MySQL Cluster is able to operate in various configurations. Please specify the settings below to define the right cluster type that fits your use case. If you intend to use remote hosts for deploying MySQL Cluster, SSH must be enabled. Unless key based SSH is possible, you must submit your user name and password below.

Cluster property	Value
Cluster name [?]	mycluster-1
Host list [?]	localhost
Application area [?]	simple testing ▾
Write load [?]	low ▾

SSH property (Cluster-wide)	Value
Key based SSH [?]	<input type="checkbox"/>
User name [?]	<input type="text"/>
Password [?]	<input type="text"/>
Key user: [?]	<input type="text"/>
Key passphrase: [?]	<input type="text"/>
Key file: [?]	<input type="text"/>

Install properties (Cluster-wide)	Value
Install MySQL Cluster [?]	NONE ▾
Open FW ports [?]	<input type="checkbox"/>

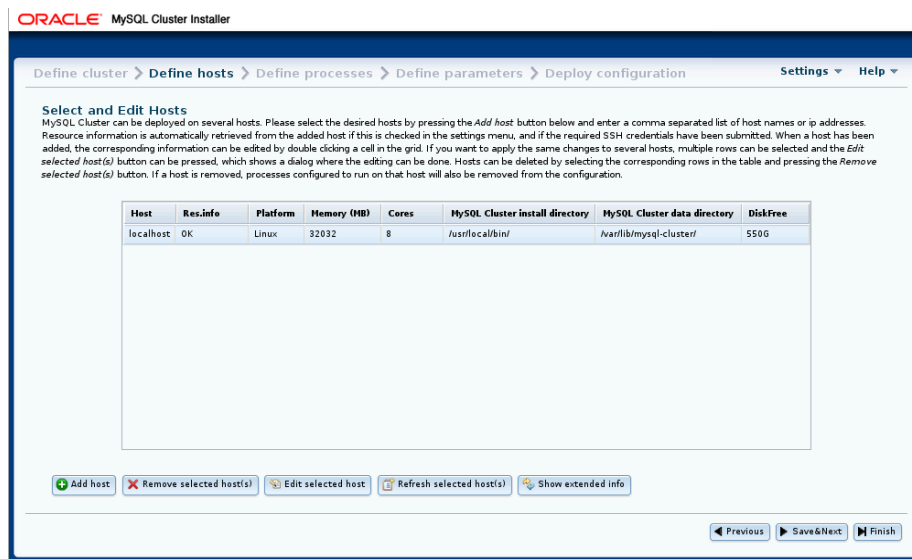

◀ Previous Save & Next Finish

After making the desired settings, you can save them to the configuration file and proceed to the **Define Hosts** screen by clicking the **Save & Next** button.

If you exit the installer without saving, no changes are made to the configuration file.

NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

Figure 22.12 NDB Cluster Define Hosts screen, start

Properties shown include the following:

- **Host:** Name or IP address of this host
- **Res.info:** Shows **OK** if the installer was able to retrieve requested resource information from this host
- **Platform:** Operating system or platform
- **Memory (MB):** Amount of RAM on this host
- **Cores:** Number of CPU cores available on this host
- **MySQL Cluster install directory:** Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory:** Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`.
- **DiskFree:** Free disk space in bytes

