',
    n + LAG(n, 1, 0)  OVER w AS 'next_n',
    n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
  FROM fib
  WINDOW w AS (ORDER BY n);
```

n	lag	lead	next_n	next_next_n
1	0	1	1	2
1	1	2	2	3
2	1	3	3	5

3	2	5	5	8
5	3	8	8	13
8	5	0	13	8

One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see [Fibonacci Series Generation](#).

- `LAST_VALUE(expr) [null_treatment] over_clause`

Returns the value of *expr* from the last row of the window frame.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

null_treatment is as described in the section introduction.

For an example, see the `FIRST_VALUE()` function description.

- `LEAD(expr [, N [, default]]) [null_treatment] over_clause`

Returns the value of *expr* from the row that leads (follows) the current row by *N* rows within its partition. If there is no such row, the return value is *default*. For example, if *N* is 3, the return value is *default* for the last two rows. If *N* or *default* are missing, the defaults are 1 and `NULL`, respectively.

N must be a literal nonnegative integer. If *N* is 0, *expr* is evaluated for the current row.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

null_treatment is as described in the section introduction.

For an example, see the `LAG()` function description.

- `NTH_VALUE(expr, N) [from_first_last] [null_treatment] over_clause`

Returns the value of *expr* from the *N*-th row of the window frame. If there is no such row, the return value is `NULL`.

N must be a literal positive integer.

from_first_last is part of the SQL standard, but the MySQL implementation permits only `FROM FIRST` (which is also the default). This means that calculations begin at the first row of the window. `FROM LAST` is parsed, but produces an error. To obtain the same effect as `FROM LAST` (begin calculations at the last row of the window), use `ORDER BY` to sort in reverse order.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

null_treatment is as described in the section introduction.

For an example, see the `FIRST_VALUE()` function description.

- `NTILE(N) over_clause`

Divides a partition into *N* groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if *N* is 4, `NTILE()` divides rows into four buckets. If *N* is 100, `NTILE()` divides rows into 100 buckets.

N must be a literal positive integer. Bucket number return values range from 1 to *N*.

This function should be used with `ORDER BY` to sort partition rows into the desired order.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

The following query shows, for the set of values in the `val` column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using `ROW_NUMBER()`:

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    NTILE(2)     OVER w AS 'ntile2',
    NTILE(4)     OVER w AS 'ntile4'
  FROM numbers
  WINDOW w AS (ORDER BY val);
```

val	row_number	ntile2	ntile4
1	1	1	1
1	2	1	1
2	3	1	1
3	4	1	2
3	5	1	2
3	6	2	3
4	7	2	3
4	8	2	4
5	9	2	4

- `PERCENT_RANK()` *over_clause*

Returns the the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where *rank* is the row rank and *rows* is the number of partition rows:

$$(\text{rank} - 1) / (\text{rows} - 1)$$

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

For an example, see the `CUME_DIST()` function description.

- `RANK()` *over_clause*

Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

over_clause is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

The following query shows the difference between `RANK()`, which produces ranks with gaps, and `DENSE_RANK()`, which produces ranks without gaps. The query shows rank values for each member of a set of values in the `val` column, which contains some duplicates. `RANK()` assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. `DENSE_RANK()` also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using `ROW_NUMBER()`:

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    RANK() OVER w AS 'rank',
    DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

val	row_number	rank	dense_rank
1	1	1	1
1	2	1	1
2	3	3	2
3	4	4	3
3	5	4	3
3	6	4	3
4	7	7	4
4	8	7	4
5	9	9	5

- `ROW_NUMBER() over_clause`

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

`ORDER BY` affects the order in which rows are numbered. Without `ORDER BY`, row numbering is nondeterministic.

`ROW_NUMBER()` assigns peers different row numbers. To assign peers the same value, use `RANK()` or `DENSE_RANK()`. For an example, see the `RANK()` function description.

`over_clause` is as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#).

12.20.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the `GROUPING()` function in [Section 12.19.2, “GROUP BY Modifiers”](#):

```
mysql> SELECT * FROM sales ORDER BY country, year, product;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2001	Finland	Phone	10
2000	India	Calculator	75
2000	India	Calculator	75
2000	India	Computer	1200
2000	USA	Calculator	75
2000	USA	Computer	1500
2001	USA	Calculator	50
2001	USA	Computer	1500
2001	USA	Computer	1200
2001	USA	TV	150
2001	USA	TV	100

A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

- The row for which function evaluation occurs is called the current row.
- The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```
mysql> SELECT SUM(profit) AS total_profit
        FROM sales;
+-----+
| total_profit |
+-----+
|          7535 |
+-----+

mysql> SELECT country, SUM(profit) AS country_profit
        FROM sales
        GROUP BY country
        ORDER BY country;
+-----+-----+
| country | country_profit |
+-----+-----+
| Finland |          1610 |
| India   |          1350 |
| USA     |          4575 |
+-----+-----+
```

By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```
mysql> SELECT
        year, country, product, profit,
        SUM(profit) OVER() AS total_profit,
        SUM(profit) OVER(PARTITION BY country) AS country_profit
        FROM sales
        ORDER BY country, year, product, profit;
+-----+-----+-----+-----+-----+-----+
| year | country | product | profit | total_profit | country_profit |
+-----+-----+-----+-----+-----+-----+

+-----+-----+-----+-----+-----+-----+
```

Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.
- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

```
AVG()
BIT_AND()
BIT_OR()
BIT_XOR()
COUNT()
MAX()
MIN()
STDDEV_POP(), STDDEV(), STD()
STDDEV_SAMP()
SUM()
VAR_POP(), VARIANCE()
VAR_SAMP()
```

For details about each aggregate function, see [Section 12.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).

MySQL also supports nonaggregate functions that are used only as window functions. For these, the `OVER` clause is mandatory:

```
CUME_DIST()
DENSE_RANK()
FIRST_VALUE()
LAG()
LAST_VALUE()
LEAD()
NTH_VALUE()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
```

For details about each nonaggregate function, see [Section 12.20.1, “Window Function Descriptions”](#).

As an example of one of those nonaggregate window functions, this query uses `ROW_NUMBER()`, which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an `ORDER BY` clause within the window definition. The query uses unordered and ordered partitions (the `row_num1` and `row_num2` columns) to illustrate the difference between omitting and including `ORDER BY`:

```
mysql> SELECT
    year, country, product, profit,
    ROW_NUMBER() OVER(PARTITION BY country) AS row_num1,
    ROW_NUMBER() OVER(PARTITION BY country ORDER BY year, product) AS row_num2
FROM sales;
```

year	country	product	profit	row_num1	row_num2
2000	Finland	Computer	1500	2	1

2000	Finland	Phone	100	1	2
2001	Finland	Phone	10	3	3
2000	India	Calculator	75	2	1
2000	India	Calculator	75	3	2
2000	India	Computer	1200	1	3
2000	USA	Calculator	75	5	1
2000	USA	Computer	1500	4	2
2001	USA	Calculator	50	2	3
2001	USA	Computer	1500	3	4
2001	USA	Computer	1200	7	5
2001	USA	TV	150	1	6
2001	USA	TV	100	6	7

As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an `OVER` clause following the function call. The `OVER` clause has two forms:

```
over_clause:
{OVER (window_spec) | OVER window_name}
```

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the `OVER` clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the `OVER` clause, between the parentheses.
- In the second case, *window_name* is the name for a window specification defined by a `WINDOW` clause elsewhere in the query. For details, see [Section 12.20.4, “Named Windows”](#).

For `OVER (window_spec)` syntax, the window specification has several parts, all optional:

```
window_spec:
[window_name] [partition_clause] [order_clause] [frame_clause]
```

If `OVER()` is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered:

- *window_name*: The name of a window defined by a `WINDOW` clause elsewhere in the query. If *window_name* appears by itself within the `OVER` clause, it completely defines the window. If partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see [Section 12.20.4, “Named Windows”](#).
- *partition_clause*: A `PARTITION BY` clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If `PARTITION BY` is omitted, there is a single partition consisting of all query rows.

Note

Partitioning for window functions differs from table partitioning. For information about table partitioning, see [Chapter 22, Partitioning](#).

partition_clause has this syntax:

```
partition_clause:
PARTITION BY expr [, expr] ...
```

Standard SQL requires `PARTITION BY` to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a `TIMESTAMP` column

named `ts`, standard SQL permits `PARTITION BY ts` but not `PARTITION BY HOUR(ts)`, whereas MySQL permits both.

- *order_clause*: An `ORDER BY` clause indicates how to sort rows in each partition. Partition rows that are equal according to the `ORDER BY` clause are considered peers. If `ORDER BY` is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.

order_clause has this syntax:

```
order_clause:
ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...
```

Each `ORDER BY` expression optionally can be followed by `ASC` or `DESC` to indicate sort direction. The default is `ASC` if no direction is specified. `NULL` values sort first for ascending sorts, last for descending sorts.

An `ORDER BY` in a window definition applies within individual partitions. To sort the result set as a whole, include an `ORDER BY` at the query top level.

- *frame_clause*: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see [Section 12.20.3, “Window Function Frame Specification”](#).

12.20.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:

- By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.
- By defining a frame as extending `N` rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered `level` values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```
mysql> SELECT
    time, subject, val,
    SUM(val) OVER (PARTITION BY subject ORDER BY time
                  ROWS UNBOUNDED PRECEDING)
      AS running_total,
    AVG(val) OVER (PARTITION BY subject ORDER BY time
                  ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
      AS running_average
FROM observations;
```

time	subject	val	running_total	running_average
07:00:00	st113	10	10	9.5000
07:15:00	st113	9	19	14.6667
07:30:00	st113	25	44	18.0000
07:45:00	st113	20	64	22.5000
07:00:00	xh458	0	0	5.0000
07:15:00	xh458	10	10	5.0000

07:30:00	xh458	5	15	15.0000
07:45:00	xh458	30	45	20.0000
08:00:00	xh458	25	70	27.5000

For the `running_average` column, there is no frame row preceding the first one or following the last. In these cases, `AVG()` computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

```
FIRST_VALUE()
LAST_VALUE()
NTH_VALUE()
```

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

```
CUME_DIST()
DENSE_RANK()
LAG()
LEAD()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
```

The frame clause, if given, has this syntax:

```
frame_clause:
    frame_units frame_extent

frame_units:
    {ROWS | RANGE}
```

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present, as described later in this section.

The `frame_units` value indicates the type of relationship between the current row and frame rows:

- **ROWS:** The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE:** The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The `frame_extent` value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use `BETWEEN` to specify both frame endpoints:

```
frame_extent:
    {frame_start | frame_between}

frame_between:
    BETWEEN frame_start AND frame_end

frame_start, frame_end: {
    CURRENT ROW
```

```

| UNBOUNDED PRECEDING
| UNBOUNDED FOLLOWING
| expr PRECEDING
| expr FOLLOWING
}

```

With **BETWEEN** syntax, *frame_start* must not occur later than *frame_end*.

The permitted *frame_start* and *frame_end* values have these meanings:

- **CURRENT ROW**: For **ROWS**, the bound is the current row. For **RANGE**, the bound is the peers of the current row.
- **UNBOUNDED PRECEDING**: The bound is the first partition row.
- **UNBOUNDED FOLLOWING**: The bound is the last partition row.
- *expr* **PRECEDING**: For **ROWS**, the bound is *expr* rows before the current row. For **RANGE**, the bound is the rows with values equal to the current row value minus *expr*; if the current row value is **NULL**, the bound is the peers of the row.

For *expr* **PRECEDING** (and *expr* **FOLLOWING**), *expr* can be a **?** parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form **INTERVAL** *val* *unit*. For **INTERVAL** expressions, *val* specifies nonnegative interval value, and *unit* is a keyword indicating the units in which the value should be interpreted. (For details about the permitted *units* specifiers, see the description of the **DATE_ADD()** function in [Section 12.7, “Date and Time Functions”](#).)

RANGE on a numeric or temporal *expr* requires **ORDER BY** on a numeric or temporal expression, respectively.

Examples of valid *expr* **PRECEDING** and *expr* **FOLLOWING** indicators:

```

10 PRECEDING
INTERVAL 5 DAY PRECEDING
5 FOLLOWING
INTERVAL '2:30' MINUTE_SECOND FOLLOWING

```

- *expr* **FOLLOWING**: For **ROWS**, the bound is *expr* rows after the current row. For **RANGE**, the bound is the rows with values equal to the current row value plus *expr*; if the current row value is **NULL**, the bound is the peers of the row.

For permitted values of *expr*, see the description of *expr* **PRECEDING**.

The following query demonstrates **FIRST_VALUE()**, **LAST_VALUE()**, and two instances of **NTH_VALUE()**:

```

mysql> SELECT
    time, subject, val,
    FIRST_VALUE(val) OVER w AS 'first',
    LAST_VALUE(val) OVER w AS 'last',
    NTH_VALUE(val, 2) OVER w AS 'second',
    NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
              ROWS UNBOUNDED PRECEDING);

```

time	subject	val	first	last	second	fourth
07:00:00	st113	10	10	10	NULL	NULL
07:15:00	st113	9	10	9	9	NULL

Window Function Frame Specification

07:30:00	st113	25	10	25	9	NULL
07:45:00	st113	20	10	20	9	20
07:00:00	xh458	0	0	0	NULL	NULL
07:15:00	xh458	10	0	10	10	NULL
07:30:00	xh458	5	0	5	10	NULL
07:45:00	xh458	30	0	30	10	30
08:00:00	xh458	25	0	25	10	30

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the `NTH_VALUE()` calls, the current frame does not always include the requested row; in such cases, the return value is `NULL`.

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present:

- With `ORDER BY`: The default frame includes rows from the partition start through the current row, including all peers of the current row (rows equal to the current row according to the `ORDER BY` clause). The default is equivalent to this frame specification:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```

- Without `ORDER BY`: The default frame includes all partition rows (because, without `ORDER BY`, all partition rows are peers). The default is equivalent to this frame specification:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
```

Because the default frame differs depending on presence or absence of `ORDER BY`, adding `ORDER BY` to a query to get deterministic results may change the results. (For example, the values produced by `SUM()` might change.) To obtain the same results but ordered per `ORDER BY`, provide an explicit frame specification to be used regardless of whether `ORDER BY` is present.

The meaning of a frame specification can be nonobvious when the current row value is `NULL`. Assuming that to be the case, these examples illustrate how various frame specifications apply:

- `ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- `ORDER BY X DESC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because a `DESC` sort puts `NULL` values last, the frame is only the `NULL` values.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 10 FOLLOWING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 1 PRECEDING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN UNBOUNDED PRECEDING AND 10 FOLLOWING`

The frame starts at the beginning of the partition and stops at rows with value `NULL`. Because an `ASC` sort puts `NULL` values first, the frame is only the `NULL` values.

12.20.4 Named Windows

Windows can be defined and given names by which to refer to them in `OVER` clauses. To do this, use a `WINDOW` clause. If present in a query, the `WINDOW` clause falls between the positions of the `HAVING` and `ORDER BY` clauses, and has this syntax:

```
WINDOW window_name AS (window_spec)  
    [, window_name AS (window_spec)] ...
```

For each window definition, *window_name* is the window name, and *window_spec* is the same type of window specification as given between the parentheses of an `OVER` clause, as described in [Section 12.20.2, “Window Function Concepts and Syntax”](#):

```
window_spec:  
    [window_name] [partition_clause] [order_clause] [frame_clause]
```

A `WINDOW` clause is useful for queries in which multiple `OVER` clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the `OVER` clauses. Consider this query, which defines the same window multiple times:

```
SELECT  
    val,  
    ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',  
    RANK()         OVER (ORDER BY val) AS 'rank',  
    DENSE_RANK()  OVER (ORDER BY val) AS 'dense_rank'  
FROM numbers;
```

The query can be written more simply by using `WINDOW` to define the window once and referring to the window by name in the `OVER` clauses:

```
SELECT  
    val,  
    ROW_NUMBER() OVER w AS 'row_number',  
    RANK()         OVER w AS 'rank',  
    DENSE_RANK()  OVER w AS 'dense_rank'  
FROM numbers  
WINDOW w AS (ORDER BY val);
```

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the `WINDOW` clause, rather than multiple `OVER` clause definitions.

If an `OVER` clause uses `OVER (window_name ...)` rather than `OVER window_name`, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses `ORDER BY` in the `OVER` clauses to modify the window in different ways:

```
SELECT  
    DISTINCT year, country,  
    FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
```

```
FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);
```

An **OVER** clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the **OVER** clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring **OVER** clause do not contain the same kind of properties:

```
OVER (w ORDER BY country)
... WINDOW w AS (PARTITION BY country)
```

- This construct is not permitted because the **OVER** clause specifies **PARTITION BY** for a named window that already has **PARTITION BY**:

```
OVER (w PARTITION BY year)
... WINDOW w AS (PARTITION BY country)
```

The definition of a named window can itself begin with a *window_name*. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:

```
WINDOW w1 AS (w2), w2 AS (), w3 AS (w1)
```

- This is not permitted because it contains a cycle:

```
WINDOW w1 AS (w2), w2 AS (w3), w3 AS (w1)
```

12.20.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in **UPDATE** or **DELETE** statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- **DISTINCT** syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.

The parser recognizes these window constructs which nevertheless are not supported:

- The **GROUPS** frame units specifier is parsed, but produces an error. Only **ROWS** and **RANGE** are supported.
- The **EXCLUDE** clause for frame specification is parsed, but produces an error.
- **IGNORE NULLS** is parsed, but produces an error. Only **RESPECT NULLS** is supported.
- **FROM LAST** is parsed, but produces an error. Only **FROM FIRST** is supported.

12.21 Internal Functions

Table 12.27 Internal Functions

Name	Description
<code>CAN_ACCESS_COLUMN()</code>	Internal use only
<code>CAN_ACCESS_DATABASE()</code>	Internal use only
<code>CAN_ACCESS_TABLE()</code>	Internal use only
<code>CAN_ACCESS_VIEW()</code>	Internal use only
<code>GET_DD_COLUMN_PRIVILEGES()</code>	Internal use only
<code>GET_DD_CREATE_OPTIONS()</code>	Internal use only
<code>GET_DD_INDEX_SUB_PART_LENGTH()</code>	Internal use only
<code>INTERNAL_AUTO_INCREMENT()</code>	Internal use only
<code>INTERNAL_AVG_ROW_LENGTH()</code>	Internal use only
<code>INTERNAL_CHECK_TIME()</code>	Internal use only
<code>INTERNAL_CHECKSUM()</code>	Internal use only
<code>INTERNAL_DATA_FREE()</code>	Internal use only
<code>INTERNAL_DATA_LENGTH()</code>	Internal use only
<code>INTERNAL_DD_CHAR_LENGTH()</code>	Internal use only
<code>INTERNAL_GET_COMMENT_OR_ERROR()</code>	Internal use only
<code>INTERNAL_GET_VIEW_WARNING_OR_ERROR()</code>	Internal use only
<code>INTERNAL_INDEX_COLUMN_CARDINALITY()</code>	Internal use only
<code>INTERNAL_INDEX_LENGTH()</code>	Internal use only
<code>INTERNAL_KEYS_DISABLED()</code>	Internal use only
<code>INTERNAL_MAX_DATA_LENGTH()</code>	Internal use only
<code>INTERNAL_TABLE_ROWS()</code>	Internal use only
<code>INTERNAL_UPDATE_TIME()</code>	Internal use only

The functions listed in this section are intended only for internal use by the server. Attempts by users to invoke them result in an error.

- `CAN_ACCESS_COLUMN(ARGS)`
- `CAN_ACCESS_DATABASE(ARGS)`
- `CAN_ACCESS_TABLE(ARGS)`
- `CAN_ACCESS_VIEW(ARGS)`
- `GET_DD_COLUMN_PRIVILEGES(ARGS)`
- `GET_DD_CREATE_OPTIONS(ARGS)`
- `GET_DD_INDEX_SUB_PART_LENGTH(ARGS)`
- `INTERNAL_AUTO_INCREMENT(ARGS)`
- `INTERNAL_AVG_ROW_LENGTH(ARGS)`
- `INTERNAL_CHECK_TIME(ARGS)`
- `INTERNAL_CHECKSUM(ARGS)`

- `INTERNAL_DATA_FREE (ARGS)`
- `INTERNAL_DATA_LENGTH (ARGS)`
- `INTERNAL_DD_CHAR_LENGTH (ARGS)`
- `INTERNAL_GET_COMMENT_OR_ERROR (ARGS)`
- `INTERNAL_GET_VIEW_WARNING_OR_ERROR (ARGS)`
- `INTERNAL_INDEX_COLUMN_CARDINALITY (ARGS)`
- `INTERNAL_INDEX_LENGTH (ARGS)`
- `INTERNAL_KEYS_DISABLED (ARGS)`
- `INTERNAL_MAX_DATA_LENGTH (ARGS)`
- `INTERNAL_TABLE_ROWS (ARGS)`
- `INTERNAL_UPDATE_TIME (ARGS)`
- `IS_VISIBLE_DD_OBJECT (ARGS)`

12.22 Miscellaneous Functions

Table 12.28 Miscellaneous Functions

Name	Description
<code>ANY_VALUE ()</code>	Suppress ONLY_FULL_GROUP_BY value rejection
<code>BIN_TO_UUID ()</code>	Convert binary UUID to string
<code>DEFAULT ()</code>	Return the default value for a table column
<code>GET_LOCK ()</code>	Get a named lock
<code>GROUPING ()</code>	Distinguish super-aggregate ROLLUP rows from regular rows
<code>INET_ATON ()</code>	Return the numeric value of an IP address
<code>INET_NTOA ()</code>	Return the IP address from a numeric value
<code>INET6_ATON ()</code>	Return the numeric value of an IPv6 address
<code>INET6_NTOA ()</code>	Return the IPv6 address from a numeric value
<code>IS_FREE_LOCK ()</code>	Whether the named lock is free
<code>IS_IPV4 ()</code>	Whether argument is an IPv4 address
<code>IS_IPV4_COMPAT ()</code>	Whether argument is an IPv4-compatible address
<code>IS_IPV4_MAPPED ()</code>	Whether argument is an IPv4-mapped address
<code>IS_IPV6 ()</code>	Whether argument is an IPv6 address
<code>IS_USED_LOCK ()</code>	Whether the named lock is in use; return connection identifier if true
<code>IS_UUID ()</code>	Whether argument is a valid UUID
<code>MASTER_POS_WAIT ()</code>	Block until the slave has read and applied all updates up to the specified position
<code>NAME_CONST ()</code>	Causes the column to have the given name
<code>RAND ()</code>	Return a random floating-point value

Name	Description
<code>RELEASE_ALL_LOCKS()</code>	Releases all current named locks
<code>RELEASE_LOCK()</code>	Releases the named lock
<code>SLEEP()</code>	Sleep for a number of seconds
<code>UUID()</code>	Return a Universal Unique Identifier (UUID)
<code>UUID_SHORT()</code>	Return an integer-valued universal identifier
<code>UUID_TO_BIN()</code>	Convert string UUID to binary
<code>VALUES()</code>	Defines the values to be used during an INSERT

- `ANY_VALUE(arg)`

This function is useful for `GROUP BY` queries when the `ONLY_FULL_GROUP_BY` SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)
- Use `ANY_VALUE()` to refer to `address`:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see [Section 12.19.3, “MySQL Handling of GROUP BY”](#).

- `BIN_TO_UUID(binary_uuid)`, `BIN_TO_UUID(binary_uuid, swap_flag)`

`BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value. The return value is a `utf8` string of five hexadecimal numbers separated by dashes. (For details about this format, see the `UUID()` function description.) If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`BIN_TO_UUID()` takes one or two arguments:

- The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.
- The two-argument form takes a binary UUID value and a swap-flag value:
 - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.
 - If `swap_flag` is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

For usage examples and information about time-part swapping, see the `UUID_TO_BIN()` function description.

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

The use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X,D)`

Formats the number *X* to a format like '*#,###,###.##*', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.5, “String Functions”](#).

- `GET_LOCK(str,timeout)`

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. A negative *timeout* value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Lock release may also occur with another call to `GET_LOCK()`:

- `GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the `OBJECT_NAME` column indicates the lock name. Also, the capability of acquiring multiple locks introduces the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

For example, suppose that you execute these statements:

```
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return `1` (success).

MySQL enforces a maximum length on lock names of 64 characters.

Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Caution

With the capability of acquiring multiple named locks in MySQL 5.7.5, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see [Section 28.3.1, “The Locking Service”](#).

- `GROUPING(expr [, expr] ...)`

For `GROUP BY` queries that include a `WITH ROLLUP` modifier, the `ROLLUP` operation produces super-aggregate output rows where `NULL` represents the set of all values. The `GROUPING()` function enables you to distinguish `NULL` values for super-aggregate rows from `NULL` values in regular grouped rows.

`GROUPING()` is permitted only in the select list or `HAVING` clause.

Each argument to `GROUPING()` must be an expression that exactly matches an expression in the `GROUP BY` clause. The expression cannot be a positional specifier. For each expression, `GROUPING()` produces 1 if the expression value in the current row is a `NULL` representing a super-aggregate value. Otherwise, `GROUPING()` produces 0, indicating that the expression value is a `NULL` for a regular result row or is not `NULL`.

Suppose that table `t1` contains these rows, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+
| name | size  | quantity |
+-----+-----+-----+
| ball | small | 10       |
| ball | large | 20       |
| ball | NULL  | 5        |
| hoop | small | 15       |
| hoop | large | 5        |
| hoop | NULL  | 3        |
+-----+-----+-----+
```

A summary of the table without `WITH ROLLUP` looks like this:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
        FROM t1
        GROUP BY name, size;
+-----+-----+-----+
| name | size | quantity |
+-----+-----+-----+
| ball | small | 10 |
| ball | large | 20 |
| ball | NULL | 5 |
| hoop | small | 15 |
| hoop | large | 5 |
| hoop | NULL | 3 |
+-----+-----+-----+
```

The result contains `NULL` values, but those do not represent super-aggregate rows because the query does not include `WITH ROLLUP`.

Adding `WITH ROLLUP` produces super-aggregate summary rows containing additional `NULL` values. However, without comparing this result to the previous one, it is not easy to see which `NULL` values occur in super-aggregate rows and which occur in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
        FROM t1
        GROUP BY name, size WITH ROLLUP;
+-----+-----+-----+
| name | size | quantity |
+-----+-----+-----+
| ball | NULL | 5 |
| ball | large | 20 |
| ball | small | 10 |
| ball | NULL | 35 |
| hoop | NULL | 3 |
| hoop | large | 5 |
| hoop | small | 15 |
| hoop | NULL | 23 |
| NULL | NULL | 58 |
+-----+-----+-----+
```

To distinguish `NULL` values in super-aggregate rows from those in regular grouped rows, use `GROUPING()`, which returns 1 only for super-aggregate `NULL` values:

```
mysql> SELECT
        name, size, SUM(quantity) AS quantity,
        GROUPING(name) AS grp_name,
        GROUPING(size) AS grp_size
        FROM t1
        GROUP BY name, size WITH ROLLUP;
+-----+-----+-----+-----+-----+
| name | size | quantity | grp_name | grp_size |
+-----+-----+-----+-----+-----+
| ball | NULL | 5 | 0 | 0 |
| ball | large | 20 | 0 | 0 |
| ball | small | 10 | 0 | 0 |
| ball | NULL | 35 | 0 | 1 |
| hoop | NULL | 3 | 0 | 0 |
| hoop | large | 5 | 0 | 0 |
| hoop | small | 15 | 0 | 0 |
| hoop | NULL | 23 | 0 | 1 |
| NULL | NULL | 58 | 1 | 1 |
+-----+-----+-----+-----+-----+
```

Common uses for `GROUPING()`:

- Substitute a label for super-aggregate `NULL` values:

```
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
  FROM t1
  GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	All sizes	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	All sizes	23
All items	All sizes	58

- Return only super-aggregate lines by filtering out the regular grouped lines:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
  FROM t1
  GROUP BY name, size WITH ROLLUP
  HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

name	size	quantity
ball	NULL	35
hoop	NULL	23
NULL	NULL	58

`GROUPING()` permits multiple expression arguments. In this case, the `GROUPING()` return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, `GROUPING(expr1, expr2, expr3)` is evaluated like this:

```
result for GROUPING(expr3)
+ result for GROUPING(expr2) << 1
+ result for GROUPING(expr1) << 2
```

The following query shows how `GROUPING()` results for single arguments combine for a multiple-argument call to produce a bitmask value:

```
mysql> SELECT
    name, size, SUM(quantity) AS quantity,
    GROUPING(name) AS grp_name,
    GROUPING(size) AS grp_size,
    GROUPING(name, size) AS grp_all
  FROM t1
  GROUP BY name, size WITH ROLLUP;
```

name	size	quantity	grp_name	grp_size	grp_all
ball	NULL	5	0	0	0
ball	large	20	0	0	0
ball	small	10	0	0	0
ball	All sizes	35	1	0	1
hoop	NULL	3	0	0	0
hoop	large	5	0	0	0
hoop	small	15	0	0	0
hoop	All sizes	23	1	1	3
All items	All sizes	58	1	1	3

ball	NULL	5	0	0	0
ball	large	20	0	0	0
ball	small	10	0	0	0
ball	NULL	35	0	1	1
hoop	NULL	3	0	0	0
hoop	large	5	0	0	0
hoop	small	15	0	0	0
hoop	NULL	23	0	1	1
NULL	NULL	58	1	1	3

With multiple expression arguments, the `GROUPING()` return value is nonzero if any expression represents a super-aggregate value. Multiple-argument `GROUPING()` syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument `GROUPING()` call rather than multiple single-argument calls:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
       FROM t1
       GROUP BY name, size WITH ROLLUP
       HAVING GROUPING(name, size) <> 0;
```

name	size	quantity
ball	NULL	35
hoop	NULL	23
NULL	NULL	58

Use of `GROUPING()` is subject to these limitations:

- Do not use subquery `GROUP BY` expressions as `GROUPING()` arguments because matching might fail. For example, matching fails for this query:

```
mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
       FROM t1
       GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;
ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY
```

- `GROUP BY` literal expressions should not be used within a `HAVING` clause as `GROUPING()` arguments. Due to differences between when the optimizer evaluates `GROUP BY` and `HAVING`, matching may succeed but `GROUPING()` evaluation does not produce the expected result. Consider this query:

```
SELECT a AS f1, 'w' AS f2
FROM t
GROUP BY f1, f2 WITH ROLLUP
HAVING GROUPING(f2) = 1;
```

`GROUPING()` is evaluated earlier for the literal constant expression than for the `HAVING` clause as a whole and returns 0. To check whether a query such as this is affected, use `EXPLAIN` and look for `Impossible having` in the `Extra` column.

For more information about `WITH ROLLUP` and `GROUPING()`, see [Section 12.19.2, “GROUP BY Modifiers”](#).

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` should not be used for such addresses.

Note

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

- `INET_NTOA(expr)`

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. `INET_NTOA()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `INET6_ATON(expr)`

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns `NULL`.

The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`, not `198.51.8.1`. These

IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address *expr* represented in numeric form as an `INT` value to an IPv6 address represented in numeric form as a `VARBINARY` value, use this expression:

```
INET6_ATON( INET_NTOA(expr) )
```

For example:

```
mysql> SELECT HEX( INET6_ATON( INET_NTOA(167773449) ) );
-> '0A000509'
```

- `INET6_NTOA(expr)`

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns `NULL`.

`INET6_NTOA()` has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA( INET6_ATON('fdfe::5a55:caff:fefa:9089') );
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA( INET6_ATON('10.0.5.9') );
-> '10.0.5.9'

mysql> SELECT INET6_NTOA( UNHEX('FDFE000000000005A55CAFFFEFA9089') );
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA( UNHEX('0A000509') );
-> '10.0.5.9'
```

- `IS_FREE_LOCK(str)`

Checks whether the lock named *str* is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_IPV4(expr)`

Returns `1` if the argument is a valid IPv4 address specified as a string, `0` otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) will return non-NULL. The converse statement is not true: In some cases, `INET_ATON()` returns non-NULL when `IS_IPV4()` returns 0.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a NULL result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.

- `IS_IPV4_COMPAT(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `198.51.100.1` has this raw hexadecimal value:

```
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'
```

Expressed in IPv4-compatible form, `::198.51.100.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`

```
mysql> SELECT
-> IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV4_MAPPED(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
```

```
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV6(expr)`

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-`NULL`.

- `IS_USED_LOCK(str)`

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_UUID(string_uuid)`

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and `NULL` if the argument is `NULL`.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee
```

These other formats are also permitted:

```
aaaaaaaaabbbbccccdddeeeeeeeeeeee
{aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee}
```

For the meanings of fields within the value, see the `UUID()` function description.

```
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB');
+-----+
| IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('6ccd780cbaba102695645b8c656024db');
+-----+
| IS_UUID('6ccd780cbaba102695645b8c656024db') |
+-----+
| 1 |
+-----+
```

```
mysql> SELECT IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}');
+-----+
| IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c6560');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c6560') |
+-----+
| 0 |
+-----+
mysql> SELECT IS_UUID(RAND());
+-----+
| IS_UUID(RAND()) |
+-----+
| 0 |
+-----+
```

- `MASTER_POS_WAIT(log_name, log_pos[, timeout][, channel])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns `NULL` if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the slave is past the specified position, the function returns immediately.

On a multithreaded slave, the function waits until expiry of the limit set by the `slave_checkpoint_group` or `slave_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the slave. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no timeout.

The optional `channel` value enables you to name which replication channel the function applies to. See [Section 17.2.3, "Replication Channels"](#) for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
| 14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 23.7, "Binary Logging of Stored Programs"](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14 |
+-----+
1 row in set (0.00 sec)
```

See [Section 13.2.10, “SELECT Syntax”](#), for more information about column aliases.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 13.2.3, “DO Syntax”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|           0 |
+-----+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
```

```
|          1 |
+-----+
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|          1 |
+-----+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
ERROR 3024 (HY000): Query execution was interrupted, maximum statement
execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (<http://www.ietf.org/rfc/rfc4122.txt>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

Warning

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In

this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

To convert between string and binary UUID values, use the `UUID_TO_BIN()` and `BIN_TO_UUID()` functions. To check whether a string is a valid UUID value, use the `IS_UUID()` function.

Note

`UUID()` does not work with statement-based replication.

• `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of master and slave servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

Note

`UUID_SHORT()` does not work with statement-based replication.

• `UUID_TO_BIN(string_uuid), UUID_TO_BIN(string_uuid, swap_flag)`

Converts a string UUID to a binary UUID and returns the result. (The `IS_UUID()` function description lists the permitted string UUID formats.) The return binary UUID is a `VARBINARY(16)` value. If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`UUID_TO_BIN()` takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.

- The two-argument form takes a string UUID value and a flag value:
 - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
 - If `swap_flag` is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the `UUID()` function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the `UUID()` function description.

Suppose that you have the following string UUID value:

```
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use `UUID_TO_BIN()`:

```
mysql> SELECT HEX(UUID_TO_BIN(@uuid));
+-----+
| HEX(UUID_TO_BIN(@uuid)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 0));
+-----+
| HEX(UUID_TO_BIN(@uuid, 0)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 1));
+-----+
| HEX(UUID_TO_BIN(@uuid, 1)) |
+-----+
| 1026BABA6CCD780C95645B8C656024DB |
+-----+
```

To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid)) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1);
```

```
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID will not be recovered properly:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1) |
+-----+
| baba1026-780c-6ccd-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0) |
+-----+
| 1026baba-6ccd-780c-9564-5b8c656024db |
+-----+
```

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

12.23 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.10, “Server SQL Modes”](#).

12.23.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

12.23.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65.
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before.

Values for `DECIMAL` columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits up to $M - D$ digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* M digits. For `DECIMAL(M,D)`, the standard requires a precision of at least M digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly M digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

12.23.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.10, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
SET sql_mode= 'TRADITIONAL' ;
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in [Section 12.23.4, “Rounding Behavior”](#). Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

sql_mode Value	Result
' ' (Default)	No warning, no error; <i>i</i> is set to <code>NULL</code> .
strict	No warning, no error; <i>i</i> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <i>i</i> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

12.23.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+-----+
| d    |
+-----+
| 3    |
| 3    |
+-----+
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see [Section 12.23.3, “Expression Handling”](#)).

12.23.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in [Section 12.23.3, “Expression Handling”](#), and [Section 12.23.4, “Rounding Behavior”](#).

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
|                1 |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
|                      0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+-----+
| d      | f      |
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `x1` and `x2` that have scale `s1` and `s2`, the scale of the result is `s1 + s2`:

```
mysql> SELECT .01 * .01;
```

```

+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+

```

Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+

```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
| 2            | -2            |
+-----+-----+

```

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127   |
+-----+
1 row in set (0.00 sec)

```

However, an error occurs if strict mode is in effect:

```

mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

```

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i      |
+-----+
| NULL   |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as `DECIMAL`:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double              | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

13.8.4 USE Syntax	2444

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

13.1 Data Definition Statements

13.1.1 Atomic Data Definition Statement Support

MySQL 8.0 supports atomic Data Definition Language (DDL) statements. This feature is referred to as *atomic DDL*. An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log, or is rolled back, even if the server halts during the operation.

Atomic DDL is made possible by the introduction of the MySQL data dictionary in MySQL 8.0. In earlier MySQL versions, metadata was stored in metadata files, nontransactional tables, and storage engine-

specific dictionaries, which necessitated intermediate commits. Centralized, transactional metadata storage provided by the MySQL data dictionary removed this barrier, making it possible to restructure DDL statement operations into atomic transactions.

The atomic DDL feature is described under the following topics in this section:

- [Supported DDL Statements](#)
- [Atomic DDL Characteristics](#)
- [Changes in DDL Statement Behavior](#)
- [Storage Engine Support](#)
- [Viewing DDL Logs](#)

Supported DDL Statements

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations require storage engine support, whereas non-table DDL operations do not. Currently, only the [InnoDB](#) storage engine supports atomic DDL.

- Supported table DDL statements include [CREATE](#), [ALTER](#), and [DROP](#) statements for databases, tablespaces, tables, and indexes, and the [TRUNCATE TABLE](#) statement.
- Supported non-table DDL statements include:
 - [CREATE](#) and [DROP](#) statements, and, if applicable, [ALTER](#) statements for stored programs, triggers, views, and user-defined functions (UDFs).
 - Account management statements: [CREATE](#), [ALTER](#), [DROP](#), and, if applicable, [RENAME](#) statements for users and roles, as well as [GRANT](#) and [REVOKE](#) statements.

The following statements are not supported by the atomic DDL feature:

- Table-related DDL statements that involve a storage engine other than [InnoDB](#).
- [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#) statements.
- [INSTALL COMPONENT](#) and [UNINSTALL COMPONENT](#) statements.
- [CREATE SERVER](#), [ALTER SERVER](#), and [DROP SERVER](#) statements.

Atomic DDL Characteristics

The characteristics of atomic DDL statements include the following:

- Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single transaction.
- There are no intermediate commits at the SQL layer during the DDL operation.
- Where applicable:
 - The state of data dictionary, routine, event, and UDF caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.

- The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL transaction.
- The storage engine supports redo and rollback of DDL operations, which is performed in the *Post-DDL* phase of the DDL operation.
- The visible behaviour of DDL operations is atomic, which changes the behavior of some DDL statements. See [Changes in DDL Statement Behavior](#).

Note

DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a [COMMIT](#) before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as [START TRANSACTION ... COMMIT](#), or combined with other statements within the same transaction.

Changes in DDL Statement Behavior

This section describes changes in DDL statement behavior due to the introduction of atomic DDL support.

- [DROP TABLE](#) operations are fully atomic if all named tables use an atomic DDL-supported storage engine. The statement either drops all tables successfully or is rolled back.

[DROP TABLE](#) fails with an error if a named table does not exist, and no changes are made, regardless of the storage engine. This change in behavior is demonstrated in the following example, where the [DROP TABLE](#) statement fails because a named table does not exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| t1              |
+-----+
```

Prior to the introduction of atomic DDL, [DROP TABLE](#) reports an error for the named table that does not exist but succeeds for the named table that does exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed [DROP TABLE](#) statement on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use [IF EXISTS](#) syntax in [DROP TABLE](#) statements to prevent errors from occurring for tables that do not exist.

- [DROP DATABASE](#) is atomic if all tables use an atomic DDL-supported storage engine. The statement either drops all objects successfully or is rolled back. However, removal of the database directory from

the file system occurs last and is not part of the atomic transaction. If removal of the database directory fails due to a file system error or server halt, the `DROP DATABASE` transaction is not rolled back.

- For tables that do not use an atomic DDL-supported storage engine, table deletion occurs outside of the atomic `DROP TABLE` or `DROP DATABASE` transaction. Such table deletions are written to the binary log individually, which limits the discrepancy between the storage engine, data dictionary, and binary log to one table at most in the case of an interrupted `DROP TABLE` or `DROP DATABASE` operation. For operations that drop multiple tables, the tables that do not use an atomic DDL-supported storage engine are dropped before tables that do.
- `CREATE TABLE`, `ALTER TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`, `CREATE TABLESPACE`, and `DROP TABLESPACE` operations for tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. In earlier MySQL releases, interruption of these operations could cause discrepancies between the storage engine, data dictionary, and binary log, or leave behind orphan files. `RENAME TABLE` operations are only atomic if all named tables use an atomic DDL-supported storage engine.
- `DROP VIEW` fails if a named view does not exist, and no changes are made. The change in behavior is demonstrated in this example, where the `DROP VIEW` statement fails because a named view does not exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
+-----+-----+
| Tables_in_test | Table_type |
+-----+-----+
| viewA          | VIEW       |
+-----+-----+
```

Prior to the introduction of atomic DDL, `DROP VIEW` returns an error for the named view that does not exist but succeeds for the named view that does exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed `DROP VIEW` operation on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist.

- Partial execution of account management statements is no longer permitted. Account management statements either succeed for all named users or roll back and have no effect if an error occurs. In earlier MySQL versions, account management statements that name multiple users could succeed for some users and fail for others.

The change in behavior is demonstrated in this example, where the second `CREATE USER` statement returns an error but fails because it cannot succeed for all named users.

```
mysql> CREATE USER userA;
mysql> CREATE USER userA, userB;
```

```
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%'
mysql> SELECT User FROM mysql.user WHERE User LIKE 'user%';
+-----+
| User |
+-----+
| userA |
+-----+
```

Prior to the introduction of atomic DDL, the second `CREATE USER` statement returns an error for the named user that does not exist but succeeds for the named user that does exist:

```
mysql> CREATE USER userA;
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%'
mysql> SELECT User FROM mysql.user WHERE User LIKE 'user%';
+-----+
| User |
+-----+
| userA |
| userB |
+-----+
```

Note

Due to this change in behavior, partially completed account management statements on a MySQL 5.7 master fail when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use `IF EXISTS` or `IF NOT EXISTS` syntax, as appropriate, in account management statements to prevent errors related to named users.

Storage Engine Support

Currently, only the `InnoDB` storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, `InnoDB` writes DDL logs to the `mysql.innodb_ddl_log` table, which is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace.

To view DDL logs that are written to the `mysql.innodb_ddl_log` table during a DDL operation, enable the `innodb_print_ddl_logs` configuration option. For more information, see [Viewing DDL Logs](#).

Note

The redo logs for changes to the `mysql.innodb_ddl_log` table are flushed to disk immediately regardless of the `innodb_flush_log_at_trx_commit` setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the `mysql.innodb_ddl_log` table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The `InnoDB` storage engine executes DDL operations in phases. DDL operations such as `ALTER TABLE` may perform the *Prepare* and *Perform* phases multiple times prior to the *Commit* phase.

1. *Prepare*: Create the required objects and write the DDL logs to the `mysql.innodb_ddl_log` table. The DDL logs define how to roll forward and roll back the DDL operation.

2. *Perform*: Perform the DDL operation. For example, perform a create routine for a `CREATE TABLE` operation.
3. *Commit*: Update the data dictionary and commit the data dictionary transaction.
4. *Post-DDL*: Replay and remove DDL logs from the `mysql.innodb_ddl_log` table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the `mysql.innodb_dynamic_metadata` data dictionary table for `DROP TABLE`, `TRUNCATE TABLE`, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the `mysql.innodb_ddl_log` table during the *Post-DDL* phase, regardless of whether the transaction is committed or rolled back. DDL logs should only remain in the `mysql.innodb_ddl_log` table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL transaction may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the *Commit* phase of a DDL operation is present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL transaction is rolled back.

Viewing DDL Logs

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_ddl_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See [Section 5.4.2.2, “Default Error Log Destination Configuration”](#).

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See [Section 14.1, “Data Dictionary Schema”](#).) The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```
CREATE TABLE mysql.innodb_ddl_log (
  id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  thread_id BIGINT UNSIGNED NOT NULL,
  type INT UNSIGNED NOT NULL,
  space_id INT UNSIGNED,
  page_no INT UNSIGNED,
  index_id BIGINT UNSIGNED,
  table_id BIGINT UNSIGNED,
  old_file_path VARCHAR(512) COLLATE UTF8_BIN,
  new_file_path VARCHAR(512) COLLATE UTF8_BIN,
  KEY(thread_id)
);
```

- **id**: A unique identifier for a DDL log record.
- **thread_id**: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL transaction. DDL transactions that involve multiple data file operations generate multiple DDL log records.
- **type**: The DDL operation type. Types include `FREE` (drop an index tree), `DELETE` (delete a file), `RENAME` (rename a file), or `DROP` (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).

- `space_id`: The tablespace ID.
- `page_no`: A page that contains allocation information; an index tree root page, for example.
- `index_id`: The index ID.
- `table_id`: The table ID.
- `old_file_path`: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.
- `new_file_path`: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `stderr` for a `CREATE TABLE` operation.

```
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;

[Note] [000000] InnoDB: DDL log insert : [DDL record: DELETE SPACE, id=18, thread_id=7,
space_id=5, old_file_path=./test/t1.ibd]
[Note] [000000] InnoDB: DDL log delete : by id 18
[Note] [000000] InnoDB: DDL log insert : [DDL record: REMOVE CACHE, id=19, thread_id=7,
table_id=1058, new_file_path=test/t1]
[Note] [000000] InnoDB: DDL log delete : by id 19
[Note] [000000] InnoDB: DDL log insert : [DDL record: FREE, id=20, thread_id=7,
space_id=5, index_id=132, page_no=4]
[Note] [000000] InnoDB: DDL log delete : by id 20
[Note] [000000] InnoDB: DDL log post ddl : begin for thread id : 7
[Note] [000000] InnoDB: DDL log post ddl : end for thread id : 7
```

13.1.2 ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

National Language Characteristics

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. [Chapter 10, Character Sets, Collations, Unicode](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the `SHOW CHARACTER SET` and `SHOW COLLATION` statements. See [Section 13.7.6.3, “SHOW CHARACTER SET Syntax”](#), and [Section 13.7.6.4, “SHOW COLLATION Syntax”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables

with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

13.1.3 ALTER EVENT Syntax

```
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 13.1.12, “CREATE EVENT Syntax”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
>     ON SCHEDULE
>     EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
  ON SCHEDULE
    EVERY 6 HOUR
  COMMENT 'A sample comment.'
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
  ON SCHEDULE
    EVERY 12 HOUR
  STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
  DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
  RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replication slave instead of `ENABLE` or `DISABLE` to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 17.4.1.16, “Replication of Invoked Features”](#), for more information.

13.1.4 ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of

a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

13.1.5 ALTER INSTANCE Syntax

```
ALTER INSTANCE ROTATE INNODB MASTER KEY
```

`ALTER INSTANCE` defines actions applicable to a MySQL server instance.

The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is used to rotate the master encryption key used for `InnoDB` tablespace encryption. A keyring plugin must be installed and configured to use this statement. By default, the MySQL server loads the `keyring_file` plugin. Key rotation requires the `ENCRYPTION_KEY_ADMIN` or `SUPER` privilege.

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with `CREATE TABLE ... ENCRYPTION` or `ALTER TABLE ... ENCRYPTION` operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

`ALTER INSTANCE` actions are written to the binary log so that they can be executed on replicated servers.

For additional `ALTER INSTANCE ROTATE INNODB MASTER KEY` usage information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#). For information about the `keyring_file` plugin, see [Section 6.5.4, “The MySQL Keyring”](#).

13.1.6 ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).

13.1.7 ALTER SERVER Syntax

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server_name*, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.8 ALTER TABLE Syntax

```
ALTER TABLE tbl_name
    [alter_specification [, alter_specification] ...]
    [partition_options]

alter_specification:
    table_options
    | ADD [COLUMN] col_name column_definition
      [FIRST | AFTER col_name]
    | ADD [COLUMN] (col_name column_definition,...)
    | ADD {INDEX|KEY} [index_name]
      [index_type] (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]] PRIMARY KEY
      [index_type] (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]]
      UNIQUE [INDEX|KEY] [index_name]
      [index_type] (key_part,...) [index_option] ...
    | ADD FULLTEXT [INDEX|KEY] [index_name]
      (key_part,...) [index_option] ...
    | ADD SPATIAL [INDEX|KEY] [index_name]
      (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]]
      FOREIGN KEY [index_name] (col_name,...)
      reference_definition
    | ALGORITHM [=] {DEFAULT|INSTANT|INPLACE|COPY}
    | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
    | ALTER INDEX index_name {VISIBLE | INVISIBLE}
    | CHANGE [COLUMN] old_col_name new_col_name column_definition
      [FIRST|AFTER col_name]
    | [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
    | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
    | {DISABLE|ENABLE} KEYS
    | {DISCARD|IMPORT} TABLESPACE
    | DROP [COLUMN] col_name
    | DROP {INDEX|KEY} index_name
    | DROP PRIMARY KEY
    | DROP FOREIGN KEY fk_symbol
    | FORCE
    | LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
    | MODIFY [COLUMN] col_name column_definition
      [FIRST | AFTER col_name]
    | ORDER BY col_name [, col_name] ...
    | RENAME COLUMN old_col_name TO new_col_name
    | RENAME {INDEX|KEY} old_index_name TO new_index_name
    | RENAME [TO|AS] new_tbl_name
    | {WITHOUT|WITH} VALIDATION
    | ADD PARTITION (partition_definition)
    | DROP PARTITION partition_names
    | DISCARD PARTITION {partition_names | ALL} TABLESPACE
    | IMPORT PARTITION {partition_names | ALL} TABLESPACE
    | TRUNCATE PARTITION {partition_names | ALL}
    | COALESCE PARTITION number
    | REORGANIZE PARTITION partition_names INTO (partition_definitions)
    | EXCHANGE PARTITION partition_name WITH TABLE tbl_name [{WITH|WITHOUT} VALIDATION]
```

```

| ANALYZE PARTITION {partition_names | ALL}
| CHECK PARTITION {partition_names | ALL}
| OPTIMIZE PARTITION {partition_names | ALL}
| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| REMOVE PARTITIONING
| UPGRADE PARTITIONING

key_part: {col_name [(length)] | (expr)} [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE [=] value
| index_type
| WITH PARSE parser_name
| COMMENT 'string'
| {VISIBLE | INVISIBLE}

table_options:
    table_option [[,] table_option] ...

table_option:

| STATS_SAMPLE_PAGES [=] value
| TABLESPACE tablespace_name
| UNION [=] (tbl_name[, tbl_name]...)

partition_options:
    (see CREATE TABLE options)

```

ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.
- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.
- The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. *column_definition* clauses use the same syntax for **ADD** and **CHANGE** as for **CREATE TABLE**. For more information, see [Section 13.1.18, “CREATE TABLE Syntax”](#).

- The word `COLUMN` is optional and can be omitted, except for `RENAME COLUMN` (to distinguish a column-renaming operation from the `RENAME` table-renaming operation).
- Multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses are permitted in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted `ALTER TABLE` operation, a warning may result. Such warnings can be displayed with `SHOW WARNINGS`. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#). For information on troubleshooting `ALTER TABLE`, see [Section B.5.6.1, “Problems with ALTER TABLE”](#).
- For information about generated columns, see [Section 13.1.8.2, “ALTER TABLE and Generated Columns”](#).
- For usage examples, see [Section 13.1.8.3, “ALTER TABLE Examples”](#).
- With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`. See [Section 27.7.7.36, “mysql_info\(\)”](#).

There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

- [Table Options](#)
- [Performance and Space Requirements](#)
- [Concurrency Control](#)
- [Adding and Dropping Columns](#)
- [Renaming, Redefining, and Reordering Columns](#)
- [Primary Keys and Indexes](#)
- [Foreign Keys](#)
- [Changing the Character Set](#)
- [Discarding and Importing InnoDB Tablespaces](#)
- [Row Order for MyISAM Tables](#)
- [Partitioning Options](#)

Table Options

table_options signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, or `TABLESPACE`.

For descriptions of all table options, see [Section 13.1.18, “CREATE TABLE Syntax”](#). However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an `InnoDB` table, this statement changes its storage engine to `InnoDB`:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

- See [Section 15.8.1.4, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the `InnoDB` storage engine.
- When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.
- Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing `InnoDB` table performs a “null” `ALTER TABLE` operation, which can be used to defragment an `InnoDB` table, as described in [Section 15.11.4, “Defragmenting a Table”](#). Running `ALTER TABLE tbl_name FORCE` on an `InnoDB` table performs the same function.
- `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 15.12, “InnoDB and Online DDL”](#).
- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.10, “Server SQL Modes”](#).
- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.
- To change the `InnoDB` table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

- To enable or disable encryption for an `InnoDB` table in a file-per-table tablespace:

```
ALTER TABLE t1 ENCRYPTION='Y';  
ALTER TABLE t1 ENCRYPTION='N';
```

A keyring plugin must be installed and configured to use the `ENCRYPTION` option. For more information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#).

- To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both `InnoDB` and `MyISAM`, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also [Changing the Character Set](#).

- To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

- Use `ALTER TABLE` with the `TABLESPACE` option to move `InnoDB` tables between existing `general tablespaces`, `file-per-table` tablespaces, and the `system tablespace`. See [Moving Tables Between Tablespaces Using ALTER TABLE](#).
- `ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.
- `ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.
- The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.
- For more information about the capabilities and limitations of the `TABLESPACE` option, see [CREATE TABLE](#).

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the `INFORMATION_SCHEMA.TABLES` table.

Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

- **COPY:** Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.
- **INPLACE:** Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.
- **INSTANT:** Operations only modify metadata in the data dictionary. No exclusive metadata locks are taken on the table during preparation and execution, and table data is unaffected, making operations instantaneous. Concurrent DML is permitted. (Introduced in MySQL 8.0.12)

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted, MySQL uses `ALGORITHM=INSTANT` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=INPLACE` is used. If `ALGORITHM=INPLACE` is not supported, `ALGORITHM=COPY` is used.

Specifying an `ALGORITHM` clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the `ALGORITHM` clause.

`ALTER TABLE` operations that use the `COPY` algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a `RENAME TO` operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An `ALTER TABLE` operation that uses the `COPY` algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict

concurrency for operations that support the `LOCK` clause by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries. For more information, see [Concurrency Control](#).

To force use of the `COPY` algorithm for an `ALTER TABLE` operation that would otherwise not use it, enable the `old_alter_table` system variable or specify `ALGORITHM=COPY`. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

For `InnoDB` tables, an `ALTER TABLE` operation that uses the `COPY` algorithm on a table that resides in a `shared tablespace` can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a `file-per-table` tablespace.

For information about space requirements for online DDL operations, see [Section 15.12.3, “Online DDL Space Requirements”](#).