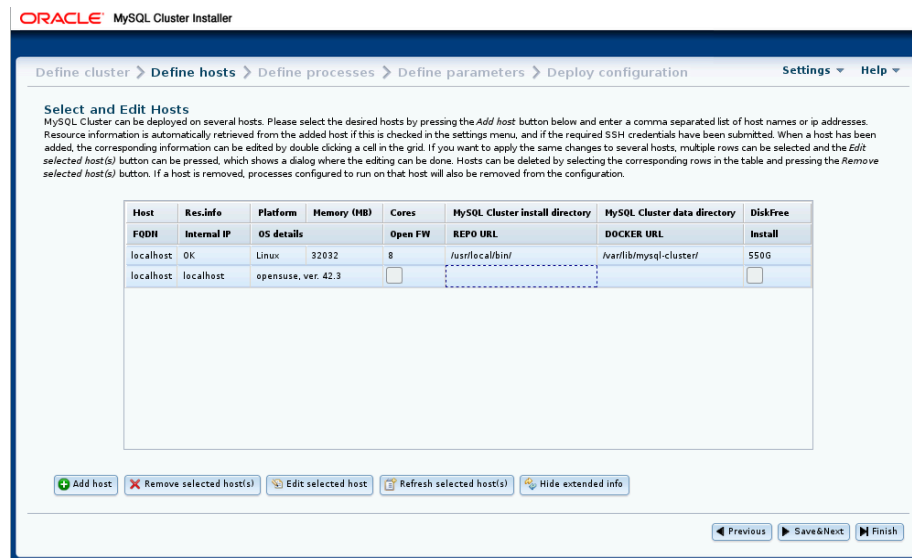

For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN:** This host's fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP:** The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details:** Detailed operating system name and version information.
- **Open FW:** If this check box is enabled, the installer attempts to open ports in the host's firewall needed by cluster processes.
- **REPO URL:** URL for MySQL NDB Cluster repository
- **DOCKER URL:** URL for MySQL NDB Cluster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.
- **Install:** If this check box is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host

The extended view is shown here:

Figure 22.13 NDB Cluster Define Hosts screen, extended host info view

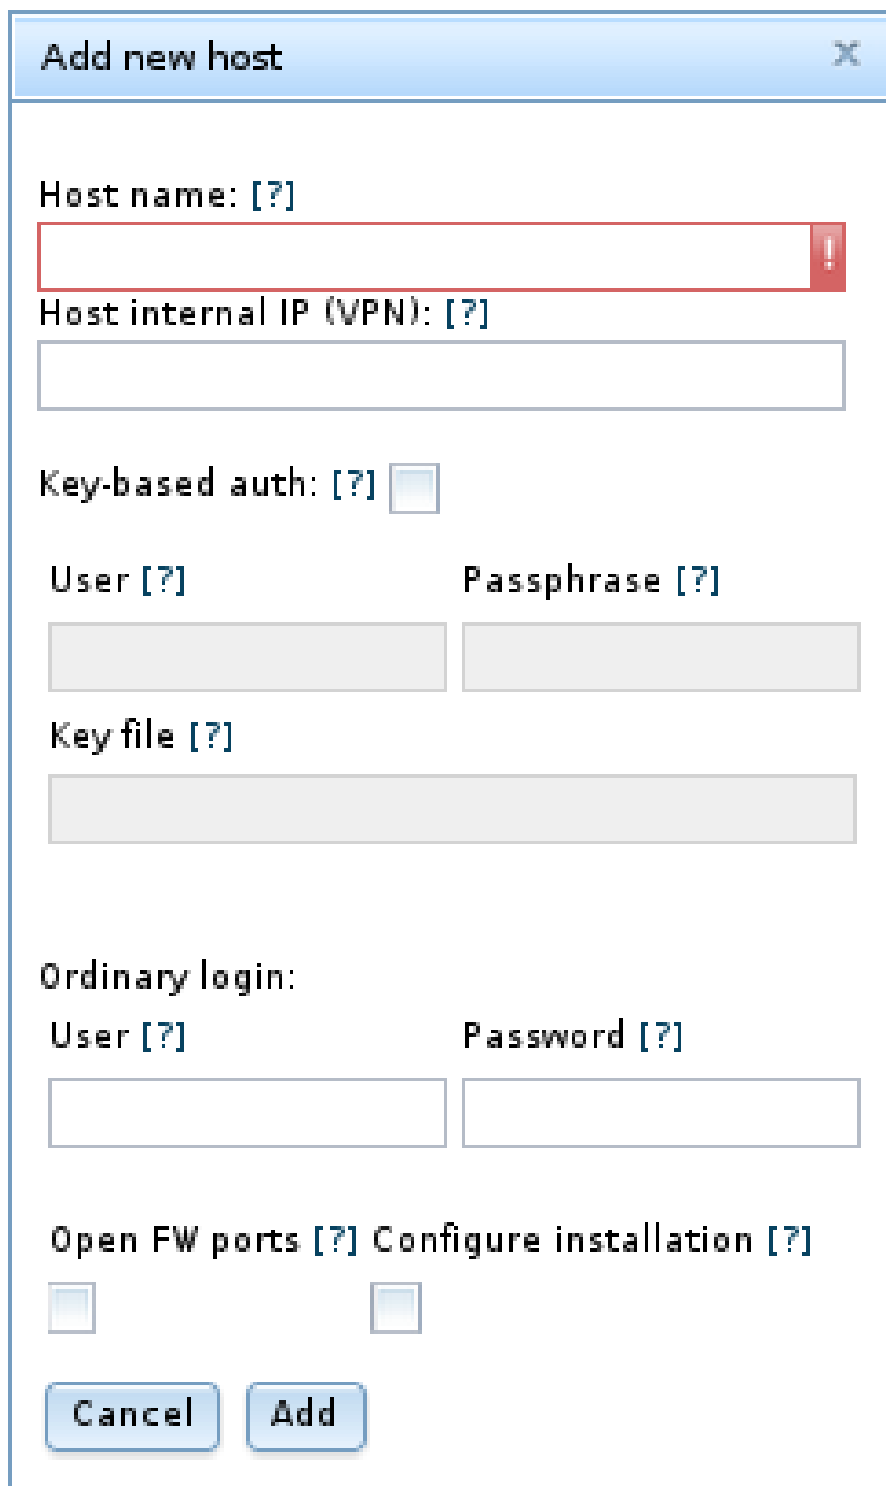

All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

Adding and Removing Hosts

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:

Figure 22.14 NDB Cluster Add Host dialog

The image shows a Windows-style dialog box titled "Add new host" with a close button (X) in the top right corner. The dialog contains several input fields and checkboxes. The first field is "Host name: [?]" with a red border and a red exclamation mark icon on the right. Below it is "Host internal IP (VPN): [?]" with a standard grey border. Then is "Key-based auth: [?] ☐". Below that are two side-by-side fields: "User [?]" and "Passphrase [?]", both with grey borders. Then is "Key file [?]" with a wide grey border. Below that is "Ordinary login:" followed by "User [?]" and "Password [?]" side-by-side, both with grey borders. At the bottom are two checkboxes: "Open FW ports [?] ☐" and "Configure installation [?] ☐". At the very bottom are two buttons: "Cancel" and "Add".

Add new host

Host name: [?]

Host internal IP (VPN): [?]

Key-based auth: [?] ☐

User [?] Passphrase [?]

Key file [?]

Ordinary login:

User [?] Password [?]

Open FW ports [?] Configure installation [?]

☐ ☐

Cancel Add

This dialog includes the following fields:

- **Host name:** A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.
- **Host internal IP (VPN):** If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.

- **Key-based auth:** If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.
- **Ordinary login:** If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.
- **Open FW ports:** Selecting this check box allows the installer try opening any ports needed by cluster processes in this host's firewall.
- **Configure installation:** Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. *When you remove a host, any process which was configured for that host is also removed.*

Warning

Remove selected host(s) acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

Figure 22.15 NDB Cluster Auto-Installer Edit Hosts dialog

Please edit the fields you want to change. The changes will be applied to all selected hosts. Fields that are not edited in the form below will be left unchanged.

Platform [?]	Memory (MB) [?]	CPU cores [?]	MySQL Cluster install directory [?]	MySQL Cluster data directory [?]	DiskFree [?]
Linux	32,032	8			550G

Host external IP: [?]
localhost

Host internal IP (VPN): [?]
localhost

Key-based auth: [?] ☐

User [?] Passphrase [?]
[] []

Key file [?]
[]

Ordinary login:
User [?] Password [?]
[] []

Open FW ports [?] ☐ Configure installation [?] ☐

Cancel Save

When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the [Define Processes screen](#), where you can set up NDB Cluster processes on one or more hosts.

NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

Figure 22.16 NDB Cluster Auto-Installer Define Processes dialog

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the [Define Hosts screen](#), remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmt`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 22.1.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this **Any host** entry.*