`ALTER TABLE` operations that support the `INPLACE` algorithm include:

- `ALTER TABLE` operations supported by the `InnoDB` online DDL feature. See [Section 15.12.1, “Online DDL Operations”](#).
- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 13.1.33, “RENAME TABLE Syntax”](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Operations that only modify table metadata. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
 - Renaming a column.
 - Changing the default value of a column.
 - Modifying the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
 - Changing the definition of a spatial column to remove the `SRID` attribute. (Adding or changing an `SRID` attribute does require a rebuild and cannot be done in place because the server must verify that all values have the specified `SRID` value.)
- Renaming an index.
- Adding or dropping a secondary index, for `InnoDB`. See [Section 15.12.1, “Online DDL Operations”](#).
- Modifying index visibility with an `ALTER INDEX` operation.
- Column modifications of tables containing generated columns that depend on columns with a `DEFAULT` value if the modified columns are not involved in the generated column expressions. For example, changing the `NULL` property of a separate column can be done in place without a table rebuild.

`ALTER TABLE` operations that support the `INSTANT` algorithm include:

- Adding a column. This feature is referred to as “Instant `ADD COLUMN`”. Limitations apply. See [Section 15.12.1, “Online DDL Operations”](#).

- Adding or dropping a virtual column.
- Adding or dropping a column default value.
- Modifying the definition of an `ENUM` or `SET` column. The same restrictions apply as described above for `ALGORITHM=INSTANT`.
- Changing the index type.
- Renaming a table. The same restrictions apply as described above for `ALGORITHM=INSTANT`.

For more information about operations that support `ALGORITHM=INSTANT`, see [Section 15.12.1, “Online DDL Operations”](#).

`ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

If an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` changes the order of the columns, it can only be performed using `ALGORITHM=COPY`.

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for [virtual generated column](#) modifications. See [Section 13.1.8.2, “ALTER TABLE and Generated Columns”](#).

`ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` does not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create temporary tables (except when used with `NDB` tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

Concurrency Control

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only `LOCK = DEFAULT` is permitted for operations that use `ALGORITHM=INSTANT`. The other `LOCK` clause parameters are not applicable.

The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`
If supported, permit concurrent reads and writes. Otherwise, an error occurs.
- `LOCK = SHARED`
If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.
- `LOCK = EXCLUSIVE`
Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For `ALTER TABLE ... ADD`, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For details, see [Section 17.1.3.6, “Restrictions on Replication with GTIDs”](#).

Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, `RENAME COLUMN`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- `CHANGE`:
 - Can rename a column and change its definition, or both.
 - Has more capability than `MODIFY` or `RENAME COLUMN`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
 - With `FIRST` or `AFTER`, can reorder columns.
- `MODIFY`:
 - Can change a column definition but not its name.
 - More convenient than `CHANGE` to change a column definition without renaming it.
 - With `FIRST` or `AFTER`, can reorder columns.

- **RENAME COLUMN**:
 - Can change a column name but not its definition.
 - More convenient than **CHANGE** to rename a column without changing its definition.
- **ALTER**: Used only to change a column default value.

CHANGE is a MySQL extension to standard SQL. **MODIFY** and **RENAME COLUMN** are MySQL extensions for Oracle compatibility.

To alter a column to change both its name and definition, use **CHANGE**, specifying the old and new names and the new definition. For example, to rename an **INT NOT NULL** column from **a** to **b** and change its definition to use the **BIGINT** data type while retaining the **NOT NULL** attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use **CHANGE** or **MODIFY**. With **CHANGE**, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column **b**, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

MODIFY is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use **CHANGE** or **RENAME COLUMN**. With **CHANGE**, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an **INT NOT NULL** column from **b** to **a**, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

RENAME COLUMN is more convenient to change the name without changing the definition because it requires only the old and new names:

```
ALTER TABLE t1 RENAME COLUMN b TO a;
```

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named **a**, **b**, and **c**, these are valid operations:

```
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
                RENAME COLUMN b TO a;
-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
                RENAME COLUMN b TO c,
                RENAME COLUMN c TO a;
```

For column definition changes using **CHANGE** or **MODIFY**, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as **PRIMARY KEY** or **UNIQUE**. Attributes present in the original definition but not specified for the new definition are not

carried forward. Suppose that a column `coll` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```
ALTER TABLE t1 MODIFY coll BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY coll BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.10, “Server SQL Modes”](#)).

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including invisible indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 11.7, “Data Type Default Values”](#).

Primary Keys and Indexes

`DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for `InnoDB` tables, see [Section 8.3.2, “Primary Key Optimization”](#).

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.25, “DROP INDEX Syntax”](#). To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is `USING type_name`. For details about `USING`, see [Section 13.1.14, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

index_option values specify additional options for an index. `USING` is one such option. For details about permissible *index_option* values, see [Section 13.1.14, “CREATE INDEX Syntax”](#).

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. *old_index_name* must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. *new_index_name* is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 13.7.6.22, “SHOW INDEX Syntax”](#).

The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see [Section 8.3.12, “Invisible Indexes”](#).

Foreign Keys

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 13.1.18, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.8.2, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores *index_name* if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...) ...
```

Important

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

**Note**

Partitioned [InnoDB](#) tables do not support foreign keys. For more information, see [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

MySQL supports the use of [ALTER TABLE](#) to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same [ALTER TABLE](#) statement is supported for [ALTER TABLE ... ALGORITHM=INPLACE](#) but not for [ALTER TABLE ... ALGORITHM=COPY](#).

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. It also prohibits changes to the data type of such columns that may be unsafe. For example, changing [VARCHAR\(20\)](#) to [VARCHAR\(30\)](#) is permitted, but changing it to [VARCHAR\(1024\)](#) is not because that alters the number of length bytes required to store individual values. A workaround is to use [ALTER TABLE ... DROP FOREIGN KEY](#) before changing the column definition and [ALTER TABLE ... ADD FOREIGN KEY](#) afterward.

[ALTER TABLE *tbl_name* RENAME *new_tbl_name*](#) changes internally generated foreign key constraint names and user-defined foreign key constraint names that contain the string “*tbl_name_ibfk_*” to reflect the new table name. [InnoDB](#) interprets foreign key constraint names that contain the string “*tbl_name_ibfk_*” as internally generated names.

Changing the Character Set

To change the table default character set and all character columns ([CHAR](#), [VARCHAR](#), [TEXT](#)) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no [COLLATE](#) clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of [VARCHAR](#) or one of the [TEXT](#) types, [CONVERT TO CHARACTER SET](#) changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a [TEXT](#) column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a [latin1 TEXT](#) column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to [utf8](#), each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a [TEXT](#) column's length bytes, so MySQL converts the data type to [MEDIUMTEXT](#), which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a [VARCHAR](#) column might be converted to [MEDIUMTEXT](#).

To avoid data type changes of the type just described, do not use [CONVERT TO CHARACTER SET](#). Instead, use [MODIFY](#) to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify [CONVERT TO CHARACTER SET binary](#), the [CHAR](#), [VARCHAR](#), and [TEXT](#) columns are converted to their corresponding binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). This means that the

columns no longer will have a character set attribute and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

Warning

The `CONVERT TO` operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

Discarding and Importing InnoDB Tablespaces

An `InnoDB` table created in its own `file-per-table` tablespace can be discarded and imported using the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` options. These options can be used to import a file-per-table tablespace from a backup or to copy a file-per-table tablespace from one database server to another. See [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

Note

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for `InnoDB` tables because `InnoDB` always orders table rows according to the `clustered index`.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

Partitioning Options

partition_options signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `DISCARD PARTITION`, `IMPORT PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see [Section 13.1.18, “CREATE TABLE Syntax”](#), and [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#). For information about and examples of `ALTER TABLE ... EXCHANGE PARTITION` statements, see [Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

13.1.8.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a *partition_options* clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the *partition_options*. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the *partition_options* clause for `CREATE TABLE` (for more detailed information, see [Section 13.1.18, “CREATE TABLE Syntax”](#)), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (  
  id INT,  
  year_col INT  
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1  
  PARTITION BY HASH(id)  
  PARTITIONS 8;
```

MySQL supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a

MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The *partition_definition* clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.18, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (  
    id INT,  
    year_col INT  
)  
PARTITION BY RANGE (year_col) (  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999)  
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see later in this section). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

The `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the [Transportable Tablespace](#) feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (`.idb` file). The [Transportable Tablespace](#) feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The [Transportable Tablespace](#) feature also supports copying or restoring partitioned [InnoDB](#) tables (all partitions at once). For additional information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#), as well as, [Section 15.7.6.1, “Transportable Tablespace Examples”](#).

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a list of one or more comma-separated partition names. Consider the table `t1` created by this statement:

```
CREATE TABLE t1 (  
  id INT,  
  year_col INT  
)  
PARTITION BY RANGE (year_col) (  
  PARTITION p0 VALUES LESS THAN (1991),  
  PARTITION p1 VALUES LESS THAN (1995),  
  PARTITION p2 VALUES LESS THAN (1999),  
  PARTITION p3 VALUES LESS THAN (2003),  
  PARTITION p4 VALUES LESS THAN (2007)  
);
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE  
  (year_col >= 1991 AND year_col < 1995)  
  OR  
  (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

COALESCE PARTITION can be used with a table that is partitioned by **HASH** or **KEY** to reduce the number of partitions by *number*. Suppose that you have created table *t2* as follows:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by *t2* from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use **REORGANIZE PARTITION**. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using **VALUES LESS THAN** or the value lists for a subset of partitions defined using **VALUES IN**.

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names *p0*, *p1*, *p2*, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of **ALTER TABLE ... REORGANIZE PARTITION** statements, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).

- To exchange a table partition or subpartition with a table, use the **ALTER TABLE ... EXCHANGE PARTITION** statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see [Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as **CHECK TABLE** and **REPAIR TABLE** (which are also supported for partitioned tables; for more information, see [Section 13.7.3, “Table Maintenance Statements”](#)). These include **ANALYZE PARTITION**, **CHECK PARTITION**, **OPTIMIZE PARTITION**, **REBUILD PARTITION**, and **REPAIR PARTITION**. Each of these options takes a *partition_names*

clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see [Section 22.3.4, “Maintenance of Partitions”](#).

InnoDB does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the InnoDB and NDB storage engines have native partitioning handlers; NDB is not currently supported in MySQL 8.0.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;

ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`REBUILD` operations are currently unsupported for subpartitions. The `REBUILD` keyword is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used.

[CHECK PARTITION](#) and [REPAIR PARTITION](#) operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see [Section 22.3.4, “Maintenance of Partitions”](#).

13.1.8.2 ALTER TABLE and Generated Columns

[ALTER TABLE](#) operations permitted for generated columns are [ADD](#), [MODIFY](#), and [CHANGE](#).

- Generated columns can be added.

```
CREATE TABLE t1 (c1 INT);
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- The data type and expression of generated columns can be modified.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;
```

- Generated columns can be renamed or dropped, if no other column refers to them.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;
ALTER TABLE t1 DROP COLUMN c3;
```

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);
ALTER TABLE t1 DROP COLUMN c2;
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Nongenerated columns can be altered to stored but not virtual generated columns.

```
CREATE TABLE t1 (c1 INT, c2 INT);
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 INT;
```

- [ADD COLUMN](#) is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.
- For non-partitioned tables, [ADD COLUMN](#) and [DROP COLUMN](#) are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other [ALTER TABLE](#) operations.

For partitioned tables, [ADD COLUMN](#) and [DROP COLUMN](#) are not in-place operations for virtual columns.

- [InnoDB](#) supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see [Section 13.1.18.9, “Secondary Indexes and Generated Columns”](#).
- When a [VIRTUAL](#) generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, [ALTER TABLE](#) supports [WITHOUT VALIDATION](#) and [WITH VALIDATION](#) clauses:
 - With [WITHOUT VALIDATION](#) (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
 - With [WITH VALIDATION](#), [ALTER TABLE](#) copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

[WITHOUT VALIDATION](#) and [WITH VALIDATION](#) are permitted only with [ADD COLUMN](#), [CHANGE COLUMN](#), and [MODIFY COLUMN](#) operations. Otherwise, an [ER_WRONG_USAGE](#) error occurs.

- If expression evaluation causes truncation or provides incorrect input to a function, the [ALTER TABLE](#) statement terminates with an error and the DDL operation is rejected.
- An [ALTER TABLE](#) statement that changes the default value of a column *col_name* may also change the value of a generated column expression that refers to the column using *col_name*, which may change the value of a generated column expression that refers to the column using [DEFAULT\(col_name\)](#). For this reason, [ALTER TABLE](#) operations that change the definition of a column cause a table rebuild if any generated column expression uses [DEFAULT\(\)](#).

13.1.8.3 ALTER TABLE Examples

Begin with a table [t1](#) created as shown here:

```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from [t1](#) to [t2](#):

```
ALTER TABLE t1 RENAME t2;
```

To change column [a](#) from [INTEGER](#) to [TINYINT NOT NULL](#) (leaving the name the same), and to change column [b](#) from [CHAR\(10\)](#) to [CHAR\(20\)](#) as well as renaming it from [b](#) to [c](#):

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new [TIMESTAMP](#) column named [d](#):

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column [d](#) and a [UNIQUE](#) index on column [a](#):

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column [c](#):

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
  ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)  
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;  
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;  
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;  
ALTER TABLE t2 RENAME t1;
```

13.1.9 ALTER TABLESPACE Syntax

```
ALTER TABLESPACE tablespace_name  
  [RENAME TO tablespace_name]
```

```
[ENCRYPTION [=] {'Y' | 'N'}]
[ENGINE [=] engine_name]
```

This statement can be used to rename an [InnoDB](#) general tablespace.

The [CREATE TABLESPACE](#) privilege is required to rename a general tablespace.

The [ENGINE](#) clause, which specifies the storage engine used by the tablespace, is deprecated and will be removed in a future release. The tablespace storage engine is known by the data dictionary, making the [ENGINE](#) clause obsolete. If the storage engine is specified, it must match the tablespace storage engine defined in the data dictionary.

[RENAME TO](#) operations are implicitly performed in [autocommit](#) mode, regardless of the [autocommit](#) setting.

A [RENAME TO](#) operation cannot be performed while [LOCK TABLES](#) or [FLUSH TABLES WITH READ LOCK](#) is in effect for tables that reside in the tablespace.

Exclusive [metadata locks](#) are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The [ENCRYPTION](#) option is used to enable or disable page-level data encryption for an [InnoDB](#) general tablespace. Option values are not case-sensitive. The Encryption support for general tablespaces was introduced in MySQL 8.0.13. A keyring plugin must be installed and configured to encrypt a tablespace using the [ENCRYPTION](#) option.

When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted general tablespace is encrypted.

The [INPLACE](#) algorithm is used when altering the [ENCRYPTION](#) attribute of a general tablespace. The [INPLACE](#) algorithm permits concurrent DML on tables that reside in the general tablespace. Concurrent DDL is blocked.

For more information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#).

13.1.10 ALTER VIEW Syntax

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for [CREATE VIEW](#) see [Section 13.1.21, “CREATE VIEW Syntax”](#)). This statement requires the [CREATE VIEW](#) and [DROP](#) privileges for the view, and some privilege for each column referred to in the [SELECT](#) statement. [ALTER VIEW](#) is permitted only to the definer or users with the [SET_USER_ID](#) or [SUPER](#) privilege.

13.1.11 CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...

create_specification:
```

```
[DEFAULT] CHARACTER SET [=] charset_name
| [DEFAULT] COLLATE [=] collation_name
```

CREATE DATABASE creates a database with the given name. To use this statement, you need the **CREATE** privilege for the database. **CREATE SCHEMA** is a synonym for **CREATE DATABASE**.

An error occurs if the database exists and you did not specify **IF NOT EXISTS**.

CREATE DATABASE is not permitted within a session that has an active **LOCK TABLES** statement.

create_specification options specify database characteristics. Database characteristics are stored in the data dictionary. The **CHARACTER SET** clause specifies the default database character set. The **COLLATE** clause specifies the default database collation. [Chapter 10, Character Sets, Collations, Unicode](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the **CREATE DATABASE** statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

Creating a database directory by manually creating a directory under the data directory (for example, with **mkdir**) is temporarily unsupported in MySQL 8.0.0.

You can also use the **mysqladmin** program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.12 CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  DO event_body;

schedule:
  AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 23.4.2, “Event Scheduler Configuration”](#).

CREATE EVENT requires the **EVENT** privilege for the schema in which the event is to be created. It might also require the **SET_USER_ID** or **SUPER** privilege, depending on the **DEFINER** value, as described later in this section.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create an event with a nonexistent `DEFINER` account, an error occurs at event execution time if the account does not exist.

For more information about event security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the *event_body* defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
->      ON SCHEDULE AT '2006-02-10 23:59:00'
->      DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 12.7, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK`

`STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 23.4.4, “Event Metadata”](#). See also [Section 13.7.6.18, “SHOW EVENTS Syntax”](#), and [Section 24.9, “The INFORMATION_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 13.1.3, “ALTER EVENT Syntax”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 17.4.1.16, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section C.1, “Restrictions on Stored Programs”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 23.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
ON SCHEDULE
  EVERY 5 SECOND
DO
  BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
```

```

        SET v = 0;

        WHILE v < 5 DO
            INSERT INTO t1 VALUES (0);
            UPDATE t2 SET s1 = s1 + 1;
            SET v = v + 1;
        END WHILE;
    END |
delimiter ;

```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```

CREATE EVENT e_call_myproc
ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);

```

If an event's definer has privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 23.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.13 CREATE FUNCTION Syntax

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).
- For information about creating user-defined functions, see [Section 13.7.4.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).

13.1.14 CREATE INDEX Syntax

```

CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part, ...)
    [index_option]
    [algorithm_option | lock_option] ...

key_part: {col_name [(length)] | (expr)} [ASC | DESC]

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'
    | {VISIBLE | INVISIBLE}

index_type:
    USING {BTREE | HASH}

algorithm_option:
    ALGORITHM [=] {DEFAULT | INPLACE | COPY}

```

```
lock_option:  
  LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.18, “CREATE TABLE Syntax”](#). This guideline is especially important for `InnoDB` tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.8, “ALTER TABLE Syntax”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

`InnoDB` supports secondary indexes on virtual columns. For more information, see [Section 13.1.18.9, “Secondary Indexes and Generated Columns”](#).

When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an `InnoDB` table after creating an index on that table.

An index specification of the form `(key_part1, key_part2, ...)` creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example `(col1, col2, col3)` specifies a multiple-column index with index keys consisting of values from `col1`, `col2`, and `col3`.

A *key_part* specification can end with `ASC` or `DESC` to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. `ASC` and `DESC` are not permitted for `HASH` indexes. As of MySQL 8.0.12, `ASC` and `DESC` are not permitted for `SPATIAL` indexes.

The following sections describe different aspects of the `CREATE INDEX` statement:

- [Column Prefix Key Parts](#)
- [Functional Key Parts](#)
- [Unique Indexes](#)
- [Full-Text Indexes](#)
- [Spatial Indexes](#)
- [Index Options](#)
- [Table Copying and Locking Options](#)

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` key parts.
- Prefixes *must* be specified for `BLOB` and `TEXT` key parts. Additionally, `BLOB` and `TEXT` columns can be indexed only for `InnoDB`, `MyISAM`, and `BLACKHOLE` tables.
- Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for [InnoDB](#) tables that use the [REDUNDANT](#) or [COMPACT](#) row format. The prefix length limit is 3072 bytes for [InnoDB](#) tables that use the [DYNAMIC](#) or [COMPRESSED](#) row format. For [MyISAM](#) tables, the prefix length limit is 1000 bytes.

If a specified index prefix exceeds the maximum column data type size, [CREATE INDEX](#) handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the [name](#) column (assuming that [name](#) has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire [name](#) column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up [INSERT](#) operations.

Functional Key Parts

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given [t1](#) row includes the full [col1](#) value and a prefix of the [col2](#) value consisting of its first 10 bytes:

```
CREATE TABLE t1 (  
  col1 VARCHAR(10),  
  col2 VARCHAR(20),  
  INDEX (col1, col2(10))  
);
```

MySQL 8.0.13 and higher supports functional key parts that index expression values rather than column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));  
CREATE INDEX idx1 ON t1 ((col1 + col2));  
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);  
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```

An index with multiple key parts can mix nonfunctional and functional key parts.

[ASC](#) and [DESC](#) are supported for functional key parts.

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:

```
INDEX ((col1 + col2), (col3 - col4))
```

This produces an error; the expressions are not enclosed within parentheses:

```
INDEX (col1 + col2, col3 - col4)
```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

```
INDEX ((col1), (col2))
```

Instead, write the key parts as nonfunctional key parts, without parentheses:

```
INDEX (col1, col2)
```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of [SUBSTRING\(\)](#) and [CAST\(\)](#) later in this section.
- Functional key parts are not permitted in foreign key specifications.

For [CREATE TABLE ... LIKE](#), the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:

- Each functional key part counts against the limit on total number of table columns; see [Section C.10.4, “Limits on Table Column Count and Row Size”](#).
- Functional key parts inherit all restrictions that apply to generated columns. Examples:
 - Only functions permitted for generated columns are permitted for functional key parts.
 - Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.

For more information about applicable restrictions, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#), and [Section 13.1.8.2, “ALTER TABLE and Generated Columns”](#).

[UNIQUE](#) is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

[SPATIAL](#) and [FULLTEXT](#) indexes cannot have functional key parts.

If a table contains no primary key, [InnoDB](#) automatically promotes the first [UNIQUE NOT NULL](#) index to the primary key. This is not supported for [UNIQUE NOT NULL](#) indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.

Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use [SUBSTRING\(\)](#) (or [CAST\(\)](#), as described later in this section). For a functional key part containing the [SUBSTRING\(\)](#) function to be used in a query, the [WHERE](#) clause must contain [SUBSTRING\(\)](#) with the same arguments. In the following example, only the second [SELECT](#) is able to use the index because that is the only query in which the arguments to [SUBSTRING\(\)](#) match the index specification:

```
CREATE TABLE tbl (
  col1 LONGTEXT,
  INDEX idx1 ((SUBSTRING(col1, 1, 10)))
);
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 9) = '123456789';
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as [JSON](#) values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```
CREATE TABLE employees (
  data JSON,
  INDEX ((data->>'$.name'))
);
```

The syntax fails because:

- The `->>` operator translates into `JSON_UNQUOTE(JSON_EXTRACT(...))`.
- `JSON_UNQUOTE()` returns a value with a data type of `LONGTEXT`, and the hidden generated column thus is assigned the same data type.
- MySQL cannot index `LONGTEXT` columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the `JSON` column, you could try using the `CAST()` function as follows:

```
CREATE TABLE employees (
  data JSON,
  INDEX ((CAST(data->>'$.name' AS CHAR(30))))
);
```

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but *only* if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- Solution 1. Assign the indexed expression the same collation as `JSON_UNQUOTE()`:

```
CREATE TABLE employees (
  data JSON,
  INDEX idx ((CAST(data->>'$.name' AS CHAR(30)) COLLATE utf8mb4_bin))
);
INSERT INTO employees VALUES
```

```
( '{ "name": "james", "salary": 9000 }' ),
( '{ "name": "James", "salary": 10000 }' ),
( '{ "name": "Mary", "salary": 12000 }' ),
( '{ "name": "Peter", "salary": 8000 }' );
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The `->>` operator is the same as `JSON_UNQUOTE(JSON_EXTRACT(...))`, and `JSON_UNQUOTE()` returns a string with collation `utf8mb4_bin`. The comparison is thus case sensitive, and only one row matches:

```
+-----+
| data                                     |
+-----+
| { "name": "James", "salary": 10000 } |
+-----+
```

- Solution 2. Specify the full expression in the query:

```
CREATE TABLE employees (
  data JSON,
  INDEX idx ((CAST(data->>"$.name" AS CHAR(30))))
);
INSERT INTO employees VALUES
( '{ "name": "james", "salary": 9000 }' ),
( '{ "name": "James", "salary": 10000 }' ),
( '{ "name": "Mary", "salary": 12000 }' ),
( '{ "name": "Peter", "salary": 8000 }' );
SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';
```

`CAST()` returns a string with collation `utf8mb4_0900_ai_ci`, so the comparison case insensitive and two rows match:

```
+-----+
| data                                     |
+-----+
| { "name": "james", "salary": 9000 } |
| { "name": "James", "salary": 10000 } |
+-----+
```

Be aware that although the optimizer supports automatically stripping `CAST()` with indexed generated columns, the following approach does not work because it produces a different result with and without an index (Bug#27337092):

```
mysql> CREATE TABLE employees (
  data JSON,
  generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))
);
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> INSERT INTO employees (data)
VALUES ('{ "name": "james" }'), ('{ "name": "James" }');
Query OK, 2 rows affected, 1 warning (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-----+-----+
| data                                     | generated_col |
+-----+-----+
| { "name": "James" } | James         |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> ALTER TABLE employees ADD INDEX idx (generated_col);
Query OK, 0 rows affected, 1 warning (0.03 sec)
Records: 0 Duplicates: 0 Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-----+-----+
| data | generated_col |
+-----+-----+
| {"name": "james"} | james |
| {"name": "James"} | James |
+-----+-----+
2 rows in set (0.01 sec)
```

Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as follows:

- `_rowid` refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, `_rowid` cannot be used.
- Otherwise, `_rowid` refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, `_rowid` cannot be used.

Full-Text Indexes

FULLTEXT indexes are supported only for **InnoDB** and **MyISAM** tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation.

Spatial Indexes

The **MyISAM**, **InnoDB**, **NDB**, and **ARCHIVE** storage engines support spatial columns such as **POINT** and **GEOMETRY**. ([Section 11.5, “Spatial Data Types”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

- Available only for **InnoDB** and **MyISAM** tables. Specifying **SPATIAL INDEX** for other storage engines results in an error.
- As of MySQL 8.0.12, an index on a spatial column *must* be a **SPATIAL** index. The **SPATIAL** keyword is thus optional but implicit for creating an index on a spatial column.
- Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.
- Indexed columns must be **NOT NULL**.
- Column prefix lengths are prohibited. The full width of each column is indexed.

- Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`) have these characteristics:

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.

Index Options

Following the key part list, index options can be given. An *index_option* value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

`KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See [Section 13.1.18, “CREATE TABLE Syntax”](#).

- *index_type*

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

[Table 13.1, “Index Types Per Storage Engine”](#) shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an *index_type* clause in index definitions.

Table 13.1 Index Types Per Storage Engine

Storage Engine	Permissible Index Types
<code>InnoDB</code>	<code>BTREE</code>
<code>MyISAM</code>	<code>BTREE</code>
<code>MEMORY/HEAP</code>	<code>HASH</code> , <code>BTREE</code>

The *index_type* clause cannot be used for `FULLTEXT INDEX` or (prior to MySQL 8.0.12) `SPATIAL INDEX` specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `BTREE` as a type name. As of MySQL 8.0.12, this is permitted only for `SPATIAL` indexes. Prior to 8.0.12, `BTREE` cannot be specified for any storage engine.

**Note**

Use of the `index_type` option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

The following tables show index characteristics for the storage engines that support the `index_type` option.

Table 13.2 InnoDB Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
<code>FULLTEXT</code>	N/A	Yes	Yes	Table	Table
<code>SPATIAL</code>	N/A	No	No	N/A	N/A

Table 13.3 MyISAM Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
<code>FULLTEXT</code>	N/A	Yes	Yes	Table	Table
<code>SPATIAL</code>	N/A	No	No	N/A	N/A

Table 13.4 MEMORY Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
Primary key	<code>HASH</code>	No	No	N/A	N/A
Unique	<code>HASH</code>	Yes	Yes	Index	Index
Key	<code>HASH</code>	Yes	Yes	Index	Index

- `WITH PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. `InnoDB` and `MyISAM` support full-text

parser plugins. See [Full-Text Parser Plugins](#) and [Section 28.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- `COMMENT 'string'`

Index definitions can include an optional comment of up to 1024 characters.

The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

`MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `VISIBLE`, `INVISIBLE`

Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see [Section 8.3.12, “Invisible Indexes”](#).

Table Copying and Locking Options

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.8, “ALTER TABLE Syntax”](#)

13.1.15 CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  COMMENT 'string'
```

```

| LANGUAGE SQL
| [NOT] DETERMINISTIC
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }

routine_body:
    Valid SQL routine statement

```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 28.4, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. They might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine

variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see [Section C.1, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //

mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 23.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by the `CHARACTER SET` attribute.

The *routine_body* consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “Compound-Statement Syntax”](#).

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section C.1, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 23.7, “Binary Logging of Stored Programs”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` attributes are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide explicit `CHARACTER SET` and `COLLATE` attributes for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 10.3.3, “Database Character Set and Collation”](#).

13.1.16 CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)

option:
```

```
{ HOST character-literal
  DATABASE character-literal
  USER character-literal
  PASSWORD character-literal
  SOCKET character-literal
  OWNER character-literal
  PORT numeric-literal }
```

This statement creates the definition of a server for use with the [FEDERATED](#) storage engine. The [CREATE SERVER](#) statement creates a new row in the `servers` table in the `mysql` database. This statement requires the [SUPER](#) privilege.

The *server_name* should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. *server_name* has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The *wrapper_name* is an identifier and may be quoted with single quotation marks.

For each *option* you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

The [OWNER](#) option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The [CREATE SERVER](#) statement creates an entry in the `mysql.servers` table that can later be used with the [CREATE TABLE](#) statement when creating a [FEDERATED](#) table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are [Server_name](#), [Host](#), [Db](#), [Username](#), [Password](#), [Port](#) and [Socket](#).

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a [FEDERATED](#) table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 16.8, “The FEDERATED Storage Engine”](#).

[CREATE SERVER](#) causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

[CREATE SERVER](#) is not written to the binary log, regardless of the logging format that is in use.

13.1.17 CREATE SPATIAL REFERENCE SYSTEM Syntax

```
CREATE OR REPLACE SPATIAL REFERENCE SYSTEM
  srid srs_attribute ...

CREATE SPATIAL REFERENCE SYSTEM
  [IF NOT EXISTS]
```

```

    srid srs_attribute ...

srs_attribute: {
    NAME 'srs_name'
  | DEFINITION 'definition'
  | ORGANIZATION 'org_name' IDENTIFIED BY org_id
  | DESCRIPTION 'description'
}

srid, org_id: 32-bit unsigned integer

```

This statement creates a [spatial reference system](#) (SRS) definition and stores it in the data dictionary. The definition can be inspected using the [INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS](#) table. This statement requires the [SUPER](#) privilege.

If neither [OR REPLACE](#) nor [IF NOT EXISTS](#) is specified, an error occurs if an SRS definition with the SRID value already exists.

With [CREATE OR REPLACE](#) syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```

mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at
least one column depending on it.

```

To identify which column or columns use the SRID, use this query:

```

SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;

```

With [CREATE ... IF NOT EXISTS](#) syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with [CREATE SPATIAL REFERENCE SYSTEM](#).
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the [European Petroleum Survey Group](#).
- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk that the SRIDs will conflict with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.

Attributes for the statement must satisfy these conditions:

- Attributes can be given in any order, but no attribute can be given more than once.
- The [NAME](#) and [DEFINITION](#) attributes are mandatory.
- The [NAME](#) *srs_name* attribute value must be unique. The combination of the [ORGANIZATION](#) *org_name* and *org_id* attribute values must be unique.
- The [NAME](#) *srs_name* attribute value and [ORGANIZATION](#) *org_name* attribute value cannot be empty or begin or end with whitespace.
- String values in attribute specifications cannot contain control characters, including newline.
- The following table shows the maximum lengths for string attribute values.

Table 13.5 CREATE SPATIAL REFERENCE SYSTEM Attribute Lengths

Attribute	Maximum Length (characters)
NAME	80
DEFINITION	4096
ORGANIZATION	256
DESCRIPTION	2048

Here is an example `CREATE SPATIAL REFERENCE SYSTEM` statement. The `DEFINITION` value is reformatted across multiple lines for readability. (For the statement to be legal, the value actually must be given on a single line.)

```
CREATE SPATIAL REFERENCE SYSTEM 4120
NAME 'Greek'
ORGANIZATION 'EPSG' IDENTIFIED BY 4120
DEFINITION
'GEOGCS["Greek",DATUM["Greek",SPHEROID["Bessel 1841",
6377397.155,299.1528128,AUTHORITY["EPSG","7004"]],
AUTHORITY["EPSG","6120"]],PRIMEM["Greenwich",0,
AUTHORITY["EPSG","8901"]],UNIT["degree",0.017453292519943278,
AUTHORITY["EPSG","9122"]],AXIS["Lat",NORTH],AXIS["Lon",EAST],
AUTHORITY["EPSG","4120"]];'
```

The grammar for SRS definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at <http://www.opengeospatial.org/standards/ct>.

MySQL incorporates these changes to the specification:

- Only the `<horz cs>` production rule is implemented (that is, geographic and projected SRSs).
- There is an optional, nonstandard `<authority>` clause for `<parameter>`. This makes it possible to recognize projection parameters by authority instead of name.
- SRS definitions may not contain newlines.

13.1.18 CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
(create_definition,...)
[table_options]

query_expression:
SELECT ... (Some valid select or union statement)

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

For information about the physical representation of a table, see [Section 13.1.18.2, “Files Created by CREATE TABLE”](#).

The original **CREATE TABLE** statement, including all specifications and table options are stored by MySQL when the table is created. For more information, see [Section 13.1.18.1, “CREATE TABLE Statement Retention”](#).

There are several aspects to the **CREATE TABLE** statement, described under the following topics in this section:

- [Table Name](#)

- [Temporary Tables](#)
- [Cloning or Copying a Table](#)
- [Column Data Types and Attributes](#)
- [Indexes and Foreign Keys](#)
- [Table Options](#)
- [Creating Partitioned Tables](#)

Table Name

- *tbl_name*

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#).

- `IF NOT EXISTS`

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see [Section 13.1.18.3, “CREATE TEMPORARY TABLE Syntax”](#).

Cloning or Copying a Table

- `LIKE`

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.18.4, “CREATE TABLE ... LIKE Syntax”](#).

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.18.5, “CREATE TABLE ... SELECT Syntax”](#).

- `IGNORE | REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see [Section 13.1.18.5, “CREATE TABLE ... SELECT Syntax”](#).

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- *data_type*

data_type represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 11, Data Types](#).

- Some attributes do not apply to all data types. [AUTO_INCREMENT](#) applies only to integer and floating-point types. Prior to MySQL 8.0.13, [DEFAULT](#) does not apply to the [BLOB](#), [TEXT](#), [GEOMETRY](#), and [JSON](#) types.
- Character data types ([CHAR](#), [VARCHAR](#), [TEXT](#)) can include [CHARACTER SET](#) and [COLLATE](#) attributes to specify the character set and collation for the column. For details, see [Chapter 10, Character Sets, Collations, Unicode](#). [CHARSET](#) is a synonym for [CHARACTER SET](#). Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 8.0 interprets length specifications in character column definitions in characters. Lengths for [BINARY](#) and [VARBINARY](#) are in bytes.

- For [CHAR](#), [VARCHAR](#), [BINARY](#), and [VARBINARY](#) columns, indexes can be created that use only the leading part of column values, using *col_name(length)* syntax to specify an index prefix length. [BLOB](#) and [TEXT](#) columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for [CHAR](#), [VARCHAR](#), and [TEXT](#) columns, and the first *length* bytes of each column value for [BINARY](#), [VARBINARY](#), and [BLOB](#) columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see [Section 13.1.14, “CREATE INDEX Syntax”](#).

Only the [InnoDB](#) and [MyISAM](#) storage engines support indexing on [BLOB](#) and [TEXT](#) columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

If a specified index prefix exceeds the maximum column data type size, [CREATE TABLE](#) handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
 - For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.
 - [JSON](#) columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the [JSON](#) column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.
- [NOT NULL](#) | [NULL](#)

If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.

In MySQL 8.0, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

- `DEFAULT`

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit `DEFAULT` value, see [Section 11.7, “Data Type Default Values”](#).

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- `AUTO_INCREMENT`

An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See [Section 12.14, “Information Functions”](#), and [Section 27.7.7.38, “mysql_insert_id\(\)”](#).

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See [Section 5.1.10, “Server SQL Modes”](#).

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to `0`. See [Section 5.1.7, “Server System Variables”](#).

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#). For information about `AUTO_INCREMENT` and MySQL Replication, see [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).

- `COMMENT`

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.

- `COLUMN_FORMAT`

Used by NDB Cluster to determine a column's storage format. This option currently has no effect on columns of tables using storage engines other than `NDB`. In MySQL 8.0 and later, `COLUMN_FORMAT` is silently ignored.

- `GENERATED ALWAYS`

Used to specify a generated column expression. For information about [generated columns](#), see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).

[Stored generated columns](#) can be indexed. `InnoDB` supports secondary indexes on [virtual generated columns](#). See [Section 13.1.18.9, “Secondary Indexes and Generated Columns”](#).

Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see [Section 13.1.14, “CREATE INDEX Syntax”](#), and [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#).

- `CONSTRAINT symbol`

If the `CONSTRAINT symbol` clause is given, the *symbol* value, if used, must be unique in the database. A duplicate *symbol* results in an error. If the clause is not given, or a *symbol* is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.

- `PRIMARY KEY`

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 15.8.2.1, “Clustered and Secondary Indexes”](#).)

In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(key_part, ...)` clause.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in [Unique Indexes](#).

In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.6.22, “SHOW INDEX Syntax”](#).

- `KEY | INDEX`

`KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.

- `UNIQUE`

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix length.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in [Unique Indexes](#).

- `FULLTEXT`

A `FULLTEXT` index is a special type of index used for full-text searches. Only the `InnoDB` and `MyISAM` storage engines support `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation. A `WITH PARSER` clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. `InnoDB` and `MyISAM` support full-text parser plugins. See [Full-Text Parser Plugins](#) and [Section 28.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- `SPATIAL`

You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `InnoDB` and `MyISAM` tables, and indexed columns must be declared as `NOT NULL`. See [Section 11.5, “Spatial Data Types”](#).

- `FOREIGN KEY`

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see *reference_definition*, and *reference_option*.

Partitioned tables employing the `InnoDB` storage engine do not support foreign keys. See [Section 22.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- `CHECK`

The `CHECK` clause is parsed but ignored by all storage engines. See [Section 1.8.2.3, “Foreign Key Differences”](#).

- *key_part*

- A *key_part* specification can end with `ASC` or `DESC` to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

- Prefixes, defined by the *length* attribute, can be up to 767 bytes long for [InnoDB](#) tables that use the [REDUNDANT](#) or [COMPACT](#) row format. The prefix length limit is 3072 bytes for [InnoDB](#) tables that use the [DYNAMIC](#) or [COMPRESSED](#) row format. For [MyISAM](#) tables, the prefix length limit is 1000 bytes.

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in [CREATE TABLE](#), [ALTER TABLE](#), and [CREATE INDEX](#) statements are interpreted as number of characters for nonbinary string types ([CHAR](#), [VARCHAR](#), [TEXT](#)) and number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- *index_type*

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is [USING type_name](#).

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for [USING](#) is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- *index_option*

index_option values specify additional options for an index.

- [KEY_BLOCK_SIZE](#)

For [MyISAM](#) tables, [KEY_BLOCK_SIZE](#) optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A [KEY_BLOCK_SIZE](#) value specified for an individual index definition overrides the table-level [KEY_BLOCK_SIZE](#) value.

For information about the table-level [KEY_BLOCK_SIZE](#) attribute, see [Table Options](#).

- [WITH_PARSER](#)

The [WITH_PARSER](#) option can only be used with [FULLTEXT](#) indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. [InnoDB](#) and [MyISAM](#) support full-text parser plugins. If you have a [MyISAM](#) table with an associated full-text parser plugin, you can convert the table to [InnoDB](#) using [ALTER TABLE](#).

- [COMMENT](#)

In MySQL 8.0, index definitions can include an optional comment of up to 1024 characters.

You can set the [InnoDB MERGE_THRESHOLD](#) value for an individual index using the *index_option COMMENT* clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

For more information about permissible *index_option* values, see [Section 13.1.14, “CREATE INDEX Syntax”](#). For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

- *reference_definition*

For *reference_definition* syntax details and examples, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in *InnoDB*, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

InnoDB tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys. For more detailed information and examples, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in *InnoDB*, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See [Section 1.8.2.3, “Foreign Key Differences”](#).

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including *InnoDB*, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. *InnoDB* essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, *InnoDB* does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

- *reference_option*

For information about the `RESTRICT`, `CASCADE`, `SET NULL`, `NO ACTION`, and `SET DEFAULT` options, see [Section 13.1.18.6, “Using FOREIGN KEY Constraints”](#).

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `ENGINE`

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

Storage Engine	Description
InnoDB	Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine , and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.
MyISAM	The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine” .
MEMORY	The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine” .
CSV	Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine” .
ARCHIVE	The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine” .
EXAMPLE	An example engine. See Section 16.9, “The EXAMPLE Storage Engine” .
FEDERATED	Storage engine that accesses remote tables. See Section 16.8, “The FEDERATED Storage Engine” .
HEAP	This is a synonym for MEMORY.
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 16.7, “The MERGE Storage Engine” .

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing `NO_ENGINE_SUBSTITUTION` from the server SQL mode (see [Section 5.1.10, “Server SQL Modes”](#)) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the `default_storage_engine` system variable. When `NO_ENGINE_SUBSTITUTION` is disabled, a warning occurs if the storage engine specification is not honored.

- **AUTO_INCREMENT**

The initial `AUTO_INCREMENT` value for the table. In MySQL 8.0, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files

that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See [Section 5.1.7, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- `[DEFAULT] CHARACTER SET`

Specifies a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (MyISAM only.)

- `[DEFAULT] COLLATE`

Specifies a default collation for the table.

- `COMMENT`

A comment for the table, up to 2048 characters long.

You can set the `InnoDB MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `COMPRESSION`

The compression algorithm used for page level compression for `InnoDB` tables. Supported values include `Zlib`, `LZ4`, and `None`. The `COMPRESSION` attribute was introduced with the transparent page compression feature. Page compression is only supported with `InnoDB` tables that reside in `file-per-table` tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- `CONNECTION`

The connection string for a `FEDERATED` table.

**Note**

Older versions of MySQL used a `COMMENT` option for the connection string.

- `DATA DIRECTORY, INDEX DIRECTORY`

For `InnoDB`, the `DATA DIRECTORY='directory'` clause permits creating a file-per-table tablespace outside of the data directory. The tablespace data file is created in the specified directory, inside a subdirectory with the same name as the schema. The `innodb_file_per_table` variable must be enabled to use the `DATA DIRECTORY` clause. The full directory path must be specified. For more information, see [Section 15.7.5, “Creating a Tablespace Outside of the Data Directory”](#).

When creating `MyISAM` tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a `MyISAM` table's data file and index file, respectively. Unlike `InnoDB` tables, MySQL does not create subdirectories that correspond

to the database name when creating a [MyISAM](#) table with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option. Files are created in the directory that is specified.

You must have the [FILE](#) privilege to use the [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) table option.

**Important**

Table-level [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a [MyISAM](#) table is created with no [DATA DIRECTORY](#) option, the `.MYD` file is created in the database directory. By default, if [MyISAM](#) finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no [INDEX DIRECTORY](#) option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case [MyISAM](#) will not overwrite existing files and returns an error instead.

If a [MyISAM](#) table is created with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option and an existing `.MYD` or `.MYI` file is found, [MyISAM](#) always returns an error. It will not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with [DATA DIRECTORY](#) or [INDEX DIRECTORY](#). This includes partitioned tables and individual table partitions. (See Bug #32167.)

- [DELAY_KEY_WRITE](#)

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 5.1.7, “Server System Variables”](#). ([MyISAM](#) only.)

- [ENCRYPTION](#)

Set the [ENCRYPTION](#) option to 'Y' to enable page-level data encryption for an [InnoDB](#) table created in a [file-per-table](#) tablespace. Option values are not case-sensitive. The [ENCRYPTION](#) option was introduced with the [InnoDB](#) tablespace encryption feature; see [Section 15.7.11, “InnoDB Tablespace Encryption”](#). A keyring plugin must be installed and configured to use the [ENCRYPTION](#) option.

- [INSERT_METHOD](#)

If you want to insert data into a [MERGE](#) table, you must specify with [INSERT_METHOD](#) the table into which the row should be inserted. [INSERT_METHOD](#) is an option useful for [MERGE](#) tables only. Use a value of [FIRST](#) or [LAST](#) to have inserts go to the first or last table, or a value of [NO](#) to prevent inserts. See [Section 16.7, “The MERGE Storage Engine”](#).

- [KEY_BLOCK_SIZE](#)

For [MyISAM](#) tables, [KEY_BLOCK_SIZE](#) optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A [KEY_BLOCK_SIZE](#) value specified for an individual index definition overrides the table-level [KEY_BLOCK_SIZE](#) value.

For [InnoDB](#) tables, [KEY_BLOCK_SIZE](#) specifies the [page](#) size in kilobytes to use for [compressed InnoDB](#) tables. The [KEY_BLOCK_SIZE](#) value is treated as a hint; a different size could

be used by `InnoDB` if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See [Section 15.9.1, “InnoDB Table Compression”](#) for more information.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

The `Create_options` column in response to `SHOW TABLE STATUS` reports the actual `KEY_BLOCK_SIZE` used by the table, as does `SHOW CREATE TABLE`.

`InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

`KEY_BLOCK_SIZE` is not supported with 32KB and 64KB `innodb_page_size` values. `InnoDB` table compression does not support these pages sizes.

`InnoDB` does not support the `KEY_BLOCK_SIZE` option when creating temporary tables.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored.

When executing a `CREATE TABLE` statement with `strict mode` disabled, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The actual row format of the table is reported in the `Row_format` and `Create_options` columns in response to `SHOW TABLE STATUS`. `SHOW CREATE TABLE` also reports the actual row format of the table.

Row format choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).
- For more efficient `InnoDB` storage of data types, especially `BLOB` types, use the `DYNAMIC`. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#) for requirements associated with the `DYNAMIC` row format.
- To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED`. The `ROW_FORMAT=COMPRESSED` option is not supported when creating temporary tables. See [Section 15.9, “InnoDB Table and Page Compression”](#) for requirements associated with the `COMPRESSED` row format.
- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, `InnoDB` returns an error.
- For additional information about `InnoDB` row formats, see [Section 15.10, “InnoDB Row Storage and Row Formats”](#).

For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the

`innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_SAMPLE_PAGES`

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `TABLESPACE`

The `TABLESPACE` clause can be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

```
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

The general tablespace that you specify must exist prior to using the `TABLESPACE` clause. For information about general tablespaces, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

The *tablespace_name* is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “innodb_” are reserved for special use.

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using `TABLESPACE [=] innodb_system`, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using `TABLESPACE [=] innodb_system`.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

Note

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` clause.

Note

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

- `UNION`

Used to access a collection of identical `MyISAM` tables as one. This works only with `MERGE` tables. See [Section 16.7, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

Creating Partitioned Tables

partition_options can be used to control partitioning of the table created with `CREATE TABLE`.

Not all options shown in the syntax for *partition_options* at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 22, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.8, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 22.3, “Partition Management”](#).

- `PARTITION BY`

If used, a *partition_options* clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to *num*, where *num* is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression (*expr*) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- `HASH(expr)`

Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 22.2.4, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 22.2.4.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`

This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 22.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
```

The `ALGORITHM={1|2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ( )
  PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11,

be sure to consult [Changes in MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing [KEY](#) partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, [ALGORITHM=1](#) is shown when necessary in the output of [SHOW CREATE TABLE](#) using versioned comments in the same manner as [mysqldump](#). [ALGORITHM=2](#) is always omitted from [SHOW CREATE TABLE](#) output, even if this option was specified when creating the original table.

You may not use either [VALUES LESS THAN](#) or [VALUES IN](#) clauses with [PARTITION BY KEY](#).

- [RANGE\(expr\)](#)

In this case, *expr* shows a range of values using a set of [VALUES LESS THAN](#) operators. When using range partitioning, you must define at least one partition using [VALUES LESS THAN](#). You cannot use [VALUES IN](#) with range partitioning.

Note

For tables partitioned by [RANGE](#), [VALUES LESS THAN](#) must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.0, you can overcome this limitation in a table that is defined using [PARTITION BY RANGE COLUMNS](#), as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 to 1994
2	1995 to 1998
3	1999 to 2002
4	2003 to 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the [CREATE TABLE](#) statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

[PARTITION ... VALUES LESS THAN ...](#) statements work in a consecutive fashion. [VALUES LESS THAN MAXVALUE](#) works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 22.2.1, “RANGE Partitioning”](#), and [Section 22.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It

is similar to [RANGE](#), except that only [VALUES IN](#) may be used to specify permissible values for each partition.

[VALUES IN](#) is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using [VALUES IN](#). You cannot use [VALUES LESS THAN](#) with [PARTITION BY LIST](#).

Note

For tables partitioned by [LIST](#), the value list used with [VALUES IN](#) must consist of integer values only. In MySQL 8.0, you can overcome this limitation using partitioning by [LIST COLUMNS](#), which is described later in this section.

- [LIST COLUMNS\(column_list\)](#)

This variant on [LIST](#) facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as [WHERE a = 5 AND b = 5](#) or [WHERE a = 1 AND b = 10 AND c = 5](#)). It enables you to specify values in multiple columns by using a list of columns in the [COLUMNS](#) clause and a set of column values in each [PARTITION ... VALUES IN \(value_list\)](#) partition definition clause.

The rules governing regarding data types for the column list used in [LIST COLUMNS\(column_list\)](#) and the value list used in [VALUES IN\(value_list\)](#) are the same as those for the column list used in [RANGE COLUMNS\(column_list\)](#) and the value list used in [VALUES LESS THAN\(value_list\)](#), respectively, except that in the [VALUES IN](#) clause, [MAXVALUE](#) is not permitted, and you may use [NULL](#).

There is one important difference between the list of values used for [VALUES IN](#) with [PARTITION BY LIST COLUMNS](#) as opposed to when it is used with [PARTITION BY LIST](#). When used with [PARTITION BY LIST COLUMNS](#), each element in the [VALUES IN](#) clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the [COLUMNS](#) clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the [column_list](#) and in the elements making up the [value_list](#) is 16.

The table defined by the following [CREATE TABLE](#) statement provides an example of a table using [LIST COLUMNS](#) partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
```

```
PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- **PARTITIONS** *num*

The number of partitions may optionally be specified with a **PARTITIONS** *num* clause, where *num* is the number of partitions. If both this clause *and* any **PARTITION** clauses are used, *num* must be equal to the total number of any partitions that are declared using **PARTITION** clauses.

Note

Whether or not you use a **PARTITIONS** clause in creating a table that is partitioned by **RANGE** or **LIST**, you must still include at least one **PARTITION VALUES** clause in the table definition (see below).

- **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional **SUBPARTITION BY** clause. Subpartitioning may be done by **HASH** or **KEY**. Either of these may be **LINEAR**. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by **LIST** or **RANGE**.)

The number of subpartitions can be indicated using the **SUBPARTITIONS** keyword followed by an integer value.

- Rigorous checking of the value used in **PARTITIONS** or **SUBPARTITIONS** clauses is applied and this value must adhere to the following rules:
 - The value must be a positive, nonzero integer.
 - No leading zeros are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, **PARTITIONS 0.2E+01** is not permitted, even though **0.2E+01** evaluates to **2**. (Bug #15890)
- *partition_definition*

Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

- **PARTITION** *partition_name*

Specifies a logical name for the partition.

- **VALUES**

For range partitioning, each partition must include a **VALUES LESS THAN** clause; for list partitioning, you must specify a **VALUES IN** clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 22, Partitioning](#), for syntax examples.

- **[STORAGE] ENGINE**

MySQL accepts a **[STORAGE] ENGINE** option for both **PARTITION** and **SUBPARTITION**. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error **ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL**.

- **COMMENT**

An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- **DATA DIRECTORY** and **INDEX DIRECTORY**

DATA DIRECTORY and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system path names.

You must have the **FILE** privilege to use the **DATA DIRECTORY** or **INDEX DIRECTORY** partition option.

Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

DATA DIRECTORY and **INDEX DIRECTORY** behave in the same way as in the **CREATE TABLE** statement's *table_option* clause as used for **MyISAM** tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

The **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored for creating partitioned tables if **NO_DIR_IN_CREATE** is in effect.

- **MAX_ROWS** and **MIN_ROWS**

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for *max_number_of_rows* and *min_number_of_rows* must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- **TABLESPACE**

May be used to designate an **InnoDB** file-per-table tablespace for the partition by specifying **TABLESPACE `innodb_file_per_table`**. All partitions must belong to the same storage engine.

Placing [InnoDB](#) table partitions in shared [InnoDB](#) tablespaces is not supported. Shared tablespaces include the [InnoDB](#) system tablespace and general tablespaces.

- *subpartition_definition*

The partition definition may optionally contain one or more *subpartition_definition* clauses. Each of these consists at a minimum of the [SUBPARTITION](#) *name*, where *name* is an identifier for the subpartition. Except for the replacement of the [PARTITION](#) keyword with [SUBPARTITION](#), the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by [HASH](#) or [KEY](#), and can be done only on [RANGE](#) or [LIST](#) partitions. See [Section 22.2.6, “Subpartitioning”](#).

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (  
  s1 INT,  
  s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) (  
  PARTITION p1 VALUES IN (1)  
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see [Section 22.6.3, “Partitioning Limitations Relating to Functions”](#)). The preceding example demonstrates this technique: [EXP\(\)](#) cannot be used directly in the [PARTITION BY](#) clause, but a generated column defined using [EXP\(\)](#) is permitted.

13.1.18.1 CREATE TABLE Statement Retention

The original [CREATE TABLE](#) statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an [ALTER TABLE](#) statement, the original table options specified are retained. This enables you to change between [InnoDB](#) and [MyISAM](#) table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured, the active table definition (accessible through [DESCRIBE](#) or with [SHOW TABLE STATUS](#)) and the table creation string (accessible through [SHOW CREATE TABLE](#)) may report different values.

For [InnoDB](#) tables, [SHOW CREATE TABLE](#) and the [Create_options](#) column reported by [SHOW TABLE STATUS](#) show the actual [ROW_FORMAT](#) and [KEY_BLOCK_SIZE](#) attributes used by the table. In previous MySQL releases, the originally specified values for these attributes were reported.

13.1.18.2 Files Created by CREATE TABLE

For an [InnoDB](#) table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in an [ibd file](#) in the database directory. When an [InnoDB](#) table is created in the system tablespace, table data and indexes are stored in the [ibdata* files](#) that represent the system tablespace. The [innodb_file_per_table](#) option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The [TABLESPACE](#) option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the [innodb_file_per_table](#) setting.

For [MyISAM](#) tables, the storage engine creates data and index files. Thus, for each [MyISAM](#) table *tbl_name*, there are two disk files.

File	Purpose
<i>tbl_name</i> .MYD	Data file
<i>tbl_name</i> .MYI	Index file

[Chapter 16, Alternative Storage Engines](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

13.1.18.3 CREATE TEMPORARY TABLE Syntax

You can use the [TEMPORARY](#) keyword when creating a table. A [TEMPORARY](#) table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-[TEMPORARY](#) table of the same name. (The existing table is hidden until the temporary table is dropped.)

[InnoDB](#) does not support compressed temporary tables. When [innodb_strict_mode](#) is enabled (the default), [CREATE TEMPORARY TABLE](#) returns an error if [ROW_FORMAT=COMPRESSED](#) or [KEY_BLOCK_SIZE](#) is specified. If [innodb_strict_mode](#) is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The [innodb_file_per-table](#) option does not affect the creation of [InnoDB](#) temporary tables.

[CREATE TABLE](#) causes an implicit commit, except when used with the [TEMPORARY](#) keyword. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

[TEMPORARY](#) tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any [TEMPORARY](#) tables created within that database. Also, you can create a [TEMPORARY](#) table in a nonexistent database if you qualify the table name with the database name in the [CREATE TABLE](#) statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the [CREATE TEMPORARY TABLES](#) privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as [DROP TABLE](#), [INSERT](#), [UPDATE](#), or [SELECT](#).

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the [CREATE TEMPORARY TABLES](#) privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have [CREATE TEMPORARY TABLES](#) and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use [CREATE TEMPORARY TABLE ... LIKE](#) to create an empty table based on the definition of a table that resides in the [mysql](#) tablespace, [InnoDB](#) system tablespace ([innodb_system](#)), or a general tablespace. The tablespace definition for such a table includes a [TABLESPACE](#) attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

**Note**

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

13.1.18.4 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE`. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... LIKE`, the destination table preserves expression default values from the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

Tables created in the `mysql` tablespace, the `InnoDB` system tablespace (`innodb_system`), or general tablespaces include a `TABLESPACE` attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression, `CREATE TABLE ... LIKE` preserves the `TABLESPACE` attribute and creates the table in the defined tablespace regardless of the `innodb_file_per_table` setting. To avoid the `TABLESPACE` attribute when creating an empty table based on the definition of such a table, use this syntax instead:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

13.1.18.5 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
->     PRIMARY KEY (a), KEY(b))
->     ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n |
+-----+-----+
| NULL   | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also [Section 17.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication"](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

For `CREATE TABLE ... SELECT`, the destination table does preserve expression default values from the original table.

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retrained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

13.1.18.6 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (col_name, ...)
  REFERENCES tbl_name (col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

index_name represents a foreign key ID. The *index_name* value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

The `FOREIGN KEY index_name` value must be unique in the database.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a [parent table](#) that holds the central data values, and a [child table](#) with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be `TEMPORARY` tables.

In MySQL 8.0, creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in [Section 13.1.8, “ALTER TABLE Syntax”](#).
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
- `InnoDB` permits a foreign key to reference any column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the `CONSTRAINT symbol` clause is given, the `symbol` value, if used, must be unique in the database. A duplicate `symbol` will result in an error similar to: `ERROR 1022 (2300): Can't write; duplicate key in table '#sql- 464_1'`. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.
- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

Additional aspects of `FOREIGN KEY` constraint usage are described under the following topics in this section:

- [Referential Actions](#)
- [Examples of Foreign Key Clauses](#)
- [Adding Foreign Keys](#)
- [Dropping Foreign Keys](#)
- [Foreign Keys and Other MySQL Statements](#)
- [Foreign Keys and the ANSI/ISO SQL Standard](#)
- [Foreign Key Metadata](#)

- [Foreign Key Errors](#)

Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an `UPDATE` or `DELETE` operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. MySQL supports five options regarding the action to be taken, listed here:

- **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, do not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

If a `FOREIGN KEY` clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an `ON UPDATE CASCADE` or `ON DELETE CASCADE` subclause defined for one `FOREIGN KEY` clause must be defined for the other in order for cascading operations to succeed. If an `ON UPDATE CASCADE` or `ON DELETE CASCADE` subclause is only defined for one `FOREIGN KEY` clause, cascading operations fail with an error.

Note

Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to `NULL`. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as `NOT NULL`*.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause.
- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to `RESTRICT`. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` is the same as `RESTRICT`.
- **SET DEFAULT**: This action is recognized by the MySQL parser, but `InnoDB` rejects table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

For an `ON DELETE` or `ON UPDATE` that is not specified, the default action is always `RESTRICT`.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

A foreign key constraint on a stored generated column cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.

A foreign key constraint cannot reference a virtual generated column.

For [InnoDB](#) restrictions related to foreign keys and generated columns, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

Examples of Foreign Key Clauses

Here is a simple example that relates [parent](#) and [child](#) tables through a single-column foreign key:

```
CREATE TABLE parent (  
    id INT NOT NULL,  
    PRIMARY KEY (id)  
) ENGINE=INNODB;  
  
CREATE TABLE child (  
    id INT,  
    parent_id INT,  
    INDEX par_ind (parent_id),  
    FOREIGN KEY (parent_id)  
        REFERENCES parent(id)  
        ON DELETE CASCADE  
) ENGINE=INNODB;
```

A more complex example in which a [product_order](#) table has foreign keys for two other tables. One foreign key references a two-column index in the [product](#) table. The other references a single-column index in the [customer](#) table:

```
CREATE TABLE product (  
    category INT NOT NULL, id INT NOT NULL,  
    price DECIMAL,  
    PRIMARY KEY(category, id)  
) ENGINE=INNODB;  
  
CREATE TABLE customer (  
    id INT NOT NULL,  
    PRIMARY KEY (id)  
) ENGINE=INNODB;  
  
CREATE TABLE product_order (  
    no INT NOT NULL AUTO_INCREMENT,  
    product_category INT NOT NULL,  
    product_id INT NOT NULL,  
    customer_id INT NOT NULL,  
  
    PRIMARY KEY(no),  
    INDEX (product_category, product_id),  
    INDEX (customer_id),  
  
    FOREIGN KEY (product_category, product_id)  
        REFERENCES product(category, id)  
        ON UPDATE CASCADE ON DELETE RESTRICT,  
  
    FOREIGN KEY (customer_id)  
        REFERENCES customer(id)  
) ENGINE=INNODB;
```

Adding Foreign Keys

You can add a new foreign key constraint to an existing table by using [ALTER TABLE](#). The syntax relating to foreign keys for this statement is shown here:

```
ALTER TABLE tbl\_name  
    ADD [CONSTRAINT [symbol]] FOREIGN KEY  
    [index\_name] (col\_name, ...)
```

```
REFERENCES tbl_name (col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk_symbol* value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a `SHOW CREATE TABLE` statement, as shown here:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY  (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=utf8mb4
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but is unsupported for `ALTER TABLE ... ALGORITHM=COPY`.

In MySQL 8.0, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.

Foreign Keys and Other MySQL Statements

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

You can find information about foreign keys used by [InnoDB](#) tables in the [INNODB_FOREIGN](#) and [INNODB_FOREIGN_COLS](#) tables, also in the [INFORMATION_SCHEMA](#) database.

[mysqldump](#) produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, [mysqldump](#) automatically includes a statement in the dump output to set [foreign_key_checks](#) to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting [foreign_key_checks](#) to 0 can also be useful for ignoring foreign key constraints during [LOAD DATA](#) and [ALTER TABLE](#) operations. However, even if [foreign_key_checks](#) = 0, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, [ALTER TABLE](#) cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue [DROP TABLE](#) for a table that is referenced by a [FOREIGN KEY](#) constraint, unless you do [SET foreign_key_checks = 0](#). When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an [ALTER TABLE](#) fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For [InnoDB](#) tables, you can obtain a detailed explanation of the most recent [InnoDB](#) foreign key error in the MySQL Server, by checking the output of [SHOW ENGINE INNODB STATUS](#).

MySQL extends metadata locks, as necessary, to tables that are related by a foreign key constraint. Extending metadata locks prevents conflicting DML and DDL operations from executing concurrently on related tables. This feature also enables updates to foreign key metadata when a parent table is modified. In earlier MySQL releases, foreign key metadata, which is owned by the child table, could not be updated safely.

If a table is locked explicitly with [LOCK TABLES](#), any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock ([LOCK TABLES READ](#)) is taken on related tables. For cascading updates, a shared-nothing write lock ([LOCK TABLES WRITE](#)) is taken on related tables that are involved in the operation.

Foreign Keys and the ANSI/ISO SQL Standard

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including [InnoDB](#), recognizes or enforces the [MATCH](#) clause used in referential-integrity constraint definitions. Use of an explicit [MATCH](#) clause will not have the specified effect, and also causes [ON DELETE](#) and [ON UPDATE](#) clauses to be ignored. For these reasons, specifying [MATCH](#) should be avoided.

The [MATCH](#) clause in the SQL standard controls how [NULL](#) values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined

by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

Furthermore, MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.

Foreign Key Metadata

The `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table identifies the key columns that have constraints. Metadata specific to `InnoDB` foreign keys is found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

Foreign Key Errors

In the event of a foreign key error involving `InnoDB` tables (usually Error 150 in the MySQL Server), information about the most recent `InnoDB` foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.

Warning

If a user has table-level privileges for all parent tables, `ER_NO_REFERENCED_ROW_2` and `ER_ROW_IS_REFERENCED_2` error messages for foreign key operations expose information about parent tables. If a user does not have table-level privileges for all parent tables, more generic error messages are displayed instead (`ER_NO_REFERENCED_ROW` and `ER_ROW_IS_REFERENCED`).

An exception is that, for stored programs defined to execute with `DEFINER` privileges, the user against which privileges are assessed is the user in the program `DEFINER` clause, not the invoking user. If that user has table-level parent table privileges, parent table information is still displayed. In this case, it is the responsibility of the stored program creator to hide the information by including appropriate condition handlers.

13.1.18.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.10, “Using Data Types from Other Database Engines”](#).

- If you include a [USING](#) clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a [VARCHAR](#) column with a length specification greater than 65535 is converted to [TEXT](#), and a [VARBINARY](#) column with a length specification greater than 65535 is converted to [BLOB](#). Otherwise, an error occurs in either of these cases.
- Specifying the [CHARACTER SET binary](#) attribute for a character data type causes the column to be created as the corresponding binary data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using [myisampack](#). See [Section 16.2.3.3, “Compressed Table Characteristics”](#).

13.1.18.8 CREATE TABLE and Generated Columns

[CREATE TABLE](#) supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

The following simple example shows a table that stores the lengths of the sides of right triangles in the [sidea](#) and [sideb](#) columns, and computes the length of the hypotenuse in [sidec](#) (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle (
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-----+-----+-----+
| sidea | sideb | sidec |
+-----+-----+-----+
|      1 |      1 | 1.4142135623730951 |
```

3	4	5
6	8	10
+-----+-----+-----+		

Any application that uses the `triangle` table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expression)
  [VIRTUAL | STORED] [NOT NULL | NULL]
  [UNIQUE [KEY]] [[PRIMARY] KEY]
  [COMMENT 'string']
```

`AS (expression)` indicates that the column is generated and defines the expression used to compute column values. `AS` may be preceded by `GENERATED ALWAYS` to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The `VIRTUAL` or `STORED` keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL:** Column values are not stored, but are evaluated when rows are read, immediately after any `BEFORE` triggers. A virtual column takes no storage.

`InnoDB` supports secondary indexes on virtual columns. See [Section 13.1.18.9, “Secondary Indexes and Generated Columns”](#).

- **STORED:** Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is `VIRTUAL` if neither keyword is specified.

It is permitted to mix `VIRTUAL` and `STORED` columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be `NULL`, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that fail this definition: `CONNECTION_ID()`, `CURRENT_USER()`, `NOW()`.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.
- The `AUTO_INCREMENT` attribute cannot be used in a generated column definition.
- An `AUTO_INCREMENT` column cannot be used as a base column in a generated column definition.
- If expression evaluation causes truncation or provides incorrect input to a function, the `CREATE TABLE` statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

**Note**

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See [Creating Partitioned Tables](#).

A foreign key constraint on a stored generated column cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.

A foreign key constraint cannot reference a virtual generated column.

For InnoDB restrictions related to foreign keys and generated columns, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns.

For `INSERT`, `REPLACE`, and `UPDATE`, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is `DEFAULT`.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.
- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as `JSON` columns; see [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see [Section 8.3.11, “Optimizer Use of Generated Column Indexes”](#).

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```
SELECT CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;

SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```
CREATE TABLE t1 (
  first_name VARCHAR(10),
  last_name VARCHAR(10),
  full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
);

SELECT full_name FROM t1;
```

13.1.18.9 Secondary Indexes and Generated Columns

InnoDB supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as **UNIQUE**.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a **covering index** (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during **INSERT** and **UPDATE** operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated *stored* columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for **COMPACT** and **REDUNDANT** row formats, and 3072 bytes for **DYNAMIC** and **COMPRESSED** row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, **JSON** columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```
mysql> CREATE TABLE jemp (
->   c JSON,
->   g INT GENERATED ALWAYS AS (c->"$.id"),
->   INDEX i (g)
```

```

-> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES
>   ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
>   ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c->>"$.name" AS name
>       FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT c->>"$.name" AS name
>       FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: jemp
  partitions: NULL
         type: range
possible_keys: i
          key: i
        key_len: 5
          ref: NULL
         rows: 2
   filtered: 100.00
      Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name'))
AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)

```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

When you use [EXPLAIN](#) on a [SELECT](#) or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using [JSON_EXTRACT\(\)](#) and (if needed) [JSON_UNQUOTE\(\)](#) instead, as shown here in the output from [SHOW WARNINGS](#) immediately following this [EXPLAIN](#) statement:

```

mysql> EXPLAIN SELECT c->>"$.name"
>       FROM jemp WHERE g > 2 ORDER BY c->>"$.name"\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: jemp
  partitions: NULL
         type: range
possible_keys: i
          key: i
        key_len: 5
          ref: NULL
         rows: 2
   filtered: 100.00

```

```

      Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name')) AS
`c->>$.name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by
json_extract(`test`.`jemp`.`c`, '$.name')
1 row in set (0.00 sec)

```

See the descriptions of the `->` and `->>` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

13.1.19 CREATE TABLESPACE Syntax

```

CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENCRYPTION [=] {'Y' | 'N'}]
  [ENGINE [=] engine_name]

```

This statement is used to create an `InnoDB` tablespace. An `InnoDB` tablespace created using `CREATE TABLESPACE` is referred to as *general tablespace*.

A general tablespace is a shared tablespace, similar to the system tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can also be created in a location relative to or independent of the MySQL data directory.

After creating an `InnoDB` general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace.

For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

Note

`CREATE TABLESPACE` is supported with `InnoDB`. In earlier releases, `CREATE TABLESPACE` only supported `NDB`, which is the MySQL NDB Cluster storage engine.

Options

- **ADD DATAFILE:** Defines the name of the tablespace data file. A data file must be specified with the `CREATE TABLESPACE` statement, and the data file name must have a `.ibd` extension. An `InnoDB` general tablespace only supports a single data file.

To place the data file in a location outside of the MySQL data directory (`DATADIR`), include an absolute directory path or a path relative to the MySQL data directory. If you do not specify a path, the general tablespace is created in the MySQL data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist and must be known to `InnoDB` prior to creating the tablespace. To make an unknown directory known to `InnoDB`, add the directory to

the `innodb_directories` argument value. `innodb_directories` is a read-only startup option. Configuring it requires restarting the server.

The `file_name`, including the path (optional), must be quoted with single or double quotations marks. File names (not counting the “.ibd” extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

- `FILE_BLOCK_SIZE`: Defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If you do not specify this option, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. `FILE_BLOCK_SIZE` is required when you intend to use the tablespace for storing compressed InnoDB tables (`ROW_FORMAT=COMPRESSED`). In this case, you must define the tablespace `FILE_BLOCK_SIZE` when creating the tablespace.

If `FILE_BLOCK_SIZE` is equal `innodb_page_size`, the tablespace can contain only tables having an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats). Tables with a `COMPRESSED` row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K`, and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

- The `ENCRYPTION` option is used to enable or disable page-level data encryption for an InnoDB general tablespace. Option values are not case-sensitive. Encryption support for general tablespaces was introduced in MySQL 8.0.13. A keyring plugin must be installed and configured to use the `ENCRYPTION` option.

When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted general tablespace is encrypted.

For more information, see [Section 15.7.11, “InnoDB Tablespace Encryption”](#)

- `ENGINE`: Defines the storage engine which uses the tablespace, where `engine_name` is the name of the storage engine. Currently, only the InnoDB storage engine is supported. `ENGINE = InnoDB` must be defined as part of the `CREATE TABLESPACE` statement or InnoDB must be defined as the default storage engine (`default_storage_engine=InnoDB`).

Notes

- `tablespace_name` is a case-sensitive identifier for the tablespace. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with `innodb_` are either not permitted or are reserved for special use.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- General tablespaces support the addition of tables of any row format using `CREATE TABLE ... TABLESPACE`. `innodb_file_per_table` does not need to be enabled.
- `innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of `innodb_strict_mode`. If `CREATE TABLESPACE` parameters are incorrect or incompatible, the operation fails regardless of the `innodb_strict_mode` setting.

When a table is added to a general tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE`, `innodb_strict_mode` is ignored but the statement is evaluated as if `innodb_strict_mode` is enabled.

- Use `DROP TABLESPACE` to remove a general tablespace. All tables must be dropped from a general tablespace using `DROP TABLE` prior to dropping the tablespace.
- All parts of a table added to a general tablespace reside in the general tablespace, including indexes and `BLOB` pages.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd` data file which can only be used for new `InnoDB` data. Space is not released back to the operating system as it is for file-per-table tablespaces.
- A general tablespace is not associated with any database or schema.
- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.
- A generated or existing tablespace cannot be changed to a general tablespace.
- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.
- `mysqldump` and `mysqlpump` do not dump `InnoDB CREATE TABLESPACE` statements.

Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.00 sec)
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

13.1.20 CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  [trigger_order]
  trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

trigger_order: { FOLLOWS | PRECEDES } other_trigger_name
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl_name*, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see [Section 23.3.1, “Trigger Syntax and Examples”](#).

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. The statement might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

trigger_time is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use `BEFORE` triggers to convert values inappropriate for the column type to valid values.

trigger_event indicates the kind of operation that activates the trigger. These *trigger_event* values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger activates whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger activates whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The *trigger_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or

both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

**Note**

Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a `trigger_order` clause that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns. For information about generated columns, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:

- The `TRIGGER` privilege for the subject table.
- The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
- The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
- Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 13.3.6.2, “LOCK TABLES and Triggers”](#).

For additional discussion of trigger use, see [Section 23.3.1, “Trigger Syntax and Examples”](#).

13.1.21 CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see [Section C.5, “Restrictions on Views”](#).

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP`

privilege for the view. `CREATE VIEW` might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
| 3    | 50    | 150   |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.

- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `FOR SHARE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If the `DEFINER` clause is present, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only valid `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

- Although it is possible to create a view with a nonexistent `DEFINER` account, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about view security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a view definition, `CURRENT_USER` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, `SELECT`) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. For more information, see [Section 23.5.2, “View Processing Algorithms”](#), as well as [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADE` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADE` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADE`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see [Section 23.5.3, “Updatable and Insertable Views”](#), and [Section 23.5.4, “The View WITH CHECK OPTION Clause”](#).

13.1.22 DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important

When a database is dropped, privileges granted specifically for the database are *not* automatically dropped. They must be dropped manually. See [Section 13.7.1.6, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following list:

- `.BAK`
- `.DAT`
- `.HSH`
- `.MRG`
- `.MYD`
- `.MYI`
- `.cfg`
- `.db`
- `.ibd`
- `.ndb`

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See [Section 13.1.18.3, “CREATE TEMPORARY TABLE Syntax”](#).

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.23 DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

13.1.24 DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 13.7.4.2, “DROP FUNCTION Syntax”](#).

13.1.25 DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
    [algorithm_option | lock_option] ...

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

DROP INDEX drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an **ALTER TABLE** statement to drop the index. See [Section 13.1.8, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always **PRIMARY**, which must be specified as a quoted identifier because **PRIMARY** is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

ALGORITHM and **LOCK** clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the **ALTER TABLE** statement. For more information, see [Section 13.1.8, “ALTER TABLE Syntax”](#).

13.1.26 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the **ALTER ROUTINE** privilege for the routine. (If the **automatic_sp_privileges** system variable is enabled, that privilege and **EXECUTE** are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).)

The **IF EXISTS** clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with **SHOW WARNINGS**.

DROP FUNCTION is also used to drop user-defined functions (see [Section 13.7.4.2, “DROP FUNCTION Syntax”](#)).

13.1.27 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server_name*. The corresponding row in the **mysql.servers** table is deleted. This statement requires the **SUPER** privilege.

Dropping a server for a table does not affect any **FEDERATED** tables that used this connection information when they were created. See [Section 13.1.16, “CREATE SERVER Syntax”](#).

DROP SERVER causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

DROP SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.28 DROP SPATIAL REFERENCE SYSTEM Syntax

```
DROP SPATIAL REFERENCE SYSTEM
  [IF EXISTS]
  srid

srid: 32-bit unsigned integer
```

This statement removes a [spatial reference system](#) (SRS) definition from the data dictionary. It requires the [SUPER](#) privilege.

Example:

```
DROP SPATIAL REFERENCE SYSTEM 4120;
```

If no SRS definition with the SRID value exists, an error occurs unless [IF EXISTS](#) is specified. In that case, a warning occurs rather than an error.

If the SRID value is used by some column in an existing table, an error occurs. For example:

```
mysql> DROP SPATIAL REFERENCE SYSTEM 4326;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at
least one column depending on it.
```

To identify which column or columns use the SRID, use this query:

```
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with [DROP SPATIAL REFERENCE SYSTEM](#).
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the [European Petroleum Survey Group](#).
- Users should not drop SRSs with SRIDs in the reserved ranges. If system-installed SRSs are dropped, the SRS definitions may be recreated for MySQL upgrades.

13.1.29 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

[DROP TABLE](#) removes one or more tables. You must have the [DROP](#) privilege for each table.

Be careful with this statement! It removes the table definition and all table data. For a partitioned table, it permanently removes the table definition, all its partitions, and all data stored in those partitions. It also removes partition definitions associated with the dropped table.

[DROP TABLE](#) causes an implicit commit, except when used with the [TEMPORARY](#) keyword. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

Important

When a table is dropped, privileges granted specifically for the table are *not* automatically dropped. They must be dropped manually. See [Section 13.7.1.6, “GRANT Syntax”](#).

If any tables named in the argument list do not exist, the statement fails with an error indicating by name which nonexistent tables it was unable to drop, and no changes are made.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. Instead of an error, a `NOTE` is generated for each nonexistent table; these notes can be displayed with `SHOW WARNINGS`. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

`IF EXISTS` can also be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not cause an implicit commit.
- No access rights are checked. A `TEMPORARY` table is visible only with the session that created it, so no check is necessary.

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

The `RESTRICT` and `CASCADE` keywords do nothing. They are permitted to make porting easier from other database systems.

`DROP TABLE` is not supported with all `innodb_force_recovery` settings. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

13.1.30 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
[ENGINE [=] engine_name]
```

This statement is used to drop an `InnoDB` general tablespace created using `CREATE TABLESPACE` syntax. (see [Section 13.1.19, “CREATE TABLESPACE Syntax”](#)).

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

tablespace_name is a case-sensitive identifier in MySQL.

ENGINE: Defines the storage engine that uses the tablespace, where *engine_name* is the name of the storage engine. Currently, only the `InnoDB` storage engine is supported.

Note

The `ENGINE` clause is deprecated and will be removed in a future release. The tablespace storage engine is known by the data dictionary, making the `ENGINE` clause obsolete.

Notes

- A general `InnoDB` tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd` data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

Example

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```
mysql> CREATE TABLESPACE `ts1`
      ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY)
      TABLESPACE ts10 Engine=InnoDB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

13.1.31 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

Triggers for a table are also dropped if you drop the table.

13.1.32 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
      view_name [, view_name] ...
      [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

If any views named in the argument list do not exist, the statement fails with an error indicating by name which nonexistent views it was unable to drop, and no changes are made.

Note

In MySQL 5.7 and earlier, `DROP VIEW` returns an error if any views named in the argument list do not exist, but also drops all views in the list that do exist. Due to the change in behavior in MySQL 8.0, a partially completed `DROP VIEW` operation on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

13.1.33 RENAME TABLE Syntax

```
RENAME TABLE
    tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

`RENAME TABLE` renames one or more tables. You must have `ALTER` and `DROP` privileges for the original table, and `CREATE` and `INSERT` privileges for the new table.

For example, to rename a table named `old_table` to `new_table`, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

`RENAME TABLE`, unlike `ALTER TABLE`, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
              old_table2 TO new_table2,
              old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
              new_table TO old_table,
              tmp_table TO new_table;
```

As of MySQL 8.0.13, you can rename tables locked with a `LOCK TABLES` statement, provided that they are locked with a `WRITE` lock or are the product of renaming `WRITE`-locked tables from earlier steps in a multiple-table rename operation. For example, this is permitted:

```
LOCK TABLE old_table1 WRITE;
RENAME TABLE old_table1 TO new_table1,
              new_table1 TO new_table2;
```

This is not permitted:

```
LOCK TABLE old_table1 READ;
RENAME TABLE old_table1 TO new_table1,
              new_table1 TO new_table2;
```

Prior to MySQL 8.0.13, to execute `RENAME TABLE`, there must be no tables locked with `LOCK TABLES`.

With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a `RENAME TABLE`, the statement fails and no changes are made.

You can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema` (`ER_TRG_IN_WRONG_SCHEMA`) error.

To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead.

`RENAME TABLE` works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

`RENAME TABLE` changes internally generated foreign key constraint names and user-defined foreign key constraint names that contain the string `"tbl_name_ibfk_"` to reflect the new table name. `InnoDB` interprets foreign key constraint names that contain the string `"tbl_name_ibfk_"` as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

13.1.34 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege. Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements.

To achieve high performance, `TRUNCATE TABLE` bypasses the DML method of deleting data. Thus, it does not cause `ON DELETE` triggers to fire, it cannot be performed for `InnoDB` tables with parent-child foreign key relationships, and it cannot be rolled back like a DML operation. However, `TRUNCATE TABLE` operations on tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- Truncation operations cannot be performed if the session holds an active table lock.

- `TRUNCATE TABLE` fails for an `InnoDB` table or `NDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table definition is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.
- Truncating a corrupted `InnoDB` table is supported.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

In MySQL 5.7 and earlier, on a system with a large buffer pool and `innodb_adaptive_hash_index` enabled, a `TRUNCATE TABLE` operation could cause a temporary drop in system performance due to an LRU scan that occurred when removing the table's adaptive hash index entries (Bug #68184). The remapping of `TRUNCATE TABLE` to `DROP TABLE` and `CREATE TABLE` in MySQL 8.0 avoids the problematic LRU scan.

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 25.11.16, “Performance Schema Summary Tables”](#).

13.2 Data Manipulation Statements

13.2.1 CALL Syntax

```
CALL sp_name([parameter[,...]])  
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the

procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an [IN](#) or [INOUT](#) parameter.) For an [INOUT](#) parameter, initialize its value before passing it to the procedure. The following procedure has an [OUT](#) parameter that the procedure sets to the current server version, and an [INOUT](#) value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the [INOUT](#) parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version          | @increment |
+-----+-----+
| 8.0.3-rc-debug-log |          11 |
+-----+-----+
```

In prepared [CALL](#) statements used with [PREPARE](#) and [EXECUTE](#), placeholders can be used for [IN](#) parameters, [OUT](#), and [INOUT](#) parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version          | @increment |
+-----+-----+
| 8.0.3-rc-debug-log |          11 |
+-----+-----+
```

To write C programs that use the [CALL](#) SQL statement to execute stored procedures that produce result sets, the [CLIENT_MULTI_RESULTS](#) flag must be enabled. This is because each [CALL](#) returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. [CLIENT_MULTI_RESULTS](#) must also be enabled if [CALL](#) is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

[CLIENT_MULTI_RESULTS](#) can be enabled when you call `mysql_real_connect()`, either explicitly by passing the [CLIENT_MULTI_RESULTS](#) flag itself, or implicitly by passing [CLIENT_MULTI_STATEMENTS](#) (which also enables [CLIENT_MULTI_RESULTS](#)). [CLIENT_MULTI_RESULTS](#) is enabled by default.

To process the result of a [CALL](#) statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 27.7.19, “C API Multiple Statement Execution Support”](#).

C programs can use the prepared-statement interface to execute [CALL](#) statements and access [OUT](#) and [INOUT](#) parameters. This is done by processing the result of a [CALL](#) statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 27.7.21, “C API Prepared CALL Statement Support”](#). Languages that provide a MySQL interface can use prepared [CALL](#) statements to directly retrieve [OUT](#) and [INOUT](#) procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.3, “Caching of Prepared Statements and Stored Programs”](#).

13.2.2 DELETE Syntax

DELETE is a DML statement that removes rows from a table.

A **DELETE** statement can start with a **WITH** clause to define common table expressions accessible within the **DELETE**. See [Section 13.2.13, “WITH Syntax \(Common Table Expressions\)”](#).

Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

The **DELETE** statement deletes rows from *tbl_name* and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in [Section 12.14, “Information Functions”](#).

Main Clauses

The conditions in the optional **WHERE** clause identify which rows to delete. With no **WHERE** clause, all rows are deleted.

where_condition is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.10, “SELECT Syntax”](#).

If the **ORDER BY** clause is specified, the rows are deleted in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name [, tbl_name [, ...]] ...
FROM table_references
  [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
FROM tbl_name [, tbl_name [, ...]] ...
USING table_references
  [WHERE where_condition]
```

Privileges

You need the **DELETE** privilege on a table to delete rows from it. You need only the **SELECT** privilege for any columns that are only read, such as those named in the **WHERE** clause.

Performance

When you do not need to know the number of deleted rows, the **TRUNCATE TABLE** statement is a faster way to empty a table than a **DELETE** statement with no **WHERE** clause. Unlike **DELETE**, **TRUNCATE TABLE** cannot be used within a transaction or if you have a lock on the table. See [Section 13.1.34, “TRUNCATE TABLE Syntax”](#) and [Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

The speed of delete operations may also be affected by factors discussed in [Section 8.2.5.3, “Optimizing DELETE Statements”](#).

To ensure that a given `DELETE` statement does not take too much time, the MySQL-specific `LIMIT row_count` clause for `DELETE` specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Tables

`DELETE` supports explicit partition selection using the `PARTITION` option, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` option can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.

For more information and examples, see [Section 22.5, “Partition Selection”](#).

Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.33, “RENAME TABLE Syntax”](#).

MyISAM Tables

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 13.7.3.4, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of [QUICK](#). They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use [DELETE](#) without [QUICK](#), unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use [OPTIMIZE TABLE](#).

If you are going to delete many rows from a table, it might be faster to use [DELETE QUICK](#) followed by [OPTIMIZE TABLE](#). This rebuilds the index rather than performing many index block merge operations.

Multi-Table Deletes

You can specify multiple tables in a [DELETE](#) statement to delete rows from one or more tables depending on the condition in the [WHERE](#) clause. You cannot use [ORDER BY](#) or [LIMIT](#) in a multiple-table [DELETE](#). The [table_references](#) clause lists the tables involved in the join, as described in [Section 13.2.10.2, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the [FROM](#) clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the [FROM](#) clause (before the [USING](#) clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables [t1](#) and [t2](#).

The preceding examples use [INNER JOIN](#), but multiple-table [DELETE](#) statements can use other types of join permitted in [SELECT](#) statements, such as [LEFT JOIN](#). For example, to delete rows that exist in [t1](#) that have no match in [t2](#), use a [LEFT JOIN](#):

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits [.*](#) after each [tbl_name](#) for compatibility with [Access](#).

If you use a multiple-table [DELETE](#) statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the [ON DELETE](#) capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly.

Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table [DELETE](#) should be declared only in the [table_references](#) part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

13.2.3 DO Syntax

```
DO expr [, expr] ...
```

DO executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT *expr*, ...**, but has the advantage that it is slightly faster when you do not care about the result.

DO is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|          0 |
+-----+
1 row in set (5.02 sec)
```

DO, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

DO only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

13.2.4 HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]
```

```
HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `InnoDB` and `MyISAM` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.

If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
 - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
 - There is less parsing involved.
 - There is no optimizer or query-checking overhead.
 - The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.

- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See [Section 15.19, “InnoDB memcached Plugin”](#) for an alternative way to adapt applications that use the key-value store paradigm.)
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

13.2.5 IMPORT TABLE Syntax

```
IMPORT TABLE FROM sdi_file [, sdi_file] ...
```

The `IMPORT TABLE` statement imports `MyISAM` tables based on information contained in `.sdi` (Serialized Dictionary Information) metadata files. `IMPORT TABLE` requires the `FILE` privilege to read the `.sdi` and table content files, and the `CREATE` privilege for the table to be created.

Tables can be exported from one server using `mysqldump` to write a file of SQL statements and imported into another server using `mysql` to process the dump file. `IMPORT TABLE` provides a faster alternative using the “raw” table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the `.sdi` file must be located in a directory accessible to the server. For example, the `.sdi` file can be placed in the directory named by the `secure_file_priv` system variable, or (if `secure_file_priv` is empty) in a directory under the server data directory.

The following example describes how to export `MyISAM` tables named `employees` and `managers` from the `hr` schema of one server and import them into the `hr` schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

- For the export server, `export_basedir` represents its base directory, and its data directory is `export_basedir/data`.
- For the import server, `import_basedir` represents its base directory, and its data directory is `import_basedir/data`.
- Table files are exported from the export server into the `/tmp/export` directory and this directory is secure (not accessible to other users).

- The import server uses `/tmp/mysql-files` as the directory named by its `secure_file_priv` system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

```
mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
```

While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the `.sdi` and table content files from the `hr` schema directory to the secure export directory:
 - The `.sdi` file is located in the `hr` schema directory, but might not have exactly the same basename as the table name. For example, the `.sdi` files for the `employees` and `managers` tables might be named `employees_125.sdi` and `managers_238.sdi`.
 - For a `MyISAM` table, the content files are its `.MYD` data file and `.MYI` index file.

Given those file names, the copy commands look like this:

```
shell> cd export_basedir/data/hr
shell> cp employees_125.sdi /tmp/export
shell> cp managers_238.sdi /tmp/export
shell> cp employees.{MYD,MYI} /tmp/export
shell> cp managers.{MYD,MYI} /tmp/export
```

3. Unlock the tables:

```
mysql> UNLOCK TABLES;
```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:

```
mysql> CREATE SCHEMA hr;
```

2. At the file system level, copy the `.sdi` files to the import server `secure_file_priv` directory, `/tmp/mysql-files`. Also, copy the table content files to the `hr` schema directory:

```
shell> cd /tmp/export
shell> cp employees_125.sdi /tmp/mysql-files
shell> cp managers_238.sdi /tmp/mysql-files
shell> cp employees.{MYD,MYI} import_basedir/data/hr
shell> cp managers.{MYD,MYI} import_basedir/data/hr
```

3. Import the tables by executing an `IMPORT TABLE` statement that names the `.sdi` files:

```
mysql> IMPORT TABLE FROM
      '/tmp/mysql-files/employees.sdi',
      '/tmp/mysql-files/managers.sdi';
```

The `.sdi` file need not be placed in the import server directory named by the `secure_file_priv` system variable if that variable is empty; it can be in any directory accessible to the server, including the schema

directory for the imported table. If the `.sdi` file is placed in that directory, however, it may be rewritten; the import operation creates a new `.sdi` file for the table, which will overwrite the old `.sdi` file if the operation uses the same file name for the new file.

Each `sdi_file` value must be a string literal that names the `.sdi` file for a table or is a pattern that matches `.sdi` files. If the string is a pattern, any leading directory path and the `.sdi` file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

- `?` matches any single character
- `*` matches any sequence of characters, including no characters

Using a pattern, the previous `IMPORT TABLE` statement could have been written like this (assuming that the `/tmp/mysql-files` directory contains no other `.sdi` files matching the pattern):

```
IMPORT TABLE FROM '/tmp/mysql-files/*.sdi';
```

To interpret the location of `.sdi` file path names, the server uses the same rules for `IMPORT TABLE` as the server-side rules for `LOAD DATA` (that is, the non-`LOCAL` rules). See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#), paying particular attention to the rules used to interpret relative path names.

`IMPORT TABLE` fails if the `.sdi` or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use `REPAIR TABLE`.

`IMPORT TABLE` is not written to the binary log.

Restrictions and Limitations

`IMPORT TABLE` applies only to non-`TEMPORARY` `MyISAM` tables. It does not apply to tables created with a transactional storage engine, tables created with `CREATE TEMPORARY TABLE`, or views.

The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the `DATA DIRECTORY` or `INDEX DIRECTORY` table options. In that case, modify the import procedure using one of these alternatives before executing the `IMPORT TABLE` statement:

- Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.
- Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the `.sdi` file to reflect the different file locations.
- Put the data and index files into the schema directory on the import server host, and modify the `.sdi` file to remove the data and index directory table options.

Any collation IDs stored in the `.sdi` file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table `.sdi` file, so triggers are not restored by the import operation.

Some edits to an `.sdi` file are permissible prior to executing the `IMPORT TABLE` statement, whereas others are problematic or may even cause the import operation to fail:

- Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.

- Changing the schema name is required to import the table into a different schema on the import server than on the export server.
- Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in [lower_case_table_names](#) settings. Changing the table names in the `.sdi` file may require renaming the table files as well.
- In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

13.2.6 INSERT Syntax

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  {VALUES | VALUE} (value_list) [, (value_list)] ...
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...

```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT` with an `ON DUPLICATE KEY UPDATE` clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`.

For additional information about `INSERT ... SELECT` and `INSERT ... ON DUPLICATE KEY UPDATE`, see [Section 13.2.6.1, “INSERT ... SELECT Syntax”](#), and [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

In MySQL 8.0, the `DELAYED` keyword is accepted but ignored by the server. For the reasons for this, see [Section 13.2.6.3, “INSERT DELAYED Syntax”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only

the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see [Section 22.5, “Partition Selection”](#).

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See [Section 13.2.9, “REPLACE Syntax”](#).

`tbl_name` is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- A `SET` clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#). See also [Section 1.8.3.3, “Constraints on Invalid Data”](#).

If strict SQL mode is enabled, an `INSERT` statement generates an error if it does not specify an explicit value for every column that has no default value. See [Section 5.1.10, “Server SQL Modes”](#).

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the `VALUES` list.
- If a generated column is inserted into explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).
- In expressions, you can use `DEFAULT(col_name)` to produce the default value for column `col_name`.
- Type conversion of an expression `expr` that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string `'1999.0e-2'` into an `INT`,

`FLOAT`, `DECIMAL(10,6)`, or `YEAR` column inserts the value `1999`, `19.9921`, `19.992100`, or `1999`, respectively. The value stored in the `INT` and `YEAR` columns is `1999` because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the `FLOAT` and `DECIMAL` columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` SQL function or the `mysql_affected_rows()` C API function. See [Section 12.14, “Information Functions”](#), and [Section 27.7.7.1, “mysql_affected_rows\(\)”](#).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 27.7.7.36, “mysql_info\(\)”](#).

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column

data type. This is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.
- For `INSERT` examples involving `AUTO_INCREMENT` column values, see [Section 3.6.9, “Using AUTO_INCREMENT”](#).

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

**Note**

These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.14, “Information Functions”](#), and [Section 27.7.7.38, “mysql_insert_id\(\)”](#).

The `INSERT` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

`LOW_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

**Note**

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.11.3, “Concurrent Inserts”](#).

- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.11.3, “Concurrent Inserts”](#).

`HIGH_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the

table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error. When `INSERT IGNORE` is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see [Section 22.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).
- `INSERT DELAYED` was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 8.0, the `DELAYED` modifier is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See [Section 13.2.6.3, “INSERT DELAYED Syntax”](#).

An `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.2.6.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from the result of a `SELECT` statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.

- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. See [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#), and [Section B.5.6.2, “TEMPORARY Table Problems”](#).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see [Section 8.11.3, “Concurrent Inserts”](#)).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` option following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see [Section 22.5, “Partition Selection”](#).

For `INSERT ... SELECT` statements, see [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#) for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause.

The order in which a `SELECT` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the master and the slave. See also [Section 17.4.1.18, “Replication and LIMIT”](#).

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Partitioning and Locking](#).

13.2.6.2 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
```

```
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE t1 SET c=c+1 WHERE a=1;
```

(The effects are not identical for an [InnoDB](#) table where [a](#) is an auto-increment column. With an auto-increment column, an [INSERT](#) statement increases the auto-increment value but [UPDATE](#) does not.)

If column [b](#) is also unique, the [INSERT](#) is equivalent to this [UPDATE](#) statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If [a=1 OR b=2](#) matches several rows, only *one* row is updated. In general, you should try to avoid using an [ON DUPLICATE KEY UPDATE](#) clause on tables with multiple unique indexes.

With [ON DUPLICATE KEY UPDATE](#), the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the [CLIENT_FOUND_ROWS](#) flag to the [mysql_real_connect\(\)](#) C API function when connecting to [mysqld](#), the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an [AUTO_INCREMENT](#) column and [INSERT ... ON DUPLICATE KEY UPDATE](#) inserts or updates a row, the [LAST_INSERT_ID\(\)](#) function returns the [AUTO_INCREMENT](#) value.

The [ON DUPLICATE KEY UPDATE](#) clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the [ON DUPLICATE KEY UPDATE](#) clause, you can use the [VALUES\(col_name\)](#) function to refer to column values from the [INSERT](#) portion of the [INSERT ... ON DUPLICATE KEY UPDATE](#) statement. In other words, [VALUES\(col_name\)](#) in the [ON DUPLICATE KEY UPDATE](#) clause refers to the value of [col_name](#) that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The [VALUES\(\)](#) function is meaningful only in the [ON DUPLICATE KEY UPDATE](#) clause or [INSERT](#) statements and returns [NULL](#) otherwise. Example:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

For [INSERT ... SELECT](#) statements, these rules apply regarding acceptable forms of [SELECT](#) query expressions that you can refer to in an [ON DUPLICATE KEY UPDATE](#) clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from [DISTINCT](#) queries.
- References to columns in other tables, as long as the [SELECT](#) does not use [GROUP BY](#). One side effect is that you must qualify references to nonunique column names.

References to columns from a [UNION](#) are not supported. To work around this restriction, rewrite the [UNION](#) as a derived table so that its rows can be treated as a single-table result set. For example, this statement produces an error:

```
INSERT INTO t1 (a, b)
  SELECT c, d FROM t2
 UNION
  SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the [UNION](#) as a derived table:

```
INSERT INTO t1 (a, b)
SELECT * FROM
  (SELECT c, d FROM t2
   UNION
   SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from [GROUP BY](#) queries.

Because the results of [INSERT ... SELECT](#) statements depend on the ordering of rows from the [SELECT](#) and this order cannot always be guaranteed, it is possible when logging [INSERT ... SELECT ON DUPLICATE KEY UPDATE](#) statements for the master and the slave to diverge. Thus, [INSERT ... SELECT ON DUPLICATE KEY UPDATE](#) statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using [MIXED](#) mode. An [INSERT ... ON DUPLICATE KEY UPDATE](#) statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An [INSERT ... ON DUPLICATE KEY UPDATE](#) on a partitioned table using a storage engine such as [MyISAM](#) that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as [InnoDB](#) that employ row-level locking.) For more information, see [Partitioning and Locking](#).

13.2.6.3 INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The [DELAYED](#) option for the [INSERT](#) statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as [MyISAM](#)), such that when a client uses [INSERT DELAYED](#), it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

[DELAYED](#) inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, [DELAYED](#) is not supported. The server recognizes but ignores the [DELAYED](#) keyword, handles the insert as a nondelayed insert, and generates an [ER_WARN_LEGACY_SYNTAX_CONVERTED](#) warning (“INSERT DELAYED is no longer supported. The statement was converted to INSERT”). The [DELAYED](#) keyword is scheduled for removal in a future release.

13.2.7 LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE tbl_name
```

```

[PARTITION (partition_name [, partition_name] ...)]
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string'
  [[OPTIONALLY] ENCLOSED BY 'char'
  [ESCAPED BY 'char']]
]
[LINES
  [STARTING BY 'string'
  [TERMINATED BY 'string']]
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var
  [, col_name_or_user_var] ...)]
[SET col_name={expr | DEFAULT},
  [, col_name={expr | DEFAULT}] ...]

```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name.

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a list of one or more comma-separated names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see [Section 22.5, “Partition Selection”](#).

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Partitioning and Locking](#).

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 17.4.1.19, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the directory where the MySQL server stores temporary files. See [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#). Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the file name is an absolute path name, the server uses it as given.
 - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

**Note**

The server also use the non-`LOCAL` rules to locate `.sdi` files for the `IMPORT TABLE` statement.

Non-[LOCAL](#) load operations read text files located on the server. For security reasons, such operations require that you have the [FILE](#) privilege. See [Section 6.2.1, “Privileges Provided by MySQL”](#). Also, non-[LOCAL](#) load operations are subject to the `secure_file_priv` system variable setting. If the variable value is a nonempty directory name, the file to be loaded must be located in that directory. If the variable value is empty (which is insecure), the file need only be readable by the server.

Using [LOCAL](#) is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the [FILE](#) privilege to load local files.

[LOCAL](#) also affects error handling:

- With [LOAD DATA INFILE](#), data-interpretation and duplicate-key errors terminate the operation.
- With [LOAD DATA LOCAL INFILE](#), data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if [IGNORE](#) is specified. [IGNORE](#) is explained further later in this section.

The [REPLACE](#) and [IGNORE](#) keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify [REPLACE](#), input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.9, “REPLACE Syntax”](#).
- If you specify [IGNORE](#), rows that duplicate an existing row on a unique key value are discarded. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).
- If you do not specify either option, the behavior depends on whether the [LOCAL](#) keyword is specified. Without [LOCAL](#), an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With [LOCAL](#), the default behavior is the same as if [IGNORE](#) is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing [LOAD DATA](#).

If you use [LOAD DATA INFILE](#) on an empty [MyISAM](#) table, all nonunique indexes are created in a separate batch (as for [REPAIR TABLE](#)). Normally, this makes [LOAD DATA INFILE](#) much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

For both the [LOAD DATA INFILE](#) and [SELECT ... INTO OUTFILE](#) statements, the syntax of the [FIELDS](#) and [LINES](#) clauses is the same. Both clauses are optional, but [FIELDS](#) must precede [LINES](#) if both are specified.

If you specify a [FIELDS](#) clause, each of its subclauses ([TERMINATED BY](#), [\[OPTIONALLY\] ENCLOSED BY](#), and [ESCAPED BY](#)) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no [FIELDS](#) or [LINES](#) clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'  
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options

for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` keywords.

Any of the field- or line-handling options can specify an empty string (`''`). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
```

```
"4","a string containing a \", quote and comma",102.20"
```

If you specify [OPTIONALLY](#), the [ENCLOSED BY](#) character is used only to enclose values from columns that have a string data type (such as [CHAR](#), [BINARY](#), [TEXT](#), or [ENUM](#)):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the [ENCLOSED BY](#) character within a field value are escaped by prefixing them with the [ESCAPED BY](#) character. Also, if you specify an empty [ESCAPED BY](#) value, it is possible to inadvertently generate output that cannot be read properly by [LOAD DATA INFILE](#). For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the [ENCLOSED BY](#) character, if present, is stripped from the ends of field values. (This is true regardless of whether [OPTIONALLY](#) is specified; [OPTIONALLY](#) has no effect on input interpretation.) Occurrences of the [ENCLOSED BY](#) character preceded by the [ESCAPED BY](#) character are interpreted as part of the current field value.

If the field begins with the [ENCLOSED BY](#) character, instances of that character are recognized as terminating a field value only if followed by the field or line [TERMINATED BY](#) sequence. To avoid ambiguity, occurrences of the [ENCLOSED BY](#) character within a field value can be doubled and are interpreted as a single instance of the character. For example, if [ENCLOSED BY](#) `' '` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss
```

[FIELDS ESCAPED BY](#) controls how to read or write special characters:

- For input, if the [FIELDS ESCAPED BY](#) character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for [NULL](#) handling are described later in this section.

Character	Escape Sequence
<code>\0</code>	An ASCII NUL (<code>x'00'</code>) character
<code>\b</code>	A backspace character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character.
<code>\z</code>	ASCII 26 (Control+Z)
<code>\N</code>	NULL

For more information about `\`-escape syntax, see [Section 9.1.1, “String Literals”](#).

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:
 - The `FIELDS ESCAPED BY` character
 - The `FIELDS [OPTIONALLY] ENCLOSED BY` character
 - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
 - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (`' '`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `' '`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.7, “Data Type Default Values”](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

Each `col_name_or_user_var` value is either a column name or a user variable. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b'` and trailing `'` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
```

```

shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
      INTO TABLE bit_test (@var1)
      SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| BIN(b+0) |
+-----+
| 10       |
| 1111111 |
+-----+
2 rows in set (0.00 sec)

```

For **BIT** values in **0b** binary notation (for example, **0b011010**), use this **SET** clause instead to strip off the leading **0b**:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

On Unix, if you need **LOAD DATA** to read from a pipe, you can use the following technique (the example loads a listing of the **/** directory into the table **db1.t1**):

```

mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1

```

Here you must run the command that generates the data to be loaded and the **mysql** commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the **mysql** process.

When the **LOAD DATA INFILE** statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the **INSERT** statement (see [Section 13.2.6, “INSERT Syntax”](#)), except that **LOAD DATA INFILE** also generates warnings when there are too few or too many fields in the input row.

You can use **SHOW WARNINGS** to get a list of the first **max_error_count** warnings as information about what went wrong. See [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

If you are using the C API, you can get information about the statement by calling the **mysql_info()** function. See [Section 27.7.36, “mysql_info\(\)”](#).

13.2.8 LOAD XML Syntax

```

LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number {LINES | ROWS}]
  [(field_name_or_user_var
    [, field_name_or_user_var] ...)]
  [SET col_name={expr | DEFAULT},
    [, col_name={expr | DEFAULT}] ...]

```

The `LOAD XML` statement reads data from an XML file into a table. The *file_name* must be given as a literal string. The *tagname* in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the *name* attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

(*field_name_or_user_var, ...*) is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first *number* rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
    <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
```

```

      3 | Likame | Örrtmons | 2007-07-13 16:18:47 |
      4 | Slar   | Manlanth | 2007-07-13 16:18:47 |
      5 | Stoma  | Nilu     | 2007-07-13 16:18:47 |
      6 | Nirtam | Sklöd    | 2007-07-13 16:18:47 |
      7 | Sungam | Dulbåd   | 2007-07-13 16:18:47 |
      8 | Sreraf | Encmelt  | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using [LOAD XML](#).

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```

shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>

  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>

  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>

  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>

  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>

  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>

  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>

```

```
<field name="lname">Encmelt</field>
</row>
</resultset>
```

Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
      Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
```

Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

```
mysql> SELECT * FROM person2;
```

person_id	fname	lname
1	Kapek	Sainnouine
2	Sajon	Rondela
3	Likema	Örrtmons
4	Slar	Manlanth
5	Stoma	Nilu
6	Nirtam	Sklöd
7	Sungam	Dulbåd
8	Sreraf	Encmelt

8 rows in set (0.00 sec)

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```
mysql> CREATE TABLE individual (
->     individual_id INT NOT NULL PRIMARY KEY,
->     name1 VARCHAR(40) NULL,
->     name2 VARCHAR(40) NULL,
->     made TIMESTAMP
-> );
```

Query OK, 0 rows affected (0.42 sec)

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
->     INTO TABLE test.individual (@person_id, @fname, @lname, @created)
->     SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
```

Query OK, 8 rows affected (0.05 sec)

Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

```
mysql> SELECT * FROM individual;
```

individual_id	name1	name2	made
1	Kapek	Sainnouine	2007-07-13 16:18:47
2	Sajon	Rondela	2007-07-13 16:18:47
3	Likema	Örrtmons	2007-07-13 16:18:47
4	Slar	Manlanth	2007-07-13 16:18:47

5	Stoma	Nilu	2007-07-13 16:18:47
6	Nirtam	Sklöd	2007-07-13 16:18:47
7	Sungam	Dulbåd	2007-07-13 16:18:47
8	Srraf	Encmelt	2007-07-13 16:18:47

8 rows in set (0.00 sec)

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required `@` prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>

<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
***** 1. row *****
      Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street | zip | city | created |
+-----+-----+-----+-----+-----+-----+
|          1 |          1 | Mill Creek Road | 45365 | Sidney | 2007-07-24 17:37:37 |
|          2 |          1 | Main Street | 28681 | Taylorsville | 2007-07-24 17:37:37 |
|          3 |          2 | River Road | 80239 | Denver | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

Security Considerations. As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML INFILE` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL INFILE`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Partitioning and Locking](#).

13.2.9 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  {VALUES | VALUE} (value_list) [, (value_list)] ...

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  SELECT ...

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See [Section 13.2.6, “INSERT Syntax”](#).

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the replace as a nondelayed replace, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning. (“REPLACE DELAYED is no longer supported. The statement was converted to REPLACE.”) The `DELAYED` keyword will be removed in a future release.

**Note**

`REPLACE` makes sense only if a table has a `PRIMARY KEY` or `UNIQUE` index. Otherwise, it becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

If a generated column is replaced explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).

`REPLACE` supports explicit partition selection using the `PARTITION` keyword with a list of comma-separated names of partitions, subpartitions, or both. As with `INSERT`, if it is not possible to insert the new row into any of these partitions or subpartitions, the `REPLACE` statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see [Section 22.5, “Partition Selection”](#).