Adding processes. To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

Figure 22.17 NDB Cluster Auto-Installer Add Process Dialog

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

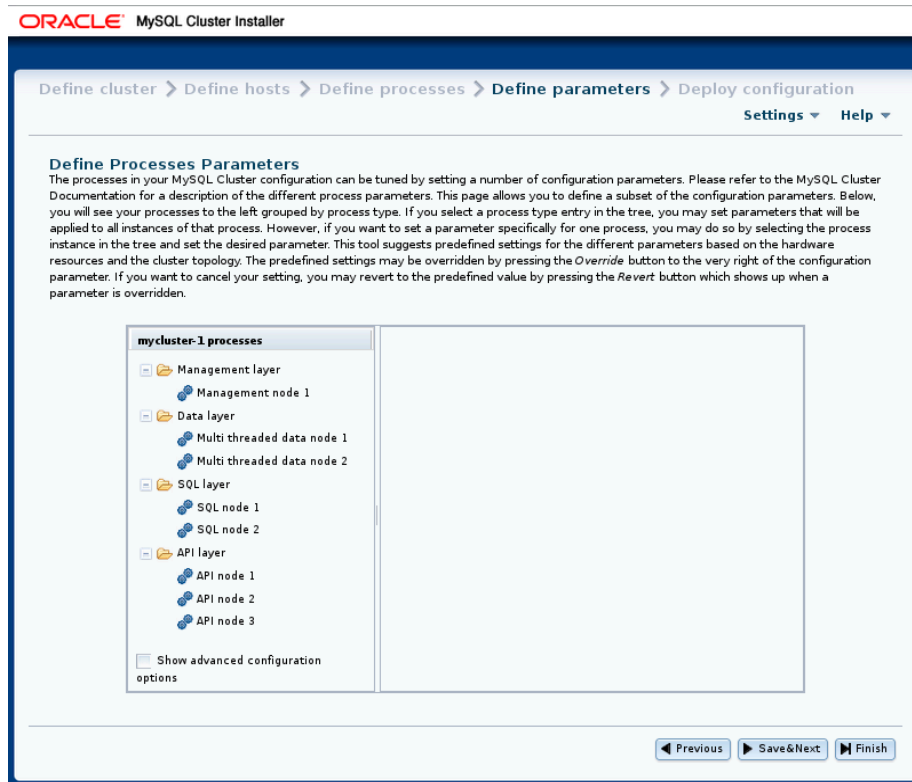

Removing processes. To delete a process, select that process in the tree and use the **Del process** button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (`ndbmt_d`) to a single-threaded data node (`ndbd`), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

NDB Cluster Auto-Installer Define Parameters Screen

Like the [Define Processes screen](#), this screen includes a process tree; the **Define Parameters** process tree is organized by process or node type, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

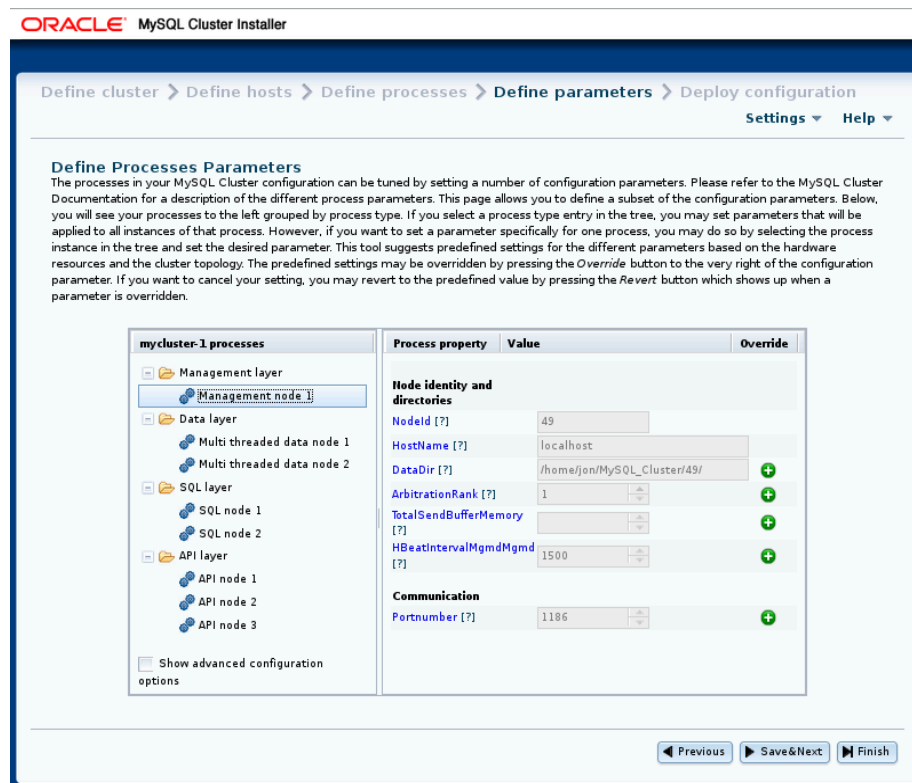

Figure 22.18 NDB Cluster Auto-Installer Define Parameters screen

The check box labelled **Show advanced configuration**, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking **Show advanced configuration options** under **Settings** (see [NDB Cluster Installer Settings and Help Menus](#)).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