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the `mysql` client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+-----+-----+
| id | data | ts                |
```

```

+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
| 1  | Old  | 2014-08-20 18:47:00 |
| 1  | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
2 rows in set (0.00 sec)

```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement `WHERE` clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.2.10 SELECT Syntax

```

SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
    [PARTITION partition_list]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}, ... [WITH ROLLUP]]
  [HAVING where_condition]
  [WINDOW window_name AS (window_spec)
    [, window_name AS (window_spec)] ...]
  [ORDER BY {col_name | expr | position}
    [ASC | DESC], ... [WITH ROLLUP]]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [INTO OUTFILE 'file_name'
    [CHARACTER SET charset_name]
    export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
  [FOR {UPDATE | SHARE} [OF tbl_name [, tbl_name] ...] [NOWAIT | SKIP LOCKED]
  | LOCK IN SHARE MODE]]

```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See [Section 13.2.10.3, “UNION Syntax”](#), and [Section 13.2.11, “Subquery Syntax”](#). A `SELECT` statement can start with a `WITH` clause to define common table expressions accessible within the `SELECT`. See [Section 13.2.13, “WITH Syntax \(Common Table Expressions\)”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.10.2, “JOIN Syntax”](#).
- `SELECT` supports explicit partition selection using the `PARTITION` with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see [Section 13.2.10.2, “JOIN Syntax”](#)). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see [Section 22.5, “Partition Selection”](#).

`SELECT ... PARTITION` from tables using storage engines such as `MyISAM` that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the `PARTITION` option.

For more information, see [Partitioning and Locking](#).

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expression Syntax”](#), and [Chapter 12, Functions and Operators](#).

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately following the `select_expr` list. For more information about `INTO`, see [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ' ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a *select_expr* with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ' ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.5.4.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.10.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 8.9.4, “Index Hints”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.7, “Server System Variables”](#).

- You can refer to a table within the default database as *tbl_name*, or as *db_name.tbl_name* to specify a database explicitly. You can refer to a column as *col_name*, *tbl_name.col_name*, or *db_name.tbl_name.col_name*. You need not specify a *tbl_name* or *db_name.tbl_name* prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;
```

```
SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;
```

```
SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the [DESC](#) (descending) keyword to the name of the column in the [ORDER BY](#) clause that you are sorting by. The default is ascending order; this can be specified explicitly using the [ASC](#) keyword.

If [ORDER BY](#) occurs within a subquery and also is applied in the outer query, the outermost [ORDER BY](#) takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- Prior to MySQL 8.0.13, MySQL supported a nonstandard syntax extension that permitted explicit [ASC](#) or [DESC](#) designators for [GROUP BY](#) columns. MySQL 8.0.12 and later supports [ORDER BY](#) with grouping functions so that use of this extension is no longer necessary. (Bug #86312, Bug #26073525) This also means you can sort on an arbitrary column or columns when using [GROUP BY](#), like this:

```
SELECT a, b, COUNT(c) AS t FROM test_table GROUP BY a,b ORDER BY a,t DESC;
```

As of MySQL 8.0.13, the [GROUP BY](#) extension is no longer supported: [ASC](#) or [DESC](#) designators for [GROUP BY](#) columns are not permitted.

- When you use [ORDER BY](#) or [GROUP BY](#) to sort a column in a [SELECT](#), the server sorts values using only the initial number of bytes indicated by the [max_sort_length](#) system variable.
- MySQL extends the use of [GROUP BY](#) to permit selecting fields that are not mentioned in the [GROUP BY](#) clause. If you are not getting the results that you expect from your query, please read the description of [GROUP BY](#) found in [Section 12.19, “Aggregate \(GROUP BY\) Functions”](#).
- [GROUP BY](#) permits a [WITH ROLLUP](#) modifier. See [Section 12.19.2, “GROUP BY Modifiers”](#).

Previously, it was not permitted to use [ORDER BY](#) in a query having a [WITH ROLLUP](#) modifier. This restriction is lifted as of MySQL 8.0.12. See [Section 12.19.2, “GROUP BY Modifiers”](#).

- The [HAVING](#) clause is applied nearly last, just before items are sent to the client, with no optimization. ([LIMIT](#) is applied after [HAVING](#).)

The SQL standard requires that [HAVING](#) must reference only columns in the [GROUP BY](#) clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits [HAVING](#) to refer to columns in the [SELECT](#) list and columns in outer subqueries as well.

If the [HAVING](#) clause refers to a column that is ambiguous, a warning occurs. In the following statement, [col2](#) is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a [HAVING](#) column name is used both in [GROUP BY](#) and as an aliased column in the output column list, preference is given to the column in the [GROUP BY](#) column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users  
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- The `WINDOW` clause, if present, defines named windows that can be referred to by window functions. For details, see [Section 12.20.4, “Named Windows”](#).
- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
 - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.
 - Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;      # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.)

`FOR SHARE` and `LOCK IN SHARE MODE` set shared locks that permit other transactions to read the examined rows but not to update or delete them. `FOR SHARE` and `LOCK IN SHARE MODE` are equivalent. However, `FOR SHARE`, like `FOR UPDATE`, supports `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. `FOR SHARE` is a replacement for `LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility.

`NOWAIT` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, returning an error if a row lock cannot be obtained due to a lock held by another transaction.

`SKIP LOCKED` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, excluding rows from the result set that are locked by another transaction.

`NOWAIT` and `SKIP LOCKED` options are unsafe for statement-based replication.

Note

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`OF tbl_name` applies `FOR UPDATE` and `FOR SHARE` queries to named tables. For example:

```
SELECT * FROM t1, t2 FOR SHARE OF t1 FOR UPDATE OF t2;
```

All tables referenced by the query block are locked when `OF tbl_name` is omitted. Consequently, using a locking clause without `OF tbl_name` in combination with another locking clause returns an error. Specifying the same table in multiple locking clauses returns an error. If an alias is specified as the table name in the `SELECT` statement, a locking clause may only use the alias. If the `SELECT` statement does not specify an alias explicitly, the locking clause may only specify the actual table name.

For more information about `FOR UPDATE` and `FOR SHARE`, see [Section 15.5.2.4, “Locking Reads”](#). For additional information about `NOWAIT` and `SKIP LOCKED` options, see [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.

In MySQL 8.0.12 and later, `DISTINCT` can be used with a query that also uses `WITH ROLLUP`. (Bug #87450, Bug #26640100)

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.10.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers were used with the query cache prior to MySQL 8.0. The query cache was removed in MySQL 8.0. The `SQL_CACHE` modifier was removed as well. `SQL_NO_CACHE` is deprecated, has no effect, and will be removed in a future MySQL release.

A `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Partitioning and Locking](#).

13.2.10.1 SELECT ... INTO Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 13.2.10, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case-sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the *export_options* part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.7, "LOAD DATA INFILE Syntax"](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 23.4.5, “Event Scheduler Status”](#).

13.2.10.2 JOIN Syntax

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```

table_references:
    escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
    table_reference
  | { OJ table_reference }

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [PARTITION (partition_names)]
      [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias [(col_list)]
  | ( table_references )

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [INNER | {LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | FORCE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...

```

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a [PARTITION](#) option, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see [Section 22.5, “Partition Selection”](#).

The syntax of *table_factor* is extended in MySQL in comparison with standard SQL. The standard accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of *table_reference* items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, [JOIN](#), [CROSS JOIN](#), and [INNER JOIN](#) are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. [INNER JOIN](#) is used with an [ON](#) clause, [CROSS JOIN](#) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See [Section 8.2.1.7, “Nested Join Optimization”](#).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 8.9.4, “Index Hints”](#). Optimizer hints and the [optimizer_switch](#) system variable are other ways to influence optimizer use of indexes. See [Section 8.9.2, “Optimizer Hints”](#), and [Section 8.9.3, “Switchable Optimizations”](#).

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```
SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A *table_subquery* is also known as a derived table or subquery in the [FROM](#) clause. See [Section 13.2.11.8, “Derived Tables”](#). Such subqueries *must* include an alias to give the subquery result a table name, and may optionally include a list of table column names in parentheses. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- [INNER JOIN](#) and [,](#) (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of [INNER JOIN](#), [CROSS JOIN](#), [LEFT JOIN](#), and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The [conditional_expr](#) used with [ON](#) is any conditional expression of the form that can be used in a [WHERE](#) clause. Generally, the [ON](#) clause serves for conditions that specify how to join tables, and the [WHERE](#) clause restricts which rows to include in the result set.
- If there is no matching row for the right table in the [ON](#) or [USING](#) part in a [LEFT JOIN](#), a row with all columns set to [NULL](#) is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See [Section 8.2.1.8, “Outer Join Optimization”](#).

- The [USING\(column_list\)](#) clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The [NATURAL \[LEFT\] JOIN](#) of two tables is defined to be semantically equivalent to an [INNER JOIN](#) or a [LEFT JOIN](#) with a [USING](#) clause that names all columns that exist in both tables.
- [RIGHT JOIN](#) works analogously to [LEFT JOIN](#). To keep code portable across databases, it is recommended that you use [LEFT JOIN](#) instead of [RIGHT JOIN](#).
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as [INNER JOIN](#) or [RIGHT OUTER JOIN](#). This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- [STRAIGHT_JOIN](#) is similar to [JOIN](#), except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
```

```
SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a `NATURAL` join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+-----+-----+-----+
| j      | i      | k      |
+-----+-----+-----+
|      1 |      1 |      1 |
+-----+-----+-----+
| j      | i      | k      |
+-----+-----+-----+
|      1 |      1 |      1 |
+-----+-----+-----+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a

coalesced column of an outer join is represented by the common column of the inner table of a [JOIN](#). Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1      t2
----  ----
1 x    2 z
2 y    3 w
```

Then, for this join, column `a` contains the values of `t1.a`:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

By contrast, for this join, column `a` contains the values of `t2.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Compare those results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 2     | y     | 2     | z     |
| NULL  | NULL  | 3     | w     |
+-----+-----+-----+-----+
```

- A [USING](#) clause can be rewritten as an [ON](#) clause that compares corresponding columns. However, although [USING](#) and [ON](#) are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The [USING](#) join selects the coalesced value of corresponding columns, whereas the [ON](#) join selects all columns from all tables. For the [USING](#) join, `SELECT *` selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the **ON** join, **SELECT *** selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, **COALESCE(a.c1, b.c1)** is the same as either **a.c1** or **b.c1** because both columns will have the same value. With an outer join (such as **LEFT JOIN**), one of the two columns can be **NULL**. That column is omitted from the result.

- An **ON** clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an **Unknown column 'i3' in 'on clause'** error because **i3** is a column in **t3**, which is not an operand of the **ON** clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- **JOIN** has higher precedence than the comma operator (**,**), so the join expression **t1, t2 JOIN t3** is interpreted as **(t1, (t2 JOIN t3))**, not as **((t1, t2) JOIN t3)**. This affects statements that use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The **JOIN** takes precedence over the comma operator, so the operands for the **ON** clause are **t2** and **t3**. Because **t1.i1** is not a column in either of the operands, the result is an **Unknown column 't1.i1' in 'on clause'** error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the **ON** clause are **(t1, t2)** and **t3**:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

- Avoid the use of the comma operator and use **JOIN** instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The same precedence interpretation also applies to statements that mix the comma operator with [INNER JOIN](#), [CROSS JOIN](#), [LEFT JOIN](#), and [RIGHT JOIN](#), all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of [NATURAL](#) or [USING](#) joins, whereas the standard disallows that.

13.2.10.3 UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

[UNION](#) is used to combine the result from multiple [SELECT](#) statements into a single result set.

The column names from the first [SELECT](#) statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each [SELECT](#) statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding [SELECT](#) columns do not match, the types and lengths of the columns in the [UNION](#) result take into account the values retrieved by all of the [SELECT](#) statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a             |
| bbbbbbbbbb   |
+-----+
```

The [SELECT](#) statements are normal select statements, but with the following restrictions:

- Only the last [SELECT](#) statement can use [INTO OUTFILE](#). (However, the entire [UNION](#) result is written to the file.)
- [HIGH_PRIORITY](#) cannot be used with [SELECT](#) statements that are part of a [UNION](#). If you specify it for the first [SELECT](#), it has no effect. If you specify it for any subsequent [SELECT](#) statements, a syntax error results.

The default behavior for [UNION](#) is that duplicate rows are removed from the result. The optional [DISTINCT](#) keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional [ALL](#) keyword, duplicate-row removal does not occur and the result includes all matching rows from all the [SELECT](#) statements.

You can mix [UNION ALL](#) and [UNION DISTINCT](#) in the same query. Mixed [UNION](#) types are treated such that a [DISTINCT](#) union overrides any [ALL](#) union to its left. A [DISTINCT](#) union can be produced explicitly by using [UNION DISTINCT](#) or implicitly by using [UNION](#) with no following [DISTINCT](#) or [ALL](#) keyword.

To apply [ORDER BY](#) or [LIMIT](#) to an individual [SELECT](#), place the clause inside the parentheses that enclose the [SELECT](#):

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
```

```
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

`UNION` queries with an aggregate function in an `ORDER BY` clause are rejected with an `ER_AGGREGATE_ORDER_FOR_UNION` error. Example:

```
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
```

13.2.11 Subquery Syntax

A subquery is a [SELECT](#) statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, [SELECT * FROM t1 ...](#) is the *outer query* (or *outer statement*), and [\(SELECT column1 FROM t2\)](#) is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
     (SELECT * FROM t3
      WHERE ROW(5*t2.s1,77)=
        (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
         (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary [SELECT](#) can contain: [DISTINCT](#), [GROUP BY](#), [ORDER BY](#), [LIMIT](#), joins, index hints, [UNION](#) constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SET](#), or [DO](#).

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and (because subqueries can be used in the [SET](#) clause) [LOAD DATA INFILE](#).

For information about how the optimizer handles subqueries, see [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#). For a discussion of restrictions

on subquery use, including performance issues for certain forms of subquery syntax, see [Section C.4, “Restrictions on Subqueries”](#).

13.2.11.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

13.2.11.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.11.5, “Row Subqueries”](#).

13.2.11.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <> !=
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is **TRUE** if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is **FALSE** if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is *unknown* (that is, **NULL**) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word **IN** is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See [Section 12.3.2, “Comparison Functions and Operators”](#).

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See [Section 13.2.11.4, “Subqueries with ALL”](#).

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

13.2.11.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ALL` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(-5, 0, +5)` because `10` is greater than all three values in `t2`. The expression is `FALSE` if table `t2` contains `(12, 6, NULL, -100)` because there is a single value `12` in table `t2` that is greater than `10`. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(0, NULL, 1)`.

Finally, the expression is `TRUE` if table `t2` is empty. So, the following expression is `TRUE` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing `NULL` values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

`NOT IN` is an alias for `<> ALL`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

13.2.11.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 12.3.2, “Comparison Functions and Operators”](#).

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
  FROM t1
  WHERE (column1,column2,column3) IN
    (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see [Section 8.2.1.20, “Row Constructor Expression Optimization”](#)

13.2.11.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x` `TRUE` for all `y`?”

13.2.11.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                    WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

13.2.11.8 Derived Tables

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `JSON_TABLE()` function generates a table and provides another way to create a derived table:

```
SELECT * FROM JSON_TABLE(arg_list) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names. Alternatively, `tbl_name` may be followed by a parenthesized list of names for the derived table columns:

```
SELECT ... FROM (subquery) [AS] tbl_name (col_list) ...
```

The number of names must be the same as the number of table columns.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
 WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
      FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

The column names for this derived table come from its select list:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt;
+-----+
| 1 | 2 | 3 | 4 |
+-----+
| 1 | 2 | 3 | 4 |
+-----+
```

To provide column names, follow the derived table name with a parenthesized list of column names:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt (a, b, c, d);
+-----+
| a | b | c | d |
+-----+
| 1 | 2 | 3 | 4 |
+-----+
```

Derived tables can return a scalar, column, row, or table.

Derived tables cannot be correlated subqueries, or contain outer references or references to other tables of the same `SELECT`.

The optimizer determines information about derived tables in such a way that materialization of them does not occur for `EXPLAIN`. See [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

It is possible under certain circumstances that using `EXPLAIN SELECT` will modify table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
***** 1. row *****
id: 1
```

```

select_type: SIMPLE
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)

```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```

mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
select_type: PRIMARY
table: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)

```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:

```

mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
select_type: PRIMARY
table: <derived2>
partitions: NULL
type: system
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: NULL
***** 2. row *****
      id: 1

```

```

select_type: PRIMARY
  table: a1
  partitions: NULL
    type: ALL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL
***** 3. row *****
      id: 2
    select_type: DERIVED
      table: NULL
      partitions: NULL
        type: NULL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+
| c1    |
+-----+
|    5  |
+-----+
1 row in set (0.00 sec)

```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

13.2.11.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```

ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"

```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```

ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"

```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 13.2.11.5, “Row Subqueries”](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

13.2.11.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
```

```
(SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (  
    SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2  
WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.11.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1  
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1  
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1  
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1  
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1  
              AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.14, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <= } (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

13.2.11.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A [LEFT \[OUTER\] JOIN](#) can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table [DELETE](#) statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table [UPDATE](#) statements are also supported. See [Section 13.2.2, “DELETE Syntax”](#), and [Section 13.2.12, “UPDATE Syntax”](#).

13.2.12 UPDATE Syntax

[UPDATE](#) is a DML statement that modifies rows in a table.

An [UPDATE](#) statement can start with a [WITH](#) clause to define common table expressions accessible within the [UPDATE](#). See [Section 13.2.13, “WITH Syntax \(Common Table Expressions\)”](#).

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
SET assignment_list
[WHERE where_condition]
[ORDER BY ...]
[LIMIT row_count]

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
SET assignment_list
[WHERE where_condition]
```

For the single-table syntax, the [UPDATE](#) statement updates columns of existing rows in the named table with new values. The [SET](#) clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword [DEFAULT](#) to set a column explicitly to its default value. The [WHERE](#) clause, if given, specifies the conditions that identify which rows to update. With no [WHERE](#) clause, all rows are updated. If the [ORDER BY](#) clause is specified, the rows are updated in the order that is specified. The [LIMIT](#) clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in *table_references* that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

For partitioned tables, both the single-table and multiple-table forms of this statement support the use of a `PARTITION` option as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the *where_condition* or not.

Note

Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the *where_condition*.

For more information and examples, see [Section 22.5, “Partition Selection”](#).

where_condition is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 9.5, “Expression Syntax”](#).

table_references and *where_condition* are specified as described in [Section 13.2.10, “SELECT Syntax”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table [UPDATE](#) assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared [NOT NULL](#) by setting to [NULL](#), an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. See [Section 11.7, “Data Type Default Values”](#).

If a generated column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 13.1.18.8, “CREATE TABLE and Generated Columns”](#).

[UPDATE](#) returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the [UPDATE](#).

You can use [LIMIT row_count](#) to restrict the scope of the [UPDATE](#). A [LIMIT](#) clause is a rows-matched restriction. The statement stops as soon as it has found [row_count](#) rows that satisfy the [WHERE](#) clause, whether or not they actually were changed.

If an [UPDATE](#) statement includes an [ORDER BY](#) clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an [ORDER BY](#) clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform [UPDATE](#) operations covering multiple tables. However, you cannot use [ORDER BY](#) or [LIMIT](#) with a multiple-table [UPDATE](#). The [table_references](#) clause lists the tables involved in the join. Its syntax is described in [Section 13.2.10.2, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table [UPDATE](#) statements can use any type of join permitted in [SELECT](#) statements, such as [LEFT JOIN](#).

If you use a multiple-table [UPDATE](#) statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the [ON UPDATE](#) capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

An [UPDATE](#) on a partitioned table using a storage engine such as [MyISAM](#) that employs table-level locks locks only those partitions containing rows that match the [UPDATE](#) statement [WHERE](#) clause, as long as

none of the table partitioning columns are updated. (For storage engines such as [InnoDB](#) that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.2.13 WITH Syntax (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

- [Common Table Expression Syntax](#)
- [Recursive Common Table Expressions](#)
- [Limiting Common Table Expression Recursion](#)
- [Recursive Common Table Expression Examples](#)
- [Common Table Expressions Compared to Similar Constructs](#)

For information about CTE optimization, see [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

Additional Resources

These articles contain additional information about using CTEs in MySQL, including many examples:

Common Table Expression Syntax

To specify common table expressions, use a [WITH](#) clause that has one or more comma-separated subclauses. Each subclause provides a subquery that produces a result set, and associates a name with the subquery. The following example defines CTEs named `cte1` and `cte2` in the [WITH](#) clause, and refers to them in the top-level [SELECT](#) that follows the [WITH](#) clause:

```
WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

In the statement containing the [WITH](#) clause, each CTE name can be referenced to access the corresponding CTE result set.

A CTE name can be referenced in other CTEs, enabling CTEs to be defined based on other CTEs.

A CTE can refer to itself to define a recursive CTE. Common applications of recursive CTEs include series generation and traversal of hierarchical or tree-structured data.

Common table expressions are an optional part of the syntax for DML statements. They are defined using a **WITH** clause:

```
with_clause:
    WITH [RECURSIVE]
        cte_name [(col_name [, col_name] ...)] AS (subquery)
        [, cte_name [(col_name [, col_name] ...)] AS (subquery)] ...
```

cte_name names a single common table expression and can be used as a table reference in the statement containing the **WITH** clause.

The *subquery* part of **AS (subquery)** is called the “subquery of the CTE” and is what produces the CTE result set. The parentheses following **AS** are required.

A common table expression is recursive if its subquery refers to its own name. The **RECURSIVE** keyword must be included if any CTE in the **WITH** clause is recursive. For more information, see [Recursive Common Table Expressions](#).

Determination of column names for a given CTE occurs as follows:

- If a parenthesized list of names follows the CTE name, those names are the column names:

```
WITH cte (col1, col2) AS
(
    SELECT 1, 2
    UNION ALL
    SELECT 3, 4
)
SELECT col1, col2 FROM cte;
```

The number of names in the list must be the same as the number of columns in the result set.

- Otherwise, the column names come from the select list of the first **SELECT** within the **AS (subquery)** part:

```
WITH cte AS
(
    SELECT 1 AS col1, 2 AS col2
    UNION ALL
    SELECT 3, 4
)
SELECT col1, col2 FROM cte;
```

A **WITH** clause is permitted in these contexts:

- At the beginning of **SELECT**, **UPDATE**, and **DELETE** statements.

```
WITH ... SELECT ...
WITH ... UPDATE ...
WITH ... DELETE ...
```

- At the beginning of subqueries (including derived table subqueries):

```
SELECT ... WHERE id IN (WITH ... SELECT ...) ...
SELECT * FROM (WITH ... SELECT ...) AS dt ...
```

- Immediately preceding **SELECT** for statements that include a **SELECT** statement:

```
INSERT ... WITH ... SELECT ...
REPLACE ... WITH ... SELECT ...
CREATE TABLE ... WITH ... SELECT ...
CREATE VIEW ... WITH ... SELECT ...
DECLARE CURSOR ... WITH ... SELECT ...
EXPLAIN ... WITH ... SELECT ...
```

Only one **WITH** clause is permitted at the same level. **WITH** followed by **WITH** at the same level is not permitted, so this is illegal:

```
WITH cte1 AS (...) WITH cte2 AS (...) SELECT ...
```

To make the statement legal, use a single **WITH** clause that separates the subclauses by a comma:

```
WITH cte1 AS (...), cte2 AS (...) SELECT ...
```

However, a statement can contain multiple **WITH** clauses if they occur at different levels:

```
WITH cte1 AS (SELECT 1)
SELECT * FROM (WITH cte2 AS (SELECT 2) SELECT * FROM cte2 JOIN cte1) AS dt;
```

A **WITH** clause can define one or more common table expressions, but each CTE name must be unique to the clause. This is illegal:

```
WITH cte1 AS (...), cte1 AS (...) SELECT ...
```

To make the statement legal, define the CTEs with unique names:

```
WITH cte1 AS (...), cte2 AS (...) SELECT ...
```

A CTE can refer to itself or to other CTEs:

- A self-referencing CTE is recursive.
- A CTE can refer to CTEs defined earlier in the same **WITH** clause, but not those defined later.

This constraint rules out mutually-recursive CTEs, where **cte1** references **cte2** and **cte2** references **cte1**. One of those references must be to a CTE defined later, which is not permitted.

- A CTE in a given query block can refer to CTEs defined in query blocks at a more outer level, but not CTEs defined in query blocks at a more inner level.

For resolving references to objects with the same names, derived tables hide CTEs; and CTEs hide base tables, **TEMPORARY** tables, and views. Name resolution occurs by searching for objects in the same query block, then proceeding to outer blocks in turn while no object with the name is found.

A CTE cannot contain outer references. As with derived tables, which also prohibit outer references, this is a MySQL restriction, not a restriction of the SQL standard. For additional syntax considerations specific to recursive CTEs, see [Recursive Common Table Expressions](#).

Recursive Common Table Expressions

A recursive common table expression is one having a subquery that refers to its own name. For example:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

When executed, the statement produces this result, a single column containing a simple linear sequence:

```
+-----+
| n     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
+-----+
```

A recursive CTE has this structure:

- The **WITH** clause must begin with **WITH RECURSIVE** if any CTE in the **WITH** clause refers to itself. (If no CTE refers to itself, **RECURSIVE** is permitted but not required.)

If you forget **RECURSIVE** for a recursive CTE, this error is a likely result:

```
ERROR 1146 (42S02): Table 'cte_name' doesn't exist
```

- The recursive CTE subquery has two parts, separated by **UNION [ALL]** or **UNION DISTINCT**:

```
SELECT ...      -- return initial row set
UNION ALL
SELECT ...      -- return additional row sets
```

The first **SELECT** produces the initial row or rows for the CTE and does not refer to the CTE name. The second **SELECT** produces additional rows and recurses by referring to the CTE name in its **FROM** clause. Recursion ends when this part produces no new rows. Thus, a recursive CTE consists of a nonrecursive **SELECT** part followed by a recursive **SELECT** part.

Each **SELECT** part can itself be a union of multiple **SELECT** statements.

- The types of the CTE result columns are inferred from the column types of the nonrecursive **SELECT** part only, and the columns are all nullable. For type determination, the recursive **SELECT** part is ignored.
- If the nonrecursive and recursive parts are separated by **UNION DISTINCT**, duplicate rows are eliminated. This is useful for queries that perform transitive closures, to avoid infinite loops.
- Each iteration of the recursive part operates only on the rows produced by the previous iteration. If the recursive part has multiple query blocks, iterations of each query block are scheduled in unspecified order, and each query block operates on rows that have been produced either by its previous iteration or by other query blocks since that previous iteration's end.

The recursive CTE subquery shown earlier has this nonrecursive part that retrieves a single row to produce the initial row set:

```
SELECT 1
```

The CTE subquery also has this recursive part:

```
SELECT n + 1 FROM cte WHERE n < 5
```

At each iteration, that `SELECT` produces a row with a new value one greater than the value of `n` from the previous row set. The first iteration operates on the initial row set (1) and produces `1+1=2`; the second iteration operates on the first iteration's row set (2) and produces `2+1=3`; and so forth. This continues until recursion ends, which occurs when `n` is no longer less than 5.

If the recursive part of a CTE produces wider values for a column than the nonrecursive part, it may be necessary to widen the column in the nonrecursive part to avoid data truncation. Consider this statement:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, 'abc' AS str
  UNION ALL
  SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
)
SELECT * FROM cte;
```

In nonstrict SQL mode, the statement produces this output:

n	str
1	abc
2	abc
3	abc

The `str` column values are all `'abc'` because the nonrecursive `SELECT` determines the column widths. Consequently, the wider `str` values produced by the recursive `SELECT` are truncated.

In strict SQL mode, the statement produces an error:

```
ERROR 1406 (22001): Data too long for column 'str' at row 1
```

To address this issue, so that the statement does not produce truncation or errors, use `CAST()` in the nonrecursive `SELECT` to make the `str` column wider:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, CAST('abc' AS CHAR(20)) AS str
  UNION ALL
  SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
)
SELECT * FROM cte;
```

Now the statement produces this result, without truncation:

n	str
1	abc
2	abccabc
3	abccabccabccabc

Columns are accessed by name, not position, which means that columns in the recursive part can access columns in the nonrecursive part that have a different position, as this CTE illustrates:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, 1 AS p, -1 AS q
  UNION ALL
  SELECT n + 1, q * 2, p * 2 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

Because `p` in one row is derived from `q` in the previous row, and vice versa, the positive and negative values swap positions in each successive row of the output:

n	p	q
1	1	-1
2	-2	2
3	4	-4
4	-8	8
5	16	-16

Some syntax constraints apply within recursive CTE subqueries:

- The recursive `SELECT` part must not contain these constructs:
 - Aggregate functions such as `SUM()`
 - Window functions
 - `GROUP BY`
 - `ORDER BY`
 - `LIMIT`
 - `DISTINCT`

This constraint does not apply to the nonrecursive `SELECT` part of a recursive CTE. The prohibition on `DISTINCT` applies only to `UNION` members; `UNION DISTINCT` is permitted.

- The recursive `SELECT` part must reference the CTE only once and only in its `FROM` clause, not in any subquery. It can reference tables other than the CTE and join them with the CTE. If used in a join like this, the CTE must not be on the right side of a `LEFT JOIN`.

These constraints come from the SQL standard, other than the MySQL-specific exclusions of `ORDER BY`, `LIMIT`, and `DISTINCT`.

For recursive CTEs, `EXPLAIN` output rows for recursive `SELECT` parts display `Recursive` in the `Extra` column.

Cost estimates displayed by `EXPLAIN` represent cost per iteration, which might differ considerably from total cost. The optimizer cannot predict the number of iterations because it cannot predict when the `WHERE` clause will become false.

CTE actual cost may also be affected by result set size. A CTE that produces many rows may require an internal temporary table large enough to be converted from in-memory to on-disk format and may

suffer a performance penalty. If so, increasing the permitted in-memory temporary table size may improve performance; see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

Limiting Common Table Expression Recursion

It is important for recursive CTEs that the recursive [SELECT](#) part include a condition to terminate recursion. As a development technique to guard against a runaway recursive CTE, you can force termination by placing a limit on execution time:

- The [cte_max_recursion_depth](#) system variable enforces a limit on the number of recursion levels for CTEs. The server terminates execution of any CTE that recurses more levels than the value of this variable.
- The [max_execution_time](#) system variable enforces an execution timeout for [SELECT](#) statements executed within the current session.
- The [MAX_EXECUTION_TIME](#) optimizer hint enforces a per-query execution timeout for the [SELECT](#) statement in which it appears.

Suppose that a recursive CTE is mistakenly written with no recursion execution termination condition:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte
)
SELECT * FROM cte;
```

By default, [cte_max_recursion_depth](#) has a value of 1000, causing the CTE to terminate when it recurses past 1000 levels. Applications can change the session value to adjust for their requirements:

```
SET SESSION cte_max_recursion_depth = 10;      -- permit only shallow recursion
SET SESSION cte_max_recursion_depth = 1000000; -- permit deeper recursion
```

You can also set the global [cte_max_recursion_depth](#) value to affect all sessions that begin subsequently.

For queries that execute and thus recurse slowly or in contexts for which there is reason to set the [cte_max_recursion_depth](#) value very high, another way to guard against deep recursion is to set a per-session timeout. To do so, execute a statement like this prior to executing the CTE statement:

```
SET max_execution_time = 1000; -- impose one second timeout
```

Alternatively, include an optimizer hint within the CTE statement itself:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte
)
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM cte;
```

If a recursive query without an execution time limit enters an infinite loop, you can terminate it from another session using [KILL QUERY](#). Within the session itself, the client program used to run the query might provide a way to kill the query. For example, in [mysql](#), typing **Control+C** interrupts the current statement.

Recursive Common Table Expression Examples

As mentioned previously, recursive common table expressions (CTEs) are frequently used for series generation and traversing hierarchical or tree-structured data. This section shows some simple examples of these techniques.

- [Fibonacci Series Generation](#)
- [Date Series Generation](#)
- [Hierarchical Data Traversal](#)

Fibonacci Series Generation

A Fibonacci series begins with the two numbers 0 and 1 (or 1 and 1) and each number after that is the sum of the previous two numbers. A recursive common table expression can generate a Fibonacci series if each row produced by the recursive `SELECT` has access to the two previous numbers from the series. The following CTE generates a 10-number series using 0 and 1 as the first two numbers:

```
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
(
  SELECT 1, 0, 1
  UNION ALL
  SELECT n + 1, next_fib_n, fib_n + next_fib_n
    FROM fibonacci WHERE n < 10
)
SELECT * FROM fibonacci;
```

The CTE produces this result:

n	fib_n	next_fib_n
1	0	1
2	1	1
3	1	2
4	2	3
5	3	5
6	5	8
7	8	13
8	13	21
9	21	34
10	34	55

How the CTE works:

- `n` is a display column to indicate that the row contains the `n`-th Fibonacci number. For example, the 8th Fibonacci number is 13.
- The `fib_n` column displays Fibonacci number `n`.
- The `next_fib_n` column displays the next Fibonacci number after number `n`. This column provides the next series value to the next row, so that row can produce the sum of the two previous series values in its `fib_n` column.
- Recursion ends when `n` reaches 10. This is an arbitrary choice, to limit the output to a small set of rows.

The preceding output shows the entire CTE result. To select just part of it, add an appropriate `WHERE` clause to the top-level `SELECT`. For example, to select the 8th Fibonacci number, do this:

```
mysql> WITH RECURSIVE fibonacci ...
      ...
      SELECT fib_n FROM fibonacci WHERE n = 8;
+-----+
| fib_n |
+-----+
|    13 |
+-----+
```

Date Series Generation

A common table expression can generate a series of successive dates, which is useful for generating summaries that include a row for all dates in the series, including dates not represented in the summarized data.

Suppose that a table of sales numbers contains these rows:

```
mysql> SELECT * FROM sales ORDER BY date, price;
+-----+-----+
| date   | price |
+-----+-----+
| 2017-01-03 | 100.00 |
| 2017-01-03 | 200.00 |
| 2017-01-06 | 50.00  |
| 2017-01-08 | 10.00  |
| 2017-01-08 | 20.00  |
| 2017-01-08 | 150.00 |
| 2017-01-10 | 5.00   |
+-----+-----+
```

This query summarizes the sales per day:

```
mysql> SELECT date, SUM(price) AS sum_price
      FROM sales
      GROUP BY date
      ORDER BY date;
+-----+-----+
| date   | sum_price |
+-----+-----+
| 2017-01-03 | 300.00 |
| 2017-01-06 | 50.00  |
| 2017-01-08 | 180.00 |
| 2017-01-10 | 5.00   |
+-----+-----+
```

However, that result contains “holes” for dates not represented in the range of dates spanned by the table. A result that represents all dates in the range can be produced using a recursive CTE to generate that set of dates, joined with a [LEFT JOIN](#) to the sales data.

Here is the CTE to generate the date range series:

```
WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)
SELECT * FROM dates;
```

The CTE produces this result:

```
+-----+
| date   |
+-----+
| 2017-01-03 |
| 2017-01-04 |
| 2017-01-05 |
| 2017-01-06 |
| 2017-01-07 |
| 2017-01-08 |
| 2017-01-09 |
| 2017-01-10 |
+-----+
```

How the CTE works:

- The nonrecursive `SELECT` produces the lowest date in the date range spanned by the `sales` table.
- Each row produced by the recursive `SELECT` adds one day to the date produced by the previous row.
- Recursion ends after the dates reach the highest date in the date range spanned by the `sales` table.

Joining the CTE with a `LEFT JOIN` against the `sales` table produces the sales summary with a row for each date in the range:

```
WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)
SELECT dates.date, COALESCE(SUM(price), 0) AS sum_price
FROM dates LEFT JOIN sales ON dates.date = sales.date
GROUP BY dates.date
ORDER BY dates.date;
```

The output looks like this:

```
+-----+-----+
| date   | sum_price |
+-----+-----+
| 2017-01-03 | 300.00 |
| 2017-01-04 | 0.00 |
| 2017-01-05 | 0.00 |
| 2017-01-06 | 50.00 |
| 2017-01-07 | 0.00 |
| 2017-01-08 | 180.00 |
| 2017-01-09 | 0.00 |
| 2017-01-10 | 5.00 |
+-----+-----+
```

Some points to note:

- Are the queries inefficient, particularly the one with the `MAX()` subquery executed for each row in the recursive `SELECT`? Checking with `EXPLAIN` shows that the subqueries are optimized away for efficiency.
- The use of `COALESCE()` avoids displaying `NULL` in the `sum_price` column on days for which no sales data occur in the `sales` table.

Hierarchical Data Traversal

Recursive common table expressions are useful for traversing data that forms a hierarchy. Consider these statements that create a small data set that shows, for each employee in a company, the employee name and ID number, and the ID of the employee's manager. The top-level employee (the CEO), has a manager ID of `NULL` (no manager).

```
CREATE TABLE employees (
  id          INT PRIMARY KEY NOT NULL,
  name        VARCHAR(100) NOT NULL,
  manager_id  INT NULL,
  INDEX (manager_id),
  FOREIGN KEY (manager_id) REFERENCES EMPLOYEES (id)
);
INSERT INTO employees VALUES
(333, "Yasmina", NULL), # Yasmina is the CEO (manager_id is NULL)
(198, "John", 333),     # John has ID 198 and reports to 333 (Yasmina)
(692, "Tarek", 333),
(29, "Pedro", 198),
(4610, "Sarah", 29),
(72, "Pierre", 29),
(123, "Adil", 692);
```

The resulting data set looks like this:

```
mysql> SELECT * FROM employees ORDER BY id;
+-----+-----+-----+
| id | name | manager_id |
+-----+-----+-----+
| 29 | Pedro | 198 |
| 72 | Pierre | 29 |
| 123 | Adil | 692 |
| 198 | John | 333 |
| 333 | Yasmina | NULL |
| 692 | Tarek | 333 |
| 4610 | Sarah | 29 |
+-----+-----+-----+
```

To produce the organizational chart with the management chain for each employee (that is, the path from CEO to employee), use a recursive CTE:

```
WITH RECURSIVE employee_paths (id, name, path) AS
(
  SELECT id, name, CAST(id AS CHAR(200))
  FROM employees
  WHERE manager_id IS NULL
  UNION ALL
  SELECT e.id, e.name, CONCAT(ep.path, ',', e.id)
  FROM employee_paths AS ep JOIN employees AS e
  ON ep.id = e.manager_id
)
SELECT * FROM employee_paths ORDER BY path;
```

The CTE produces this output:

```
+-----+-----+-----+
| id | name | path |
+-----+-----+-----+
| 333 | Yasmina | 333 |
| 198 | John | 333,198 |
| 29 | Pedro | 333,198,29 |
+-----+-----+-----+
```

4610	Sarah	333,198,29,4610
72	Pierre	333,198,29,72
692	Tarek	333,692
123	Adil	333,692,123

How the CTE works:

- The nonrecursive `SELECT` produces the row for the CEO (the row with a `NULL` manager ID).

The `path` column is widened to `CHAR(200)` to ensure that there is room for the longer `path` values produced by the recursive `SELECT`.

- Each row produced by the recursive `SELECT` finds all employees who report directly to an employee produced by a previous row. For each such employee, the row includes the employee ID and name, and the employee management chain. The chain is the manager's chain, with the employee ID added to the end.
- Recursion ends when employees have no others who report to them.

To find the path for a specific employee or employees, add a `WHERE` clause to the top-level `SELECT`. For example, to display the results for Tarek and Sarah, modify that `SELECT` like this:

```
mysql> WITH RECURSIVE ...
...
SELECT * FROM employees_extended
WHERE id IN (692, 4610)
ORDER BY path;
```

id	name	path
4610	Sarah	333,198,29,4610
692	Tarek	333,692

Common Table Expressions Compared to Similar Constructs

Common table expressions (CTEs) are similar to derived tables in some ways:

- Both constructs are named.
- Both constructs exist for the scope of a single statement.

Because of these similarities, CTEs and derived tables often can be used interchangeably. As a trivial example, these statements are equivalent:

```
WITH cte AS (SELECT 1) SELECT * FROM cte;
SELECT * FROM (SELECT 1) AS dt;
```

However, CTEs have some advantages over derived tables:

- A derived table can be referenced only a single time within a query. A CTE can be referenced multiple times. To use multiple instances of a derived table result, you must derive the result multiple times.
- A CTE can be self-referencing (recursive).
- One CTE can refer to another.
- A CTE may be easier to read when its definition appears at the beginning of the statement rather than embedded within it.

CTEs are similar to tables created with `CREATE [TEMPORARY] TABLE` but need not be defined or dropped explicitly. For a CTE, you need no privileges to create tables.

13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.3.8, “XA Transactions”](#).

13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION
    [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic: {
    WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
}

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of [transactions](#):

- `START TRANSACTION` or `BEGIN` start a new transaction.
- `COMMIT` commits the current transaction, making its changes permanent.
- `ROLLBACK` rolls back the current transaction, canceling its changes.
- `SET autocommit` disables or enables the default autocommit mode for the current session.

By default, MySQL runs with `autocommit` mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, `autocommit` remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The `autocommit` mode then reverts to its previous state.

`START TRANSACTION` permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The `WITH CONSISTENT SNAPSHOT` modifier starts a [consistent read](#) for storage engines that are capable of it. This applies only to `InnoDB`. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any `InnoDB` table. See [Section 15.5.2.3, “Consistent Nonlocking Reads”](#).

The `WITH CONSISTENT SNAPSHOT` modifier does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is `REPEATABLE READ`. For all other isolation levels, the `WITH CONSISTENT SNAPSHOT` clause is ignored. A warning is generated when the `WITH CONSISTENT SNAPSHOT` clause is ignored.

- The `READ WRITE` and `READ ONLY` modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The `READ ONLY` restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on [InnoDB](#) tables when the transaction is known to be read-only. Specifying `READ ONLY` ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see [Section 13.3.7, “SET TRANSACTION Syntax”](#).

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `CONNECTION_ADMIN` or `SUPER` privilege.

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 27, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for [InnoDB](#) or [NDB](#)) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at [Section 5.1.7, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.7, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (`READ WRITE` or `READ ONLY`) as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 5.4.4, “The Binary Log”](#).

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See [Section 13.3.7, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

In MySQL 8.0, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER EVENT`, `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE ROLE`, `CREATE SERVER`, `CREATE SPATIAL REFERENCE SYSTEM`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP ROLE`, `DROP SERVER`, `DROP SPATIAL REFERENCE SYSTEM`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `INSTALL PLUGIN`, `RENAME TABLE`, `TRUNCATE TABLE`, `UNINSTALL PLUGIN`.

`CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.)

- **Statements that implicitly use or modify tables in the `mysql` database.** `ALTER USER`, `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

- **Data loading statements.** `LOAD DATA INFILE`. `LOAD DATA INFILE` causes an implicit commit only for tables using the `NDB` storage engine.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `FLUSH`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, `RESET` (but not `RESET PERSIST`).
- **Replication control statements.** `START SLAVE`, `STOP SLAVE`, `RESET SLAVE`, `CHANGE MASTER TO`.

13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

13.3.5 LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE Syntax

```
LOCK INSTANCE FOR BACKUP
```

```
UNLOCK INSTANCE
```

LOCK INSTANCE FOR BACKUP acquires an instance-level *backup lock* that permits DML during an online backup while preventing operations that could result in an inconsistent snapshot.

Executing the **LOCK INSTANCE FOR BACKUP** statement requires the **BACKUP_ADMIN** privilege. The **BACKUP_ADMIN** privilege is automatically granted to users with the **RELOAD** privilege when performing an in-place upgrade to MySQL 8.0 from an earlier version.

Multiple sessions can hold a backup lock simultaneously.

UNLOCK INSTANCE releases a backup lock held by the current session. A backup lock held by a session is also released if the session is terminated.

LOCK INSTANCE FOR BACKUP prevents files from being created, renamed, or removed. **REPAIR TABLE TRUNCATE TABLE**, **OPTIMIZE TABLE**, and account management statements are blocked. See [Section 13.7.1, “Account Management Statements”](#). Operations that modify InnoDB files that are not recorded in the InnoDB redo log are also blocked.

LOCK INSTANCE FOR BACKUP permits DDL operations that only affect user-created temporary tables. In effect, files that belong to user-created temporary tables can be created, renamed, or removed while a backup lock is held. Creation of binary log files is also permitted.

A backup lock acquired by **LOCK INSTANCE FOR BACKUP** is independent of transactional locks and locks taken by **FLUSH TABLES *tbl_name* [, *tbl_name*] ... WITH READ LOCK**, and the following sequences of statements are permitted:

```
LOCK INSTANCE FOR BACKUP;
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
UNLOCK TABLES;
UNLOCK INSTANCE;
```

```
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
LOCK INSTANCE FOR BACKUP;
UNLOCK INSTANCE;
UNLOCK TABLES;
```

The **lock_wait_timeout** setting defines the amount of time that a **LOCK INSTANCE FOR BACKUP** statement waits to acquire a lock before giving up.

13.3.6 LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type: {
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE
}

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 13.3.6.2, “LOCK TABLES and Triggers”](#).

If you lock a table explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 13.7.7.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

For information about other conditions on the use of `LOCK TABLES` and statements that cannot be used while `LOCK TABLES` is in effect, see [Section 13.3.6.3, “Table-Locking Restrictions and Conditions”](#)

Rules for Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement. The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).
- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 8.11.3, “Concurrent Inserts”](#).) However, `READ LOCAL`

cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For [InnoDB](#) tables, [READ LOCAL](#) is the same as [READ](#).

[\[LOW_PRIORITY\]](#) [WRITE](#) lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the [WRITE](#) lock is held.
- The [LOW_PRIORITY](#) modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use [WRITE](#) without [LOW_PRIORITY](#) instead.

If the [LOCK TABLES](#) statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single [LOCK TABLES](#) statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access [t2](#) because it was not locked in the [LOCK TABLES](#) statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the [INFORMATION_SCHEMA](#) database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with [LOCK TABLES](#).

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first [INSERT](#) because there are two references to the same name for a locked table. The second [INSERT](#) succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

WRITE locks normally have higher priority than **READ** locks to ensure that updates are processed as soon as possible. This means that if one session obtains a **READ** lock and then another session requests a **WRITE** lock, subsequent **READ** lock requests wait until the session that requested the **WRITE** lock has obtained the lock and released it.

LOCK TABLES acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free.

Note

LOCK TABLES or **UNLOCK TABLES**, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See [Partitioning and Locking](#).

Rules for Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with **UNLOCK TABLES**.
- If a session issues a **LOCK TABLES** statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with **START TRANSACTION**), an implicit **UNLOCK TABLES** is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Section 13.3.6.1, “Interaction of Table Locking and Transactions”](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 27.7.24, “C API Automatic Reconnection Control”](#).

Note

If you use **ALTER TABLE** on a locked table, it may become unlocked. For example, if you attempt a second **ALTER TABLE** operation, the result may be an error `Table`

`'tbl_name'` was not locked with `LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

13.3.6.1 Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 13.7.7.3, “FLUSH Syntax”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

13.3.6.2 LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.

- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

13.3.6.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 13.7.7.4, “KILL Syntax”](#).

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
```

```
mysql.help_relation
mysql.help_topic
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a [WRITE](#) lock on any of those tables with a [LOCK TABLES](#) statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single [UPDATE](#) statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of [MyISAM](#) tables, it is much faster to lock the tables you are going to use. Locking [MyISAM](#) tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until [UNLOCK TABLES](#) is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a [READ](#)-locked table (including the one holding the lock) and no session can access a [WRITE](#)-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use [LOCK TABLES](#) if you want to ensure that no other session modifies the tables between a [SELECT](#) and an [UPDATE](#). The example shown here requires [LOCK TABLES](#) to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without [LOCK TABLES](#), it is possible that another session might insert a new row in the [trans](#) table between execution of the [SELECT](#) and [UPDATE](#) statements.

You can avoid using [LOCK TABLES](#) in many cases by using relative updates ([UPDATE customer SET value=value+new_value](#)) or the [LAST_INSERT_ID\(\)](#) function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions [GET_LOCK\(\)](#) and [RELEASE_LOCK\(\)](#). These locks are saved in a hash table in the server and implemented with [pthread_mutex_lock\(\)](#) and [pthread_mutex_unlock\(\)](#) for high speed. See [Section 12.22, “Miscellaneous Functions”](#).

See [Section 8.11.1, “Internal Locking Methods”](#), for more information on locking policy.

13.3.7 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic: {
    ISOLATION LEVEL level
  | READ WRITE
  | READ ONLY
}
```

```

level: {
    REPEATABLE READ
  | READ COMMITTED
  | READ UNCOMMITTED
  | SERIALIZABLE
}

```

This statement specifies [transaction](#) characteristics. It takes a list of one or more characteristic values separated by commas. These characteristics set the transaction [isolation level](#) or access mode. The isolation level is used for operations on [InnoDB](#) tables. The access mode may be specified as to whether transactions operate in read/write or read-only mode.

In addition, [SET TRANSACTION](#) can include an optional [GLOBAL](#) or [SESSION](#) keyword to indicate the scope of the statement.

Scope of Transaction Characteristics

You can set transaction characteristics globally, for the current session, or for the next transaction:

- With the [GLOBAL](#) keyword, the statement applies globally for all subsequent sessions. Existing sessions are unaffected.
- With the [SESSION](#) keyword, the statement applies to all subsequent transactions performed within the current session.
- Without any [SESSION](#) or [GLOBAL](#) keyword, the statement applies to the next (not started) transaction performed within the current session. Subsequent transactions revert to using the [SESSION](#) isolation level.

A global change to transaction characteristics requires the [CONNECTION_ADMIN](#) or [SUPER](#) privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction.

[SET TRANSACTION](#) without [GLOBAL](#) or [SESSION](#) is not permitted while there is an active transaction:

```

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed
while a transaction is in progress

```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to [mysqld](#) on the command line or in an option file. Values of *level* for this option use dashes rather than spaces, so the permissible values are [READ-UNCOMMITTED](#), [READ-COMMITTED](#), [REPEATABLE-READ](#), or [SERIALIZABLE](#). For example, to set the default isolation level to [REPEATABLE READ](#), use these lines in the `[mysqld]` section of an option file:

```

[mysqld]
transaction-isolation = REPEATABLE-READ

```

It is possible to check or set the global and session transaction isolation levels at runtime by using the [transaction_isolation](#) system variable:

```

SELECT @@GLOBAL.transaction_isolation, @@transaction_isolation;
SET GLOBAL transaction_isolation='REPEATABLE-READ';

```

```
SET SESSION transaction_isolation='SERIALIZABLE';
```

Similarly, to set the transaction access mode at server startup or at runtime, use the `--transaction-read-only` option or `transaction_read_only` system variable. By default, these are `OFF` (the mode is read/write) but can be set to `ON` for a default mode of read only.

Setting the global or session value of `transaction_isolation` or `transaction_read_only` is equivalent to setting the isolation level or access mode with `SET GLOBAL TRANSACTION` or `SET SESSION TRANSACTION`.

Transaction Isolation Levels

For information about transaction isolation levels, see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

Transaction Access Mode

The transaction access mode may be specified with `SET TRANSACTION`. By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

13.3.8 XA Transactions

Support for [XA](#) transactions is available for the [InnoDB](#) storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section C.6, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, [SERIALIZABLE](#)

may be preferred if your applications are sensitive to read phenomena. [REPEATABLE READ](#) may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.8.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER [CONVERT XID]
```

For **XA START**, the **JOIN** and **RESUME** clauses are not supported.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

gtrid is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is `' '` if not given. The default *formatID* value is 1 if not given.

gtrid and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`X'6162'`, `0x6162`), or bit value (`b'nnnn'`).

formatID is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

xid values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the **XA RECOVER** statement.

XA START *xid* starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the **XA START** statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See [Section 13.3.8.2, “XA Transaction States”](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` requires the `XA_RECOVER_ADMIN` privilege. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

`XA RECOVER` output rows look like this (for an example `xid` value consisting of the parts `'abc'`, `'def'`, and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |             3 |             3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- `formatID` is the `formatID` part of the transaction `xid`
- `gtrid_length` is the length in bytes of the `gtrid` part of the `xid`
- `bqual_length` is the length in bytes of the `bqual` part of the `xid`
- `data` is the concatenation of the `gtrid` and `bqual` parts of the `xid`

XID values may contain nonprintable characters. `XA RECOVER` permits an optional `CONVERT XID` clause so that clients can request XID values in hexadecimal.

13.3.8.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
 - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
 - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls master servers, a group which controls slave servers, and a group which can be applied to any replication servers.

13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following `SHOW` statements are used with master servers in replication. For information about these statements, see [Section 13.7.6, “SHOW Syntax”](#).

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

13.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 5.4.4, “The Binary Log”](#)).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The `BEFORE` variant's *datetime_expr* argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. A warning message is issued in this situation. However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. You can specify an alternative expiration period using the `binlog_expire_logs_seconds` system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your slaves might lag behind the master.

13.4.1.2 RESET MASTER Syntax

```
RESET MASTER [TO binary_log_file_index_number]
```

`RESET MASTER` enables you to delete any binary log files and their related binary log index file, returning the master to its state before binary logging was started.

**Warning**

Use this statement with caution to ensure you do not lose binary log file data.

Issuing `RESET MASTER` without the optional `TO` clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at 1. Use the optional `TO` clause to start the binary log file index from a number other than 1 after the reset. Issuing `RESET MASTER` also clears the values of the `gtid_purged` system variable and the `gtid_executed` system variable; that is, issuing this statement sets each of these values to an empty string (''). This statement also clears the `mysql.gtid_executed` table (see [mysql.gtid_executed Table](#)).

Using `RESET MASTER` with the `TO` clause to specify a binary log file index number to start from simplifies failover by providing a single statement alternative to the `FLUSH BINARY LOGS` and `PURGE BINARY LOGS TO` statements.

The following example demonstrates `TO` clause usage:

```
RESET MASTER TO 1234;

SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| master-bin.001234 |        154 |
+-----+-----+
```

**Important**

The effects of `RESET MASTER` without the `TO` clause differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` without the `TO` clause can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that no unwanted data from the test queries exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup, resetting the master and slave and ensuring that no unwanted data or binary log files generated by testing remain on the master or slave, you can start the slave and begin replicating.

13.4.1.3 SET sql_log_bin Syntax

```
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the master you do not want replicated to the slave.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 13.7.6.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 13.7.6.32, “SHOW RELAYLOG EVENTS Syntax”](#).

13.4.2.1 CHANGE MASTER TO Syntax

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

option:

```
MASTER_BIND = 'interface_name'
| MASTER_HOST = 'host_name'
| MASTER_USER = 'user_name'
| MASTER_PASSWORD = 'password'
| MASTER_PORT = port_num
| MASTER_CONNECT_RETRY = interval
| MASTER_RETRY_COUNT = count
| MASTER_DELAY = interval
| MASTER_HEARTBEAT_PERIOD = interval
| MASTER_LOG_FILE = 'master_log_name'
| MASTER_LOG_POS = master_log_pos
| MASTER_AUTO_POSITION = {0|1}
| RELAY_LOG_FILE = 'relay_log_name'
| RELAY_LOG_POS = relay_log_pos
| MASTER_SSL = {0|1}
| MASTER_SSL_CA = 'ca_file_name'
| MASTER_SSL_CAPATH = 'ca_directory_name'
| MASTER_SSL_CERT = 'cert_file_name'
| MASTER_SSL_CRL = 'crl_file_name'
| MASTER_SSL_CRLPATH = 'crl_directory_name'
```

```

MASTER_SSL_KEY = 'key_file_name'
MASTER_SSL_CIPHER = 'cipher_list'
MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
MASTER_TLS_VERSION = 'protocol_list'
MASTER_PUBLIC_KEY_PATH = 'key_file_name'
GET_MASTER_PUBLIC_KEY = {0|1}
IGNORE_SERVER_IDS = (server_id_list)

channel_option:
  FOR CHANNEL channel

server_id_list:
  [server_id [, server_id] ... ]

```

CHANGE MASTER TO changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the master info and relay log info repositories (see [Section 17.2.4, “Replication Relay and Status Logs”](#)). **CHANGE MASTER TO** requires the [REPLICATION_SLAVE_ADMIN](#) or [SUPER](#) privilege.

You can issue **CHANGE MASTER TO** statements on a running slave without first stopping it, depending on the states of the slave SQL thread and slave I/O thread. The rules governing such use are provided later in this section.

When using a multithreaded slave (in other words [slave_parallel_workers](#) is greater than 0), stopping the slave can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the slave was stopped intentionally or otherwise. When such gaps exist, issuing **CHANGE MASTER TO** fails. The solution in this situation is to issue **START SLAVE UNTIL SQL_AFTER_MTS_GAPS** which ensures that the gaps are closed.

The optional **FOR CHANNEL channel** clause enables you to name which replication channel the statement applies to. Providing a **FOR CHANNEL channel** clause applies the **CHANGE MASTER TO** statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel2:

```
CHANGE MASTER TO MASTER_HOST=host1, MASTER_PORT=3002 FOR CHANNEL 'channel2'
```

If no clause is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a **CHANGE MASTER TO** statement does not name a channel using a **FOR CHANNEL channel** clause, an error occurs. See [Section 17.2.3, “Replication Channels”](#) for more information.

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change.

[MASTER_HOST](#), [MASTER_USER](#), [MASTER_PASSWORD](#), and [MASTER_PORT](#) provide information to the slave about how to connect to its master:

- [MASTER_HOST](#) and [MASTER_PORT](#) are the host name (or IP address) of the master host and its TCP/IP port.

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the [MASTER_HOST](#) or [MASTER_PORT](#) option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old

values for the master binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Trying to set `MASTER_HOST` to an empty string fails with an error.

Values used for `MASTER_HOST` and other `CHANGE MASTER TO` options are checked for linefeed (`\n` or `0x0A`) characters; the presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`. (Bug #11758581, Bug #50801)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

`MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail.

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_XXX` options, and the `MASTER_TLS_VERSION` option, specify how the slave uses encryption and ciphers to secure the replication connection. These options can be changed even on slaves that are compiled without SSL support. They are saved to the master info repository, but are ignored if the slave does not have SSL support enabled. The `MASTER_SSL_XXX` options perform the same functions as the `--ssl-xxx` options described in [Section 6.4.2, “Command Options for Encrypted Connections”](#). The correspondence between the two sets of options, and the use of the `MASTER_SSL_XXX` and `MASTER_TLS_VERSION` options to set up a secure connection, is explained in [Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”](#).

Important

To connect to the replication master using a user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in [Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”](#), or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users created from MySQL 8.0 (for details, see [Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”](#)). If the user account that you create or use for replication (as specified by the `MASTER_USER` option) uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection.

To enable RSA key pair-based password exchange, specify either the `MASTER_PUBLIC_KEY_PATH` or the `GET_MASTER_PUBLIC_KEY=1` option. Either of these options provides the RSA public key to the slave:

- `MASTER_PUBLIC_KEY_PATH` indicates the path name to a file containing a slave-side copy of the public key required by the master for RSA key pair-based password exchange. The file must be in PEM format. This option applies to slaves that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. (For `sha256_password`, `MASTER_PUBLIC_KEY_PATH` can be used only if MySQL was built using OpenSSL.)

- `GET_MASTER_PUBLIC_KEY` indicates whether to request from the master the public key required for RSA key pair-based password exchange. This option applies to slaves that authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the master does not send the public key unless requested, so it must be requested or specified in the client. If `MASTER_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_MASTER_PUBLIC_KEY`.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60.

`MASTER_RETRY_COUNT` limits the *number* of reconnection attempts and updates the value of the `Master_Retry_Count` column in the output of `SHOW SLAVE STATUS`. The default value is $24 * 3600 = 86400$. `MASTER_RETRY_COUNT` is intended to replace the older `--master-retry-count` server option, and is now the preferred method for setting this limit. You are encouraged not to rely on `--master-retry-count` in new applications and, when upgrading from versions earlier than MySQL 5.6, to update any existing applications that rely on it, so that they use `CHANGE MASTER TO ... MASTER_RETRY_COUNT` instead.

`MASTER_DELAY` specifies how many seconds behind the master the slave must lag. An event received from the master is not executed until at least *interval* seconds later than its execution on the master. The default is 0. An error occurs if *interval* is not a nonnegative integer in the range from 0 to $2^{31}-1$. For more information, see [Section 17.3.11, “Delayed Replication”](#).

A `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running slave when the slave SQL thread is stopped.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. In the master info repository table `mysql.slave_master_info`, the value can be seen as the `Master_bind` column.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than *interval*. `MASTER_HEARTBEAT_PERIOD` can be seen as the value of the `Heartbeat` column of the `mysql.slave_master_info` table.

Setting *interval* to 0 disables heartbeats altogether. The default value for *interval* is equal to the value of `slave_net_timeout` divided by 2.

Setting `@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

A `CHANGE MASTER TO` statement employing `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running slave when the slave SQL thread is stopped. Relay logs are preserved if at least one of the slave SQL thread and the slave I/O thread is running; if both threads are stopped, all relay log files are deleted unless at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified.

`RELAY_LOG_FILE` can use either an absolute or relative path, and uses the same base name as `MASTER_LOG_FILE`.

When `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the slave attempts to connect to the master using the GTID-based replication protocol. This option can be used with `CHANGE MASTER TO` only if both the slave SQL and slave I/O threads are stopped. Both the slave and the master must have GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE` on the slave, and `GTID_MODE=ON` on the master). Auto-positioning is used for the connection, so the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and the use of either or both of these options together with `MASTER_AUTO_POSITION = 1` causes an error. If multi-source replication is enabled on the slave, you need to set the `MASTER_AUTO_POSITION = 1` option for each applicable replication channel.

With `MASTER_AUTO_POSITION = 1` set, in the initial connection handshake, the slave sends a GTID set containing the transactions that it has already received, committed, or both. The master responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the slave. This exchange ensures that the master only sends the transactions with a GTID that the slave has not already recorded or committed. If the slave receives transactions from more than one master, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the slave is computed, see [Section 17.1.3.3, “GTID Auto-Positioning”](#).

If any of the transactions that should be sent by the master have been purged from the master's binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the master sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the slave, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the master's error log in the warning message `ER_FOUND_MISSING_GTIDS`. Also, if during the exchange of transactions it is found that the slave has recorded or committed transactions with the master's UUID in the GTID, but the master itself has not committed them, the master sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the slave and replication does not start. For information on how to handle these situations, see [Section 17.1.3.3, “GTID Auto-Positioning”](#).

You can see whether replication is running with auto-positioning enabled by checking the Performance Schema `replication_connection_status` table or the output of `SHOW SLAVE STATUS`. Disabling the `MASTER_AUTO_POSITION` option again makes the slave revert to file-based replication, in which case you must also specify one or both of the `MASTER_LOG_FILE` or `MASTER_LOG_POS` options.

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

**Note**

When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored, so the `IGNORE_SERVER_IDS` function is not required and is deprecated. If `gtid_mode=ON` is set for the server, a deprecation warning is issued if you include the `IGNORE_SERVER_IDS` option in a `CHANGE MASTER TO` statement.

The master info repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see [Section 17.2.4.2, “Slave Status Logs”](#), and [Section 13.7.6.34, “SHOW SLAVE STATUS Syntax”](#).

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

`RESET SLAVE ALL` clears `IGNORE_SERVER_IDS`.

**Note**

A deprecation warning is issued if `SET GTID_MODE=ON` is issued when any channel has existing server IDs set with `IGNORE_SERVER_IDS`. Before starting GTID-based replication, check for and clear all ignored server ID lists on the servers involved. The `SHOW_SLAVE_STATUS` statement displays the list of ignored IDs, if there is one. If you do receive the deprecation warning, you can still clear a list after `gtid_mode=ON` is set by issuing a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

Invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

`CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

From MySQL 5.7, the strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement (and `START SLAVE` afterward) is removed. Instead of depending on whether the slave is stopped, the behavior of `CHANGE MASTER TO` depends on the states of the slave SQL thread and slave I/O threads; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

- If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the slave I/O thread is running. No other options may be used with this statement when the I/O thread is running.
- If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) *except* `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or `MASTER_DELAY`, even when the SQL thread is running. These three options may not be used when the I/O thread is running.
- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1`.

You can check the current state of the slave SQL and I/O threads using `SHOW SLAVE STATUS`.

For more information, see [Section 17.3.8, “Switching Masters During Failover”](#).

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the slave. A warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.example.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='password',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

The following table shows the maximum permissible length for the string-valued options.

Option	Maximum Length
<code>MASTER_HOST</code>	60
<code>MASTER_USER</code>	96
<code>MASTER_PASSWORD</code>	32
<code>MASTER_LOG_FILE</code>	511
<code>RELAY_LOG_FILE</code>	511
<code>MASTER_SSL_CA</code>	511
<code>MASTER_SSL_CAPATH</code>	511
<code>MASTER_SSL_CERT</code>	511
<code>MASTER_SSL_CRL</code>	511
<code>MASTER_SSL_CRLPATH</code>	511
<code>MASTER_SSL_KEY</code>	511

Option	Maximum Length
MASTER_SSL_CIPHER	511
MASTER_TLS_VERSION	511
MASTER_PUBLIC_KEY_PATH	511

13.4.2.2 CHANGE REPLICATION FILTER Syntax

```
CHANGE REPLICATION FILTER filter [, filter]
[ , ... ] [FOR CHANNEL channel]

filter:
    REPLICATE_DO_DB = (db_list)
    | REPLICATE_IGNORE_DB = (db_list)
    | REPLICATE_DO_TABLE = (tbl_list)
    | REPLICATE_IGNORE_TABLE = (tbl_list)
    | REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
    | REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
    | REPLICATE_REWRITE_DB = (db_pair_list)

db_list:
    db_name [, db_name] [, ...]

tbl_list:
    db_name.table_name [, db_name.table_name] [, ...]

wild_tbl_list:
    'db_pattern.table_pattern' [, 'db_pattern.table_pattern' ] [, ...]

db_pair_list:
    (db_pair) [, (db_pair) ] [, ...]

db_pair:
    from_db , to_db
```

CHANGE REPLICATION FILTER sets one or more replication filtering rules on the slave in the same way as starting the slave `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the slave SQL thread be stopped using `STOP SLAVE SQL_THREAD` first (and restarted with `START SLAVE SQL_THREAD` afterwards). **CHANGE REPLICATION FILTER** requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege. Use the `FOR CHANNEL channel` clause to make a replication filter specific to a replication channel, for example on a multi-source replication slave. Filters applied without a specific `FOR CHANNEL` clause are considered global filters, meaning that they are applied to all replication channels.

Note

Global replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be set on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be set on the `group_replication_applier` or `group_replication_recovery` channels.

The following list shows the **CHANGE REPLICATION FILTER** options and how they relate to `--replicate-*` server options:

- `REPLICATE_DO_DB`: Include updates based on database name. Equivalent to `--replicate-do-db`.

- `REPLICATE_IGNORE_DB`: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- `REPLICATE_DO_TABLE`: Include updates based on table name. Equivalent to `--replicate-do-table`.
- `REPLICATE_IGNORE_TABLE`: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.
- `REPLICATE_WILD_DO_TABLE`: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.
- `REPLICATE_WILD_IGNORE_TABLE`: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.
- `REPLICATE_REWRITE_DB`: Perform updates on slave after substituting new name on slave for specified database on master. Equivalent to `--replicate-rewrite-db`.

The precise effects of `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` filters are dependent on whether statement-based or row-based replication is in effect. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

Multiple replication filtering rules can be created in a single `CHANGE REPLICATION FILTER` statement by separating the rules with commas, as shown here:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the slave `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`.

On a multi-source replication slave, which uses multiple replication channels to process transaction from different sources, use the `FOR CHANNEL channel` clause to set a replication filter on a replication channel:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB = (d1) FOR CHANNEL channel_1;
```

This enables you to create a channel specific replication filter to filter out selected data from a source. When a `FOR CHANNEL` clause is provided, the replication filter statement acts on that slave replication channel removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a slave replication channel which is not configured, the statement fails with an `ER_SLAVE_CONFIGURATION` error. If issued against Group Replication channels, the statement fails with an `ER_SLAVE_CHANNEL_OPERATION_NOT_ALLOWED` error.

On a replication slave with multiple replication channels configured, issuing `CHANGE REPLICATION FILTER` with no `FOR CHANNEL` clause configures the replication filter for every configured slave replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see [Section 17.2.5.4, “Replication Channel Based Filters”](#).

If the same filtering rule is specified multiple times, only the *last* such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db3, db4);
```

Caution

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent *pairs* of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the master to database `db2` on the slave:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

The `CHANGE REPLICATION FILTER` statement replaces replication filtering rules only for the filter types and replication channels affected by the statement, and leaves other rules and channels unchanged. If you want to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

The `RESET SLAVE ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the slave are copied to them, and no channel specific replication filters are applied.

For more information, see [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

13.4.2.3 MASTER_POS_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout][, channel])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.22, “Miscellaneous Functions”](#), for a full description.

13.4.2.4 RESET SLAVE Syntax

```
RESET SLAVE [ALL] [channel_option]
```

channel_option:

```
FOR CHANNEL channel
```

RESET SLAVE makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It clears the master info and relay log info repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the **MASTER_DELAY** option to **CHANGE MASTER TO**. **RESET SLAVE** does not change the values of **gtid_executed** or **gtid_purged**.

Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a **STOP SLAVE** statement or if the slave is highly loaded.)

To use **RESET SLAVE**, the slave replication threads must be stopped, so on a running slave use **STOP SLAVE** before issuing **RESET SLAVE**. To use **RESET SLAVE** on a Group Replication group member, the member status must be **OFFLINE**, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a **STOP GROUP REPLICATION** statement.

The optional **FOR CHANNEL channel** clause enables you to name which replication channel the statement applies to. Providing a **FOR CHANNEL channel** clause applies the **RESET SLAVE** statement to a specific replication channel. Combining a **FOR CHANNEL channel** clause with the **ALL** option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a **RESET SLAVE ALL** statement without a **FOR CHANNEL channel** clause when multiple replication channels exist deletes *all* replication channels and recreates only the default channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

RESET SLAVE does not change any replication connection parameters such as master host, master port, master user, or master password.

- From MySQL 8.0.13, when **master_info_repository=TABLE** is set on the server (which is the default from MySQL 8.0), replication connection parameters are preserved in the crash-safe InnoDB table **mysql.slave_master_info** as part of the **RESET SLAVE** operation. They are also retained in memory. In the event of a server crash or deliberate restart after issuing **RESET SLAVE** but before issuing **START SLAVE**, the replication connection parameters are retrieved from the table and reused for the new connection.
- When **master_info_repository=FILE** is set on the server, replication connection parameters are only retained in memory. If the slave **mysqld** is restarted immediately after issuing **RESET SLAVE** due to a server crash or deliberate restart, the connection parameters are lost. In that case, you must issue a **CHANGE MASTER TO** statement after the server start to respecify the connection parameters before issuing **START SLAVE**.

If you want to reset the connection parameters intentionally, you need to use `RESET SLAVE ALL`, which clears the connection parameters. In that case, you must issue a `CHANGE MASTER TO` statement after the server start to specify the new connection parameters.

`RESET SLAVE ALL` clears the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`.

`RESET SLAVE` does not change any replication filter settings (such as `--replicate-ignore-table`) for channels affected by the statement. However, `RESET SLAVE ALL` removes the replication filters that were set on the channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the slave are copied to them, and no channel specific replication filters are applied. For more information see [Section 17.2.5.4, “Replication Channel Based Filters”](#).

`RESET SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

`RESET SLAVE` does not reset the heartbeat period (`Slave_heartbeat_period`) or `SSL_VERIFY_SERVER_CERT`.

13.4.2.5 SET GLOBAL sql_slave_skip_counter Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

Note

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

13.4.2.6 START SLAVE Syntax

```
START SLAVE [thread_types] [until_option] [connection_options] [channel_option]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type:
  IO_THREAD | SQL_THREAD
```

```

until_option:
    UNTIL {
        {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
        | MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
        | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
        | SQL_AFTER_MTS_GAPS }

connection_options:
    [USER='user_name' ] [PASSWORD='user_pass' ] [DEFAULT_AUTH='plugin_name' ] [PLUGIN_DIR='plugin_dir']

channel_option:
    FOR CHANNEL channel

gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
    [0-9,A-F]

interval:
    n[-n]

    (n >= 1)

```

`START SLAVE` with no `thread_type` options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

`START SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`gtid_next` must be set to `AUTOMATIC` before issuing this statement.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `START SLAVE` statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a `START SLAVE` statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. This statement is disallowed for the `group_replication_recovery` channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

MySQL supports pluggable user-password authentication with `START SLAVE` with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list:

- `USER`: User name. Cannot be set to an empty or null string, or left unset if `PASSWORD` is used.
- `PASSWORD`: Password.

- `DEFAULT_AUTH`: Name of plugin; default is MySQL native authentication.
- `PLUGIN_DIR`: Location of plugin.

You cannot use the `SQL_THREAD` option when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

See [Section 6.3.10, “Pluggable Authentication”](#), for more information.

If an insecure connection is used with any these options, the server issues the warning `Sending passwords in plain text without SSL/TLS is extremely insecure`.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#)). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see [GTID Sets](#), for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process transactions until it has reached the *first* transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to process all transactions until the *last* transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the slave SQL thread to process all transactions originating from the master whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the slave SQL thread to obtain all transactions just mentioned from the master, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the slave SQL thread.

When using a multithreaded slave with `slave_preserve_commit_order=0` set, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
- after an error occurs in the applier threads
- `mysqld` shuts down unexpectedly

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multithreaded slave's worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an `SQL_THREAD` option, but the effects of the statement remain unchanged. It has no effect on the slave I/O thread (and cannot be used with the `IO_THREAD` option).

Issuing `START SLAVE` on a multithreaded slave with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use `START SLAVE`

`UNTIL SQL_AFTER_MTS_GAPS`, then issue `RESET SLAVE` to remove any remaining relay logs. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

To change a failed multithreaded slave to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;

SET @@GLOBAL.slave_parallel_workers = 0;

START SLAVE SQL_THREAD;
```

Note

It is possible to view the entire text of a running `START SLAVE ...` statement, including any `USER` or `PASSWORD` values used, in the output of `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for `MASTER_USER` or `MASTER_PASSWORD`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see [Section 13.7.6.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 17.1.7.1, “Checking Replication Status”](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. The `SQL_THREAD` option is disallowed when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

An `UNTIL` clause (*until_option*, in the preceding grammar) may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log, specified by the `MASTER_LOG_POS` and `MASTER_LOG_FILE` options, or a given point in the slave relay log, indicated with the `RELAY_LOG_POS` and `RELAY_LOG_FILE` options. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the slave SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the slave I/O is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the SQL and I/O threads are affected by the statement.

For an `UNTIL` clause, you must specify any one of the following:

- *Both* a log file name and a position in that file
- *Either* of `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`
- `SQL_AFTER_MTS_GAPS`

Do not mix master and relay log options. Do not mix log file options with GTID options.

The `UNTIL` clause is not supported for multithreaded slaves except when also using `SQL_AFTER_MTS_GAPS`. If `UNTIL` is used on a multithreaded slave without `SQL_AFTER_MTS_GAPS`, the slave operates in single-threaded (sequential) mode for replication until the point specified by the `UNTIL` clause is reached.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In very old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. That syntax now produces an error.

13.4.2.7 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]  
  
thread_types:  
    [thread_type [, thread_type] ... ]  
  
thread_type: IO_THREAD | SQL_THREAD  
  
channel_option:  
    FOR CHANNEL channel
```

Stops the slave threads. `STOP SLAVE` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 5.1.16, “The Server Shutdown Process”](#), for more information).

When using the row-based logging format: You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

`STOP SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`gtid_next` must be set to `AUTOMATIC` before issuing this statement.

You can control how long `STOP SLAVE` waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the `STOP SLAVE` instruction remains in effect. Once the slave threads are no longer busy, the `STOP SLAVE` statement is executed and the slave stops.

Some `CHANGE MASTER TO` statements are allowed while the slave is running, depending on the states of the slave SQL and I/O threads. However, using `STOP SLAVE` prior to executing `CHANGE MASTER TO` in such cases is still supported. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 17.3.8, “Switching Masters During Failover”](#), for more information.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `STOP SLAVE` statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a `STOP SLAVE` statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. This statement cannot be used with the `group_replication_recovery` channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

When using statement-based replication: changing the master while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the slave by checking the value of `Slave_open_temp_tables`; when using statement-based replication, this value should be 0 before executing `CHANGE MASTER TO`. If there are any temporary tables open on the slave, issuing a `CHANGE MASTER TO` statement after issuing a `STOP SLAVE` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

When using a multithreaded slave (`slave_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the slave is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP SLAVE` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

If the current replication event group has modified one or more nontransactional tables, `STOP SLAVE` waits for up to 60 seconds for the event group to complete, unless you issue a `KILL QUERY` or `KILL CONNECTION` statement for the slave SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

13.4.3.1 START GROUP_REPLICATION Syntax

```
START GROUP_REPLICATION
```

Starts group replication. This statement requires the `GROUP_REPLICATION_ADMIN` or `SUPER` privilege. If `super_read_only=ON` and the member should join as a primary, `super_read_only` is set to `OFF` once Group Replication successfully starts.

13.4.3.2 STOP GROUP_REPLICATION Syntax

STOP GROUP_REPLICATION

Stops group replication. This statement requires the `GROUP_REPLICATION_ADMIN` or `SUPER` privilege. As soon as you issue `STOP GROUP_REPLICATION` the member is set to `super_read_only=ON`, which ensures that no writes can be made to the member while Group Replication stops.

**Warning**

Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication's consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.

13.4.3.3 Functions which Configure the Group Replication Mode

The following functions enable you to control the mode which a replication group is running in, either single-primary or multi-primary mode.

group_replication_switch_to_single_primary_mode() Syntax

Use `group_replication_switch_to_single_primary_mode()` to change a group running in multi-primary mode to single-primary mode. Must be issued on a member of a replication group running in multi-primary mode. For example:

```
SELECT group_replication_switch_to_single_primary_mode()
```

The election of the single-primary is controlled by the configured election weights. To override the election process and configure a specific member as the primary in the process, use `SELECT group_replication_switch_to_single_primary_mode(member_uuid);` where `member_uuid` is the `server_uuid` of the member which should become the primary.

group_replication_switch_to_multi_primary_mode(); Syntax

Use `group_replication_switch_to_multi_primary_mode()` to change a group running in single-primary mode to multi-primary mode. Must be issued on a member of a replication group running in single-primary mode. For example:

```
SELECT group_replication_switch_to_multi_primary_mode()
```

All members which belong to the group become primaries.

group_replication_set_as_primary(); Syntax

Use `group_replication_set_as_primary(member_uuid)` to appoint a specific member of the group as the new primary, overriding any election process. Pass in `member_uuid` which is the `server_uuid` of the member which should become the new primary. Must be issued on a member of a replication group running in single-primary mode. For example:

```
SELECT group_replication_set_as_primary(member_uuid)
```

13.4.3.4 Functions which Configure the Maximum Consensus Instances of a Group

The following functions enable you to control the maximum number of consensus instances for a replication group.

group_replication_set_write_concurrency() Syntax

Use `group_replication_set_write_concurrency()` to configure the maximum number of members used to reach a consensus when writing a transaction to the group. For example:

```
SELECT group_replication_set_write_concurrency(members)
```

The number of members passed in by *members* sets the maximum number of members used when reaching a consensus in the group.

group_replication_get_write_concurrency(); Syntax

Use `group_replication_get_write_concurrency()` to check the maximum number of members a group uses to reach a consensus. For example:

```
SELECT group_replication_get_write_concurrency()
```

13.5 Prepared SQL Statement Syntax

MySQL 8.0 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.
- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the [MySQL C API client library](#) or [MySQL Connector/C](#) for C programs, [MySQL Connector/J](#) for Java programs, and [MySQL Connector/NET](#) for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 27.7.8, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the [mysql extension](#), available in PHP 5.0 and later.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library, as long as you connect to a server running MySQL 4.1 or higher.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.

- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 13.5.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 13.5.2, “EXECUTE Syntax”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 13.5.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
```

```
mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+-----+
| a      |
+-----+
| 4      |
| 8      |
| 11     |
| 32     |
| 80     |
+-----+

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

SQL Syntax Allowed in Prepared Statements

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE}
REVOKE
SELECT
SET
SHOW {WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
```

```
SLAVE {START | STOP}  
TRUNCATE TABLE  
UNINSTALL PLUGIN  
UPDATE
```

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS`, `SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS`, `SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Other statements are not supported in MySQL 8.0.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section C.1, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.10.3, “Caching of Prepared Statements and Stored Programs”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.10, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 8.0. See [Section 13.2.1, “CALL Syntax”](#), for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 13.2.1, “CALL Syntax”](#).

13.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The **PREPARE** statement prepares a SQL statement and assigns it a name, *stmt_name*, by which to refer to the statement later. The prepared statement is executed with **EXECUTE** and released with **DEALLOCATE PREPARE**. For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

Statement names are not case-sensitive. *preparable_stmt* is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, **?** characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The **?** characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 27.7.24, “C API Automatic Reconnection Control”](#).
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 9.4, “User-Defined Variables”](#).

13.5.2 EXECUTE Syntax

```
EXECUTE stmt_name  
[USING @var_name [, @var_name] ...]
```

After preparing a statement with **PREPARE**, you execute it with an **EXECUTE** statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a **USING** clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the **USING** clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

13.5.3 DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

13.6 Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 23, *Stored Programs and Views*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see [Section 23.1, “Defining Stored Programs”](#).

A `BEGIN ... END` block can be labeled. See [Section 13.6.2, “Statement Label Syntax”](#).

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

Note

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

13.6.2 Statement Label Syntax

```
[begin_label:] BEGIN
    [statement_list]
```

```

END [end_label]

[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]

```

Labels are permitted for **BEGIN ... END** blocks and for the **LOOP**, **REPEAT**, and **WHILE** statements. Label use for those statements follows these rules:

- *begin_label* must be followed by a colon.
- *begin_label* can be given without *end_label*. If *end_label* is present, it must be the same as *begin_label*.
- *end_label* cannot be given without *begin_label*.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an **ITERATE** or **LEAVE** statement. The following example uses those statements to continue iterating or terminate the loop:

```

CREATE PROCEDURE doitrate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE label1; END IF;
        LEAVE label1;
    END LOOP label1;
END;

```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

13.6.3 DECLARE Syntax

The **DECLARE** statement is used to define various items local to a program:

- Local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 13.6.7, “Condition Handling”](#).
- Cursors. See [Section 13.6.6, “Cursors”](#).

DECLARE is permitted only inside a **BEGIN ... END** compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in [Section 13.6.4.1, “Local Variable DECLARE Syntax”](#).
- Variables can be set directly with the `SET` statement. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).
- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See [Section 13.2.10.1, “SELECT ... INTO Syntax”](#), and [Section 13.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 8.0, this results in a syntax error.

13.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 9.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current

session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Syntax”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
    FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
read_loop: LOOP
  FETCH FROM cur1 INTO newname, xid;
  IF done THEN LEAVE read_loop; END IF;
  SELECT newname;
END LOOP;
CLOSE cur1;
END;
```

See also [Section C.1, “Restrictions on Stored Programs”](#).

13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

13.6.5.1 CASE Syntax

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

Note

There is also a `CASE` expression, which differs from the `CASE` statement described here. See [Section 12.4, “Control Flow Functions”](#). The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, *case_value* is an expression. This value is compared to the *when_value* expression in each `WHEN` clause until one of them is equal. When an equal *when_value* is found, the corresponding `THEN` clause *statement_list* executes. If no *when_value* is equal, the `ELSE` clause *statement_list* executes, if there is one.

This syntax cannot be used to test for equality with `NULL` because `NULL = NULL` is false. See [Section 3.3.4.6, “Working with NULL Values”](#).

For the second syntax, each `WHEN` clause *search_condition* expression is evaluated until one is true, at which point its corresponding `THEN` clause *statement_list* executes. If no *search_condition* is equal, the `ELSE` clause *statement_list* executes, if there is one.

If no *when_value* or *search_condition* matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |

CREATE PROCEDURE p()
  BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
      WHEN 2 THEN SELECT v;
      WHEN 3 THEN SELECT 0;
      ELSE
        BEGIN

```

```

        END;
    END CASE;
END;
|

```

13.6.5.2 IF Syntax

```

IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF

```

The `IF` statement for stored programs implements a basic conditional construct.

Note

There is also an `IF()` function, which differs from the `IF statement` described here. See [Section 12.4, “Control Flow Functions”](#). The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If the *search_condition* evaluates to true, the corresponding `THEN` or `ELSEIF` clause *statement_list* executes. If no *search_condition* matches, the `ELSE` clause *statement_list* executes.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```

DELIMITER //

CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

BEGIN
  DECLARE s VARCHAR(20);

  IF n > m THEN SET s = '>';
  ELSEIF n = m THEN SET s = '=';
  ELSE SET s = '<';
  END IF;

  SET s = CONCAT(n, ' ', s, ' ', m);

  RETURN s;
END //

DELIMITER ;

```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```

DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

```

```

BEGIN
  DECLARE s VARCHAR(50);

  IF n = m THEN SET s = 'equals';
  ELSE
    IF n > m THEN SET s = 'greater';
    ELSE SET s = 'less';
    END IF;

    SET s = CONCAT('is ', s, ' than');
  END IF;

  SET s = CONCAT(n, ' ', s, ' ', m, '.');

  RETURN s;
END //

DELIMITER ;

```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

13.6.5.3 ITERATE Syntax

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “start the loop again.”

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

13.6.5.4 LEAVE Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN . . . END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

13.6.5.5 LOOP Syntax

```

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a `LEAVE` statement. Within a stored function, `RETURN` can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A `LOOP` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE doitrate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

13.6.5.6 REPEAT Syntax

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a **REPEAT** statement is repeated until the *search_condition* expression is true. Thus, a **REPEAT** always enters the loop at least once. *statement_list* consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A **REPEAT** statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT
->     SET @x = @x + 1;
->   UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

13.6.5.7 RETURN Syntax

```
RETURN expr
```

The **RETURN** statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one **RETURN** statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The [LEAVE](#) statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a [WHILE](#) statement is repeated as long as the [search_condition](#) expression is true. [statement_list](#) consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A [WHILE](#) statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE a CHAR(16);
    DECLARE b, c INT;
    DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
    DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

    OPEN cur1;
    OPEN cur2;

    read_loop: LOOP
        FETCH cur1 INTO a, b;
        FETCH cur2 INTO c;
        IF done THEN
```

```

        LEAVE read_loop;
    END IF;
    IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
    ELSE
        INSERT INTO test.t3 VALUES (a,c);
    END IF;
END LOOP;

CLOSE cur1;
CLOSE cur2;
END;

```

13.6.6.1 Cursor CLOSE Syntax

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see [Section 13.6.6, “Cursors”](#).

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN . . . END` block in which it was declared.

13.6.6.2 Cursor DECLARE Syntax

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see [Section 13.6.6, “Cursors”](#).

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

13.6.6.3 Cursor FETCH Syntax

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 13.6.6, “Cursors”](#).

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN . . . END` block so that it can be associated with its own handler.

13.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see [Section 13.6.6, “Cursors”](#).

13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

13.6.7.1 DECLARE ... CONDITION Syntax

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#)).

Condition declarations must appear before cursor or handler declarations.

The *condition_value* for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- *mysql_error_code*: An integer literal indicating a MySQL error code.

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- SQLSTATE [VALUE] *sqlstate_value*: A 5-character string literal indicating an SQLSTATE value.

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

13.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action:
    CONTINUE
  | EXIT
  | UNDO

condition_value:
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified *statement* executes. *statement* can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#)).

Handler declarations must appear after variable or condition declarations.

The *handler_action* value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.

- **UNDO**: Not supported.

The *condition_value* for **DECLARE ... HANDLER** indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- *mysql_error_code*: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- **SQLSTATE [VALUE] *sqlstate_value***: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
    -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

- *condition_name*: A condition name previously specified with **DECLARE ... CONDITION**. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#).
- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
    -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a **NOT FOUND** condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    -- body of handler
END;
```

For another example, see [Section 13.6.6, “Cursors”](#). The **NOT FOUND** condition also occurs for **SELECT ... INTO var_list** statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    -- body of handler
```

```
END;
```

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6](#), “Scope Rules for Handlers”.

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For [SQLEXCEPTION](#) conditions, the stored program terminates at the statement that raised the condition, as if there were an [EXIT](#) handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For [SQLWARNING](#) conditions, the program continues executing, as if there were a [CONTINUE](#) handler.
- For [NOT FOUND](#) conditions, if the condition was raised normally, the action is [CONTINUE](#). If it was raised by [SIGNAL](#) or [RESIGNAL](#), the action is [EXIT](#).

The following example uses a handler for [SQLSTATE](#) '23000', which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

Notice that [@x](#) is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the [DECLARE ... HANDLER](#) statement had not been present, MySQL would have taken the default action ([EXIT](#)) after the second [INSERT](#) failed due to the [PRIMARY KEY](#) constraint, and [SELECT @x](#) would have returned 2.

To ignore a condition, declare a [CONTINUE](#) handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use [ITERATE](#) or [LEAVE](#) to refer to labels for blocks that

enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry;    # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;      # legal
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;
```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;
```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      SET done = TRUE;
    END;
    IF done OR i < 0 THEN
      LEAVE retry;
    END IF;
    SET i = i - 1;
  END;
```

```
UNTIL FALSE END REPEAT;
END;
```

13.6.7.3 GET DIAGNOSTICS Syntax

```
GET [CURRENT | STACKED] DIAGNOSTICS
{
    statement_information_item
    [, statement_information_item] ...
    | CONDITION condition_number
    condition_information_item
    [, condition_information_item] ...
}

statement_information_item:
    target = statement_information_item_name

condition_information_item:
    target = condition_information_item_name

statement_information_item_name:
    NUMBER
    | ROW_COUNT

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | RETURNED_SQLSTATE
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_number, target:
    (see following discussion)
```

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
```

```

-> @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-----+-----+
| @p1   | @p2                                     |
+-----+-----+
| 42S02 | Unknown table 'test.no_such_table' |
+-----+-----+

```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#). Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```

Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...

```

`GET DIAGNOSTICS` can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

```
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

```
GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or

`condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
-> @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+-----+-----+
| @p5 | @p6 |
+-----+-----+
|     |     |
+-----+-----+
```

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see [Diagnostics Area Information Items](#).

Here is an example that uses `GET DIAGNOSTICS` and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses `GET DIAGNOSTICS` to get the rows-affected count. This shows that you can use `GET DIAGNOSTICS` multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE rows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
```

```

-- Perform the insert
INSERT INTO t1 (int_col) VALUES(value);
-- Check whether the insert was successful
IF code = '00000' THEN
    GET DIAGNOSTICS rows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',rows);
ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
END IF;
-- Say what happened
SELECT result;
END;

```

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-`NULL` and `NULL` values, respectively:

```

mysql> CALL do_insert(1);
+-----+
| result |
+-----+
| insert succeeded, row count = 1 |
+-----+

mysql> CALL do_insert(NULL);
+-----+
| result |
+-----+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+-----+

```

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, *as long as* you execute no statements within the handler that change its current diagnostics area.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except `RESIGNAL`. For information about when the current diagnostics area is set and cleared, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The next example shows how `GET STACKED DIAGNOSTICS` can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a `TEXT NOT NULL` column. The first value is a non-`NULL` string and the second is `NULL`. The column prohibits `NULL` values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert `NULL` into inserts of the empty string:

```

DROP TABLE IF EXISTS t1;

```

```

CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        -- Here the current DA is nonempty because no prior statements
        -- executing within the handler have cleared it
        GET CURRENT DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA before mapped insert' AS op, errno, msg;
        GET STACKED DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'stacked DA before mapped insert' AS op, errno, msg;

        -- Map attempted NULL insert to empty string insert
        INSERT INTO t1 (c1) VALUES('');

        -- Here the current DA should be empty (if the INSERT succeeded),
        -- so check whether there are conditions before attempting to
        -- obtain condition information
        GET CURRENT DIAGNOSTICS errcount = NUMBER;
        IF errcount = 0
        THEN
            SELECT 'mapped insert succeeded, current DA is empty' AS op;
        ELSE
            GET CURRENT DIAGNOSTICS CONDITION 1
                errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
            SELECT 'current DA after mapped insert' AS op, errno, msg;
        END IF ;
        GET STACKED DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'stacked DA after mapped insert' AS op, errno, msg;
    END;
    INSERT INTO t1 (c1) VALUES('string 1');
    INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
CALL p();
SELECT * FROM t1;

```

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```

+-----+-----+-----+
| op                | errno | msg                                     |
+-----+-----+-----+
| current DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                                     |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an

empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

```
+-----+
| op |
+-----+
| mapped insert succeeded, current DA is empty |
+-----+

+-----+-----+-----+
| op | errno | msg |
+-----+-----+-----+
| stacked DA after mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+
```

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

```
+-----+
| c1 |
+-----+
| string 1 |
+-----+
```

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This will not be the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    ...
  
```

In this case, the result is version dependent:

- Before MySQL 5.7.2, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and higher, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:

op	errno	msg
current DA before mapped insert	NULL	NULL
op	errno	msg
stacked DA before mapped insert	1048	Column 'c1' cannot be null

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

13.6.7.4 RESIGNAL Syntax

```
RESIGNAL [condition_value]
  [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME

condition_name, simple_value_specification:
  (see following discussion)
```

RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

RESIGNAL makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

For *condition_value* and *signal_information_item*, the definitions and rules are the same for `RESIGNAL` as for `SIGNAL`. For example, the *condition_value* can be an `SQLSTATE` value, and the value can indicate errors, warnings, or “not found.” For additional information, see [Section 13.6.7.5, “SIGNAL Syntax”](#).

The `RESIGNAL` statement takes *condition_value* and `SET` clauses, both of which are optional. This leads to several possible uses:

- `RESIGNAL` alone:

```
RESIGNAL;
```

- `RESIGNAL` with new signal information:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

- `RESIGNAL` with a condition value and possibly new signal information:

```
RESIGNAL condition_value  
[SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the `SQLSTATE` value, `MYSQL_ERRNO`, or `MESSAGE_TEXT`.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but will be overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See [Diagnostics Area-Related System Variables](#).

RESIGNAL Alone

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL; END IF;
    END;
    DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```

DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```

DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means “push a condition into the current diagnostics area.” If the `SET` clause is present, it also changes the error information.

```
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

This form of `RESIGNAL` restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple `RESIGNAL` alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
```

```

BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
END;
DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;

```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```

DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'

```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```

mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Error | 1051 | Unknown table 'xx'                   |
| Error | 5    | Unknown table 'xx'                   |
+-----+-----+-----+

```

RESIGNAL Requires Condition Handler Context

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```

mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active

```

Here is a more difficult example:

```

delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
    RESIGNAL;
    RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
    SIGNAL SQLSTATE '55555';
END//
delimiter ;

```

```
CALL p();
```

`RESIGNAL` occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the `EXIT` handler, execution within `f()` has its own context, which is not handler context. Thus, `RESIGNAL` within `f()` results in a “handler not active” error.

13.6.7.5 SIGNAL Syntax

```
SIGNAL condition_value
    [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_name, simple_value_specification:
    (see following discussion)
```

`SIGNAL` is the way to “return” an error. `SIGNAL` provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, `SQLSTATE` value, message). Without `SIGNAL`, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the `SIGNAL` statement.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The *condition_value* in a `SIGNAL` statement indicates the error value to be returned. It can be an `SQLSTATE` value (a 5-character string literal) or a *condition_name* that refers to a named condition previously defined with `DECLARE ... CONDITION` (see [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#)).

An `SQLSTATE` value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in [Signal Condition Information Items](#). Some signal values cause statement termination; see [Effect of Signals on Handlers, Cursors, and Statements](#).

The `SQLSTATE` value for a `SIGNAL` statement should not start with `'00'` because such values indicate success and are not valid for signaling an error. This is true whether the `SQLSTATE` value is specified directly in the `SIGNAL` statement or in a named condition referred to in the statement. If the value is invalid, a `Bad SQLSTATE` error occurs.

To signal a generic `SQLSTATE` value, use `'45000'`, which means “unhandled user-defined exception.”

The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a comma-separated list of `condition_information_item_name = simple_value_specification` assignments.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a `Duplicate condition information item` error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see [Signal Condition Information Items](#).

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
      SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
      SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
      SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
      SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with `'01'` are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
mysql> SIGNAL SQLSTATE '77777';
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
-> FOR EACH ROW SIGNAL SQLSTATE '77777';
```

```
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
-> DO SIGNAL SQLSTATE '77777';
```

SIGNAL executes according to the following rules:

If the **SIGNAL** statement indicates a particular **SQLSTATE** value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the **SIGNAL** statement uses a named condition, the condition must be declared in some scope that applies to the **SIGNAL** statement, and must be defined using an **SQLSTATE** value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the **SIGNAL** statement, an **Undefined CONDITION** error occurs.

If **SIGNAL** refers to a named condition that is defined with a MySQL error number rather than an **SQLSTATE** value, a **SIGNAL/RESIGNAL** can only use a **CONDITION** defined with **SQLSTATE** error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If **divisor** is 0, the first **SIGNAL** statement executes. The innermost **my_error** condition declaration applies, raising **SQLSTATE '22012'**.

If **divisor** is not 0, the second **SIGNAL** statement executes. The outermost **my_error** condition declaration applies, raising **SQLSTATE '45000'**.

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error (“no such table”) and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

Item Name	Definition
-----	-----
CLASS_ORIGIN	VARCHAR(64)
SUBCLASS_ORIGIN	VARCHAR(64)
CONSTRAINT_CATALOG	VARCHAR(64)
CONSTRAINT_SCHEMA	VARCHAR(64)
CONSTRAINT_NAME	VARCHAR(64)
CATALOG_NAME	VARCHAR(64)
SCHEMA_NAME	VARCHAR(64)
TABLE_NAME	VARCHAR(64)
COLUMN_NAME	VARCHAR(64)
CURSOR_NAME	VARCHAR(64)
MESSAGE_TEXT	VARCHAR(128)
MYSQL_ERRNO	SMALLINT UNSIGNED

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

```
MESSAGE_TEXT = 'Unhandled user-defined warning condition';
MYSQL_ERRNO = ER_SIGNAL_WARN
```

- Class = '02' (not found)

```
MESSAGE_TEXT = 'Unhandled user-defined not found condition';
MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
```

- Class > '02' (exception)

```
MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `SQLSTATE` value: Call `mysql_sqlstate()`
- `MYSQL_ERRNO` value: Call `mysql_errno()`
- `MESSAGE_TEXT` value: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- Class = '02' (not found)

`NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- Class > '02' (exception)

`SQLException` handlers catch the signal. If the signal is unhandled in a function, statements end.

- Class = '40'

Treated as an ordinary exception.

Example:

```
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
-> BEGIN
->   SIGNAL SQLSTATE '01234'; -- signal a warning
->   RETURN 5;
-> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
mysql> INSERT INTO t VALUES (f());
```

The result is that a row containing 5 is inserted into table `t`. The warning that is signaled can be viewed with `SHOW WARNINGS`.

13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for `stmt1` in the inner block, but not for `stmt2` in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
  END;
  stmt2;
END;
```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.
- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLException`, or `NOT FOUND` handlers.
- An `SQLException` handler takes precedence over an `SQLWARNING` handler.
- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For `SQLException` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific `SQLSTATE` value (`'42S02'`) that occurs for attempts to drop a nonexistent table, and one for the general `SQLException` class:

```
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLException
    SELECT 'SQLException handler was activated' AS msg;

  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, `SQLSTATE` handlers take precedence over `SQLException` handlers, so if the table `t` is nonexistent, the `DROP TABLE` statement raises a condition that activates the `SQLSTATE` handler:

```
mysql> CALL p1();
```

```
+-----+
| msg   |
```

```
+-----+
| SQLSTATE handler was activated |
+-----+
```

This procedure contains the same two handlers. But this time, the `DROP TABLE` statement and `SQLExceptionHandler` handler are in an inner block relative to the `SQLSTATE` handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        SELECT 'SQLSTATE handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLExceptionHandler
            SELECT 'SQLExceptionHandler handler was activated' AS msg;

        DROP TABLE test.t; -- occurs within inner block
    END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The `SQLExceptionHandler` handler activates, even though it is more general than the `SQLSTATE` handler:

```
mysql> CALL p2();
+-----+
| msg |
+-----+
| SQLExceptionHandler handler was activated |
+-----+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p3()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLExceptionHandler
        SELECT 'SQLExceptionHandler handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
    END;

    DROP TABLE test.t; -- occurs within outer block
END;
```

Only the `SQLExceptionHandler` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```
mysql> CALL p3();
+-----+
| msg |
+-----+
| SQLExceptionHandler handler was activated |
+-----+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLExceptionHandler
```

```

    SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  END;

  DROP TABLE test.t; -- occurs within outer block
END;

```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```

mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'

```

13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL supports the `STACKED` keyword since MySQL 5.7.

This section describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```

Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...

```

Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is not

set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- **NUMBER**: An integer indicating the number of condition areas that have information.
- **ROW_COUNT**: An integer indicating the number of rows affected by the statement. **ROW_COUNT** has the same value as the **ROW_COUNT()** function (see [Section 12.14, “Information Functions”](#)).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the **NUMBER** statement condition item. If **NUMBER** is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except **MYSQL_ERRNO**, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a **SIGNAL** or **RESIGNAL** statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS_ORIGIN**: A string containing the class of the **RETURNED_SQLSTATE** value. If the **RETURNED_SQLSTATE** value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, **SQLSTATE**), **CLASS_ORIGIN** is 'ISO 9075'. Otherwise, **CLASS_ORIGIN** is 'MySQL'.
- **SUBCLASS_ORIGIN**: A string containing the subclass of the **RETURNED_SQLSTATE** value. If **CLASS_ORIGIN** is 'ISO 9075' or **RETURNED_SQLSTATE** ends with '000', **SUBCLASS_ORIGIN** is 'ISO 9075'. Otherwise, **SUBCLASS_ORIGIN** is 'MySQL'.
- **RETURNED_SQLSTATE**: A string that indicates the **SQLSTATE** value for the condition.
- **MESSAGE_TEXT**: A string that indicates the error message for the condition.
- **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.
- **CONSTRAINT_CATALOG**, **CONSTRAINT_SCHEMA**, **CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- **CATALOG_NAME**, **SCHEMA_NAME**, **TABLE_NAME**, **COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the **RETURNED_SQLSTATE**, **MESSAGE_TEXT**, and **MYSQL_ERRNO** values for particular errors, see [Section B.3, “Server Error Codes and Messages”](#).

If a **SIGNAL** (or **RESIGNAL**) statement populates the diagnostics area, its **SET** clause can assign to any condition information item except **RETURNED_SQLSTATE** any value that is legal for the item data type. **SIGNAL** also sets the **RETURNED_SQLSTATE** value, but not directly in its **SET** clause. That value comes from the **SIGNAL** statement **SQLSTATE** argument.

SIGNAL also sets statement information items. It sets **NUMBER** to 1. It sets **ROW_COUNT** to -1 for errors and 0 otherwise.

How the Diagnostics Area is Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the **SIGNAL** and **RESIGNAL** statements. The diagnostics area can be examined with **GET**

`DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area (`SHOW WARNINGS`, `SHOW ERRORS`, `GET DIAGNOSTICS`).
- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'test.no_such_table'         |
+-----+-----+-----+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'x'                 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'xx'               |
| Error | 1753 | Invalid condition number                   |
+-----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+-----+
| @p    |
+-----+
| Invalid condition number |
+-----+
1 row in set (0.01 sec)
```

How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- Execution of a stored program

A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

Any warning or error conditions occurring during stored program execution then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- Execution of a condition handler within a stored program

When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- Execution of `RESIGNAL`

The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in [Section 13.6.7.4, "RESIGNAL Syntax"](#).

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)
- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.
- `error_count` indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.
- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, `NUMBER` is 10, `warning_count` is 20, and `error_count` is 12.

Changes to the value of `max_error_count` have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and `max_error_count` is set to 5, that has no immediate effect on the size or content of the diagnostics area.

13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` system database. This database and the access control system are discussed extensively in [Chapter 5, MySQL Server Administration](#), which you should consult for additional details.

Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

When the `read_only` system variable is enabled, account-management statements require the `CONNECTION_ADMIN` or `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` system database.

Account management statements are atomic and crash safe. For more information, see [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

13.7.1.1 ALTER USER Syntax

```
ALTER USER [IF EXISTS]
    user [auth_option] [, user [auth_option]] ...
    [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
    [WITH resource_option [resource_option] ...]
    [password_option | lock_option] ...

ALTER USER [IF EXISTS]
```

```

    USER() IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string']

ALTER USER [IF EXISTS]
    user DEFAULT ROLE
        {NONE | ALL | role [, role ] ...}

user:
    (see Section 6.2.4, "Specifying Account Names")

auth_option: {
    IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string']
    | IDENTIFIED WITH auth_plugin
    | IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string']
    | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
    SSL
    | X509
    | CIPHER 'cipher'
    | ISSUER 'issuer'
    | SUBJECT 'subject'
}

resource_option: {
    MAX_QUERIES_PER_HOUR count
    | MAX_UPDATES_PER_HOUR count
    | MAX_CONNECTIONS_PER_HOUR count
    | MAX_USER_CONNECTIONS count
}

password_option: {
    PASSWORD EXPIRE [DEFAULT | NEVER | INTERVAL N DAY]
    | PASSWORD HISTORY {DEFAULT | N}
    | PASSWORD REUSE INTERVAL {DEFAULT | N DAY}
    | PASSWORD REQUIRE CURRENT [DEFAULT | OPTIONAL]
}

lock_option: {
    ACCOUNT LOCK
    | ACCOUNT UNLOCK
}

```

The **ALTER USER** statement modifies MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, and password-management properties to be modified for existing accounts, and enables account locking and unlocking.

In most cases, **ALTER USER** requires the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql** system database. The exceptions are:

- Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the **CURRENT_USER()** function:

```
SELECT CURRENT_USER();
```

- For **DEFAULT ROLE** syntax, **ALTER USER** requires these privileges:
 - Setting the default roles for another user requires the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql.default_roles** system table.
 - Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

Important

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

There are several aspects to the `ALTER USER` statement, described under the following topics:

- [ALTER USER Overview](#)
- [ALTER USER Authentication Options](#)
- [ALTER USER Role Options](#)
- [ALTER USER SSL/TLS Options](#)
- [ALTER USER Resource-Limit Options](#)
- [ALTER USER Password-Management Options](#)
- [ALTER USER Account-Locking Options](#)
- [ALTER USER Binary Logging](#)

ALTER USER Overview

For each affected account, `ALTER USER` modifies the corresponding `mysql.user` table row to reflect the properties specified in the statement. Unspecified properties retain their current values.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally.

For `ALTER USER` syntaxes that permit an `auth_option` value to follow a `user` value, `auth_option` indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each `auth_option` value applies *only* to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are *global* to the statement and apply to *all* accounts named in the statement.

Example: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH sha256_password BY 'new_password'  
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;  
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Example: This statement alters two accounts, specifying some per-account properties and some global properties:

```
ALTER USER  
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password',  
  'jeanne'@'localhost'  
  REQUIRE SSL WITH MAX_USER_CONNECTIONS 2  
  PASSWORD HISTORY 5;
```

The `auth_option` value following `jeffrey` (`IDENTIFIED BY`) applies only to its immediately preceding account, so it changes the password only for `jeffrey`. For `jeanne`, there is no per-account value (thus leaving the password unchanged). The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.
- Password changes cannot reuse any of the five most recent passwords.

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

ALTER USER Authentication Options

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both. It may also include a `REPLACE` clause that specifies the current account password to be replaced.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

For *auth_option* syntaxes that do not specify an authentication plugin, the default plugin is indicated by the value of the *default_authentication_plugin* system variable. For descriptions of each plugin, see [Section 6.5.1, “Authentication Plugins”](#).

- Credentials are stored in the *authentication_string* column of the *mysql.user* system table. An *'auth_string'* or *'hash_string'* value specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:
 - For syntaxes that use *'auth_string'*, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the *authentication_string* column. A plugin may use the value as specified, in which case no hashing occurs.
 - For syntaxes that use *'hash_string'*, the string is assumed to be already hashed in the format required by the authentication plugin. If the hash format is inappropriate for the plugin, it will not be usable and correct authentication of client connections will not occur.
- A *REPLACE 'current_auth_string'* clause (available as of MySQL 8.0.13) specifies the current account password to be replaced, as a cleartext (unencrypted) string:
 - The clause must be given if password changes for the account are required to specify the current password (to verify that the user attempting to make the change actually knows the current password).
 - The clause is optional if password changes for the account may but need not specify the current password.
 - The statement fails if the clause is given but does not match the current password, even if the clause is optional.
 - *REPLACE* can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see [Section 6.3.8, “Password Management”](#).

ALTER USER permits these *auth_option* syntaxes:

- *IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string']*

Sets the account authentication plugin to the default plugin, passes the cleartext *'auth_string'* value to the plugin for hashing, and stores the result in the *mysql.user* account row.

The *REPLACE* clause, if given, specifies the current account password, as described previously in this section.

- *IDENTIFIED WITH auth_plugin*

Sets the account authentication plugin to *auth_plugin*, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the *mysql.user* account row.

In addition, the password is marked expired. The user must choose a new one when next connecting.

- *IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string']*

Sets the account authentication plugin to *auth_plugin*, passes the cleartext *'auth_string'* value to the plugin for hashing, and stores the result in the *mysql.user* account row.

The `REPLACE` clause, if given, specifies the current account password, as described previously in this section.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin` and stores the hashed '`hash_string`' value as is in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

Example 1: Specify the password as cleartext; the default plugin is used:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'password';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password  
  BY 'password';
```

Example 3: Like Example 2, but in addition, specify the current password as a cleartext value to satisfy any account requirement that the user making the change knows that password:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password  
  BY 'password'  
  REPLACE 'current_password';
```

The preceding statement fails unless the current user is `jeffrey` because `REPLACE` is permitted only for changes to the current user's password.

Example 4: Specify the authentication plugin, along with a hashed password value:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password  
  AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see [Section 6.3.7, “Assigning Account Passwords”](#), and [Section 6.3.10, “Pluggable Authentication”](#).

ALTER USER Role Options

`ALTER USER ... DEFAULT ROLE` defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`ALTER USER ... DEFAULT ROLE` is alternative syntax for `SET DEFAULT ROLE` (see [Section 13.7.1.9, “SET DEFAULT ROLE Syntax”](#)). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

Each user account name uses the format described previously.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to `'%'`.

The clause following the `DEFAULT ROLE` keywords permits these values:

- `NONE`: Set the default to `NONE` (no roles).
- `ALL`: Set the default to all roles granted to the account.
- `role [, role] ...`: Set the default to the named roles, which must exist and be granted to the account at the time `ALTER USER ... DEFAULT ROLE` is executed.

ALTER USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see [Section 6.4, “Using Encrypted Connections”](#).

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`ALTER USER` permits these `tls_option` values:

- `NONE`

Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;
```

Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

- `SSL`

Tells the server to permit only encrypted connections for all accounts named by the statement.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
```

Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- `X509`

For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
```

For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA `'issuer'`. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL/CN=CA/emailAddress=ca@example.com';
```

Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- `SUBJECT 'subject'`

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL demo client certificate/  
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the `'subject'` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because `SUBJECT` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- `CIPHER 'cipher'`

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL demo client certificate/  
    CN=client/emailAddress=client@example.com'
```

```
AND ISSUER ' /C=SE/ST=Stockholm/L=Stockholm/  
O=MySQL/CN=CA/emailAddress=ca@example.com '  
AND CIPHER 'EDH-RSA-DES-CBC3-SHA' ;
```

ALTER USER Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.6, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more *resource_option* values.

Order of `WITH` options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

`ALTER USER` permits these *resource_option* values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`,
`MAX_CONNECTIONS_PER_HOUR count`

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If *count* is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
ALTER USER 'jeffrey'@'localhost'  
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

ALTER USER Password-Management Options

`ALTER USER` supports several *password_option* values for password management:

- Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.
- Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.
- Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

This section describes the syntax for password-management options. For information about establishing policy for password management, see [Section 6.3.8, “Password Management”](#).

Password-management options apply only to accounts that store credentials internally in the `mysql.user` system table (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). For accounts that use plugins that perform authentication against an external credential system, password management must be handled externally against that system as well.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see [Section 6.3.9, “Server Handling of Expired Passwords”](#)). Operations performed by a restricted client result in an error until the user establishes a new account password.

`ALTER USER` permits these *password_option* values for controlling password expiration:

- `PASSWORD EXPIRE`

Immediately marks the password expired for all accounts named by the statement.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to *N* days. The following statement requires the password to be changed every 180 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

`ALTER USER` permits these *password_option* values for controlling reuse of previous passwords based on required minimum number of password changes:

- `PASSWORD HISTORY DEFAULT`

Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the `password_history` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
```

- `PASSWORD HISTORY N`

This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to *N* passwords, to prohibit reusing any of the *N* most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
```

`ALTER USER` permits these *password_option* values for controlling reuse of previous passwords based on time elapsed:

- `PASSWORD REUSE INTERVAL DEFAULT`

Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
```

- `PASSWORD REUSE INTERVAL N DAY`

This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to *N* days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
```

`ALTER USER` permits these *password_option* values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- `PASSWORD REQUIRE CURRENT`

This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
```

- `PASSWORD REQUIRE CURRENT OPTIONAL`

This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

- `PASSWORD REQUIRE CURRENT DEFAULT`

Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

If multiple password-management options of a given type (`PASSWORD EXPIRE`, `PASSWORD HISTORY`, `PASSWORD REUSE INTERVAL`, `PASSWORD REQUIRE`) are specified, the last one takes precedence.

Note

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

ALTER USER Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 6.3.12, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

ALTER USER Binary Logging

`ALTER USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

13.7.1.2 CREATE ROLE Syntax

```
CREATE ROLE [IF NOT EXISTS] role [, role ] ...
```

`CREATE ROLE` creates one or more roles, which are named collections of privileges. To use this statement, you must have the global `CREATE ROLE` or `CREATE USER` privilege. When the `read_only` system variable is enabled, `CREATE ROLE` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

A role when created is locked, has no password, and is assigned the default authentication plugin.

`CREATE ROLE` either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the `IF NOT EXISTS` clause is given, this includes even roles that already exist and were not created.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
CREATE ROLE 'administrator', 'developer';
CREATE ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `'%'`.