Figure 22.19 Define Parameters—Process Attributes

Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X. The X button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

NDB Cluster Auto-Installer Deploy Configuration Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Configuration** screen is shown here:

Figure 22.20 NDB Cluster Auto-Installer Deploy Configuration screen

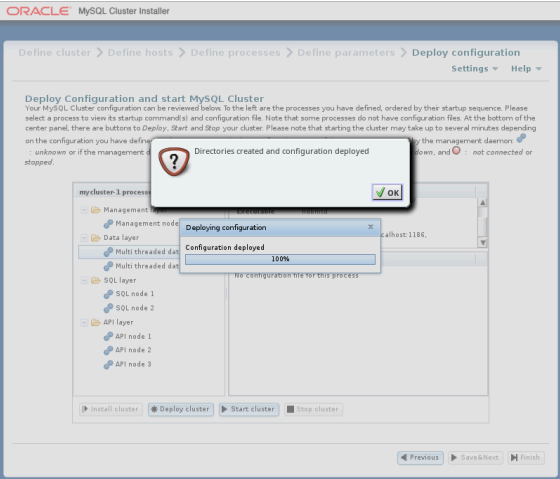

Like the [Define Parameters](#) screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (**CONNECTED**), starting (**STARTING**), running (**STARTED**), stopping (**STOPPING**), or disconnected (**NO_CONTACT**). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster:** Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:

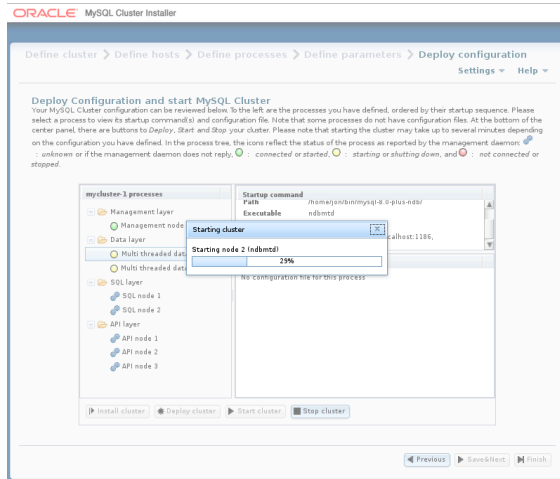

Figure 22.21 Cluster Deployment Process

- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

Figure 22.22 Cluster Startup Process with Progress Bar

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:

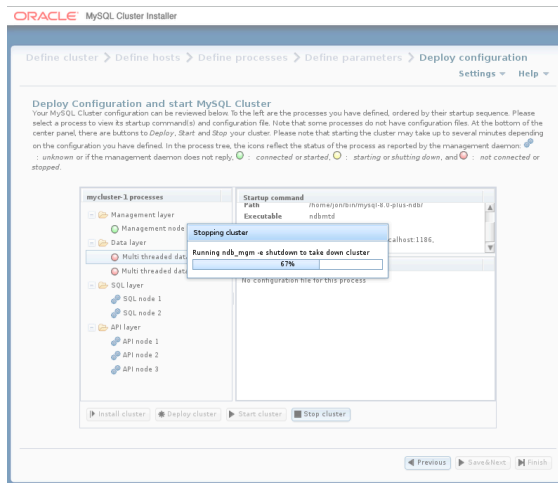

Figure 22.23 Cluster Startup, Process Completed Dialog

- **Stop cluster:** After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster

shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

Figure 22.24 Cluster Shutdown Process, with Progress Bar

A confirmation dialog indicates when the shutdown process is complete:

Figure 22.25 Cluster Shutdown, Process Completed Dialog

The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

22.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be

done in `my.cnf`, or with the `mysql` client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see [The NDB Cluster Auto-Installer \(NDB 7.5\) \(DEPRECATED\)](#).