For role usage examples, see [Section 6.3.4, “Using Roles”](#).

13.7.1.3 CREATE USER Syntax

```
CREATE USER [IF NOT EXISTS]
```

```

user [auth_option] [, user [auth_option]] ...
DEFAULT ROLE role [, role ] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH resource_option [resource_option] ...]
[password_option | lock_option] ...

user:
    (see Section 6.2.4, "Specifying Account Names")

auth_option: {
    IDENTIFIED BY 'auth_string'
    | IDENTIFIED WITH auth_plugin
    | IDENTIFIED WITH auth_plugin BY 'auth_string'
    | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
    SSL
    | X509
    | CIPHER 'cipher'
    | ISSUER 'issuer'
    | SUBJECT 'subject'
}

resource_option: {
    MAX_QUERIES_PER_HOUR count
    | MAX_UPDATES_PER_HOUR count
    | MAX_CONNECTIONS_PER_HOUR count
    | MAX_USER_CONNECTIONS count
}

password_option: {
    PASSWORD EXPIRE [DEFAULT | NEVER | INTERVAL N DAY]
    | PASSWORD HISTORY {DEFAULT | N}
    | PASSWORD REUSE INTERVAL {DEFAULT | N DAY}
    | PASSWORD REQUIRE CURRENT [DEFAULT | OPTIONAL]
}

lock_option: {
    ACCOUNT LOCK
    | ACCOUNT UNLOCK
}

```

The **CREATE USER** statement creates new MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, and password-management properties to be established for new accounts, and controls whether accounts are initially locked or unlocked.

To use **CREATE USER**, you must have the global **CREATE USER** privilege, or the **INSERT** privilege for the **mysql** system database. When the **read_only** system variable is enabled, **CREATE USER** additionally requires the **CONNECTION_ADMIN** or **SUPER** privilege.

CREATE USER either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a user that already exists. If the **IF NOT EXISTS** clause is given, the statement produces a warning for each named user that already exists, rather than an error.

Important

Under some circumstances, **CREATE USER** may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

There are several aspects to the `CREATE USER` statement, described under the following topics:

- [CREATE USER Overview](#)
- [CREATE USER Authentication Options](#)
- [CREATE USER Role Options](#)
- [CREATE USER SSL/TLS Options](#)
- [CREATE USER Resource-Limit Options](#)
- [CREATE USER Password-Management Options](#)
- [CREATE USER Account-Locking Options](#)
- [CREATE USER Binary Logging](#)

CREATE USER Overview

For each account, `CREATE USER` creates a new row in the `mysql.user` system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- Authentication: The authentication plugin defined by the `default_authentication_plugin` system variable, and empty credentials
- Default role: `NONE`
- SSL/TLS: `NONE`
- Resource limits: Unlimited
- Password management: `PASSWORD EXPIRE DEFAULT PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT`
- Account locking: `ACCOUNT UNLOCK`

An account when first created has no privileges and a default role of `NONE`. To assign privileges or roles, use the `GRANT` statement.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to `'%'`.

Each `user` value naming an account may be followed by an optional `auth_option` value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for example, a password) to be specified. Each `auth_option` value applies *only* to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are *global* to the statement and apply to *all* accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Create an account that uses the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH sha256_password BY 'new_password'  
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example: This statement creates two accounts, specifying some per-account properties and some global properties:

```
CREATE USER  
  'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password  
                        BY 'new_password1',  
  'jeanne'@'localhost' IDENTIFIED WITH sha256_password  
                        BY 'new_password2'  
  REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60  
  PASSWORD HISTORY 5  
  ACCOUNT LOCK;
```

Each `auth_option` value (`IDENTIFIED WITH ... BY` in this case) applies only to the account named immediately preceding it, so each account uses the immediately following authentication plugin and password. The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections must be made using a valid X.509 certificate.
- Up to 60 queries per hour are permitted.
- Password changes cannot reuse any of the five most recent passwords.
- The account is locked initially, so effectively it is a placeholder and cannot be used until an administrator unlocks it.

CREATE USER Authentication Options

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both:

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

For `auth_option` syntaxes that do not specify an authentication plugin, the default plugin is indicated by the value of the `default_authentication_plugin` system variable. For descriptions of each plugin, see [Section 6.5.1, “Authentication Plugins”](#).

- Credentials are stored in the `authentication_string` column of the `mysql.user` system table. An `'auth_string'` or `'hash_string'` value specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:
 - For syntaxes that use `'auth_string'`, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `authentication_string` column. A plugin may use the value as specified, in which case no hashing occurs.

- For syntaxes that use `'hash_string'`, the string is assumed to be already hashed in the format required by the authentication plugin. If the hash format is inappropriate for the plugin, it will not be usable and correct authentication of client connections will not occur.

`CREATE USER` permits these *auth_option* syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, passes the cleartext `'auth_string'` value to the plugin for hashing, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, passes the cleartext `'auth_string'` value to the plugin for hashing, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin` and stores the hashed `'hash_string'` value as is in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

Example 1: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'password';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value `'password'` after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see [Section 6.3.7, “Assigning Account Passwords”](#), and [Section 6.3.10, “Pluggable Authentication”](#).

CREATE USER Role Options

The `DEFAULT ROLE` clause defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
CREATE USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to `'%'`.

The `DEFAULT ROLE` clause permits a list of one or more comma-separated role names. These roles need not exist at the time `CREATE USER` is executed.

CREATE USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see [Section 6.4, “Using Encrypted Connections”](#).

To specify SSL/TLS-related options for a MySQL account, use a [REQUIRE](#) clause that specifies one or more *tls_option* values.

Order of [REQUIRE](#) options does not matter, but no option can be specified twice. The [AND](#) keyword is optional between [REQUIRE](#) options.

[CREATE USER](#) permits these *tls_option* values:

- [NONE](#)

Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;
```

Clients attempt to establish a secure connection by default. For clients that have [REQUIRE NONE](#), the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the [--ssl-mode=REQUIRED](#) option; the connection attempt fails if a secure connection cannot be established.

[NONE](#) is the default if no SSL-related [REQUIRE](#) options are specified.

- [SSL](#)

Tells the server to permit only encrypted connections for all accounts named by the statement.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

Clients attempt to establish a secure connection by default. For accounts that have [REQUIRE SSL](#), the connection attempt fails if a secure connection cannot be established.

- [X509](#)

For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For accounts with [REQUIRE X509](#), clients must specify the [--ssl-key](#) and [--ssl-cert](#) options to connect. (It is recommended but not required that [--ssl-ca](#) also be specified so that the public certificate provided by the server can be verified.) This is true for [ISSUER](#) and [SUBJECT](#) as well because those [REQUIRE](#) options imply the requirements of [X509](#).

- [ISSUER](#) *'issuer'*

For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA *'issuer'*. If a client presents a certificate that is valid but has a different issuer, the server rejects

the connection. Use of X.509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost'  
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL/CN=CA/emailAddress=ca@example.com';
```

Because [ISSUER](#) implies the requirements of [X509](#), clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- [SUBJECT](#) '*subject*'

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject *subject*. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost'  
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL demo client certificate/  
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because [SUBJECT](#) implies the requirements of [X509](#), clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- [CIPHER](#) '*cipher*'

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```
CREATE USER 'jeffrey'@'localhost'  
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The [SUBJECT](#), [ISSUER](#), and [CIPHER](#) options can be combined in the [REQUIRE](#) clause:

```
CREATE USER 'jeffrey'@'localhost'  
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL demo client certificate/  
    CN=client/emailAddress=client@example.com'  
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/  
    O=MySQL/CN=CA/emailAddress=ca@example.com'  
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

CREATE USER Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.6](#), “[Setting Account Resource Limits](#)”. To do so, use a [WITH](#) clause that specifies one or more [resource_option](#) values.

Order of [WITH](#) options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

`CREATE USER` permits these *resource_option* values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`,
`MAX_CONNECTIONS_PER_HOUR count`

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If *count* is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
CREATE USER 'jeffrey'@'localhost'  
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

CREATE USER Password-Management Options

`CREATE USER` supports several *password_option* values for password management:

- Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.
- Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.
- Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

This section describes the syntax for password-management options. For information about establishing policy for password management, see [Section 6.3.8, “Password Management”](#).

Password-management options apply only to accounts that store credentials internally in the `mysql.user` system table (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). For accounts that use plugins that perform authentication against an external credential system, password management must be handled externally against that system as well.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see [Section 6.3.9, “Server Handling of Expired Passwords”](#)). Operations performed by a restricted client result in an error until the user establishes a new account password.

`CREATE USER` permits these *password_option* values for controlling password expiration:

- `PASSWORD EXPIRE`

Immediately marks the password expired for all accounts named by the statement.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- **PASSWORD EXPIRE DEFAULT**

Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- **PASSWORD EXPIRE NEVER**

This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- **PASSWORD EXPIRE INTERVAL *N* DAY**

This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to *N* days. The following statement requires the password to be changed every 180 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

`CREATE USER` permits these *password_option* values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**

Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the `password_history` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
```

- **PASSWORD HISTORY *N***

This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to *N* passwords, to prohibit reusing any of the *N* most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
```

`CREATE USER` permits these *password_option* values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**

Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
```

- **PASSWORD REUSE INTERVAL *N* DAY**

This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to *N* days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
```

CREATE USER permits these *password_option* values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
```

- **PASSWORD REQUIRE CURRENT OPTIONAL**

This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

- **PASSWORD REQUIRE CURRENT DEFAULT**

Sets all statements named by the account so that the global policy about password verification applies, as specified by the *password_require_current* system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

If multiple password-management options of a given type (**PASSWORD EXPIRE**, **PASSWORD HISTORY**, **PASSWORD REUSE INTERVAL**, **PASSWORD REQUIRE**) are specified, the last one takes precedence.

CREATE USER Account-Locking Options

MySQL supports account locking and unlocking using the **ACCOUNT LOCK** and **ACCOUNT UNLOCK** options, which specify the locking state for an account. For additional discussion, see [Section 6.3.12, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

CREATE USER Binary Logging

CREATE USER is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the **IF NOT EXISTS** clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the default authentication plugin. In particular, if a user `u1` already exists and uses a nondefault authentication plugin, the statement written to the binary log for `CREATE USER IF NOT EXISTS u1` names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexistent users in the statement written to the binary log, it writes a warning to the error log naming those users.

13.7.1.4 DROP ROLE Syntax

```
DROP ROLE [IF EXISTS] role [, role ] ...
```

`DROP ROLE` removes one or more roles (named collections of privileges). To use this statement, you must have the global `DROP ROLE` or `CREATE USER` privilege. When the `read_only` system variable is enabled, `DROP ROLE` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

`DROP ROLE` either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named role that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the `IF EXISTS` clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
DROP ROLE 'administrator', 'developer';
DROP ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `'%'`.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its privileges are adjusted for the next statement executed.

13.7.1.5 DROP USER Syntax

```
DROP USER [IF EXISTS] user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

`DROP USER` either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not dropped.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 23.6, “Access Control for Stored Programs and Views”](#).)

13.7.1.6 GRANT Syntax

```
GRANT
    priv_type [(column_list)]
    [, priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]

GRANT PROXY ON user_or_role
TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]

GRANT role [, role] ...
TO user_or_role [, user_or_role] ...
[WITH ADMIN OPTION]

object_type: {
    TABLE
  | FUNCTION
  | PROCEDURE
}

priv_level: {
    *
  | *.*
  | db_name.*
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name
}

user_or_role: {
    user
  | role
}

user:
    (see Section 6.2.4, “Specifying Account Names”)
```

```
role:
  (see Section 6.2.5, "Specifying Role Names")
```

The [GRANT](#) statement assigns privileges and roles to MySQL user accounts and roles. There are several aspects to the [GRANT](#) statement, described under the following topics:

- [GRANT General Overview](#)
- [Object Quoting Guidelines](#)
- [Account Names](#)
- [Privileges Supported by MySQL](#)
- [Global Privileges](#)
- [Database Privileges](#)
- [Table Privileges](#)
- [Column Privileges](#)
- [Stored Routine Privileges](#)
- [Proxy User Privileges](#)
- [Granting Roles](#)
- [Other Account Characteristics](#)
- [MySQL and Standard SQL Versions of GRANT](#)

GRANT General Overview

The [GRANT](#) statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

The [GRANT](#) statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

- [GRANT](#) cannot mix granting both privileges and roles in the same statement. A given [GRANT](#) statement must grant either privileges or roles.
- The [ON](#) clause distinguishes whether the statement grants privileges or roles:
 - With [ON](#), the statement grants privileges.
 - Without [ON](#), the statement grants roles.
- It is permitted to assign both privileges and roles to an account, but you must use separate [GRANT](#) statements, each with syntax appropriate to what is to be granted.

For more information about roles, see [Section 6.3.4](#), "Using Roles".

To use [GRANT](#), you must have the [GRANT OPTION](#) privilege, and you must have the privileges that you are granting. When the [read_only](#) system variable is enabled, [GRANT](#) additionally requires the [CONNECTION_ADMIN](#) or [SUPER](#) privilege.

GRANT either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The **REVOKE** statement is related to **GRANT** and enables administrators to remove account privileges. See [Section 13.7.1.8, “REVOKE Syntax”](#).

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';
```

The host name part of the account or role name, if omitted, defaults to `'%'`.

Normally, a database administrator first uses **CREATE USER** to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses **GRANT** to define its privileges. **ALTER USER** may be used to change the nonprivilege characteristics of existing accounts. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

From the `mysql` program, **GRANT** responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use **SHOW GRANTS**. See [Section 13.7.6.21, “SHOW GRANTS Syntax”](#).

Important

Under some circumstances, **GRANT** may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

GRANT supports host names up to 60 characters long. User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

Warning

Do not attempt to change the permissible length for user names by altering the `mysql.user` system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the `mysql` system database in any manner except by means of the procedure described in [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

Object Quoting Guidelines

Several objects within **GRANT** statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However,

quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters (such as `%`); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.
- Quote user names and host names as identifiers or as strings.
- Quote passwords as strings.

For string-quoting and identifier-quoting guidelines, see [Section 9.1.1, “String Literals”](#), and [Section 9.2, “Schema Object Names”](#).

The `_` and `%` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level (`GRANT ... ON db_name.*`). This means, for example, that to use a `_` character as part of a database name, specify it as `_` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo_bar`. * TO ...`

When a database name not is used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, `GRANT ... ON db_name.tbl_name`), wildcard characters are treated as normal characters.

Account Names

A `user` value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the `user` value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `'user_name'@'198.51.100.%'` applies to `user_name` for any host in the `198.51.100` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see [Section 6.2.4, “Specifying Account Names”](#).

Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'user_name'@'localhost'`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` system table is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#).

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic *priv_type* privilege types that can be specified for the [GRANT](#) and [REVOKE](#) statements, and the levels at which each privilege can be granted. For additional information about each privilege, see [Section 6.2.1, “Privileges Provided by MySQL”](#). For information about the differences between static and dynamic privileges, see [Section 6.2.2, “Static Versus Dynamic Privileges”](#).

Table 13.6 Permissible Static Privileges for GRANT and REVOKE

Privilege	Meaning and Grantable Levels
ALL [PRIVILEGES]	Grant all privileges at specified access level except GRANT OPTION and PROXY .
ALTER	Enable use of ALTER TABLE . Levels: Global, database, table.
ALTER ROUTINE	Enable stored routines to be altered or dropped. Levels: Global, database, routine.
CREATE	Enable database and table creation. Levels: Global, database, table.
CREATE ROUTINE	Enable stored routine creation. Levels: Global, database.
CREATE TABLESPACE	Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.
CREATE TEMPORARY TABLES	Enable use of CREATE TEMPORARY TABLE . Levels: Global, database.
CREATE USER	Enable use of CREATE USER , DROP USER , RENAME USER , and REVOKE ALL PRIVILEGES . Level: Global.
CREATE VIEW	Enable views to be created or altered. Levels: Global, database, table.
DELETE	Enable use of DELETE . Level: Global, database, table.
DROP	Enable databases, tables, and views to be dropped. Levels: Global, database, table.
EVENT	Enable use of events for the Event Scheduler. Levels: Global, database.
EXECUTE	Enable the user to execute stored routines. Levels: Global, database, routine.
FILE	Enable the user to cause the server to read or write files. Level: Global.
GRANT OPTION	Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy.
INDEX	Enable indexes to be created or dropped. Levels: Global, database, table.
INSERT	Enable use of INSERT . Levels: Global, database, table, column.

Privilege	Meaning and Grantable Levels
LOCK TABLES	Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.
PROCESS	Enable the user to see all processes with <code>SHOW PROCESSLIST</code> . Level: Global.
PROXY	Enable user proxying. Level: From user to user.
REFERENCES	Enable foreign key creation. Levels: Global, database, table, column.
RELOAD	Enable use of <code>FLUSH</code> operations. Level: Global.
REPLICATION CLIENT	Enable the user to ask where master or slave servers are. Level: Global.
REPLICATION SLAVE	Enable replication slaves to read binary log events from the master. Level: Global.
SELECT	Enable use of <code>SELECT</code> . Levels: Global, database, table, column.
SHOW DATABASES	Enable <code>SHOW DATABASES</code> to show all databases. Level: Global.
SHOW VIEW	Enable use of <code>SHOW CREATE VIEW</code> . Levels: Global, database, table.
SHUTDOWN	Enable use of <code>mysqladmin shutdown</code> . Level: Global.
SUPER	Enable use of other administrative operations such as <code>CHANGE MASTER TO</code> , <code>KILL</code> , <code>PURGE BINARY LOGS</code> , <code>SET GLOBAL</code> , and <code>mysqladmin debug</code> command. Level: Global.
TRIGGER	Enable trigger operations. Levels: Global, database, table.
UPDATE	Enable use of <code>UPDATE</code> . Levels: Global, database, table, column.
USAGE	Synonym for “no privileges”

Table 13.7 Permissible Dynamic Privileges for GRANT and REVOKE

Privilege	Meaning and Grantable Levels
AUDIT_ADMIN	Enable audit log configuration. Level: Global.
BINLOG_ADMIN	Enable binary log control. Level: Global.
CONNECTION_ADMIN	Enable connection limit/restriction control. Level: Global.
ENCRYPTION_KEY_ADMIN	Enable <code>InnoDB</code> key rotation. Level: Global.
FIREWALL_ADMIN	Enable firewall rule administration, any user. Level: Global.
FIREWALL_USER	Enable firewall rule administration, self. Level: Global.
GROUP_REPLICATION_ADMIN	Enable Group Replication control. Level: Global.
REPLICATION_SLAVE_ADMIN	Enable regular replication control. Level: Global.
ROLE_ADMIN	Enable use of <code>WITH ADMIN OPTION</code> . Level: Global.
SET_USER_ID	Enable setting non-self <code>DEFINER</code> values. Level: Global.
SYSTEM_VARIABLES_ADMIN	Enable modifying or persisting global system variables. Level: Global.
VERSION_TOKEN_ADMIN	Enable use of Version Tokens UDFs. Level: Global.

A trigger is associated with a table. To create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

In `GRANT` statements, the `ALL [PRIVILEGES]` or `PROXY` privilege must be named by itself and cannot be specified along with other privileges. `ALL [PRIVILEGES]` stands for all privileges available for the level at which privileges are to be granted except for the `GRANT OPTION` and `PROXY` privileges.

MySQL account information is stored in the tables of the `mysql` system database. For additional details, consult [Section 6.2, “The MySQL Access Privilege System”](#), which discusses the `mysql` system database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting that variable. The `lower_case_table_names` setting can only be configured at server startup.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to remove.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`. Granting `ALL` does not assign the `GRANT OPTION` or `PROXY` privilege.

The `object_type` clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical `OR` of the account privileges at each of the privilege levels. For example, if a user has a global `SELECT` privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in [Section 6.2.7, “Access Control, Stage 2: Request Verification”](#).

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

Important

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of `GRANT OPTION` granted at the global level differs for static and dynamic privileges:

- `GRANT OPTION` granted for any static global privilege applies to all static global privileges.
- `GRANT OPTION` granted for any dynamic privilege applies only to that dynamic privilege.

`GRANT ALL` at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the `GRANT` statement is not granted retroactively to any account.

MySQL stores global privileges in the `mysql.user` system table.

Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*`), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, `LOCK TABLES`, and `REFERENCES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` system table.

Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table-level privileges apply to base tables and views. They do not apply to tables created with `CREATE TEMPORARY TABLE`, even if the table names match. For information about `TEMPORARY` table privileges, see [Section 13.1.18.3, “CREATE TEMPORARY TABLE Syntax”](#).

MySQL stores table privileges in the `mysql.tables_priv` system table.

Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible *priv_type* values for a column (that is, when you use a *column_list* clause) are [INSERT](#), [REFERENCES](#), [SELECT](#), and [UPDATE](#).

MySQL stores column privileges in the [mysql.columns_priv](#) system table.

Stored Routine Privileges

The [ALTER ROUTINE](#), [CREATE ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#) privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for [CREATE ROUTINE](#), these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible *priv_type* values at the routine level are [ALTER ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#). [CREATE ROUTINE](#) is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the [mysql.procs_priv](#) system table.

Proxy User Privileges

The [PROXY](#) privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When [PROXY](#) is granted, it must be the only privilege named in the [GRANT](#) statement, and the only permitted [WITH](#) option is [WITH GRANT OPTION](#).

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the [PROXY](#) privilege for the proxied user. For details and examples, see [Section 6.3.11, “Proxy Users”](#).

MySQL stores proxy privileges in the [mysql.proxies_priv](#) system table.

Granting Roles

[GRANT](#) syntax without an [ON](#) clause grants roles rather than individual privileges. A role is a named collection of privileges; see [Section 6.3.4, “Using Roles”](#). For example:

```
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
```

Each role to be granted must exist, as well as each user account or role to which it is to be granted.

If the [GRANT](#) statement includes the [WITH ADMIN OPTION](#) clause, each named user becomes able to grant the named roles to other users or roles, or revoke them from other users or roles. This includes the ability to use [WITH ADMIN OPTION](#) itself.

It is possible to create circular references with [GRANT](#). For example:

```
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';

GRANT 'u1' TO 'u1';    -- simple loop: u1 => u1
GRANT 'r1' TO 'r1';    -- simple loop: r1 => r1

GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';    -- mixed user/role loop: u2 => r2 => u2
```

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

Other Account Characteristics

The optional [WITH](#) clause is used to enable a user to grant privileges to other users. The [WITH GRANT OPTION](#) clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the [GRANT OPTION](#) privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the [GRANT OPTION](#) privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the [GRANT OPTION](#) privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the [GRANT OPTION](#) privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the [INSERT](#) privilege on a database. If you then grant the [SELECT](#) privilege on the database and specify [WITH GRANT OPTION](#), that user can give to other users not only the [SELECT](#) privilege, but also [INSERT](#). If you then grant the [UPDATE](#) privilege to the user on the database, the user can grant [INSERT](#), [SELECT](#), and [UPDATE](#).

For a nonadministrative user, you should not grant the [ALTER](#) privilege globally or for the `mysql` system database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 6.2.1](#), “Privileges Provided by MySQL”.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of [GRANT](#) are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL [UNDER](#) privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use [DROP USER](#). See [Section 13.7.1.5](#), “[DROP USER Syntax](#)”.

- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see [Section 5.1.10, “Server SQL Modes”](#), and [Section 11.7, “Data Type Default Values”](#).

13.7.1.7 RENAME USER Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 23.6, “Access Control for Stored Programs and Views”](#).)

The privilege changes take effect as indicated in [Section 6.2.8, “When Privilege Changes Take Effect”](#).

13.7.1.8 REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user_or_role [, user_or_role] ...

REVOKE ALL [PRIVILEGES], GRANT OPTION
FROM user_or_role [, user_or_role] ...

REVOKE PROXY ON user_or_role
FROM user_or_role [, user_or_role] ...

REVOKE role [, role] ...
FROM user_or_role [, user_or_role] ...

user_or_role: {
  user
```

```
| role
}

user:
  (see Section 6.2.4, "Specifying Account Names")

role:
  (see Section 6.2.5, "Specifying Role Names").
```

The **REVOKE** statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.

For information about roles, see [Section 6.3.4, "Using Roles"](#).

When the **read_only** system variable is enabled, **REVOKE** requires the **CONNECTION_ADMIN** or **SUPER** privilege in addition to any other required privileges described in the following discussion.

REVOKE either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

Each account name uses the format described in [Section 6.2.4, "Specifying Account Names"](#). Each role name uses the format described in [Section 6.2.5, "Specifying Role Names"](#). For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';
REVOKE SELECT ON world.* FROM 'role3';
```

The host name part of the account or role name, if omitted, defaults to **'%'**.

For details on the levels at which privileges exist, the permissible *priv_type*, *priv_level*, and *object_type* values, and the syntax for specifying users and passwords, see [Section 13.7.1.6, "GRANT Syntax"](#).

To use the first **REVOKE** syntax, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```
REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user_or_role [, user_or_role] ...
```

REVOKE ALL PRIVILEGES, GRANT OPTION does not revoke any roles.

To use this **REVOKE** syntax, you must have the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql** system database.

The syntax for which the **REVOKE** keyword is followed by one or more role names takes a **FROM** clause indicating one or more users or roles from which to revoke the roles.

Roles named in the **mandatory_roles** system variable value cannot be revoked.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.

Revoking a role revokes the role itself, not the privileges that it represents. If an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the

privilege, the account still is granted that privilege after the first role is revoked. For example, if an account is granted two roles that each include `SELECT`, the account still can select after either role is revoked.

`REVOKE ALL ON *.*` (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

User accounts and roles from which privileges and roles are to be revoked must exist, but the roles to be revoked need not be currently granted to them.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER`. See [Section 13.7.1.5, “DROP USER Syntax”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable. The `lower_case_table_names` setting can only be configured when initializing the server.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See [Section 13.7.6.21, “SHOW GRANTS Syntax”](#).

13.7.1.9 SET DEFAULT ROLE Syntax

```
SET DEFAULT ROLE
  {NONE | ALL | role [, role ] ...}
  TO user [, user ] ...
```

For each `user` named immediately after the `TO` keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`SET DEFAULT ROLE` is alternative syntax for `ALTER USER ... DEFAULT ROLE` (see [Section 13.7.1.1, “ALTER USER Syntax”](#)). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

`SET DEFAULT ROLE` requires these privileges:

- Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.
- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
SET DEFAULT ROLE administrator, developer TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to `'%'`.

The clause following the `DEFAULT ROLE` keywords permits these values:

- `NONE`: Set the default to `NONE` (no roles).
- `ALL`: Set the default to all roles granted to the account.

- `role [, role] ...`: Set the default to the named roles, which must exist and be granted to the account at the time `SET DEFAULT ROLE` is executed.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.
- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

13.7.1.10 SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = 'auth_string' [REPLACE 'current_auth_string']
```

The `SET PASSWORD` statement assigns a password to a MySQL user account. `'auth_string'` represents a cleartext (unencrypted) password.

If given, the `REPLACE` clause (available as of MySQL 8.0.13), must specify the current account password to be replaced:

- The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
- The clause is optional if password changes for the account may but need not specify the current password.
- The statement fails if the clause is given but does not match the current password, even if the clause is optional.
- `REPLACE` can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see [Section 6.3.8, “Password Management”](#).

**Note**

Rather than using `SET PASSWORD ... = 'auth_string'` syntax, `ALTER USER` syntax is the preferred statement for account alterations, including assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

**Important**

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

`SET PASSWORD` can be used with or without a `FOR` clause that explicitly names a user account:

- With a `FOR user` clause, the statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
```

- With no `FOR user` clause, the statement sets the password for the current user:

```
SET PASSWORD = 'auth_string';
```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

If the statement is changing the current user's password, the `REPLACE` clause can be given to satisfy any account requirement that the user making the change knows the current password. If an account is named but is not that of the current user, the `REPLACE` clause cannot be given.

Setting the password for a named account (with a `FOR` clause) requires the `UPDATE` privilege for the `mysql` system database. Setting the password for yourself (for a nonanonymous account with no `FOR` clause) requires no special privileges. When the `read_only` system variable is enabled, `SET PASSWORD` requires the `CONNECTION_ADMIN` or `SUPER` privilege in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
SET PASSWORD FOR 'bob'@'%.example.org' = 'auth_string';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`SET PASSWORD` interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the `mysql.user` account row. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

For additional information about setting passwords and authentication plugins, see [Section 6.3.7, “Assigning Account Passwords”](#), and [Section 6.3.10, “Pluggable Authentication”](#).

13.7.1.11 SET ROLE Syntax

```
SET ROLE {
  DEFAULT
| NONE
| ALL
| ALL EXCEPT role [, role ] ...
| role [, role ] ...
}
```

`SET ROLE` modifies the current user's effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
SET ROLE ALL EXCEPT 'role1', 'role2';
```

The host name part of the role name, if omitted, defaults to `'%'`.

The statement permits these role specifiers:

- **DEFAULT**: Activate the account default roles. Default roles are those specified with `SET DEFAULT ROLE`.

When a user connects to the server and authenticates successfully, the server determines which roles to activate as the default roles. If the `activate_all_roles_on_login` system variable is enabled, the server activates all granted roles. Otherwise, The server executes `SET ROLE DEFAULT` implicitly. The server activates only default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings.

If a user executes `SET ROLE DEFAULT` during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

- **NONE**: Set the active roles to **NONE** (no active roles).
- **ALL**: Activate all roles granted to the account.
- **ALL EXCEPT role [, role] ...**: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.
- **role [, role] ...**: Activate the named roles, which must be granted to the account.

Note

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.
- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

13.7.2 Resource Group Management Statements

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. This section describes the SQL statements available for resource group management. For general discussion of the resource group capability, see [Section 8.12.5, “Resource Groups”](#).

13.7.2.1 ALTER RESOURCE GROUP Syntax

```
ALTER RESOURCE GROUP group_name
    [VCPU [=] vcpu_spec [, vcpu_spec] ...]
    [THREAD_PRIORITY [=] N]
    [ENABLE|DISABLE [FORCE]]
```

```
vcpu_spec: {N | M - N}
```

ALTER RESOURCE GROUP is used for resource group management (see [Section 8.12.5, “Resource Groups”](#)). This statement alters modifiable attributes of an existing resource group. It requires the **RESOURCE_GROUP_ADMIN** privilege.

group_name identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with **ALTER RESOURCE GROUP**. These attributes are specified the same way as described for **CREATE RESOURCE GROUP** (see [Section 13.7.2.2, “CREATE RESOURCE GROUP Syntax”](#)). Only the attributes specified are altered. Unspecified attributes retain their current values.

The **FORCE** modifier is used with **DISABLE**. It determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to **SYS_default**, user threads to **USR_default**).

The name and type attributes are set at group creation time and cannot be modified thereafter with **ALTER RESOURCE GROUP**.

Examples:

- Alter a group CPU affinity:

```
ALTER RESOURCE GROUP rg1 VCPU = 0-63;
```

- Alter a group thread priority:

```
ALTER RESOURCE GROUP rg2 THREAD_PRIORITY = 5;
```

- Disable a group, moving any threads assigned to it to the default groups:

```
ALTER RESOURCE GROUP rg3 DISABLE FORCE;
```

Resource group management is local to the server on which it occurs. **ALTER RESOURCE GROUP** statements are not written to the binary log and are not replicated.

13.7.2.2 CREATE RESOURCE GROUP Syntax

```
CREATE RESOURCE GROUP group_name
  TYPE = {SYSTEM|USER}
  [VCPU [=] vcpu_spec [, vcpu_spec] ...]
  [THREAD_PRIORITY [=] N]
  [ENABLE|DISABLE]
```

```
vcpu_spec: {N | M - N}
```

CREATE RESOURCE GROUP is used for resource group management (see [Section 8.12.5, “Resource Groups”](#)). This statement creates a new resource group and assigns its initial attribute values. It requires the **RESOURCE_GROUP_ADMIN** privilege.

group_name identifies which resource group to create. If the group already exists, an error occurs.

The **TYPE** attribute is required. It should be **SYSTEM** for a system resource group, **USER** for a user resource group. The group type affects permitted **THREAD_PRIORITY** values, as described later.

The **VCPU** attribute indicates the CPU affinity; that is, the set of virtual CPUs the group can use:

- If **VCPU** is not given, the resource group has no CPU affinity and can use all available CPUs.
- If **VCPU** is given, the attribute value is a list of comma-separated CPU numbers or ranges:
 - Each number must be an integer in the range from 0 to the number of CPUs – 1. For example, on a system with 64 CPUs, the number can range from 0 to 63.
 - A range is given in the form *M* – *N*, where *M* is less than or equal to *N* and both numbers are in the CPU range.
- If a CPU number is an integer outside the permitted range or is not an integer, an error occurs.

Example **VCPU** specifiers (these are all equivalent):

```
VCPU = 0,1,2,3,9,10
VCPU = 0-3,9-10
VCPU = 9,10,0-3
VCPU = 0,10,1,9,3,2
```

The **THREAD_PRIORITY** attribute indicates the priority for threads assigned to the group:

- If **THREAD_PRIORITY** is not given, the default priority is 0.
- If **THREAD_PRIORITY** is given, the attribute value must be in the range from -20 (highest priority) to 19 (lowest priority). The priority for system resource groups must be in the range from -20 to 0. The priority for user resource groups must be in the range from 0 to 19. Use of different ranges for system and user groups ensures that user threads never have a higher priority than system threads.

ENABLE and **DISABLE** specify that the resource group is initially enabled or disabled. If neither is specified, the group is enabled by default. A disabled group cannot have threads assigned to it.

Examples:

- Create an enabled user group that has a single CPU and the lowest priority:

```
CREATE RESOURCE GROUP rg1
  TYPE = USER
  VCPU = 0
  THREAD_PRIORITY = 19;
```

- Create a disabled system group that has no CPU affinity (can use all CPUs) and the highest priority:

```
CREATE RESOURCE GROUP rg2
  TYPE = SYSTEM
  THREAD_PRIORITY = -20
  DISABLE;
```

Resource group management is local to the server on which it occurs. **CREATE RESOURCE GROUP** statements are not written to the binary log and are not replicated.

13.7.2.3 DROP RESOURCE GROUP Syntax

```
DROP RESOURCE GROUP group_name [FORCE]
```

DROP RESOURCE GROUP is used for resource group management (see [Section 8.12.5, “Resource Groups”](#)). This statement drops a resource group. It requires the [RESOURCE_GROUP_ADMIN](#) privilege.

group_name identifies which resource group to drop. If the group does not exist, an error occurs.

The **FORCE** modifier determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given and any threads are assigned to the group, an error occurs.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to [SYS_default](#), user threads to [USR_default](#)).

Examples:

- Drop a group, failing if the group contains any threads:

```
DROP RESOURCE GROUP rg1;
```

- Drop a group and move existing threads to the default groups:

```
DROP RESOURCE GROUP rg2 FORCE;
```

Resource group management is local to the server on which it occurs. **DROP RESOURCE GROUP** statements are not written to the binary log and are not replicated.

13.7.2.4 SET RESOURCE GROUP Syntax

```
SET RESOURCE GROUP group_name  
[FOR thread_id [, thread_id] ...]
```

SET RESOURCE GROUP is used for resource group management (see [Section 8.12.5, “Resource Groups”](#)). This statement assigns threads to a resource group. It requires the [RESOURCE_GROUP_ADMIN](#) or [RESOURCE_GROUP_USER](#) privilege.

group_name identifies which resource group to be assigned. Any *thread_id* values indicate threads to assign to the group. Thread IDs can be determined from the Performance Schema [threads](#) table. If the resource group or any named thread ID does not exist, an error occurs.

With no **FOR** clause, the statement assigns the current thread for the session to the resource group.

With a **FOR** clause that names thread IDs, the statement assigns those threads to the resource group.

For attempts to assign a system thread to a user resource group or a user thread to a system resource group, a warning occurs.

Examples:

- Assign the current session thread to a group:

```
SET RESOURCE GROUP rg1;
```

- Assign the named threads to a group:

```
SET RESOURCE GROUP rg2 FOR 14, 78, 4;
```

Resource group management is local to the server on which it occurs. `SET RESOURCE GROUP` statements are not written to the binary log and are not replicated.

An alternative to `SET RESOURCE GROUP` is the `RESOURCE_GROUP` optimizer hint, which assigns individual statements to a resource group. See [Section 8.9.2, “Optimizer Hints”](#).

13.7.3 Table Maintenance Statements

13.7.3.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name [, tbl_name] ...

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  UPDATE HISTOGRAM ON col_name [, col_name] ...
  [WITH N BUCKETS]

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  DROP HISTOGRAM ON col_name [, col_name] ...
```

`ANALYZE TABLE` generates table statistics:

- `ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the named table or tables. For `MyISAM` tables, `ANALYZE TABLE` for key distribution analysis is equivalent to using `myisamchk --analyze`.
- `ANALYZE TABLE` with the `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.
- `ANALYZE TABLE` with the `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use `InnoDB`. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` works with `InnoDB`, `NDB`, and `MyISAM` tables. It does not work with views.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see [Section 13.1.8, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

During the analysis, the table is locked with a read lock for `InnoDB` and `MyISAM`.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- [ANALYZE TABLE Output](#)
- [Key Distribution Analysis](#)
- [Histogram Statistics Analysis](#)

ANALYZE TABLE Output

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	<code>analyze</code> or <code>histogram</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

Key Distribution Analysis

`ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

For more information on how key distribution analysis works within `InnoDB`, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#) and [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#). Also see [Section 15.8.1.7, “Limits on InnoDB Tables”](#). In particular, when you enable the `innodb_stats_persistent` option, you must run `ANALYZE TABLE` after loading substantial data into an `InnoDB` table, or creating a new index for one.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See [Section 13.7.6.22, “SHOW INDEX Syntax”](#), and [Section 24.24, “The INFORMATION_SCHEMA STATISTICS Table”](#).

Histogram Statistics Analysis

`ANALYZE TABLE` with the `HISTOGRAM` clauses enables management of histogram statistics for table column values. For information about histogram statistics, see [Section 8.9.6, “Optimizer Statistics”](#).

These histogram operations are available:

- `ANALYZE TABLE` with an `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

The optional `WITH N BUCKETS` clause specifies the number of buckets for the histogram. The value of `N` must be an integer in the range from 1 to 1024. If this clause is omitted, the number of buckets is 100.

- **ANALYZE TABLE** with a **DROP HISTOGRAM** clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Stored histogram management statements affect only the named columns. Consider these statements:

```
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;  
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;  
ANALYZE TABLE t DROP HISTOGRAM ON c2;
```

The first statement updates the histograms for columns **c1**, **c2**, and **c3**, replacing any existing histograms for those columns. The second statement updates the histograms for **c1** and **c3**, leaving the **c2** histogram unaffected. The third statement removes the histogram for **c2**, leaving those for **c1** and **c3** unaffected.

Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or **TEMPORARY** tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and **JSON**.

Histograms can be generated for stored and virtual generated columns.

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an **UPDATE HISTOGRAM** statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

The **histogram_generation_max_mem_size** system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime.

Changing the global **histogram_generation_max_mem_size** value requires privileges sufficient to set global system variables. Changing the session **histogram_generation_max_mem_size** value requires privileges sufficient to set restricted session system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

For information about memory allocations performed for histogram generation, monitor the Performance Schema **memory/sql/histograms** instrument. See [Section 25.11.16.10, “Memory Summary Tables”](#).

Histograms are affected by these DDL statements:

- **DROP TABLE** removes histograms for columns in the dropped table.
- **DROP DATABASE** removes histograms for any table in the dropped database because the statement drops all tables in the database.
- **RENAME TABLE** does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.
- **ALTER TABLE** statements that remove or modify a column remove histograms for that column.
- **ALTER TABLE ... CONVERT TO CHARACTER SET** removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

13.7.3.2 CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option: {
    FOR UPGRADE
  | QUICK
  | FAST
  | MEDIUM
  | EXTENDED
  | CHANGED
}
```

CHECK TABLE checks a table or tables for errors. **CHECK TABLE** can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

CHECK TABLE works for InnoDB, MyISAM, ARCHIVE, and CSV tables.

Before running **CHECK TABLE** on InnoDB tables, see [CHECK TABLE Usage Notes for InnoDB Tables](#).

CHECK TABLE is supported for partitioned tables, and you can use **ALTER TABLE ... CHECK PARTITION** to check one or more partitions; for more information, see [Section 13.1.8, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

CHECK TABLE ignores virtual generated columns that are not indexed.

- [CHECK TABLE Output](#)
- [Checking Version Compatibility](#)
- [Checking Data Consistency](#)
- [CHECK TABLE Usage Notes for InnoDB Tables](#)
- [CHECK TABLE Usage Notes for MyISAM Tables](#)

CHECK TABLE Output

CHECK TABLE returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	Always <i>check</i>
Msg_type	<i>status</i> , <i>error</i> , <i>info</i> , <i>note</i> , or <i>warning</i>
Msg_text	An informational message

The statement might produce many rows of information for each checked table. The last row has a *Msg_type* value of *status* and the *Msg_text* normally should be *OK*. *Table is already up to date* means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The **FOR UPGRADE** option checks whether the named tables are compatible with the current version of MySQL. With **FOR UPGRADE**, the server checks each table to determine whether there have been any

incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

FOR UPGRADE discovers these incompatibilities:

- The indexing order for end-space in **TEXT** columns for **InnoDB** and **MyISAM** tables changed between MySQL 4.1 and 5.0.
- The storage method of the new **DECIMAL** data type changed between MySQL 5.0.3 and 5.0.5.
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see [Section 2.11.1.3, “Changes in MySQL 8.0”](#). For information about rebuilding tables, see [Section 2.11.3, “Rebuilding or Repairing Tables or Indexes”](#).
- MySQL 8.0 does not support the **YEAR(2)** data type permitted in older versions of MySQL. For tables containing **YEAR(2)** columns, **CHECK TABLE** recommends **REPAIR TABLE**, which converts **YEAR(2)** to **YEAR(4)**.
- Trigger creation time is maintained.
- A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (**TIME**, **DATETIME**, and **TIMESTAMP** columns without support for fractional seconds precision) and the **avoid_temporal_upgrade** system variable is disabled. This helps **mysql_upgrade** detect and upgrade tables containing old temporal columns. If **avoid_temporal_upgrade** is enabled, **FOR UPGRADE** ignores the old temporal columns present in the table; consequently, **mysql_upgrade** does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable **avoid_temporal_upgrade** before executing **CHECK TABLE ... FOR UPGRADE**.

- Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is removed in MySQL 8.0. See [Chapter 22, Partitioning](#).

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

Type	Meaning
QUICK	Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.
FAST	Check only tables that have not been closed properly. Ignored for InnoDB ; applies only to MyISAM tables and views.
CHANGED	Check only tables that have been changed since the last check or that have not been closed properly. Ignored for InnoDB ; applies only to MyISAM tables and views.
MEDIUM	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Ignored for InnoDB ; applies only to MyISAM tables and views.

Type	Meaning
<code>EXTENDED</code>	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Ignored for <code>InnoDB</code> ; applies only to <code>MyISAM</code> tables and views.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note

If `CHECK TABLE` finds no problems with a table that is marked as “corrupted” or “not closed properly”, `CHECK TABLE` may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) to check tables periodically. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence execution plans generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to `InnoDB` tables:

- If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.
- If `CHECK TABLE` encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, `CHECK TABLE` can cause `InnoDB` to access an invalid undo log record, resulting in an `MVCC`-related server exit.

- If `CHECK TABLE` encounters errors in `InnoDB` tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.
- If `CHECK TABLE` finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.
- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for `BLOB` pointers.
- When an `InnoDB` table is stored in its own `.ibd` file, the first 3 pages of the `.ibd` file contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an `InnoDB .ibd` file, use the `innochecksum` command.
- When running `CHECK TABLE` on large `InnoDB` tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If `InnoDB` detects semaphore waits of 240 seconds or more, it starts printing `InnoDB` monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, `InnoDB` aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run `CHECK TABLE QUICK` instead of `CHECK TABLE`.
- `CHECK TABLE` functionality for `InnoDB SPATIAL` indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.
- `CHECK TABLE` supports secondary indexes on virtual generated columns, which are supported by `InnoDB`.

CHECK TABLE Usage Notes for MyISAM Tables

The following notes apply to `MyISAM` tables:

- `CHECK TABLE` updates key statistics for `MyISAM` tables.
- If `CHECK TABLE` output does not return `OK` or `Table is already up to date`, you should normally run a repair of the table. See [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).
- If none of the `CHECK TABLE` options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

13.7.3.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a `checksum` for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the `Checksum` value is always `NULL`, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

During the checksum operation, the table is locked with a read lock for `InnoDB` and `MyISAM`.

Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with `InnoDB` and all other storage engines other than `MyISAM`, and with `MyISAM` tables not created with the `CHECKSUM=1` clause.

For `MyISAM` tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. The `QUICK` method is not supported with `InnoDB` tables. See [Section 13.1.18, “CREATE TABLE Syntax”](#) for the syntax of the `CHECKSUM` clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.3.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the [storage engine](#) used by that table.

Use `OPTIMIZE TABLE` in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an `InnoDB` table that has its own `.ibd` file because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.
- After doing substantial insert, update, or delete operations on columns that are part of a `FULLTEXT` index in an `InnoDB` table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.
- After deleting a large part of a `MyISAM` or `ARCHIVE` table, or making many changes to a `MyISAM` or `ARCHIVE` table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` works for `InnoDB`, `MyISAM`, and `ARCHIVE` tables.

By default, `OPTIMIZE TABLE` does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

This statement does not work with views.

`OPTIMIZE TABLE` is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see [Section 22.3.4, "Maintenance of Partitions"](#).

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- [OPTIMIZE TABLE Output](#)
- [InnoDB Details](#)
- [MyISAM Details](#)
- [Other Considerations](#)

OPTIMIZE TABLE Output

`OPTIMIZE TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	Always <code>optimize</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

`OPTIMIZE TABLE` catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

InnoDB Details

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an `InnoDB` table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+-----+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK       |
```

`OPTIMIZE TABLE` uses [online DDL](#) for regular and partitioned [InnoDB](#) tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by `OPTIMIZE TABLE` and performed under the cover by `ALTER TABLE ... FORCE` is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

`OPTIMIZE TABLE` rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.
- When the `mysqld --skip-new` option is enabled.

`OPTIMIZE TABLE` using [online DDL](#) is not supported for [InnoDB](#) tables that contain [FULLTEXT](#) indexes. The table copy method is used instead.

[InnoDB](#) stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as [MyISAM](#)) will. When considering whether or not to run optimize, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. [InnoDB](#) only fills [pages](#) 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#) and [Section 15.10.1, “Overview of InnoDB Row Storage”](#).
- High-concurrency workloads might leave gaps in indexes over time, as [InnoDB](#) retains multiple versions of the same data due through its [MVCC](#) mechanism. See [Section 15.3, “InnoDB Multi-Versioning”](#).

MyISAM Details

For [MyISAM](#) tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

`OPTIMIZE TABLE` is performed online for regular and partitioned [InnoDB](#) tables. Otherwise, MySQL [locks the table](#) during the time `OPTIMIZE TABLE` is running.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on [POINT](#) columns. (Bug #23578)

13.7.3.5 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...
[QUICK] [EXTENDED] [USE_FRM]
```

REPAIR TABLE repairs a possibly corrupted table, for certain storage engines only.

This statement requires **SELECT** and **INSERT** privileges for the table.

Although normally you should never have to run **REPAIR TABLE**, if disaster strikes, this statement is very likely to get back all your data from a **MyISAM** table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use **REPAIR TABLE**. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 16.2.4, “MyISAM Table Problems”](#).

REPAIR TABLE checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as **CHECK TABLE ... FOR UPGRADE**. See [Section 13.7.3.2, “CHECK TABLE Syntax”](#), for more information.

Important

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See [Chapter 7, Backup and Recovery](#).
- If the server crashes during a **REPAIR TABLE** operation, it is essential after restarting it that you immediately execute another **REPAIR TABLE** statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.
- In the event that a table on the master becomes corrupted and you run **REPAIR TABLE** on it, any resulting changes to the original table are *not* propagated to slaves.

- [REPAIR TABLE Storage Engine and Partitioning Support](#)
- [REPAIR TABLE Options](#)
- [REPAIR TABLE Output](#)
- [Table Repair Considerations](#)

REPAIR TABLE Storage Engine and Partitioning Support

REPAIR TABLE works for **MyISAM**, **ARCHIVE**, and **CSV** tables. For **MyISAM** tables, it has the same effect as `myisamchk --recover tbl_name` by default. This statement does not work with views.

REPAIR TABLE is supported for partitioned tables. However, the **USE_FRM** option cannot be used with this statement on a partitioned table.

You can use **ALTER TABLE ... REPAIR PARTITION** to repair one or more partitions; for more information, see [Section 13.1.8, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

REPAIR TABLE Options

- **NO_WRITE_TO_BINLOG** or **LOCAL**

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- `QUICK`

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- `EXTENDED`

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- `USE_FRM`

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

Caution

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` does not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is used, `REPAIR TABLE` does not check the table to see whether an upgrade is required.

REPAIR TABLE Output

`REPAIR TABLE` returns a result set with the columns shown in the following table.

Column	Value
<code>Table</code>	The table name
<code>Op</code>	Always <code>repair</code>

Column	Value
Msg_type	status, error, info, note, or warning
Msg_text	An informational message

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. For a `MyISAM` table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.)

`REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

Table Repair Considerations

`REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE`.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See [Section 8.6.3, "Optimizing REPAIR TABLE Statements"](#).

13.7.4 Component, Plugin, and User-Defined Function Statements

13.7.4.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name
  RETURNS {STRING|INTEGER|REAL|DECIMAL}
  SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

function_name is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

shared_library_name is the base name of the shared library file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 5.7.1, "Installing and Uninstalling User-Defined Functions"](#).

To create a function, you must have the `INSERT` privilege for the `mysql` system database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name.

UDFs registered using `CREATE FUNCTION` are listed in the Performance Schema `user_defined_functions` table; see [Section 25.11.17.4, "The user_defined_functions Table"](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 28.4.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`.

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

13.7.4.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` system database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

13.7.4.3 INSTALL COMPONENT Syntax

```
INSTALL COMPONENT component_name [, component_name ] ...
```

This statement installs one or more server components, which become active immediately. A component provides services that are available to the server and other components; see [Section 5.5, “MySQL Server Components”](#). `INSTALL COMPONENT` requires the `INSERT` privilege for the `mysql.component` system table.

Example:

```
INSTALL COMPONENT 'file://component1', 'file://component2';
```

Component names are URNs that begin with `file://` and indicate the base name of the file that implements the component, located in the directory named by the `plugin_dir` system variable. Component names do not include any platform-dependent file name suffix such as `.so` or `.dll`. (These

naming details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.)

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

A loader service handles component loading, which includes adding installed components to the `mysql.component` system table that serves as a registry. For subsequent server restarts, any components listed in `mysql.component` are loaded by the loader service during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services on which it depends, an error occurs:

```
ERROR 3527 (HY000): Cannot satisfy dependency for service 'component_a'
required by component 'component_b'.
```

To avoid this problem, either install all components in the same statement, or install the dependent component after installing any components on which it depends.

13.7.4.4 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table.

plugin_name is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Section 28.2.4.2, “Plugin Data Structures”](#)). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

shared_library_name is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. At server startup, the server loads and initializes any plugin

that is listed in `mysql.plugin`. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.6, “Server Command Options”](#).

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA` the `PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

13.7.4.5 UNINSTALL COMPONENT Syntax

```
UNINSTALL COMPONENT component_name [, component_name ] ...
```

This statement deactivates and uninstalls one or more server components. A component provides services that are available to the server and other components; see [Section 5.5, “MySQL Server Components”](#). `UNINSTALL COMPONENT` is the complement of `INSTALL COMPONENT`. It requires the `DELETE` privilege for the `mysql.component` system table.

Example:

```
UNINSTALL COMPONENT 'file://component1', 'file://component2';
```

For information about component naming, see [Section 13.7.4.3, “INSTALL COMPONENT Syntax”](#).

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

A loader service handles component unloading, which includes removing uninstalled components from the `mysql.component` system table that serves as a registry. As a result, unloaded components are not loaded during the startup sequence for subsequent server restarts.

13.7.4.6 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` system table. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`.

plugin_name must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` system table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

13.7.5 SET Syntax

The `SET` statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).
- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See [Section 13.7.5.2, “SET CHARACTER SET Syntax”](#), and [Section 13.7.5.3, “SET NAMES Syntax”](#).

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

- `SET DEFAULT ROLE` and `SET ROLE` set the default role and current role for user accounts. See [Section 13.7.1.9, “SET DEFAULT ROLE Syntax”](#), and [Section 13.7.1.11, “SET ROLE Syntax”](#).
- `SET PASSWORD` assigns account passwords. See [Section 13.7.1.10, “SET PASSWORD Syntax”](#).
- `SET RESOURCE GROUP` assigns threads to a resource group. See [Section 13.7.2.4, “SET RESOURCE GROUP Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 13.3.7, “SET TRANSACTION Syntax”](#).

13.7.5.1 SET Syntax for Variable Assignment

```
SET variable = expr [, variable = expr] ...

variable: {
    user_var_name
  | param_name
  | local_var_name
  | {GLOBAL | @@global.} system_var_name
  | {PERSIST | @@persist.} system_var_name
  | {PERSIST_ONLY | @@persist_only.} system_var_name
  | [SESSION | @@session. | @@] system_var_name
}
```

SET syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- User-defined variables. See [Section 9.4, “User-Defined Variables”](#).
- Stored procedure and function parameters, and stored program local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- System variables. See [Section 5.1.7, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.8, “Using System Variables”](#).

A **SET** statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe **SET** syntax for setting variables. They use the **=** assignment operator, but the **:=** assignment operator is also permitted for this purpose.

- [User-Defined Variable Assignment](#)
- [Parameter and Local Variable Assignment](#)
- [System Variable Assignment](#)
- [SET Error Handling](#)
- [Multiple Variable Assignment](#)
- [System Variable References in Expressions](#)

User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see [Section 9.4, “User-Defined Variables”](#).

A user-defined variable is written as **@var_name** and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, *expr* can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema `user_variables_by_thread` table contains information about user-defined variables. See [Section 25.11.10, “Performance Schema User-Defined Variable Tables”](#).

Parameter and Local Variable Assignment

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
```

System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

To make a global system variable setting permanent so that it applies across server restarts, you can persist it to the `mysqld-auto.cnf` file in the data directory. It is also possible to make persistent configuration changes by manually modifying a `my.cnf` option file, but that is more cumbersome, and an error in a manually entered setting might not be discovered until much later. `SET` statements that persist system variables are more convenient and avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration. For more information about persisting system variables and the `mysqld-auto.cnf` file, see [Section 5.1.8.3, “Persisted System Variables”](#).

Note

Setting or persisting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see [Section 5.1.8.1, “System Variable Privileges”](#).

The following discussion describes the syntax options for setting and persisting system variables:

- To assign a value to a global system variable, precede the variable name by the `GLOBAL` keyword or the `@@global.` qualifier:

```
SET GLOBAL max_connections = 1000;
```

```
SET @@global.max_connections = 1000;
```

- To assign a value to a session system variable, precede the variable name by the `SESSION` or `LOCAL` keyword, or by the `@@session.`, `@@local.`, or `@@` qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET LOCAL sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@local.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

If no keyword or modifier is present, `SET` changes the session variable.

```
SET sql_mode = 'TRADITIONAL';
```

A client can change its own session variables, but not those of any other client.

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@persist.` qualifier:

```
SET PERSIST max_connections = 1000;
SET @@persist.max_connections = 1000;
```

This `SET` syntax enables you to make configuration changes at runtime that also persist across server restarts. Like `SET GLOBAL`, `SET PERSIST` sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@persist_only.` qualifier:

```
SET PERSIST_ONLY back_log = 100;
SET @@persist_only.back_log = 100;
```

Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However, unlike `PERSIST`, `PERSIST_ONLY` does not modify the global variable runtime value. This makes `PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size = DEFAULT;
SET @@session.max_join_size = @@global.max_join_size;
```

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted. See [Section 5.1.8.4, “Nonpersistent System Variables”](#).

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server

restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable will not exist when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

To display system variable names and values:

- Use the `SHOW VARIABLES` statement; see [Section 13.7.6.39, “SHOW VARIABLES Syntax”](#).
- Several Performance Schema tables provide system variable information. See [Section 25.11.13, “Performance Schema System Variable Tables”](#).
- The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See [Section 25.11.13.2, “Performance Schema variables_info Table”](#).
- The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See [Section 25.11.13.1, “Performance Schema persisted_variables Table”](#).

SET Error Handling

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed, nor is the `mysqld-auto.cnf` file changed.

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, `@@global.` or `@@session.`).

- Use of `SET` (any variant) to set a read-only variable:

```
mysql> SET GLOBAL version = 'abc';
ERROR 1238 (HY000): Variable 'version' is a read only variable
```

- Use of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1228 (HY000): Variable 'sql_log_bin' is a SESSION
variable and can't be used with SET GLOBAL
```

- Use of `SESSION` to set a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Omission of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a global value:

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Use of `PERSIST` or `PERSIST_ONLY` to set a variable that cannot be persisted:

```
mysql> SET PERSIST port = 3307;
ERROR 1238 (HY000): Variable 'port' is a read only variable
mysql> SET PERSIST_ONLY port = 3307;
ERROR 1238 (HY000): Variable 'port' is a non persistent read only variable
```

- The @@global., @@persist., @@persist_only., @@session., and @@ modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.
- Not all system variables can be set to DEFAULT. In such cases, assigning DEFAULT results in an error.
- An error occurs for attempts to assign DEFAULT to user-defined variables, stored procedure or function parameters, or stored program local variables.

Multiple Variable Assignment

A SET statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent GLOBAL, PERSIST, PERSIST_ONLY, or SESSION keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The @@global., @@persist., @@persist_only., @@session., and @@ modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the sort_buffer_size global value to 50000 and the session value to 1000000:

```
SET @@global.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the @@-modifiers (except @@persist. and @@persist_only., which are not permitted in expressions). For example, you can retrieve system variable values in a SELECT statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

A reference to a system variable in an expression as @@var_name (with @@ rather than @@global. or @@session.) returns the session value if it exists and the global value otherwise. This differs from SET @@var_name = expr, which always refers to the session value.

13.7.5.2 SET CHARACTER SET Syntax

```
SET {CHARACTER SET | CHARSET}
    {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 10.4, “Connection Character Sets and Collations”](#).

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

13.7.5.3 SET NAMES Syntax

```
SET NAMES { 'charset_name'
           [ COLLATE 'collation_name' ] | DEFAULT }
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See [Section 10.4, “Connection Character Sets and Collations”](#).

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` produces an error. See [Impermissible Client Character Sets](#).

13.7.6 SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW { BINARY | MASTER } LOGS
SHOW BINLOG EVENTS [ IN 'log_name' ] [ FROM pos ] [ LIMIT [ offset, ] row_count ]
SHOW CHARACTER SET [ like_or_where ]
SHOW COLLATION [ like_or_where ]
SHOW [ FULL ] COLUMNS FROM tbl_name [ FROM db_name ] [ like_or_where ]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [ like_or_where ]
SHOW ENGINE engine_name { STATUS | MUTEX }
SHOW [ STORAGE ] ENGINES
SHOW ERRORS [ LIMIT [ offset, ] row_count ]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [ like_or_where ]
```

```

SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
    LIKE 'pattern'
    | WHERE expr

```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 24.39, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 27, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 24, INFORMATION_SCHEMA Tables](#).

13.7.6.1 SHOW BINARY LOGS Syntax

```

SHOW BINARY LOGS
SHOW MASTER LOGS

```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#), that shows how to determine which logs can be purged.

```

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935   |
| binlog.000016     | 733481   |
+-----+-----+

```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

A user with the `SUPER` or `REPLICATION CLIENT` privilege may execute this statement.

13.7.6.2 SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
  [IN 'log_name']
  [FROM pos]
  [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

`SHOW BINLOG EVENTS` displays the following fields for each event in the binary log:

- `Log_name`

The name of the file that is being listed.

- `Pos`

The position at which the event occurs.

- `Event_type`

An identifier that describes the event type.

- `Server_id`

The server ID of the server on which the event originated.

- `End_log_pos`

The position at which the next event begins, which is equal to `Pos` plus the size of the event.

- `Info`

More detailed information about the event type. The format of this information depends on the event type.

Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

Note

`SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

13.7.6.3 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#). For example:

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

SHOW CHARACTER SET output has these columns:

- Charset

The character set name.

- Description

A description of the character set.

- Default collation

The default collation for the character set.

- Maxlen

The maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

Character set information is also available from the `INFORMATION_SCHEMA.CHARACTER_SETS` table. See [Section 24.2, “The INFORMATION_SCHEMA.CHARACTER_SETS Table”](#).

13.7.6.4 SHOW COLLATION Syntax

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39](#), “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_general_ci	latin1	94	0	1	17
latin1_bin	latin1	95	0	1	17
latin1_danish_ci	latin1	96	0	1	17
latin1_german1_ci	latin1	97	0	1	17

latin1_german_swiss_24_ci	latin1	138	0	1	17
latin1_german_swiss_25_ci	latin1	139	0	1	17
latin1_german_swiss_26_ci	latin1	140	0	1	17
latin1_german_swiss_27_ci	latin1	141	0	1	17
latin1_german_swiss_28_ci	latin1	142	0	1	17
latin1_german_swiss_29_ci	latin1	143	0	1	17
latin1_german_swiss_30_ci	latin1	144	0	1	17
latin1_german_swiss_31_ci	latin1	145	0	1	17
latin1_german_swiss_32_ci	latin1	146	0	1	17
latin1_german_swiss_33_ci	latin1	147	0	1	17
latin1_german_swiss_34_ci	latin1	148	0	1	17
latin1_german_swiss_35_ci	latin1	149	0	1	17
latin1_german_swiss_36_ci	latin1	150	0	1	17
latin1_german_swiss_37_ci	latin1	151	0	1	17
latin1_german_swiss_38_ci	latin1	152	0	1	17
latin1_german_swiss_39_ci	latin1	153	0	1	17
latin1_german_swiss_40_ci	latin1	154	0	1	17
latin1_german_swiss_41_ci	latin1	155	0	1	17
latin1_german_swiss_42_ci	latin1	156	0	1	17
latin1_german_swiss_43_ci	latin1	157	0	1	17
latin1_german_swiss_44_ci	latin1	158	0	1	17
latin1_german_swiss_45_ci	latin1	159	0	1	17
latin1_german_swiss_46_ci	latin1	160	0	1	17
latin1_german_swiss_47_ci	latin1	161	0	1	17
latin1_german_swiss_48_ci	latin1	162	0	1	17
latin1_german_swiss_49_ci	latin1	163	0	1	17
latin1_german_swiss_50_ci	latin1	164	0	1	17
latin1_german_swiss_51_ci	latin1	165	0	1	17
latin1_german_swiss_52_ci	latin1	166	0	1	17
latin1_german_swiss_53_ci	latin1	167	0	1	17
latin1_german_swiss_54_ci	latin1	168	0	1	17
latin1_german_swiss_55_ci	latin1	169	0	1	17
latin1_german_swiss_56_ci	latin1	17			

latin1_german1_ci	latin1	5		Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1
latin1_danish_ci	latin1	15		Yes	1
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	1
latin1_general_ci	latin1	48		Yes	1
latin1_general_cs	latin1	49		Yes	1
latin1_spanish_ci	latin1	94		Yes	1

`SHOW COLLATION` output has these columns:

- **Collation**

The collation name.

- **Charset**

The name of the character set with which the collation is associated.

- **Id**

The collation ID.

- **Default**

Whether the collation is the default for its character set.

- **Compiled**

Whether the character set is compiled into the server.

- **Sortlen**

This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

Collation	Charset	Id	Default	Compiled	Sortlen
big5_chinese_ci	big5	1	Yes	Yes	1
dec8_swedish_ci	dec8	3	Yes	Yes	1
cp850_general_ci	cp850	4	Yes	Yes	1
hp8_english_ci	hp8	6	Yes	Yes	1
koi8r_general_ci	koi8r	7	Yes	Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1
...					

Collation information is also available from the `INFORMATION_SCHEMA COLLATIONS` table. See [Section 24.3, “The INFORMATION_SCHEMA COLLATIONS Table”](#).

13.7.6.5 SHOW COLUMNS Syntax

```
SHOW [EXTENDED] [FULL] {COLUMNS | FIELDS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. `SHOW COLUMNS` displays information only for those columns for which you have some privilege.

```
mysql> SHOW COLUMNS FROM City;
```

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO	MUL		
District	char(20)	NO			
Population	int(11)	NO		0	

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional `EXTENDED` keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 13.1.18.7, “Silent Column Specification Changes”](#).

`SHOW COLUMNS` displays the following values for each table column:

- **Field**
The name of the column.
- **Type**
The column data type.
- **Collation**
The collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.
- **Null**
The column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.
- **Key**
Whether the column is indexed:
 - If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.

- If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` field.)
- If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- `Default`

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- `Extra`

Any additional information that is available about a given column. The value is nonempty in these cases:

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute.
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.
- `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns.
- `DEFAULT_GENERATED` for columns that have an expression default value.

- `Privileges`

The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

- `Comment`

Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

Table column information is also available from the `INFORMATION_SCHEMA COLUMNS` table. See [Section 24.5, “The INFORMATION_SCHEMA COLUMNS Table”](#). The extended information about hidden columns is available only using `SHOW EXTENDED COLUMNS`; it cannot be obtained from the `COLUMNS` table.

You can list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 13.8.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.6, “SHOW Syntax”](#).

13.7.6.6 SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                /*!40100 DEFAULT CHARACTER SET utf8mb4 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                /*!40100 DEFAULT CHARACTER SET utf8mb4 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.7, “Server System Variables”](#).

13.7.6.7 SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in [Section 13.7.6.18, “SHOW EVENTS Syntax”](#)):

```
mysql> SHOW CREATE EVENT myschema.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
                NO_ZERO_IN_DATE,NO_ZERO_DATE,
                ERROR_FOR_DIVISION_BY_ZERO,
                NO_ENGINE_SUBSTITUTION
      time_zone: SYSTEM
Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
              ON COMPLETION NOT PRESERVE
              ENABLE
              COMMENT 'Saves total number of sessions then
                      clears the table each day'
              DO BEGIN
                INSERT INTO site_activity.totals (time, total)
                  SELECT CURRENT_TIMESTAMP, COUNT(*)
                    FROM site_activity.sessions;
                DELETE FROM site_activity.sessions;
              END
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection`

system variable when the event was created. [Database Collation](#) is the collation of the database with which the event is associated.

The output reflects the current status of the event ([ENABLE](#)) rather than the status with which it was created.

13.7.6.8 SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to [SHOW CREATE PROCEDURE](#) but for stored functions. See [Section 13.7.6.9, “SHOW CREATE PROCEDURE Syntax”](#).

13.7.6.9 SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, [SHOW CREATE FUNCTION](#), displays information about stored functions (see [Section 13.7.6.8, “SHOW CREATE FUNCTION Syntax”](#)).

To use either statement, you must have the global [SELECT](#) privilege.

```
mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
                NO_ZERO_IN_DATE,NO_ZERO_DATE,
                ERROR_FOR_DIVISION_BY_ZERO,
                NO_ENGINE_SUBSTITUTION
      Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
                        BEGIN
                        SELECT COUNT(*) INTO param1 FROM t;
                        END
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
  Database Collation: utf8mb4_0900_ai_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
                NO_ZERO_IN_DATE,NO_ZERO_DATE,
                ERROR_FOR_DIVISION_BY_ZERO,
                NO_ENGINE_SUBSTITUTION
      Create Function: CREATE FUNCTION `hello`(s CHAR(20))
                      RETURNS char(50) CHARSET utf8mb4
                      RETURN CONCAT('Hello, ',s, '!')
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
  Database Collation: utf8mb4_0900_ai_ci
```

[character_set_client](#) is the session value of the [character_set_client](#) system variable when the routine was created. [collation_connection](#) is the session value of the [collation_connection](#) system variable when the routine was created. [Database Collation](#) is the collation of the database with which the routine is associated.

13.7.6.10 SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.7, “Server System Variables”](#).

For information about how `CREATE TABLE` statements are stored by MySQL, see [Section 13.1.18.1, “CREATE TABLE Statement Retention”](#).

13.7.6.11 SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the `CREATE TRIGGER` statement that creates the named trigger. This statement requires the `TRIGGER` privilege for the table associated with the trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
      Trigger: ins_sum
      sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
                NO_ZERO_IN_DATE,NO_ZERO_DATE,
                ERROR_FOR_DIVISION_BY_ZERO,
                NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER `ins_sum`
                        BEFORE INSERT ON `account`
                        FOR EACH ROW SET @sum = @sum + NEW.amount
      character_set_client: utf8mb4
      collation_connection: utf8mb4_0900_ai_ci
      Database Collation: utf8mb4_0900_ai_ci
                        Created: 2018-08-08 10:10:12.61
```

`SHOW CREATE TRIGGER` output has these columns:

- `Trigger`: The trigger name.
- `sql_mode`: The SQL mode in effect when the trigger executes.
- `SQL Original Statement`: The `CREATE TRIGGER` statement that defines the trigger.
- `character_set_client`: The session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection`: The session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation`: The collation of the database with which the trigger is associated.

- **Created:** The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See [Section 24.31, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

13.7.6.12 SHOW CREATE USER Syntax

```
SHOW CREATE USER user
```

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` system database, except to see information for the current user. For the current user, the `SELECT` privilege for the `mysql.user` system table is required for display of the password hash in the `IDENTIFIED AS` clause; otherwise, the hash displays as `<secret>`.

To name the account, use the format described in [Section 6.2.4, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

```
mysql> SHOW CREATE USER 'root'@'localhost'\G
***** 1. row *****
CREATE USER for root@localhost: CREATE USER 'root'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
AS '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
```

To display the privileges granted to an account, use the `SHOW GRANTS` statement. See [Section 13.7.6.21, “SHOW GRANTS Syntax”](#).

13.7.6.13 SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows the `CREATE VIEW` statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
View: v
Create View: CREATE ALGORITHM=UNDEFINED
DEFINER='bob'@'localhost'
SQL SECURITY DEFINER VIEW
`v` AS select 1 AS `a`,2 AS `b`
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

View information is also available from the `INFORMATION_SCHEMA VIEWS` table. See [Section 24.33, “The INFORMATION_SCHEMA VIEWS Table”](#).

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
          View: v
      Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

13.7.6.14 SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the `INFORMATION_SCHEMA.SCHEMATA` table. See [Section 24.22, “The INFORMATION_SCHEMA SCHEMATA Table”](#).

13.7.6.15 SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard [InnoDB Monitor](#) about the state of the [InnoDB](#) storage engine. For information about the standard monitor and other [InnoDB Monitors](#) that provide information about [InnoDB](#) processing, see [Section 15.16, “InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays [InnoDB mutex](#) and [rw-lock](#) statistics.

Note

[InnoDB](#) mutexes and rwlocks can also be monitored using [Performance Schema](#) tables. See [Section 15.15.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

Mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_enable='latch';
```

- To reset mutex statistics, run:

```
SET GLOBAL innodb_monitor_reset='latch';
```

- To disable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_disable='latch';
```

Collection of mutex statistics for `SHOW ENGINE INNODB MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB MUTEX` output has these columns:

- [Type](#)

Always [InnoDB](#).

- [Name](#)

For mutexes, the [Name](#) field reports only the mutex name. For rwlocks, the [Name](#) field reports the source file where the rwlock is implemented, and the line number in the file where the rwlock is created. The line number is specific to your version of MySQL.

- [Status](#)

The mutex status. This field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of [InnoDB](#), are not reported.

- [spins](#) indicates the number of spins.
- [waits](#) indicates the number of mutex waits.
- [calls](#) indicates how many times the mutex was requested.

`SHOW ENGINE INNODB MUTEX` skips the [mutexes](#) and [rw-locks](#) of [buffer pool](#) blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) `SHOW ENGINE INNODB MUTEX`

also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
  Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
  Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
  Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
  Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

`Name` values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).size`, `(pfs_mutex_class).memory`.
- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.size`, `mutex_instances.count`.
- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- `size` is the size of the internal record used by the implementation, such as the size of a row in a table. `size` values cannot be changed.
- `count` is the number of internal records, such as the number of rows in a table. `count` values can be changed using Performance Schema configuration options.
- For a table, `tbl_name.memory` is the product of `size` and `count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long.size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to

`performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

13.7.6.16 SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 16, Alternative Storage Engines](#).

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
  Savepoints: NO
***** 3. row *****
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO
***** 4. row *****
  Engine: FEDERATED
  Support: NO
  Comment: Federated MySQL storage engine
Transactions: NULL
          XA: NULL
  Savepoints: NULL
***** 5. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
***** 6. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
***** 7. row *****
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
  Savepoints: YES
```

```

***** 8. row *****
      Engine: MEMORY
      Support: YES
      Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
      XA: NO
      Savepoints: NO
***** 9. row *****
      Engine: CSV
      Support: YES
      Comment: CSV storage engine
Transactions: NO
      XA: NO
      Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- `Engine`

The name of the storage engine.

- `Support`

The server's level of support for the storage engine, as shown in the following table.

Value	Meaning
<code>YES</code>	The engine is supported and is active
<code>DEFAULT</code>	Like <code>YES</code> , plus this is the default engine
<code>NO</code>	The engine is not supported
<code>DISABLED</code>	The engine is supported but has been disabled

A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See [Section 5.4.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

- `Comment`

A brief description of the storage engine.

- `Transactions`

Whether the storage engine supports transactions.

- `XA`

Whether the storage engine supports XA transactions.

- `Savepoints`

Whether the storage engine supports savepoints.

Storage engine information is also available from the `INFORMATION_SCHEMA.ENGINES` table. See [Section 24.8, “The INFORMATION_SCHEMA ENGINES Table”](#).

13.7.6.17 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see [Section 13.7.6.40, “SHOW WARNINGS Syntax”](#).

13.7.6.18 SHOW EVENTS Syntax

```
SHOW EVENTS
  [{FROM | IN} schema_name]
  [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events, which are discussed in [Section 23.4, “Using the Event Scheduler”](#). It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
```

```
      Type: RECURRING
      Execute at: NULL
      Interval value: 1
      Interval field: DAY
      Starts: 2018-08-08 11:06:34
      Ends: NULL
      Status: ENABLED
      Originator: 1
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

To see events for a specific schema, use the [FROM](#) clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The [LIKE](#) clause, if present, indicates which event names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

`SHOW EVENTS` output has these columns:

- [Db](#)

The name of the schema (database) to which the event belongs.

- [Name](#)

The name of the event.

- [Definer](#)

The account of the user who created the event, in '`user_name`'@'`host_name`' format.

- [Time zone](#)

The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is [SYSTEM](#).

- [Type](#)

The event repetition type, either [ONE TIME](#) (transient) or [RECURRING](#) (repeating).

- [Execute At](#)

For a one-time event, this is the [DATETIME](#) value specified in the [AT](#) clause of the [CREATE EVENT](#) statement used to create the event, or of the last [ALTER EVENT](#) statement that modified the event. The value shown in this column reflects the addition or subtraction of any [INTERVAL](#) value included in the event's [AT](#) clause. For example, if an event is created using [ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR](#), and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '`2018-02-10 20:05:30`'. If the event's timing is determined by an [EVERY](#) clause instead of an [AT](#) clause (that is, if the event is recurring), the value of this column is [NULL](#).

- [Interval Value](#)

For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always [NULL](#).

- `Interval Field`

The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always `NULL`.

- `Starts`

The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. For a transient event, this column is always `NULL`. For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `Execute At` column, this value resolves any expressions used. If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`.

- `Ends`

For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `Execute At` column, this value resolves any expressions used. If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- `Status`

The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`. `SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. For more information, see [Section 17.4.1.16, “Replication of Invoked Features”](#). information.

- `Originator`

The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.

- `character_set_client`

The session value of the `character_set_client` system variable when the event was created.

- `collation_connection`

The session value of the `collation_connection` system variable when the event was created.

- `Database Collation`

The collation of the database with which the event is associated.

For more information about `SLAVESIDE_DISABLED` and the `Originator` column, see [Section 17.4.1.16, “Replication of Invoked Features”](#).

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in [Section 23.4.4, “Event Metadata”](#).

Event information is also available from the `INFORMATION_SCHEMA EVENTS` table. See [Section 24.9, “The INFORMATION_SCHEMA EVENTS Table”](#).

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA EVENTS` table.

13.7.6.19 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 13.7.6.27](#), “`SHOW PROCEDURE CODE Syntax`”.

13.7.6.20 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
  [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 13.7.6.28](#), “`SHOW PROCEDURE STATUS Syntax`”.

13.7.6.21 SHOW GRANTS Syntax

```
SHOW GRANTS
  [FOR user_or_role
    [USING role [, role] ...]]

user_or_role: {
  user
| role
}
```

This statement displays the privileges and roles that are assigned to a MySQL user account or role, in the form of `GRANT` statements that must be executed to duplicate the privilege and role assignments.

Note

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See [Section 13.7.6.12](#), “`SHOW CREATE USER Syntax`”.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system database, except to display privileges and roles for the current user.

To name the account or role for `SHOW GRANTS`, use the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`:

```
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
+-----+
| Grants for jeffrey@localhost |
+-----+
| GRANT USAGE ON *.* TO `jeffrey`@`localhost` |
| GRANT SELECT, INSERT, UPDATE ON `db1`.* TO `jeffrey`@`localhost` |
+-----+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account and role names, see [Section 6.2.4](#), “`Specifying Account Names`”, and [Section 6.2.5](#), “`Specifying Role Names`”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
```

```
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

In MySQL 8.0 compared to previous series, `SHOW GRANTS` no longer displays `ALL PRIVILEGES` in its global-privileges output because the meaning of `ALL PRIVILEGES` at the global level varies depending on which dynamic privileges are defined. Instead, `SHOW GRANTS` explicitly lists each granted global privilege:

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, |
| SHUTDOWN, PROCESS, FILE, REFERENCES, INDEX, ALTER, SHOW DATABASES, |
| SUPER, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION |
| SLAVE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, |
| ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE TABLESPACE, |
| CREATE ROLE, DROP ROLE ON *.* TO `root`@`localhost` WITH GRANT |
| OPTION |
| GRANT PROXY ON ''@'' TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

Applications that process `SHOW GRANTS` output should be adjusted accordingly.

At the global level, `GRANT OPTION` applies to all granted static global privileges if granted for any of them, but applies individually to granted dynamic privileges. `SHOW GRANTS` displays global privileges this way:

- One line listing all granted static privileges, if there are any, including `WITH GRANT OPTION` if appropriate.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is granted, if there are any, including `WITH GRANT OPTION`.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is not granted, if there are any, without `WITH GRANT OPTION`.

With the optional `USING` clause, `SHOW GRANTS` enables you to examine the privileges associated with roles for the user. Each role named in the `USING` clause must be granted to the user.

Suppose that user `u1` is assigned roles `r1` and `r2`, as follows:

```
CREATE ROLE 'r1', 'r2';
GRANT SELECT ON db1.* TO 'r1';
GRANT INSERT, UPDATE, DELETE ON db1.* TO 'r2';
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'ulpass';
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

`SHOW GRANTS` without `USING` shows the granted roles:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
```

Adding a `USING` clause causes the statement to also display the privileges associated with each role named in the clause:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT SELECT ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r2';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1', 'r2';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
```

Note

A privileges granted an an account is always in effect, but a role is not. The active roles for an account can differ across and within sessions, depending on the value of the `activate_all_roles_on_login` system variable, the account default roles, and whether `SET ROLE` has been executed within a session.

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` displays mandatory roles named in the `mandatory_roles` system variable value as follows:

- `SHOW GRANTS` without a `FOR` clause displays privileges for the current user, and includes mandatory roles.
- `SHOW GRANTS FOR user` displays privileges for the named user, and does not include mandatory roles.

This behavior is for the benefit of applications that use the output of `SHOW GRANTS FOR user` to determine which privileges are granted explicitly to the named user. Were that output to include mandatory roles, it would be difficult to distinguish roles granted explicitly to the user from mandatory roles.

For the current user, applications can determine privileges with or without mandatory roles by using `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER`, respectively.

13.7.6.22 SHOW INDEX Syntax

```
SHOW [EXTENDED] {INDEX | INDEXES | KEYS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [WHERE expr]
```

SHOW INDEX returns table index information. The format resembles that of the [SQLStatistics](#) call in ODBC. This statement requires some privilege for any column in the table.

```
mysql> SHOW INDEX FROM City\G
***** 1. row *****
      Table: city
      Non_unique: 0
      Key_name: PRIMARY
      Seq_in_index: 1
      Column_name: ID
      Collation: A
      Cardinality: 4188
      Sub_part: NULL
      Packed: NULL
      Null:
      Index_type: BTREE
      Comment:
      Index_comment:
      Visible: YES
      Expression: NULL
***** 2. row *****
      Table: city
      Non_unique: 1
      Key_name: CountryCode
      Seq_in_index: 1
      Column_name: CountryCode
      Collation: A
      Cardinality: 232
      Sub_part: NULL
      Packed: NULL
      Null:
      Index_type: BTREE
      Comment:
      Index_comment:
      Visible: YES
      Expression: NULL
```

An alternative to *tbl_name* FROM *db_name* syntax is *db_name.tbl_name*. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The optional **EXTENDED** keyword causes the output to include information about hidden indexes that MySQL uses internally and are not accessible by users.

The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

SHOW INDEX returns the following fields:

- **Table**

The name of the table.

- **Non_unique**

0 if the index cannot contain duplicates, 1 if it can.

- `Key_name`

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `Seq_in_index`

The column sequence number in the index, starting with 1.

- `Column_name`

The column name. See also the description for the `Expression` column.

- `Collation`

How the column is sorted in the index. This can have values `A` (ascending), `D` (descending), or `NULL` (not sorted).

- `Cardinality`

An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

`Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `Sub_part`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

Note

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 8.3.5, “Column Indexes”](#), and [Section 13.1.14, “CREATE INDEX Syntax”](#).

- `Packed`

Indicates how the key is packed. `NULL` if it is not.

- `Null`

Contains `YES` if the column may contain `NULL` values and `' '` if not.

- `Index_type`

The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `Comment`

Information about the index not described in its own column, such as `disabled` if the index is disabled.

- `Index_comment`

Any comment provided for the index with a `COMMENT` attribute when the index was created.

- `Visible`

Whether the index is visible to the optimizer. See [Section 8.3.12, “Invisible Indexes”](#).

- `Expression`

MySQL 8.0.13 and higher supports functional key parts (see [Functional Key Parts](#)), which affects both the `Column_name` and `Expression` columns:

- For a nonfunctional key part, `Column_name` indicates the column indexed by the key part and `Expression` is `NULL`.
- For a functional key part, `Column_name` column is `NULL` and `Expression` indicates the expression for the key part.

Information about table indexes is also available from the `INFORMATION_SCHEMA_STATISTICS` table. See [Section 24.24, “The INFORMATION_SCHEMA_STATISTICS Table”](#). The extended information about hidden indexes is available only using `SHOW EXTENDED INDEX`; it cannot be obtained from the `STATISTICS` table.

You can list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

13.7.6.23 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
***** 1. row *****
      File: master-bin.000002
      Position: 1307
      Binlog_Do_DB: test
      Binlog_Ignore_DB: manual, mysql
      Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, `Executed_Gtid_Set` shows the set of GTIDs for transactions that have been executed on the master. This is the same as the value for the `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW SLAVE STATUS` on this server.

13.7.6.24 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES
  [{FROM | IN} db_name]
```

```
[LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

`SHOW OPEN TABLES` output has these columns:

- `Database`

The database containing the table.

- `Table`

The table name.

- `In_use`

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- `Name_locked`

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

13.7.6.25 SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
***** 1. row *****
Name: binlog
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
***** 2. row *****
Name: CSV
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
***** 3. row *****
Name: MEMORY
Status: ACTIVE
Type: STORAGE ENGINE
```

```

Library: NULL
License: GPL
***** 4. row *****
  Name: MyISAM
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
  ...

```

`SHOW PLUGINS` output has these columns:

- **Name**

The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**

The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETING`, or `DELETED`.

- **Type**

The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

- **Library**

The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **License**

How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the **Name** and **Library** values are also registered in the `mysql.plugin` system table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [Section 28.2, “The MySQL Plugin API”](#).

Plugin information is also available from the `INFORMATION_SCHEMA . PLUGINS` table. See [Section 24.16, “The INFORMATION_SCHEMA PLUGINS Table”](#).

13.7.6.26 SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The privileges displayed include all static privileges, and all currently registered dynamic privileges.

```

mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****

```

```

Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Databases
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...

```

Privileges belonging to a specific user are displayed by the [SHOW GRANTS](#) statement. See [Section 13.7.6.21, “SHOW GRANTS Syntax”](#), for more information.

13.7.6.27 SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, [SHOW FUNCTION CODE](#), displays information about stored functions (see [Section 13.7.6.19, “SHOW FUNCTION CODE Syntax”](#)).

To use either statement, you must have the global [SELECT](#) privilege.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is *Pos*, which is an ordinal number beginning with 0. The second column is *Instruction*, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```

mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
->   LOOP
->     INSERT INTO t3 VALUES (fanta);
->   END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0 | set fanta@0 55 |
| 1 | stmt 9 "DROP TABLE t2" |
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3 | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)

```

In this example, the nonexecutable [BEGIN](#) and [END](#) statements have disappeared, and for the [DECLARE variable_name](#) statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word *stmt* followed by a type (9 means [DROP](#), 5

means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

13.7.6.28 SHOW PROCEDURE STATUS Syntax

```
SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see [Section 13.7.6.20](#), “`SHOW FUNCTION STATUS Syntax`”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39](#), “`Extensions to SHOW Statements`”.

```
mysql> SHOW PROCEDURE STATUS LIKE 'spl'\G
***** 1. row *****
      Db: test
      Name: spl
      Type: PROCEDURE
      Definer: testuser@localhost
      Modified: 2018-08-08 13:54:11
      Created: 2018-08-08 13:54:11
      Security_type: DEFINER
      Comment:
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
      Database Collation: utf8mb4_0900_ai_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

Stored routine information is also available from the `INFORMATION_SCHEMA PARAMETERS` and `ROUTINES` tables. See [Section 24.14](#), “The `INFORMATION_SCHEMA PARAMETERS` Table”, and [Section 24.21](#), “The `INFORMATION_SCHEMA ROUTINES` Table”.

13.7.6.29 SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows which threads are running. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

The `SHOW PROCESSLIST` statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `CONNECTION_ADMIN` or `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 13.7.7.4](#), “`KILL Syntax`”.

Example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)
```

`SHOW PROCESSLIST` output has these columns:

- `Id`

The connection identifier. This is the same type of value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.

- `User`

The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. For `system user`, there is no host specified in the `Host` column.

`unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events (see [Section 23.4, “Using the Event Scheduler”](#)).

- `Host`

The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- `db`

The default database, if one is selected; otherwise `NULL`.

- `Command`

The type of command the thread is executing. For descriptions for thread commands, see [Section 8.14, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.9, “Server Status Variables”](#).

- `Time`

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See [Section 17.2.2, “Replication Implementation Details”](#).

- `State`

An action, event, or state that indicates what the thread is doing. Descriptions for `State` values can be found at [Section 8.14, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- `Info`

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

Process information is also available from the `mysqladmin processlist` command, the `INFORMATION_SCHEMA PROCESSLIST` table, and the Performance Schema `threads` table (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), [Section 24.17, “The INFORMATION_SCHEMA PROCESSLIST Table”](#), and [Section 25.11.17.3, “The threads Table”](#)). In contrast to the `INFORMATION_SCHEMA PROCESSLIST` table and `SHOW PROCESSLIST` statement, which have negative performance consequences because they require a mutex, access to `threads` does not require a mutex and has minimal impact on server performance. The `threads` table also shows information about background threads, which the `PROCESSLIST` table and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

13.7.6.30 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
```

```

[FOR QUERY n]
[LIMIT row_count [OFFSET offset]]

type: {
  ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
}

```

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Note

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 25.18.1, “Query Profiling Using Performance Schema”](#).

To control profiling, use the `profiling` session variable, which has a default value of 0 (`OFF`). Enable profiling by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to *row_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output *offset* rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 8.14, “Examining Thread Information”](#)).

Optional `type` values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times

- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|          0 |
+-----+
1 row in set (0.00 sec)

+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SHOW PROFILE CPU FOR QUERY 2;
```

Status	Duration	CPU_user	CPU_system
checking permissions	0.000040	0.000038	0.000002
creating table	0.000056	0.000028	0.000028
After create	0.011363	0.000217	0.001571
query end	0.000375	0.000013	0.000028
freeing items	0.000089	0.000010	0.000014
logging slow query	0.000019	0.000009	0.000010
cleaning up	0.000005	0.000003	0.000002

7 rows in set (0.00 sec)

Note

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the `INFORMATION_SCHEMA.PROFILING` table. See [Section 24.18, “The INFORMATION_SCHEMA.PROFILING Table”](#). For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

13.7.6.31 SHOW PROFILES Syntax

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see [Section 13.7.6.30, “SHOW PROFILE Syntax”](#).

Note

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 25.18.1, “Query Profiling Using Performance Schema”](#).

13.7.6.32 SHOW RELAYLOG EVENTS Syntax

```
SHOW RELAYLOG EVENTS
  [IN 'log_name']
  [FROM pos]
  [LIMIT [offset,] row_count]
  [channel_option]

channel_option:
  FOR CHANNEL channel
```

Shows the events in the relay log of a replication slave. If you do not specify `'log_name'`, the first relay log is displayed. This statement has no effect on the master.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

Note

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the slave).

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a `SHOW RELAYLOG EVENTS` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See [Section 17.2.3, “Replication Channels”](#) for more information.

`SHOW RELAYLOG EVENTS` displays the following fields for each event in the relay log:

- `Log_name`

The name of the file that is being listed.

- `Pos`

The position at which the event occurs.

- `Event_type`

An identifier that describes the event type.

- `Server_id`

The server ID of the server on which the event originated.

- `End_log_pos`

The value of `End_log_pos` for this event in the master's binary log.

- `Info`

More detailed information about the event type. The format of this information depends on the event type.

Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

13.7.6.33 SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master.

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host      | Port | Master_id | Slave_UUID |
+-----+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306 | 192168011 | 07af4990-f41f-11df-a566-7ac56fdaf645 |
+-----+-----+-----+-----+-----+
```

- **Server_id:** The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with `--server-id=value`.
- **Host:** The host name of the slave server as specified on the slave with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User:** The slave server user name as, specified on the slave with the `--report-user` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Password:** The slave server password as, specified on the slave with the `--report-password` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Port:** The port on the master to which the slave server is listening, as specified on the slave with the `--report-port` option.

A zero in this column means that the slave port (`--report-port`) was not set.

- **Master_id:** The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.
- **Slave_UUID:** The globally unique ID of this slave, as generated on the slave and found in the slave's `auto.cnf` file.

13.7.6.34 SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

`SHOW SLAVE STATUS` is nonblocking. When run concurrently with `STOP SLAVE`, `SHOW SLAVE STATUS` returns without waiting for `STOP SLAVE` to finish shutting down the slave SQL thread or slave I/O thread (or both). This permits use in monitoring and other applications where getting an immediate response from `SHOW SLAVE STATUS` more important than ensuring that it returned the latest data.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
```

```

        Master_User: repl

```

The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but represented in table form. For details, see [Section 25.11.11, “Performance Schema Replication Tables”](#).

The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see [Section 17.1.7.1, “Checking Replication Status”](#).

- `Slave_IO_State`

A copy of the `State` field of the `SHOW PROCESSLIST` output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see [Section 8.14.4, “Replication Slave I/O Thread States”](#).

- `Master_Host`

The master host that the slave is connected to.

- `Master_User`

The user name of the account used to connect to the master.

- `Master_Port`

The port used to connect to the master.

- `Connect_Retry`

The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- `Master_Log_File`

The name of the master binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

The position in the current master binary log file up to which the I/O thread has read.

- `Relay_Log_File`

The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

The position in the current relay log file up to which the SQL thread has read and executed.

- `Relay_Master_Log_File`

The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

- **MYSQL_SLAVE_NOT_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is `No`.
- **MYSQL_SLAVE_RUN_NOT_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` is `Connecting`.
- **MYSQL_SLAVE_RUN_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is `Yes`.

The value of the `Slave_running` system status variable corresponds with this value.

- `Slave_SQL_Running`

Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

The names of any databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The names of any tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- `Last_Errno`, `Last_Error`

These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

**Note**

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

The current value of the `sql_slave_skip_counter` system variable. See [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

- `Exec_Master_Log_Pos`

The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `Relay_Log_Space`

The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary log
- `Relay` if the slave is reading until a given position in its relay log
- `SQL_BEFORE_GTIDS` if the slave SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
- `SQL_AFTER_GTIDS` if the slave threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
- `SQL_AFTER_MTS_GAPS` if a multithreaded slave's SQL threads are running until no more gaps are found in the relay log.

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on `UNTIL` clauses, see [Section 13.4.2.6, “START SLAVE Syntax”](#).

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_CRL_File`, `Master_SSL_CRL_Path`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.
- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite

often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

In MySQL 8.0, this field is `NULL` (undefined or unknown) if the slave SQL thread is not running, or if the SQL thread has consumed all of the relay log and the slave I/O thread is not running. (In older versions of MySQL, this field was `NULL` if the slave SQL thread or the slave I/O thread was not running or was not connected to the master.) If the I/O thread is running but the relay log is exhausted, `Seconds_Behind_Master` is set to 0.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multithreaded slave, you should keep in mind that this value is based on `Exec_Master_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave's error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_IO_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave's error log.

If the slave is multithreaded, the SQL thread is the coordinator for worker threads. In this case, the `Last_SQL_Error` field shows exactly what the `Last_Error_Message` column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the slave error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by `SHOW SLAVE STATUS` or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

In MySQL 8.0, all error codes and messages displayed in the `Last_SQL_Errno` and `Last_SQL_Error` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#). This was not always true in previous versions. (Bug #11760365, Bug #52768)

- `Replicate_Ignore_Server_Ids`

Any server IDs that have been specified using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement, so that the slave ignores events from these servers. This option is used in a circular or other multi-master replication setup when one of the servers is removed. If any server IDs have been set in this way, a comma-delimited list of one or more numbers is shown. If no server IDs have been set, the field is blank.

Note

The `Ignored_server_ids` value in the `slave_master_info` table also shows the server IDs to be ignored, but as a space-delimited list, preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Replicate_Ignore_Server_Ids: 2, 6, 9
```

```
Ignored_server_ids: 3, 2, 6, 9
```

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

Note

From MySQL 8.0.3, a deprecation warning is issued if `SET GTID_MODE=ON` is issued when any channel has existing server IDs set with `IGNORE_SERVER_IDS`. Before starting GTID-based replication, use `SHOW_SLAVE_STATUS` to check for and clear all ignored server ID lists on the servers involved. You can clear a list by issuing a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

- `Master_Server_Id`

The `server_id` value from the master.

- `Master_UUID`

The `server_uuid` value from the master.

- `Master_Info_File`

The location of the `master.info` file, if a file rather than a table is used for the slave's master info repository.

- `SQL_Delay`

The number of seconds that the slave must lag the master.

- `SQL_Remaining_Delay`

When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`

The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. [Section 8.14.5, “Replication Slave SQL Thread States”](#), provides a listing of possible states

- `Master_Retry_Count`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).

- `Master_Bind`

The network interface that the slave is bound to, if any. This is set using the `MASTER_BIND` option for the `CHANGE MASTER TO` statement.

- `Last_IO_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `Last_SQL_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the last SQL error occurred.

- `Retrieved_Gtid_Set`

The set of global transaction IDs corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

When all relay logs are lost due to executing `RESET SLAVE` or `CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

- `Executed_Gtid_Set`

The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `Auto_Position`

1 if autopositioning is in use; otherwise 0.

- `Replicate_Rewrite_DB`

The `Replicate_Rewrite_DB` value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=( (db1,db2), (db3,db4) );
```

the `Replicate_Rewrite_DB` value displays:

```
Replicate_Rewrite_DB: (db1,db2), (db3,db4)
```

For more information, see [Section 13.4.2.2, “CHANGE REPLICATION FILTER Syntax”](#).

- `Channel_name`

The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- `Master_TLS_Version`

The TLS version used on the master. For TLS version information, see [Section 6.4.6, “Encrypted Connection Protocols and Ciphers”](#).

- `Master_public_key_path`

The path name to a file containing a slave-side copy of the public key required by the master for RSA key pair-based password exchange. The file must be in PEM format. This column applies to slaves that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin.

If `Master_public_key_path` is given and specifies a valid public key file, it takes precedence over `Get_master_public_key`.

- `Get_master_public_key`

Whether to request from the master the public key required for RSA key pair-based password exchange. This column applies to slaves that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the master does not send the public key unless requested.

If `Master_public_key_path` is given and specifies a valid public key file, it takes precedence over `Get_master_public_key`.

13.7.6.35 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see [Section 5.1.9, “Server Status Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See [Section 25.11.14, “Performance Schema Status Variable Tables”](#).

- The `mysqladmin extended-status` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at [Section 5.1.9, “Server Status Variables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in [Section 5.1.9, “Server Status Variables”](#).

```
mysql> SHOW STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_tables | 8340 |
| Created_tmp_files | 60 |
| ... |
| Open_tables | 1 |
| Open_files | 2 |
| Open_streams | 0 |
| Opened_tables | 44600 |
| Questions | 2026873 |
| ... |
| Table_locks_immediate | 1920382 |
| Table_locks_waited | 0 |
| Threads_cached | 0 |
| Threads_created | 30022 |
| Threads_connected | 1 |
| Threads_running | 1 |
| Uptime | 80380 |
+-----+-----+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

Key_blocks_used	14955
Key_read_requests	96854827
Key_reads	162040
Key_write_requests	7589728
Key_writes	3813196

13.7.6.36 SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- `Name`

The name of the table.

- `Engine`

The storage engine for the table. See [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 16, Alternative Storage Engines](#).

For partitioned tables, `Engine` shows the name of the storage engine used by all partitions.

- `Version`

This column is unused. With the removal of `.frm` files in MySQL 8.0, this column now reports a hardcoded value of `10`, which is the last `.frm` file version used in MySQL 5.7.

- `Row_format`

The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, `Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`.

- `Rows`

The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for `INFORMATION_SCHEMA` tables.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- `Avg_row_length`

The average row length.

- `Data_length`

For `MyISAM`, `Data_length` is the length of the data file, in bytes.

For `InnoDB`, `Data_length` is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Max_data_length`

For `MyISAM`, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for `InnoDB`.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Index_length`

For `MyISAM`, `Index_length` is the length of the index file, in bytes.

For `InnoDB`, `Index_length` is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Data_free`

The number of allocated but unused bytes.

`InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA PARTITIONS` table, as shown in this example:

```
SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_SCHEMA = 'mydb'
    AND TABLE_NAME   = 'mytable';
```

For more information, see [Section 24.15, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

- `Auto_increment`

The next `AUTO_INCREMENT` value.

- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its `system tablespace` and the data file timestamp does not apply. Even with `file-per-table` mode with each `InnoDB` table in a separate `.ibd` file, `change buffering` can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For `MyISAM`, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

`Update_time` displays a timestamp value for the last `UPDATE`, `INSERT`, or `DELETE` performed on `InnoDB` tables that are not partitioned. For MVCC, the timestamp value reflects the `COMMIT` time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the `InnoDB` data dictionary cache.

- `Check_time`

When the table was last checked. Not all storage engines update this time, in which case, the value is always `NULL`.

For partitioned `InnoDB` tables, `Check_time` is always `NULL`.

- `Collation`

The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- `Checksum`

The live checksum value, if any.

- `Create_options`

Extra options used with `CREATE TABLE`. The original options from when `CREATE TABLE` was executed are retained and the options reported here may differ from the active table settings and options.

For `InnoDB` tables, the actual `ROW_FORMAT` and `KEY_BLOCK_SIZE` options are reported. Prior to MySQL 8.0, `Create_options` reports the originally supplied `ROW_FORMAT` and `KEY_BLOCK_SIZE`. For more information, see [Section 13.1.18, “CREATE TABLE Syntax”](#).

`Create_options` shows `partitioned` if the table is partitioned. It also shows the `ENCRYPTION` option specified when creating or altering a file-per-table tablespace. This column does not show the encryption option specified when creating or altering a general tablespace. The `ENCRYPTION` column of the `INNODB_TABLESPACES` table is applicable to both file-per-table and general tablespaces.

- `Comment`

The comment used when creating the table (or information as to why MySQL could not access the table information).

Notes

- For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, most columns displayed by `SHOW TABLE STATUS` are 0 or `NULL` except that `Name` indicates the view name, `Create_time` indicates the creation time, and `Comment` says `VIEW`.

Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See [Section 24.27](#), “The `INFORMATION_SCHEMA TABLES` Table”.

13.7.6.37 SHOW TABLES Syntax

```
SHOW [EXTENDED] [FULL] TABLES
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39](#), “Extensions to `SHOW` Statements”.

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

The optional `EXTENDED` modifier causes `SHOW TABLES` to list hidden tables created by failed `ALTER TABLE` statements. These temporary tables have names beginning with `#sql` and can be dropped using `DROP TABLE`.

This statement also lists any views in the database. The optional `FULL` modifier causes `SHOW TABLES` to display a second output column with values of `BASE TABLE` for a table, `VIEW` for a view, or `SYSTEM VIEW` for an `INFORMATION_SCHEMA` table.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See [Section 24.27](#), “The `INFORMATION_SCHEMA TABLES` Table”.

13.7.6.38 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the `TRIGGER` privilege. The `LIKE` clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39](#), “Extensions to `SHOW` Statements”.

For the `ins_sum` trigger defined in [Section 23.3](#), “Using Triggers”, the output of `SHOW TRIGGERS` is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
***** 1. row *****
      Trigger: ins_sum
        Event: INSERT
         Table: account
Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
    Created: 2018-08-08 10:10:12.61
    sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
              NO_ZERO_IN_DATE,NO_ZERO_DATE,
              ERROR_FOR_DIVISION_BY_ZERO,
              NO_ENGINE_SUBSTITUTION
```

```
Definer: me@localhost
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

`SHOW TRIGGERS` output has these columns:

- `Trigger`

The name of the trigger.

- `Event`

The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- `Table`

The table for which the trigger is defined.

- `Statement`

The trigger body; that is, the statement executed when the trigger activates.

- `Timing`

Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- `Created`

The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

- `sql_mode`

The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 5.1.10, “Server SQL Modes”](#).

- `Definer`

The account of the user who created the trigger, in `'user_name'@'host_name'` format.

- `character_set_client`

The session value of the `character_set_client` system variable when the trigger was created.

- `collation_connection`

The session value of the `collation_connection` system variable when the trigger was created.

- `Database Collation`

The collation of the database with which the trigger is associated.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See [Section 24.31, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

13.7.6.39 SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
     [LIKE 'pattern' | WHERE expr]
```

`SHOW VARIABLES` shows the values of MySQL system variables (see [Section 5.1.7, “Server System Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- Performance Schema tables. See [Section 25.11.13, “Performance Schema System Variable Tables”](#).
- The `mysqladmin variables` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.39, “Extensions to SHOW Statements”](#).

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.
- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at [Section 5.1.7, “Server System Variables”](#).

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See [Section 5.1.8, “Using System Variables”](#), and [Section 13.7.5.1, “SET Syntax for Variable Assignment”](#).

Partial output is shown here. The list of names and values may differ for your server. [Section 5.1.7, “Server System Variables”](#), describes the meaning of each variable, and [Section 5.1.1, “Configuring the Server”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `_` to match it literally. In practice, this is rarely necessary.

13.7.6.40 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA INFILE` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

`SHOW WARNINGS` is also used following `EXPLAIN`, to display the extended information generated by `EXPLAIN`. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

`SHOW WARNINGS` displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, `SHOW WARNINGS` shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a `SELECT` statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See [Section 13.7.6.17, “SHOW ERRORS Syntax”](#). `GET DIAGNOSTICS` can be used to examine information for individual conditions. See [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#).

Here is a simple example that shows data-conversion warnings for `INSERT`. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the `INSERT`.

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
```

```

Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Warning
      Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
      Level: Warning

      Level: Warning
      Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)

```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```

mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 1024 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
1 row in set (0.01 sec)

```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'test.no_such_table'        |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 27.7.7.82, “mysql_warning_count\(\)”](#).

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see [Section 4.5.1.2, “mysql Commands”](#)). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+-----+
| 1/0   |
+-----+
| NULL  |
+-----+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

13.7.7 Other Administrative Statements

13.7.7.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).) The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `BINLOG_ADMIN` or `SUPER` privilege.

This statement can execute only format description events and row events.

13.7.7.2 CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  [PARTITION (partition_list | ALL)]
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

partition_list:
  partition_name[, partition_name][, ...]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.1.8.5, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 8.0, this statement is also supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
```

```

PARTITION BY HASH(c1)
PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;

```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either one of the following 2 statements:

```

CACHE INDEX pt PARTITION (ALL) IN kc_all;

CACHE INDEX pt IN kc_all;

```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any partitions that are not explicitly assigned to a key cache automatically use the server's default key cache.

In MySQL 8.0, index preloading is also supported for partitioned `MyISAM` tables. For more information, see [Section 13.7.7.5, “LOAD INDEX INTO CACHE Syntax”](#).

13.7.7.3 FLUSH Syntax

```

FLUSH [NO_WRITE_TO_BINLOG | LOCAL] {
    flush_option [, flush_option] ...
    | tables_option
}

flush_option: {
    BINARY LOGS
    | ENGINE LOGS
    | ERROR LOGS
    | GENERAL LOGS
    | HOSTS
    | LOGS
    | PRIVILEGES
    | OPTIMIZER_COSTS
    | RELAY LOGS [FOR CHANNEL channel]
    | SLOW LOGS
    | STATUS
    | USER_RESOURCES
}

tables_option: {
    TABLES

```

```

| TABLES tbl_name [, tbl_name] ...
| TABLES WITH READ LOCK
| TABLES tbl_name [, tbl_name] ... WITH READ LOCK
| TABLES tbl_name [, tbl_name] ... FOR EXPORT
}

```

The **FLUSH** statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute **FLUSH**, you must have the **RELOAD** privilege. Specific flush options might require additional privileges, as described later.

Note

It is not possible to issue **FLUSH** statements within stored functions or triggers. However, you may use **FLUSH** in stored procedures, so long as these are not called from stored functions or triggers. See [Section C.1, “Restrictions on Stored Programs”](#).

By default, the server writes **FLUSH** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

Note

FLUSH LOGS, **FLUSH TABLES WITH READ LOCK** (with or without a table list), and **FLUSH TABLES *tbl_name* ... FOR EXPORT** are not written to the binary log in any case because they would cause problems if replicated to a slave.

The **FLUSH** statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The **mysqladmin** utility provides a command-line interface to some flush operations, using commands such as **flush-hosts**, **flush-logs**, **flush-privileges**, **flush-status**, and **flush-tables**. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

Sending a **SIGHUP** signal to the server causes several flush operations to occur that are similar to various forms of the **FLUSH** statement. See [Section 5.1.15, “Server Response to Signals”](#).

The **RESET** statement is similar to **FLUSH**. See [Section 13.7.7.6, “RESET Syntax”](#), for information about using the **RESET** statement with replication.

The following list describes the permitted **FLUSH** statement *flush_option* values. For descriptions of **FLUSH TABLES** variants, see [FLUSH TABLES Syntax](#).

- **FLUSH BINARY LOGS**

Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

- **FLUSH ENGINE LOGS**

Closes and reopens any flushable logs for installed storage engines. This causes **InnoDB** to flush its logs to disk.

- **FLUSH ERROR LOGS**

Closes and reopens any error log file to which the server is writing.

- **FLUSH GENERAL LOGS**

Closes and reopens any general query log file to which the server is writing.

- `FLUSH HOSTS`

Empties the host cache. Flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs for connections from legitimate hosts. (See [Section B.5.2.5, “Host 'host_name' is blocked”](#).) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 100. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- `FLUSH LOGS`

Closes and reopens any log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

- `FLUSH OPTIMIZER_COSTS`

Rereads the cost model tables so that the optimizer starts using the current cost estimates stored in them. The server writes a warning to the error log for any unrecognized entries. (For information about these tables, see [Section 8.9.5, “The Optimizer Cost Model”](#).) This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

- `FLUSH PRIVILEGES`

Reloads the privileges from the grant tables in the `mysql` system database, and clears the in-memory cache used by the `caching_sha2_password` authentication plugin.

As part of this operation, the server reads the `global_grants` table containing dynamic privilege assignments and registers any unregistered privileges found there.

The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

- `FLUSH RELAY LOGS [FOR CHANNEL channel]`

Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

The `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Execute `FLUSH RELAY LOGS FOR CHANNEL channel` to flush the relay log for a specific replication channel. If no channel is named and no extra replication channels exist, the statement applies to the default channel. If no channel is named and multiple replication channels exist, the statement applies to all replication channels. For more information, see [Section 17.2.3, “Replication Channels”](#).

- `FLUSH SLOW LOGS`

Closes and reopens any slow query log file to which the server is writing.

- `FLUSH STATUS`

This option adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions. See [Section 25.11.14, “Performance Schema Status Variable Tables”](#). This information may be of use when debugging a query. See [Section 1.7, “How to Report Bugs or Problems”](#).

- `FLUSH USER_RESOURCES`

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections that is controlled by the `max_user_connections` system variable. See [Section 6.3.6, “Setting Account Resource Limits”](#).

FLUSH TABLES Syntax

`FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. Any `TABLES` variant used in a `FLUSH` statement must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

Note

The descriptions here that indicate tables are flushed by closing them apply differently for `InnoDB`, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- `FLUSH TABLES`

Closes all open tables, forces all tables in use to be closed, and flushes the prepared statement cache. For information about prepared statement caching, see [Section 8.10.3, “Caching of Prepared Statements and Stored Programs”](#).

`FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

- `FLUSH TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base (non-`TEMPORARY`) tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This `FLUSH TABLES` variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT`

This `FLUSH TABLES` variant applies to `InnoDB` tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

The statement works like this:

1. It acquires shared metadata locks for the named tables. The statement blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the statement blocks transactions that attempt to update the tables, while permitting read-only operations to continue.
2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL_HA` error occurs and the statement fails.
3. The statement notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.
4. The statement puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` statement completes.

The `FLUSH TABLES ... FOR EXPORT` statement requires that you have the `SELECT` privilege for each table. Because this statement acquires table locks, you must also have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base (non-`TEMPORARY`) tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

InnoDB supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables created with the `innodb_file_per_table` setting enabled). InnoDB ensures when notified by the `FOR EXPORT` statement that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the `FOR EXPORT` statement is in effect because the `.ibd` file is transaction consistent and can be copied while the server is running. `FOR EXPORT` does not apply to InnoDB system tablespace files, or to InnoDB tables that have `FULLTEXT` indexes.

`FLUSH TABLES ...FOR EXPORT` is supported for partitioned InnoDB tables.

When notified by `FOR EXPORT`, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` statement completes, InnoDB will have flushed all `dirty pages` to the table data files. Any `change buffer` entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

13.7.7.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *processlist_id*, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `CONNECTION_ADMIN` or `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

13.7.7.5 LOAD INDEX INTO CACHE Syntax

```

LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list | ALL)]
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list:
  partition_name[, partition_name][, ...]