For general information about installing NDB Cluster, see [Section 22.2, “NDB Cluster Installation”](#).

22.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.23

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the [SHOW](#) command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 8.0.22-ndb-8.0.22)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 8.0.22-ndb-8.0.22)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with [ENGINE=NDBCLUSTER](#) or its alias [ENGINE=NDB](#).

22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the [config.ini](#) file to govern various aspects of node behavior, as well as of options and variables read by [mysqld](#) from a [my.cnf](#) file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type ([ndbd](#), [ndb_mgmd](#), [mysqld](#), [computer](#), [tcp](#), or [shm](#)). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with [--initial](#)—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as [node](#) online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each [ndbd](#) process with the [--initial](#) option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#). In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RN1L` and is equal to `0xFFFFFFFF`, or $2^{32} - 2^8 - 1$.

22.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#).

These parameters also apply to `ndbmt`, the multithreaded version of `ndbd`. For more information, see [Section 22.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

- **Arbitration**: How arbitration should be performed to avoid split-brain issues in event of node failure.
- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal.
- **BackupDataBufferSize**: Default size of databuffer for a backup (in bytes).
- **BackupDataDir**: Path to where to store backups. Note that string `'/BACKUP'` is always appended to this setting, so that *effective* default is `FilePath/BACKUP`.
- **BackupDiskWriteSpeedPct**: Sets percentage of data node's allocated maximum write speed (`MaxDiskWriteSpeed`) to reserve for LCPs when starting a backup.
- **BackupLogBufferSize**: Default size of log buffer for a backup (in bytes).
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes).
- **BackupMemory**: Total memory allocated for backups per node (in bytes).
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds.
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes).
- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock.
- **BuildIndexThreads**: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running `ndb_restore --rebuild-indexes`. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- **CompressedBackup**: Use zlib to compress backups as they are written.
- **CompressedLCP**: Write compressed LCPs using zlib.
- **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects a corrupted tuple.
- **DataDir**: Data directory for this node.
- **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of `IndexMemory`.
- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840..

- [DictTrace](#): Enable DBDICT debugging; for NDB development.
- [DiskDataUsingSameDisk](#): Set to false if Disk Data tablespaces are located on separate physical disks.
- [DiskIOThreadPool](#): Number of unbound threads for file access, applies to disk data only.
- [Diskless](#): Run without using disk.
- [DiskPageBufferEntries](#): Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.
- [DiskPageBufferMemory](#): Number of bytes on each data node allocated for disk page buffer cache.
- [DiskSyncSize](#): Amount of data written to file before a synch is forced.
- [EnablePartialLcp](#): Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
- [EnableRedoControl](#): Enable adaptive checkpointing speed for controlling redo log usage.
- [EventLogBufferSize](#): Size of circular buffer for NDB log events within data nodes.
- [ExecuteOnComputer](#): String referencing an earlier defined COMPUTER.
- [ExtraSendBufferMemory](#): Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- [FileSystemPath](#): Path to directory where data node stores its data (directory must exist).
- [FileSystemPathDataFiles](#): Path to directory where data node stores its Disk Data files. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- [FileSystemPathDD](#): Path to directory where data node stores its Disk Data and undo files. Default value is FilesystemPath, if set; otherwise, value of DataDir is used.
- [FileSystemPathUndoFiles](#): Path to directory where data node stores its undo files for Disk Data. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- [FragmentLogFileSize](#): Size of each redo log file.
- [HeartbeatIntervalDbApi](#): Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
- [HeartbeatIntervalDbDb](#): Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.
- [HeartbeatOrder](#): Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- [HostName](#): Host name or IP address for this data node.
- [IndexMemory](#): Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- [IndexStatAutoCreate](#): Enable/disable automatic statistics collection when indexes are created.
- [IndexStatAutoUpdate](#): Monitor indexes for changes and trigger automatic statistics updates.
- [IndexStatSaveScale](#): Scaling factor used in determining size of stored index statistics.