```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. In MySQL 8.0, it is also supported for partitioned `MyISAM` tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```

mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+

```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```

LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);

```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```

LOAD INDEX INTO CACHE pt PARTITION (ALL);

LOAD INDEX INTO CACHE pt;

```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

13.7.7.6 RESET Syntax

```
RESET reset_option [, reset_option] ...

reset_option: {
    MASTER
  | SLAVE
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

For information about the `RESET PERSIST` statement that removes persisted global system variables, see [Section 13.7.7.7, “RESET PERSIST Syntax”](#).

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 13.7.7.3, “FLUSH Syntax”](#).

The `RESET` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The following list describes the permitted `RESET` statement *reset_option* values:

- `RESET MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `RESET SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

13.7.7.7 RESET PERSIST Syntax

```
RESET PERSIST [[IF EXISTS] system_var_name]
```

`RESET PERSIST` removes persisted global system variable settings from the `mysqld-auto.cnf` option file in the data directory. Removing a persisted system variable causes the variable no longer to be initialized from `mysqld-auto.cnf` at server startup. For more information about persisting system variables and the `mysqld-auto.cnf` file, see [Section 5.1.8.3, “Persisted System Variables”](#).

The privileges required for `RESET PERSIST` depend on the type of system variable to be removed:

- For dynamic system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- For read-only system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.

See [Section 5.1.8.1, “System Variable Privileges”](#).

Depending on whether the variable name and `IF EXISTS` clauses are present, the `RESET PERSIST` statement has these forms:

- To remove all persisted variables from `mysqld-auto.cnf`, use `RESET PERSIST` without naming any system variable:

```
RESET PERSIST;
```

You must have privileges for removing both dynamic and read-only system variables if `mysqld-auto.cnf` contains both kinds of variables.

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

```
RESET PERSIST system_var_name;
```

This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

```
RESET PERSIST IF EXISTS system_var_name;
```

`RESET PERSIST` is not affected by the value of the `persisted_globals_load` system variable.

`RESET PERSIST` affects the contents of the Performance Schema `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the Performance Schema `variables_info` table until the server is restarted.

For information about `RESET` statement variants that clear the state of other server operations, see [Section 13.7.7.6, “RESET Syntax”](#).

13.7.7.8 RESTART Syntax

```
RESTART
```

This statement stops and restarts the MySQL server. It requires the `SHUTDOWN` privilege.

One use for `RESTART` is when it is not possible or convenient to gain command-line access to the MySQL server on the server host to restart it. For example, `SET PERSIST_ONLY` can be used at runtime to make configuration changes to system variables that can be set only at server startup, but the server must still be restarted for those changes to take effect. The `RESTART` statement provides a way to do so from within client sessions, without requiring command-line access on the server host.

Note

After executing a `RESTART` statement, the client can expect the current connection to be lost. If auto-reconnect is enabled, the connection will be reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

A successful `RESTART` operation requires `mysqld` to be running in an environment that has a monitoring process available to detect a server shutdown performed for restart purposes:

- In the presence of a monitoring process, `RESTART` causes `mysqld` to terminate such that the monitoring process can determine that it should start a new `mysqld` instance.
- If no monitoring process is present, `RESTART` fails with an error.

These platforms provide the necessary monitoring support for the `RESTART` statement:

- Windows, when `mysqld` is started as a Windows service or standalone. (`mysqld` forks, and one process acts as a monitor to the other, which acts as the server.)
- Unix and Unix-like systems that use `systemd` or `mysqld_safe` to manage `mysqld`.

On Windows, the forking used to implement `RESTART` makes determining the server process to attach to for debugging more difficult. To alleviate this, starting the server with `--gdb` suppresses forking, in addition to its other actions done to set up a debugging environment. In non-debug settings, `--no-monitor` may be used for the sole purpose of suppressing forking the monitor process. For a server started with either `--gdb` or `--no-monitor`, executing `RESTART` causes the server to simply exit without restarting.

13.7.7.9 SHUTDOWN Syntax

`SHUTDOWN`

This statement stops the MySQL server. It requires the `SHUTDOWN` privilege.

`SHUTDOWN` provides an SQL-level interface to the same functionality available using the `mysqladmin shutdown` command.

13.8 Utility Statements

13.8.1 DESCRIBE Syntax

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see [Section 13.7.6.5, “SHOW COLUMNS Syntax”](#), and [Section 13.8.2, “EXPLAIN Syntax”](#).

13.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC}
    tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
    [explain_type]
    {explainable_stmt | FOR CONNECTION connection_id}

explain_type: {
    FORMAT = format_name
}

format_name: {
    TRADITIONAL
    | JSON
}

explainable_stmt: {
    SELECT statement
    | DELETE statement
    | INSERT statement
    | REPLACE statement
    | UPDATE statement
}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- [Obtaining Table Structure Information](#)
- [Obtaining Execution Plan Information](#)

Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See [Section 13.7.6.5, “SHOW COLUMNS Syntax”](#).

By default, `DESCRIBE` displays information about all columns in the table. *col_name*, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. *wild*, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.6, “SHOW Syntax”](#).

Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).
- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- For explainable statements, `EXPLAIN` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).
- `EXPLAIN` is useful for examining queries involving partitioned tables. See [Section 22.3.5, “Obtaining Information About Partitions”](#).

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

`EXPLAIN` requires the `SELECT` privilege for any tables or views accessed, including any underlying tables or views. For views, `EXPLAIN` also requires the `SHOW VIEW` privilege.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.10, “SELECT Syntax”](#).)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.3.1, “ANALYZE TABLE Syntax”](#).

Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See [Tutorial: Using Explain to Improve Query Performance](#).

13.8.3 HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.14, “Server-Side Help”](#)).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response [HELP](#) returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the [mysql](#) client, but note that [mysql](#) itself reformats [HELP](#) result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- [name](#): The topic name.
- [description](#): Descriptive help text for the topic.
- [example](#): Usage example or examples. This column might be blank.

Example: [HELP](#) 'replace'

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- [name](#): The help topic name.
- [is_it_category](#): [Y](#) if the name represents a help category, [N](#) if it does not. If it does not, the [name](#) value when specified as the argument to the [HELP](#) statement should yield a single-row result set containing a description for the named item.

Example: [HELP](#) 'status'

Yields:

name	is_it_category
SHOW	N

SHOW ENGINE	N
SHOW MASTER STATUS	N
SHOW PROCEDURE STATUS	N
SHOW SLAVE STATUS	N
SHOW STATUS	N
SHOW TABLE STATUS	N

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- `source_category_name`: The help category name.
- `name`: The category or topic name
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

source_category_name	name	is_it_category
Functions	CREATE FUNCTION	N
Functions	DROP FUNCTION	N
Functions	Bit Functions	Y
Functions	Comparison operators	Y
Functions	Control flow functions	Y
Functions	Date and Time Functions	Y
Functions	Encryption Functions	Y
Functions	Information Functions	Y
Functions	Logical operators	Y
Functions	Miscellaneous Functions	Y
Functions	Numeric Functions	Y
Functions	String Functions	Y

13.8.4 USE Syntax

```
USE db_name
```

The `USE db_name` statement tells MySQL to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the `USE` statement does not preclude accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;  
SELECT author_name,editor_name FROM author,db2.editor  
WHERE author.editor_id = db2.editor.editor_id;
```

Chapter 14 MySQL Data Dictionary

Table of Contents

14.1 Data Dictionary Schema	2447
14.2 Removal of File-based Metadata Storage	2449
14.3 Transactional Storage of Dictionary Data	2449
14.4 Dictionary Object Cache	2449
14.5 INFORMATION_SCHEMA and Data Dictionary Integration	2450
14.6 Serialized Dictionary Information (SDI)	2452
14.7 Data Dictionary Usage Differences	2453
14.8 Data Dictionary Limitations	2454

MySQL Server incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files, nontransactional tables, and storage engine-specific data dictionaries.

This chapter describes the main features, benefits, usage differences, and limitations of the data dictionary. For other implications of the data dictionary feature, refer to the “Data Dictionary Notes” section in the [MySQL 8.0 Release Notes](#).

Benefits of the MySQL data dictionary include:

- Simplicity of a centralized data dictionary schema that uniformly stores dictionary data. See [Section 14.1, “Data Dictionary Schema”](#).
- Removal of file-based metadata storage. See [Section 14.2, “Removal of File-based Metadata Storage”](#).
- Transactional, crash-safe storage of dictionary data. See [Section 14.3, “Transactional Storage of Dictionary Data”](#).
- Uniform and centralized caching for dictionary objects. See [Section 14.4, “Dictionary Object Cache”](#).
- A simpler and improved implementation for some `INFORMATION_SCHEMA` tables. See [Section 14.5, “INFORMATION_SCHEMA and Data Dictionary Integration”](#).
- Atomic DDL. See [Section 13.1.1, “Atomic Data Definition Statement Support”](#).

Important

A data dictionary-enabled server entails some general operational differences compared to a server that does not have a data dictionary; see [Section 14.7, “Data Dictionary Usage Differences”](#). Also, for upgrades to MySQL 8.0, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see [Section 2.11.1, “Upgrading MySQL”](#), particularly [Section 2.11.1.4, “Preparing Your Installation for Upgrade”](#).

14.1 Data Dictionary Schema

Data dictionary tables are protected and may only be accessed in debug builds of MySQL. However, MySQL supports access to data stored in data dictionary tables through `INFORMATION_SCHEMA` tables

and `SHOW` statements. For an overview of the tables that comprise the data dictionary, see [Data Dictionary Tables](#).

MySQL system tables still exist in MySQL 8.0 and can be viewed by issuing a `SHOW TABLES` statement on the `mysql` system database. Generally, the difference between MySQL system tables and data dictionary tables is that system tables contain auxiliary data such as time zone and help information, whereas data dictionary tables contain data required to execute SQL queries. MySQL system tables and data dictionary tables also differ in how they are upgraded. Upgrading MySQL system tables requires running `mysql_upgrade`. Data dictionary upgrades are managed by the MySQL server. See [How the Data Dictionary is Upgraded](#).

How the Data Dictionary is Upgraded

New versions of MySQL may include changes to data dictionary table definitions. Such changes are present in newly installed versions of MySQL, but when performing an in-place upgrade of MySQL binaries, changes are applied when the MySQL server is restarted using the new binaries. At startup, the data dictionary version of the server is compared to the version information stored in the data dictionary to determine if data dictionary tables should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating the data dictionary tables.

Upgrade of data dictionary tables is an atomic operation, which means that all of the data dictionary tables are upgraded as necessary or the operation fails. If the upgrade operation fails, server startup fails with an error. In this case, the old server binaries can be used with the old data directory to start the server. When the new server binaries are used again to start the server, the data dictionary upgrade is reattempted.

Generally, after data dictionary tables are successfully upgraded, it is not possible to restart the server using the old server binaries. As a result, downgrading MySQL server binaries to a previous MySQL version is not supported after data dictionary tables are upgraded.

The `mysqld --no-dd-upgrade` option can be used to prevent automatic upgrade of data dictionary tables at startup. When `--no-dd-upgrade` is specified, and the server finds that the data dictionary version of the server is different from the version stored in the data dictionary, startup fails with an error stating that the data dictionary upgrade is prohibited.

Viewing Data Dictionary Tables Using a Debug Build of MySQL

Data dictionary tables are protected by default but can be accessed by compiling MySQL with debugging support (using the `-DWITH_DEBUG=1` `CMake` option) and specifying the `+d,skip_dd_table_access_check` debug option and modifier. For information about compiling debug builds, see [Section 28.5.1.1, “Compiling MySQL for Debugging”](#).

Warning

Modifying or writing to data dictionary tables directly is not recommended and may render your MySQL instance inoperable.

After compiling MySQL with debugging support, use this `SET` statement to make data dictionary tables visible to the `mysql` client session:

```
mysql> SET SESSION debug='+d,skip_dd_table_access_check';
```

Use this query to retrieve a list of data dictionary tables:

```
mysql> SELECT name, schema_id, hidden, type FROM mysql.tables where schema_id=1 AND hidden='System';
```

Use `SHOW CREATE TABLE` to view data dictionary table definitions. For example:

```
mysql> SHOW CREATE TABLE mysql.catalogs\G
```

14.2 Removal of File-based Metadata Storage

In previous MySQL releases, dictionary data was partially stored in metadata files. Issues with file-based metadata storage included expensive file scans, susceptibility to file system-related bugs, complex code for handling of replication and crash recovery failure states, and a lack of extensibility that made it difficult to add metadata for new features and relational objects.

The metadata files listed below are removed from MySQL. Unless otherwise noted, data previously stored in metadata files is now stored in data dictionary tables.

- `.frm` files: Table metadata files. With the removal of `.frm` files:
 - The 64KB table definition size limit imposed by the `.frm` file structure is removed.
 - The `INFORMATION_SCHEMA.TABLES.VERSION` column reports a hardcoded value of `10`, which is the last `.frm` file version used in MySQL 5.7.
- `.par` files: Partition definition files. `InnoDB` stopped using partition definition files in MySQL 5.7 with the introduction of native partitioning support for `InnoDB` tables.
- `.TRN` files: Trigger namespace files.
- `.TRG` files: Trigger parameter files.
- `.isl` files: `InnoDB` Symbolic Link files containing the location of `file-per-table` tablespace files created outside of the data directory.
- `db.opt` files: Database configuration files. These files, one per database directory, contained database default character set attributes.

14.3 Transactional Storage of Dictionary Data

The data dictionary schema stores dictionary data in transactional (`InnoDB`) tables. Data dictionary tables are located in the `mysql` database together with non-data dictionary system tables.

Data dictionary tables are created in a single `InnoDB` tablespace named `mysql.ibd`, which resides in the MySQL data directory. The `mysql.ibd` tablespace file must reside in the MySQL data directory and its name cannot be modified or used by another tablespace.

Dictionary data is protected by the same commit, rollback, and crash-recovery capabilities that protect user data that is stored in `InnoDB` tables.

14.4 Dictionary Object Cache

The dictionary object cache is a shared global cache that stores previously accessed data dictionary objects in memory to enable object reuse and minimize disk I/O. Similar to other cache mechanisms used by MySQL, the dictionary object cache uses an `LRU`-based eviction strategy to evict least recently used objects from memory.

The dictionary object cache comprises cache partitions that store different object types. Some cache partition size limits are configurable, whereas others are hardcoded.

- **tablespace definition cache partition:** Stores tablespace definition objects. The `tablespace_definition_cache` option sets a limit for the number of tablespace definition objects that can be stored in the dictionary object cache. The default value is 256.
- **schema definition cache partition:** Stores schema definition objects. The `schema_definition_cache` option sets a limit for the number of schema definition objects that can be stored in the dictionary object cache. The default value is 256.
- **table definition cache partition:** Stores table definition objects. The object limit is set to the value of `max_connections`, which has a default value of 151.

The table definition cache partition exists in parallel with the table definition cache that is configured using the `table_definition_cache` configuration option. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence of objects in the other.

- **stored program definition cache partition:** Stores stored program definition objects. The `stored_program_definition_cache` option sets a limit for the number of stored program definition objects that can be stored in the dictionary object cache. The default value is 256.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

- **character set definition cache partition:** Stores character set definition objects and has a hardcoded object limit of 256.
- **collation definition cache partition:** Stores collation definition objects and has a hardcoded object limit of 256.

For information about valid values for dictionary object cache configuration options, refer to [Section 5.1.7, “Server System Variables”](#).

14.5 INFORMATION_SCHEMA and Data Dictionary Integration

With the introduction of the data dictionary, the following `INFORMATION_SCHEMA` tables are implemented as views on data dictionary tables:

- `CHARACTER_SETS`
- `COLLATIONS`
- `COLLATION_CHARACTER_SET_APPLICABILITY`
- `COLUMNS`
- `COLUMN_STATISTICS`

- [EVENTS](#)
- [FILES](#)
- [INNODB_COLUMNS](#)
- [INNODB_DATAFILES](#)
- [INNODB_FIELDS](#)
- [INNODB_FOREIGN](#)
- [INNODB_FOREIGN_COLS](#)
- [INNODB_INDEXES](#)
- [INNODB_TABLES](#)
- [INNODB_TABLESPACES](#)
- [INNODB_TABLESPACES_BRIEF](#)
- [INNODB_TABLESTATS](#)
- [KEY_COLUMN_USAGE](#)
- [KEYWORDS](#)
- [PARAMETERS](#)
- [PARTITIONS](#)
- [REFERENTIAL_CONSTRAINTS](#)
- [RESOURCE_GROUPS](#)
- [ROUTINES](#)
- [SCHEMATA](#)
- [STATISTICS](#)
- [ST_GEOMETRY_COLUMNS](#)
- [ST_SPATIAL_REFERENCE_SYSTEMS](#)
- [TABLES](#)
- [TABLE_CONSTRAINTS](#)
- [TRIGGERS](#)
- [VIEWS](#)
- [VIEW_ROUTINE_USAGE](#)
- [VIEW_TABLE_USAGE](#)

Queries on those tables are now more efficient because they obtain information from data dictionary tables rather than by other, slower means. In particular, for each [INFORMATION_SCHEMA](#) table that is a view on data dictionary tables:

- The server no longer must create a temporary table for each query of the `INFORMATION_SCHEMA` table.
- When the underlying data dictionary tables store values previously obtained by directory scans (for example, to enumerate database names or table names within databases) or file-opening operations (for example, to read information from `.frm` files), `INFORMATION_SCHEMA` queries for those values now use table lookups instead. (Additionally, even for a non-view `INFORMATION_SCHEMA` table, values such as database and table names are retrieved by lookups from the data dictionary and do not require directory or file scans.)
- Indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans, something not true for the previous implementation that processed the `INFORMATION_SCHEMA` table using a temporary table per query.

The preceding improvements also apply to `SHOW` statements that display information corresponding to the `INFORMATION_SCHEMA` tables that are views on data dictionary tables. For example, `SHOW DATABASES` displays the same information as the `SCHEMATA` table.

In addition to the introduction of views on data dictionary tables, table statistics contained in the `STATISTICS` and `TABLES` tables is now cached to improve `INFORMATION_SCHEMA` query performance. The `information_schema_stats_expiry` system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engine when querying table statistics columns. To update cached values at any time for a given table, use `ANALYZE TABLE`

`information_schema_stats_expiry` can be set to 0 to have `INFORMATION_SCHEMA` queries retrieve the latest statistics directly from the storage engine, which is not as fast as retrieving cached statistics.

For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

14.6 Serialized Dictionary Information (SDI)

In addition to storing metadata about database objects in the data dictionary, MySQL stores it in serialized form. This data is referred to as Serialized Dictionary Information (SDI). `InnoDB` stores SDI data within its tablespace files. Other storage engines store SDI data in `.sdi` files that are created in the schema directory. SDI data is generated in a compact `JSON` format.

Serialized Dictionary Information (SDI) is present in all `InnoDB` tablespace files except for temporary tablespace and undo tablespace files. SDI records in an `InnoDB` tablespace file only describe table and tablespace objects contained within the tablespace.

SDI data in within an `InnoDB` tablespace file is only updated by DDL operations on tables within the tablespace.

The presence of SDI data provides metadata redundancy. For example, if the data dictionary becomes unavailable, object metadata can be extracted directly from `InnoDB` tablespace files using the `ibd2sdi` tool.

For `InnoDB`, an SDI record requires a single index page, which is 16KB in size by default. However, SDI data is compressed to reduce the storage footprint.

For partitioned `InnoDB` tables comprised of multiple tablespaces, SDI data is stored in the tablespace file of the first partition.

The MySQL server uses an internal API that is accessed during `DDL` operations to create and maintain SDI records.

The `IMPORT TABLE` statement imports `MyISAM` tables based on information contained in `.sdi` files. For more information, see [Section 13.2.5, “IMPORT TABLE Syntax”](#).

14.7 Data Dictionary Usage Differences

Use of a data dictionary-enabled MySQL server entails some operational differences compared to a server that does not have a data dictionary:

- Previously, enabling the `innodb_read_only` system variable prevented creating and dropping tables only for the `InnoDB` storage. As of MySQL 8.0, enabling `innodb_read_only` prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the `mysql` system database, but those tables use the `InnoDB` storage engine and cannot be modified when `innodb_read_only` is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:
- `ANALYZE TABLE` fails because it updates table statistics, which are stored in the data dictionary.
- `ALTER TABLE tbl_name ENGINE=engine_name` fails because it updates the storage engine designation, which is stored in the data dictionary.

Note

Enabling `innodb_read_only` also has important implications for non-data dictionary tables in the `mysql` system database. For details, see the description of `innodb_read_only` in [Section 15.13, “InnoDB Startup Options and System Variables”](#)

- Previously, tables in the `mysql` system database were visible to DML and DDL statements. As of MySQL 8.0, data dictionary tables are invisible and cannot be modified or queried directly. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried instead. This enables the underlying data dictionary tables to be changed as server development proceeds, while maintaining a stable `INFORMATION_SCHEMA` interface for application use.
- `INFORMATION_SCHEMA` tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences:
 - Previously, `INFORMATION_SCHEMA` queries for table statistics in the `STATISTICS` and `TABLES` tables retrieved statistics directly from storage engines. As of MySQL 8.0, cached table statistics are used by default. The `information_schema_stats_expiry` system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). (To update the cached values at any time for a given table, use `ANALYZE TABLE`.) If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To always retrieve the latest statistics directly from storage engines, set `information_schema_stats_expiry` to 0. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).
 - Several `INFORMATION_SCHEMA` tables are views on data dictionary tables, which enables the optimizer to use indexes on those underlying tables. Consequently, depending on optimizer choices, the row order of results for `INFORMATION_SCHEMA` queries might differ from previous results. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.
 - `mysqldump` and `mysqlpump` no longer dump the `INFORMATION_SCHEMA` database, even if explicitly named on the command line.
 - `CREATE TABLE dst_tbl LIKE src_tbl` requires that `src_tbl` be a base table and fails if it is an `INFORMATION_SCHEMA` table that is a view on data dictionary tables.

- Previously, result set headers of columns selected from `INFORMATION_SCHEMA` tables used the capitalization specified in the query. This query produces a result set with a header of `table_name`:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES;
```

As of MySQL 8.0, these headers are capitalized; the preceding query produces a result set with a header of `TABLE_NAME`. If necessary, a column alias can be used to achieve a different lettercase. For example:

```
SELECT table_name AS 'table_name' FROM INFORMATION_SCHEMA.TABLES;
```

- The data directory affects how `mysqldump` and `mysqlpump` dump information from the `mysql` system database:
 - Previously, it was possible to dump all tables in the `mysql` system database. As of MySQL 8.0, `mysqldump` and `mysqlpump` dump only non-data dictionary tables in that database.
 - Previously, the `--routines` and `--events` options were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `proc` and `event` tables containing stored routine and event definitions. As of MySQL 8.0, the `event` and `proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.
 - Previously, the `--routines` option required the `SELECT` privilege for the `proc` table. As of MySQL 8.0, that table is not used; `--routines` requires the global `SELECT` privilege instead.
 - Previously, it was possible to dump stored routine and event definitions together with their creation and modification timestamps, by dumping the `proc` and `event` tables. As of MySQL 8.0, those tables are not used, so it is not possible to dump timestamps.
- Previously, creating a stored routine that contains illegal characters produced a warning. As of MySQL 8.0, this is an error.

14.8 Data Dictionary Limitations

This section describes temporary limitations introduced with the MySQL data dictionary.

- Manual creation of database directories under the data directory (for example, with `mkdir`) is unsupported. Manually created database directories are not recognized by the MySQL Server.
- DDL operations take longer due to writing to storage, undo logs, and redo logs instead of `.frm` files.

Chapter 15 The InnoDB Storage Engine

15.1 Introduction to InnoDB

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 8.0, **InnoDB** is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE=` clause creates an **InnoDB** table.

Key Advantages of InnoDB

- Its **DML** operations follow the **ACID** model, with **transactions** featuring **commit**, **rollback**, and **crash-recovery** capabilities to protect user data. See [Section 15.2, “InnoDB and the ACID Model”](#) for more information.
- Row-level **locking** and Oracle-style **consistent reads** increase multi-user concurrency and performance. See [Section 15.5, “InnoDB Locking and Transaction Model”](#) for more information.
- **InnoDB** tables arrange your data on disk to optimize queries based on **primary keys**. Each **InnoDB** table has a primary key index called the **clustered index** that organizes the data to minimize I/O for primary key lookups. See [Section 15.8.2.1, “Clustered and Secondary Indexes”](#) for more information.
- To maintain data **integrity**, **InnoDB** supports **FOREIGN KEY** constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#) for more information.

Table 15.1 InnoDB Storage Engine Features

Feature	Support
B-tree indexes	Yes
Backup/point-in-time recovery (Implemented in the server, rather than in the storage engine.)	Yes
Cluster database support	No
Clustered indexes	Yes
Compressed data	Yes
Data caches	Yes
Encrypted data (Implemented in the server via encryption functions. Data-at-rest tablespace encryption is available in MySQL 5.7 and later.)	Yes
Foreign key support	Yes
Full-text search indexes	Yes (InnoDB support for FULLTEXT indexes is available in MySQL 5.6 and later.)

Feature	Support
Geospatial data type support	Yes
Geospatial indexing support	Yes (InnoDB support for geospatial indexing is available in MySQL 5.7 and later.)
Hash indexes	No (InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.)
Index caches	Yes
Locking granularity	Row
MVCC	Yes
Replication support (Implemented in the server, rather than in the storage engine.)	Yes
Storage limits	64TB
T-tree indexes	No
Transactions	Yes
Update statistics for data dictionary	Yes

To compare the features of [InnoDB](#) with other storage engines provided with MySQL, see the *Storage Engine Features* table in [Chapter 16, Alternative Storage Engines](#).

InnoDB Enhancements and New Features

For information about [InnoDB](#) enhancements and new features, refer to:

- The [InnoDB](#) enhancements list in [Section 1.4, “What Is New in MySQL 8.0”](#).
- The [Release Notes](#).

Additional InnoDB Information and Resources

- For [InnoDB](#)-related terms and definitions, see the [MySQL Glossary](#).
- For a forum dedicated to the [InnoDB](#) storage engine, see [MySQL Forums::InnoDB](#).
- [InnoDB](#) is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

15.1.1 Benefits of Using InnoDB Tables

You may find [InnoDB](#) tables beneficial for the following reasons:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. [InnoDB crash recovery](#) automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off.
- The [InnoDB](#) storage engine maintains its own [buffer pool](#) that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool.

- If you split up related data into different tables, you can set up [foreign keys](#) that enforce [referential integrity](#). Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.
- If data becomes corrupted on disk or in memory, a [checksum](#) mechanism alerts you to the bogus data before you use it.
- When you design your database with appropriate [primary key](#) columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in [WHERE](#) clauses, [ORDER BY](#) clauses, [GROUP BY](#) clauses, and [join](#) operations.
- Inserts, updates, and deletes are optimized by an automatic mechanism called [change buffering](#). [InnoDB](#) not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.
- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the [Adaptive Hash Index](#) takes over to make these lookups even faster, as if they came out of a hash table.
- You can compress tables and associated indexes.
- You can create and drop indexes with much less impact on performance and availability.
- Truncating a [file-per-table](#) tablespace is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the [system tablespace](#) that only [InnoDB](#) can reuse.
- The storage layout for table data is more efficient for [BLOB](#) and long text fields, with the [DYNAMIC](#) row format.
- You can monitor the internal workings of the storage engine by querying [INFORMATION_SCHEMA](#) tables.
- You can monitor the performance details of the storage engine by querying [Performance Schema](#) tables.
- You can freely mix [InnoDB](#) tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a [join](#) operation to combine data from [InnoDB](#) and [MEMORY](#) tables in a single query.
- [InnoDB](#) has been designed for CPU efficiency and maximum performance when processing large data volumes.
- [InnoDB](#) tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For [InnoDB](#)-specific tuning techniques you can apply in your application code, see [Section 8.5](#), “[Optimizing for InnoDB Tables](#)”.

15.1.2 Best Practices for InnoDB Tables

This section describes best practices when using [InnoDB](#) tables.

- Specifying a [primary key](#) for every table using the most frequently queried column or columns, or an [auto-increment](#) value if there is no obvious primary key.
- Using [joins](#) wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define [foreign keys](#) on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which

can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

- Turning off [autocommit](#). Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).
- Grouping sets of related [DML](#) operations into [transactions](#), by bracketing them with [START TRANSACTION](#) and [COMMIT](#) statements. While you don't want to commit too often, you also don't want to issue huge batches of [INSERT](#), [UPDATE](#), or [DELETE](#) statements that run for hours without committing.
- Not using [LOCK TABLES](#) statements. [InnoDB](#) can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the [SELECT ... FOR UPDATE](#) syntax to lock just the rows you intend to update.
- Enabling the [innodb_file_per_table](#) option or using general tablespaces to put the data and indexes for tables into separate files, instead of the [system tablespace](#).

The [innodb_file_per_table](#) option is enabled by default.

- Evaluating whether your data and access patterns benefit from the [InnoDB](#) table or page [compression](#) features. You can compress [InnoDB](#) tables without sacrificing read/write capability.
- Running your server with the option [--sql_mode=NO_ENGINE_SUBSTITUTION](#) to prevent tables being created with a different storage engine if there is an issue with the engine specified in the [ENGINE=](#) clause of [CREATE TABLE](#).

15.1.3 Verifying that InnoDB is the Default Storage Engine

Issue the [SHOW ENGINES](#) statement to view the available MySQL storage engines. Look for [DEFAULT](#) in the [InnoDB](#) line.

```
mysql> SHOW ENGINES;
```

Alternatively, query the [INFORMATION_SCHEMA.ENGINES](#) table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES;
```

15.1.4 Testing and Benchmarking with InnoDB

If [InnoDB](#) is not your default storage engine, you can determine if your database server or applications work correctly with [InnoDB](#) by restarting the server with [--default-storage-engine=InnoDB](#) defined on the command line or with [default-storage-engine=innodb](#) defined in the [\[mysqld\]](#) section of your MySQL server option file.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you will receive an error; add the [ENGINE=other_engine_name](#) clause to the [CREATE TABLE](#) statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using [InnoDB](#), issue the command [ALTER TABLE table_name ENGINE=InnoDB;](#) for each table. Or, to run test queries and other statements without disturbing the original table, make a copy:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM other_engine_table;
```

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and slaves.

15.2 InnoDB and the ACID Model

The [ACID](#) model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the [InnoDB](#) storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the [InnoDB](#) storage engine, interact with the categories of the ACID model:

- **A:** atomicity.
- **C:** consistency.
- **I:** isolation.
- **D:** durability.

Atomicity

The **atomicity** aspect of the ACID model mainly involves [InnoDB transactions](#). Related MySQL features include:

- Autocommit setting.
- [COMMIT](#) statement.
- [ROLLBACK](#) statement.
- Operational data from the [INFORMATION_SCHEMA](#) tables.

Consistency

The **consistency** aspect of the ACID model mainly involves internal [InnoDB](#) processing to protect data from crashes. Related MySQL features include:

- [InnoDB doublewrite buffer](#).
- [InnoDB crash recovery](#).

Isolation

The **isolation** aspect of the ACID model mainly involves [InnoDB transactions](#), in particular the [isolation level](#) that applies to each transaction. Related MySQL features include:

- [Autocommit](#) setting.
- `SET ISOLATION LEVEL` statement.
- The low-level details of [InnoDB locking](#). During performance tuning, you see these details through `INFORMATION_SCHEMA` tables.

Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- [InnoDB doublewrite buffer](#), turned on and off by the `innodb_doublewrite` configuration option.
- Configuration option `innodb_flush_log_at_trx_commit`.
- Configuration option `sync_binlog`.
- Configuration option `innodb_file_per_table`.
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

15.3 InnoDB Multi-Versioning

[InnoDB](#) is a [multi-versioned storage engine](#): it keeps information about old versions of changed rows, to support transactional features such as concurrency and [rollback](#). This information is stored in the tablespace in a data structure called a [rollback segment](#) (after an analogous data structure in Oracle). [InnoDB](#) uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a [consistent read](#).

Internally, [InnoDB](#) adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If [InnoDB](#) generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction

present for which [InnoDB](#) has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, [InnoDB](#) cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the [InnoDB](#) multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. [InnoDB](#) only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a [purge](#), and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the [innodb_max_purge_lag](#) system variable. See [Section 15.13, “InnoDB Startup Options and System Variables”](#) for more information.

Multi-Versioning and Secondary Indexes

[InnoDB](#) multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, [InnoDB](#) looks up the database record in the clustered index. In the clustered index, the record's [DB_TRX_ID](#) is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the [covering index](#) technique is not used. Instead of returning values from the index structure, [InnoDB](#) looks up the record in the clustered index.

However, if the [index condition pushdown \(ICP\)](#) optimization is enabled, and parts of the [WHERE](#) condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the [WHERE](#) condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, [InnoDB](#) looks up the record in the clustered index.

15.4 InnoDB Architecture

This section provides an introduction to the major components of the [InnoDB](#) storage engine architecture.

15.4.1 Buffer Pool

The buffer pool is an area in main memory where [InnoDB](#) caches table and index data as data is accessed. The buffer pool allows frequently used data to be processed directly from memory, which

speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into [pages](#) that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the [LRU](#) algorithm.

For more information, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#), and [Section 15.6.3, “InnoDB Buffer Pool Configuration”](#).

15.4.2 Change Buffer

The change buffer is a special data structure that caches changes to [secondary index](#) pages when affected pages are not in the [buffer pool](#). The buffered changes, which may result from [INSERT](#), [UPDATE](#), or [DELETE](#) operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

Unlike [clustered indexes](#), secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read-in secondary index pages from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are numerous secondary indexes to update and many affected rows. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed. In fact, change buffer merging may continue to occur after a server shutdown and restart (see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for more information).

In memory, the change buffer occupies part of the [InnoDB](#) buffer pool. On disk, the change buffer is part of the system tablespace, so that index changes remain buffered across database restarts.

The type of data cached in the change buffer is governed by the [innodb_change_buffering](#) configuration option. For more information, see [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). You can also configure the maximum change buffer size. For more information, see [Section 15.6.4.1, “Configuring the Change Buffer Maximum Size”](#).

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- [InnoDB](#) Standard Monitor output includes status information for the change buffer. To view monitor data, issue the [SHOW ENGINE INNODB STATUS](#) command.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Change buffer status information is located under the [INSERT BUFFER AND ADAPTIVE HASH INDEX](#) heading and appears similar to the following:

```

-----
INSERT BUFFER AND ADAPTIVE HASH INDEX
-----
Ibuf: size 1, free list len 0, seg size 2, 0 merges
merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
13577.57 hash searches/s, 202.47 non-hash searches/s

```

For more information, see [Section 15.16.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

- The `INFORMATION_SCHEMA.INNODB_METRICS` table provides most of the data points found in InnoDB Standard Monitor output, plus other data points. To view change buffer metrics and a description of each, issue the following query:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'\G
```

For `INNODB_METRICS` table usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

- The `INFORMATION_SCHEMA.INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```
mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE PAGE_TYPE LIKE 'IBUF%') AS change_buffer_pages,
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
(SELECT ((change_buffer_pages/total_pages)*100))
AS change_buffer_page_percentage;
+-----+-----+-----+
| change_buffer_pages | total_pages | change_buffer_page_percentage |
+-----+-----+-----+
| 25 | 8192 | 0.3052 |
+-----+-----+-----+
```

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see [Section 24.36.1, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”](#). For related usage information, see [Section 15.14.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

- [Performance Schema](#) provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
+-----+-----+-----+
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/ibuf_bitmap_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	YES	YES

For information about monitoring [InnoDB](#) mutex waits, see [Section 15.15.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

15.4.3 Adaptive Hash Index

The [adaptive hash index](#) (AHI) lets [InnoDB](#) perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the [buffer pool](#), without sacrificing any transactional features or reliability. This feature is enabled by the `innodb_adaptive_hash_index` option, or turned off by `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. [InnoDB](#) has a mechanism that monitors index searches. If [InnoDB](#) notices that queries could benefit from building a hash index, it does so automatically.

With some [workloads](#), the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with `LIKE` operators and `%` wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload. The architectural changes in MySQL 5.6 and higher make more workloads suitable for disabling the adaptive hash index than in earlier releases, although it is still enabled by default.

The adaptive hash index search system is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the `innodb_adaptive_hash_index_parts` configuration option. The `innodb_adaptive_hash_index_parts` option is set to 8 by default. The maximum setting is 512.

The hash index is always built based on an existing [B-tree](#) index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that [InnoDB](#) observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the [SEMAPHORES](#) section of the output of the `SHOW ENGINE INNODB STATUS` command. If you see many threads waiting on an RW-latch created in `btr0sea.c`, then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see [Section 8.3.9, “Comparison of B-Tree and Hash Indexes”](#).

15.4.4 Redo Log Buffer

The redo log buffer is the memory area that holds data to be written to the [redo log](#). Redo log buffer size is defined by the `innodb_log_buffer_size` configuration option. The redo log buffer is periodically flushed to the log file on disk. A large redo log buffer enables large transactions to run without the need to

write redo log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O.

The `innodb_flush_log_at_trx_commit` option controls how the contents of the redo log buffer are written to the log file. The `innodb_flush_log_at_timeout` option controls redo log flushing frequency.

15.4.5 System Tablespace

The `InnoDB` system tablespace contains the `InnoDB` data dictionary (metadata for `InnoDB`-related objects) and is the storage area for the doublewrite buffer, the change buffer, and undo logs. The system tablespace also contains table and index data for any user-created tables that are created in the system tablespace. The system tablespace is considered a shared tablespace since it is shared by multiple tables.

The system tablespace is represented by one or more data files. By default, one system data file, named `ibdata1`, is created in the MySQL `data` directory. The size and number of system data files is controlled by the `innodb_data_file_path` startup option.

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

15.4.6 Doublewrite Buffer

The doublewrite buffer is a storage area located in the system tablespace where `InnoDB` writes pages that are flushed from the `InnoDB` buffer pool, before the pages are written to their proper positions in the data file. Only after flushing and writing pages to the doublewrite buffer, does `InnoDB` write pages to their proper positions. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write, `InnoDB` can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer itself as a large sequential chunk, with a single `fsync()` call to the operating system.

The doublewrite buffer is enabled by default in most cases. To disable the doublewrite buffer, set `innodb_doublewrite` to 0.

If system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

15.4.7 Undo Logs

An undo log is a collection of undo log records associated with a single transaction. An undo log record contains information about how to undo the latest change by a transaction to a [clustered index](#) record. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from the undo log records. Undo logs exist within [undo log segments](#), which are contained within [rollback segments](#). Rollback segments reside in undo [undo tablespaces](#) and in the [temporary tablespace](#). For more information about undo tablespaces, see [Section 15.7.8, “Configuring Undo Tablespaces”](#). For information about multi-versioning, see [Section 15.3, “InnoDB Multi-Versioning”](#).

The global temporary tablespace (`ibtmp1`) and each undo tablespace individually support a maximum of 128 rollback segments. The `innodb_rollback_segments` configuration option defines the number of rollback segments. Each rollback segment supports up to 1023 concurrent data-modifying transactions.

15.4.8 File-Per-Table Tablespaces

A file-per-table tablespace is a single-table tablespace that is created in its own data file rather than in the system tablespace. Tables are created in file-per-table tablespaces when the `innodb_file_per_table` option is enabled. Otherwise, InnoDB tables are created in the system tablespace. Each file-per-table tablespace is represented by a single `.ibd` data file, which is created in the database directory by default.

File per-table tablespaces support `DYNAMIC` and `COMPRESSED` row formats which support features such as off-page storage for variable length data and table compression. For information about these features, and about other advantages of file-per-table tablespaces, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

15.4.9 General Tablespaces

A shared InnoDB tablespace created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

For more information, see [Section 15.7.10, “InnoDB General Tablespaces”](#).

15.4.10 Undo Tablespace

An undo tablespace comprises one or more files that contain [undo logs](#). The number of undo tablespaces used by InnoDB is defined by the `innodb_undo_tablespaces` configuration option. For more information, see [Section 15.7.8, “Configuring Undo Tablespaces”](#).

Note

`innodb_undo_tablespaces` is deprecated and will be removed in a future release.

15.4.11 Temporary Tablespace

User-created temporary tables and on-disk internal temporary tables are created in a shared temporary tablespace. The `innodb_temp_data_file_path` configuration option defines the relative path, name, size, and attributes for temporary tablespace data files. If no value is specified for `innodb_temp_data_file_path`, the default behavior is to create an auto-extending data file named `ibtmp1` in the `innodb_data_home_dir` directory that is slightly larger than 12MB.

The temporary tablespace is removed on normal shutdown or on an aborted initialization, and is recreated each time the server is started. The temporary tablespace receives a dynamically generated space ID when it is created. Startup is refused if the temporary tablespace cannot be created. The temporary tablespace is not removed if the server halts unexpectedly. In this case, a database administrator can remove the temporary tablespace manually or restart the server, which removes and recreates the temporary tablespace automatically.

The temporary tablespace cannot reside on a raw device.

`INFORMATION_SCHEMA.FILES` provides metadata about the InnoDB temporary tablespace. Issue a query similar to this one to view temporary tablespace metadata:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='innodb_temporary'\G
```

`INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO` provides metadata about user-created temporary tables that are currently active within an `InnoDB` instance. For more information, see [Section 15.14.7, “InnoDB INFORMATION_SCHEMA Temporary Table Info Table”](#).

Managing Temporary Tablespace Data File Size

By default, the temporary tablespace data file is autoextending and increases in size as necessary to accommodate on-disk temporary tables. For example, if an operation creates a temporary table that is 20MB in size, the temporary tablespace data file, which is 12MB in size by default when created, extends in size to accommodate it. When temporary tables are dropped, freed space can be reused for new temporary tables, but the data file remains at the extended size.

An autoextending temporary tablespace data file can become large in environments that use large temporary tables or that use temporary tables extensively. A large data file can also result from long running queries that use temporary tables.

To determine if a temporary tablespace data file is autoextending, check the `innodb_temp_data_file_path` setting:

```
mysql> SELECT @@innodb_temp_data_file_path;
+-----+
| @@innodb_temp_data_file_path |
+-----+
| ibtmp1:12M:autoextend        |
+-----+
```

To check the size of temporary tablespace data files, query the `INFORMATION_SCHEMA.FILES` table using a query similar to this:

```
mysql> SELECT FILE_NAME, TABLESPACE_NAME, ENGINE, INITIAL_SIZE, TOTAL_EXTENTS*EXTENT_SIZE
        AS TotalSizeBytes, DATA_FREE, MAXIMUM_SIZE FROM INFORMATION_SCHEMA.FILES
        WHERE TABLESPACE_NAME = 'innodb_temporary'\G
***** 1. row *****
FILE_NAME: ./ibtmp1
TABLESPACE_NAME: innodb_temporary
ENGINE: InnoDB
INITIAL_SIZE: 12582912
TotalSizeBytes: 12582912
DATA_FREE: 6291456
MAXIMUM_SIZE: NULL
```

The `TotalSizeBytes` value reports the current size of the temporary tablespace data file. For information about other field values, see [Section 24.10, “The INFORMATION_SCHEMA FILES Table”](#).

Alternatively, check the temporary tablespace data file size on your operating system. By default, the temporary tablespace data file is located in the directory defined by the `innodb_temp_data_file_path` configuration option. If a value was not specified for this option explicitly, a temporary tablespace data file named `ibtmp1` is created in `innodb_data_home_dir`, which defaults to the MySQL data directory if unspecified.

To reclaim disk space occupied by a temporary tablespace data file, restart the MySQL server. Restarting the server removes and recreates the temporary tablespace data file according to the attributes defined by `innodb_temp_data_file_path`.

To prevent the temporary data file from becoming too large, you can configure the `innodb_temp_data_file_path` option to specify a maximum file size. For example:

```
[mysqld]
```

```
innodb_temp_data_file_path=ibtmp1:12M:autoextend:max:500M
```

When the data file reaches the maximum size, queries fail with an error indicating that the table is full. Configuring `innodb_temp_data_file_path` requires restarting the server.

Alternatively, configure the `default_tmp_storage_engine` and `internal_tmp_disk_storage_engine` options, which define the storage engine to use for user-created and on-disk internal temporary tables, respectively. Both options are set to `InnoDB` by default. The `MyISAM` storage engine uses an individual file for each temporary table, which is removed when the temporary table is dropped.

Temporary Table Undo Logs

Temporary table undo logs reside in the global temporary tablespace (`ibtmp1`) and are used for user-created temporary tables and related objects. Temporary table undo logs are not redo-logged, as they are not required for crash recovery. They are only used for rollback while the server is running. This special type of undo log benefits performance by avoiding redo logging I/O.

The `innodb_rollback_segments` configuration option defines the number of rollback segments used by the global temporary tablespace.

15.4.12 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change `InnoDB` table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see [Section 15.17.2, “InnoDB Recovery”](#).

By default, the redo log is physically represented on disk as a set of files, named `ib_logfile0` and `ib_logfile1`. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing `LSN` value.

For related information, see:

- [Section 15.6.1, “InnoDB Startup Configuration”](#)
- [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#)
- [Section 15.7.2, “Changing the Number or Size of InnoDB Redo Log Files”](#)
- [InnoDB Crash Recovery](#)

15.4.12.1 Group Commit for Redo Log Flushing

`InnoDB`, like any other `ACID`-compliant database engine, flushes the `redo log` of a transaction before it is committed. `InnoDB` uses `group commit` functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, `InnoDB` issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of `COMMIT` and other transactional operations, see [Section 8.5.2, “Optimizing InnoDB Transaction Management”](#).

15.5 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand [InnoDB](#) locking and the [InnoDB](#) transaction model.

This section discusses several topics related to [InnoDB](#) locking and the [InnoDB](#) transaction model with which you should be familiar.

- [Section 15.5.1, “InnoDB Locking”](#) describes lock types used by [InnoDB](#).
- [Section 15.5.2, “InnoDB Transaction Model”](#) describes transaction isolation levels and the locking strategies used by each. It also discusses the use of [autocommit](#), consistent non-locking reads, and locking reads.
- [Section 15.5.3, “Locks Set by Different SQL Statements in InnoDB”](#) discusses specific types of locks set in [InnoDB](#) for various statements.
- [Section 15.5.4, “Phantom Rows”](#) describes how [InnoDB](#) uses next-key locking to avoid phantom rows.
- [Section 15.5.5, “Deadlocks in InnoDB”](#) provides a deadlock example, discusses deadlock detection and rollback, and provides tips for minimizing and handling deadlocks in [InnoDB](#).

15.5.1 InnoDB Locking

This section describes lock types used by [InnoDB](#).

- [Shared and Exclusive Locks](#)
- [Intention Locks](#)
- [Record Locks](#)
- [Gap Locks](#)
- [Next-Key Locks](#)
- [Insert Intention Locks](#)
- [AUTO-INC Locks](#)
- [Predicate Locks for Spatial Indexes](#)

Shared and Exclusive Locks

[InnoDB](#) implements standard row-level locking where there are two types of locks, [shared \(S\) locks](#) and [exclusive \(X\) locks](#).

- A [shared \(S\) lock](#) permits the transaction that holds the lock to read a row.
- An [exclusive \(X\) lock](#) permits the transaction that holds the lock to update or delete a row.

If transaction [T1](#) holds a shared ([S](#)) lock on row [r](#), then requests from some distinct transaction [T2](#) for a lock on row [r](#) are handled as follows:

- A request by [T2](#) for an [S](#) lock can be granted immediately. As a result, both [T1](#) and [T2](#) hold an [S](#) lock on [r](#).
- A request by [T2](#) for an [X](#) lock cannot be granted immediately.

If a transaction [T1](#) holds an exclusive ([X](#)) lock on row [r](#), a request from some distinct transaction [T2](#) for a lock of either type on [r](#) cannot be granted immediately. Instead, transaction [T2](#) has to wait for transaction [T1](#) to release its lock on row [r](#).

Intention Locks

InnoDB supports *multiple granularity locking* which permits coexistence of row locks and table locks. For example, a statement such as `LOCK TABLES ... WRITE` takes an exclusive lock (an `X` lock) on the specified table. To make locking at multiple granularity levels practical, InnoDB uses *intention locks*. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:

- An *intention shared lock* (`IS`) indicates that a transaction intends to set a *shared* lock on individual rows in a table.
- An *intention exclusive lock* (`IX`) indicates that that a transaction intends to set an exclusive lock on individual rows in a table.

For example, `SELECT ... FOR SHARE` sets an `IS` lock, and `SELECT ... FOR UPDATE` sets an `IX` lock.

The intention locking protocol is as follows:

- Before a transaction can acquire a shared lock on a row in a table, it must first acquire an `IS` lock or stronger on the table.
- Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an `IX` lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

	<code>X</code>	<code>IX</code>	<code>S</code>	<code>IS</code>
<code>X</code>	Conflict	Conflict	Conflict	Conflict
<code>IX</code>	Conflict	Compatible	Conflict	Compatible
<code>S</code>	Conflict	Conflict	Compatible	Compatible
<code>IS</code>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause *deadlock*, an error occurs.

Intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and *InnoDB monitor* output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See [Section 15.8.2.1, “Clustered and Secondary Indexes”](#).

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc    'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in `InnoDB` are “purely inhibitive”, which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED`. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, `InnoDB` does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record *R* in an index, another session cannot insert a new index record in the gap immediately before *R* in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in `REPEATABLE READ` transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 15.5.4, “Phantom Rows”](#)).

Transaction data for a next-key lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
0: len 8; hex 737570722656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 8000000a; asc      ;;

```

Insert Intention Locks

An insert intention lock is a type of gap lock set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
```

```
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id |
+-----+
| 102 |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and [InnoDB monitor](#) output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc f;;
 1: len 6; hex 000000002215; asc " ;;
 2: len 7; hex 9000000172011c; asc r ;;...
```

AUTO-INC Locks

An [AUTO-INC](#) lock is a special table-level lock taken by transactions inserting into tables with [AUTO_INCREMENT](#) columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

Predicate Locks for Spatial Indexes

[InnoDB](#) supports [SPATIAL](#) indexing of columns containing spatial columns (see [Section 11.5.9, “Optimizing Spatial Analysis”](#)).

To handle locking for operations involving [SPATIAL](#) indexes, next-key locking does not work well to support [REPEATABLE READ](#) or [SERIALIZABLE](#) transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with [SPATIAL](#) indexes, [InnoDB](#) uses predicate locks. A [SPATIAL](#) index contains minimum bounding rectangle (MBR) values, so [InnoDB](#) enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

15.5.2 InnoDB Transaction Model

In the [InnoDB](#) transaction model, the goal is to combine the best properties of a [multi-versioning](#) database with traditional two-phase locking. [InnoDB](#) performs locking at the row level and runs queries as nonlocking [consistent reads](#) by default, in the style of Oracle. The lock information in [InnoDB](#) is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in [InnoDB](#) tables, or any random subset of the rows, without causing [InnoDB](#) memory exhaustion.

15.5.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym [ACID](#); the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: [READ UNCOMMITTED](#), [READ COMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#). The default isolation level for InnoDB is [REPEATABLE READ](#).

A user can change the isolation level for a single session or for all subsequent connections with the [SET TRANSACTION](#) statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 13.3.7, “SET TRANSACTION Syntax”](#).

InnoDB supports each of the transaction isolation levels described here using different [locking](#) strategies. You can enforce a high degree of consistency with the default [REPEATABLE READ](#) level, for operations on crucial data where [ACID](#) compliance is important. Or you can relax the consistency rules with [READ COMMITTED](#) or even [READ UNCOMMITTED](#), in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. [SERIALIZABLE](#) enforces even stricter rules than [REPEATABLE READ](#), and is used mainly in specialized situations, such as with [XA](#) transactions and for troubleshooting issues with concurrency and [deadlocks](#).

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- [REPEATABLE READ](#)

This is the default isolation level for InnoDB. [Consistent reads](#) within the same transaction read the [snapshot](#) established by the first read. This means that if you issue several plain (nonlocking) [SELECT](#) statements within the same transaction, these [SELECT](#) statements are consistent also with respect to each other. See [Section 15.5.2.3, “Consistent Nonlocking Reads”](#).

For [locking reads](#) ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#), and [DELETE](#) statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

- For a unique index with a unique search condition, InnoDB locks only the index record found, not the [gap](#) before it.
- For other search conditions, InnoDB locks the index range scanned, using [gap locks](#) or [next-key locks](#) to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 15.5.1, “InnoDB Locking”](#).

- [READ COMMITTED](#)

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see [Section 15.5.2.3, “Consistent Nonlocking Reads”](#).

For locking reads ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#) statements, and [DELETE](#) statements, InnoDB locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see [Section 15.5.4, “Phantom Rows”](#).

Only row-based binary logging is supported with the `READ COMMITTED` isolation level. If you use `READ COMMITTED` with `binlog_format=MIXED`, the server automatically uses row-based logging.

Using `READ COMMITTED` has additional effects:

- For `UPDATE` or `DELETE` statements, `InnoDB` holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, `InnoDB` performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time `InnoDB` either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 15.8.2.1, “Clustered and Secondary Indexes”](#)) rather than indexed columns.

Suppose that one session performs an `UPDATE` using these statements:

```
# Session A
START TRANSACTION;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second session performs an `UPDATE` by executing these statements following those of the first session:

```
# Session B
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default `REPEATABLE READ` isolation level, the first `UPDATE` acquires an x-lock on each row that it reads and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `READ COMMITTED` is used instead, the first `UPDATE` acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

However, if the `WHERE` condition includes an indexed column, and InnoDB uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first `UPDATE` takes and retains an x-lock on each row where `b = 2`. The second `UPDATE` blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column `b`.

```
CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;

# Session A
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;

# Session B
UPDATE t SET b = 4 WHERE b = 2 AND c = 4;
```

The effects of using the `READ COMMITTED` isolation level are the same as enabling the deprecated `innodb_locks_unsafe_for_binlog` configuration option, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a *dirty read*. Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... FOR SHARE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its

own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

15.5.2.2 autocommit, Commit, and Rollback

In `InnoDB`, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 15.20.4, “InnoDB Error Handling”](#).

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all `InnoDB` locks that were set during the current transaction.

Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of [DML](#) statements and commit them or roll them back all together.

To use multiple-statement [transactions](#), switch `autocommit` off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave `autocommit` on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test
```

```
mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
```

```

Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b       |
+-----+-----+
| 10    | Heikki  |
+-----+-----+
1 row in set (0.00 sec)
mysql>

```

Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

15.5.2.3 Consistent Nonlocking Reads

A **consistent read** means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction **isolation level** is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-

committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another [SELECT](#) or [START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

	Session A	Session B
time	SET autocommit=0;	SET autocommit=0;
	SELECT * FROM t;	
	empty set	
		INSERT INTO t VALUES (1, 2);
	SELECT * FROM t;	
v	empty set	
		COMMIT;
	SELECT * FROM t;	
	empty set	
	COMMIT;	
	SELECT * FROM t;	

	1 2	

If you want to see the “freshest” state of the database, use either the [READ COMMITTED](#) isolation level or a [locking read](#):

```
SELECT * FROM t FOR SHARE;
```

With [READ COMMITTED](#) isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With [FOR SHARE](#), a locking read occurs instead: A [SELECT](#) blocks until the transaction containing the freshest rows ends (see [Section 15.5.2.4, “Locking Reads”](#)).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over [DROP TABLE](#), because MySQL cannot use a table that has been dropped and [InnoDB](#) destroys the table.

- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `FOR SHARE`:

- By default, InnoDB uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` (that is, anything other than `SERIALIZABLE`). In this case, no locks are set on rows read from the selected table.

15.5.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- `SELECT ... FOR SHARE`

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

Note