- [IndexStatSaveSize](#): Maximum size in bytes for saved statistics per index.
- [IndexStatTriggerPct](#): Threshold percent change in DML operations for index statistics updates. Value is scaled down by [IndexStatTriggerScale](#).
- [IndexStatTriggerScale](#): Scale down [IndexStatTriggerPct](#) by this amount, multiplied by base 2 logarithm of index size, for a large index. Set to 0 to disable scaling.
- [IndexStatUpdateDelay](#): Minimum delay between automatic index statistics updates for a given index. 0 means no delay.
- [InitFragmentLogFiles](#): Initialize fragment logfiles (sparse/full).
- [InitialLogFileGroup](#): Describes a log file group that is created during an initial start. See documentation for format.
- [InitialNoOfOpenFiles](#): Initial number of files open per data node. (One thread is created per file).
- [InitialTablespace](#): Describes a tablespace that is created during an initial start. See documentation for format.
- [InsertRecoveryWork](#): Percentage of [RecoveryWork](#) used for inserted rows; has no effect unless partial local checkpoints are in use.
- [LateAlloc](#): Allocate memory after connection to management server has been established.
- [LcpScanProgressTimeout](#): Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- [LockExecuteThreadToCPU](#): A comma-delimited list of CPU IDs.
- [LockMaintThreadsToCPU](#): CPU ID indicating which CPU runs maintenance threads.
- [LockPagesInMainMemory](#): 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.
- [LogLevelCheckpoint](#): Log level of local and global checkpoint information printed to stdout.
- [LogLevelCongestion](#): Level of congestion information printed to stdout.
- [LogLevelConnection](#): Level of node connect/disconnect information printed to stdout.
- [LogLevelError](#): Transporter, heartbeat errors printed to stdout.
- [LogLevelInfo](#): Heartbeat and log information printed to stdout.
- [LogLevelNodeRestart](#): Level of node restart and node failure information printed to stdout.
- [LogLevelShutdown](#): Level of node shutdown information printed to stdout.
- [LogLevelStartup](#): Level of node startup information printed to stdout.
- [LogLevelStatistic](#): Level of transaction, operation, and transporter information printed to stdout.
- [LongMessageBuffer](#): Number of bytes allocated on each data node for internal long messages.
- [MaxAllocate](#): Maximum size of allocation to use when allocating memory for tables.
- [MaxBufferedEpochs](#): Allowed numbered of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.
- [MaxBufferedEpochBytes](#): Total number of bytes allocated for buffering epochs.
- [MaxDiskDataLatency](#): Maximum allowed mean latency of disk access (ms) before starting to abort transactions.

- [MaxDiskWriteSpeed](#): Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- [MaxDiskWriteSpeedOtherNodeRestart](#): Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- [MaxDiskWriteSpeedOwnRestart](#): Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- [MaxFKBuildBatchSize](#): Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- [MaxDMLOperationsPerTransaction](#): Limit size of a transaction; aborts transaction if it requires more than this many DML operations. Set to 0 to disable.
- [MaxLCPStartDelay](#): Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- [MaxNoOfAttributes](#): Suggests a total number of attributes stored in database (sum over all tables).
- [MaxNoOfConcurrentIndexOperations](#): Total number of index operations that can execute simultaneously on one data node.
- [MaxNoOfConcurrentOperations](#): Maximum number of operation records in transaction coordinator.
- [MaxNoOfConcurrentScans](#): Maximum number of scans executing concurrently on data node.
- [MaxNoOfConcurrentSubOperations](#): Maximum number of concurrent subscriber operations.
- [MaxNoOfConcurrentTransactions](#): Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.
- [MaxNoOfFiredTriggers](#): Total number of triggers that can fire simultaneously on one data node.
- [MaxNoOfLocalOperations](#): Maximum number of operation records defined on this data node.
- [MaxNoOfLocalScans](#): Maximum number of fragment scans in parallel on this data node.
- [MaxNoOfOpenFiles](#): Maximum number of files open per data node. (One thread is created per file).
- [MaxNoOfOrderedIndexes](#): Total number of ordered indexes that can be defined in system.
- [MaxNoOfSavedMessages](#): Maximum number of error messages to write in error log and maximum number of trace files to retain.
- [MaxNoOfSubscribers](#): Maximum number of subscribers (default 0 = MaxNoOfTables * 2).
- [MaxNoOfSubscriptions](#): Maximum number of subscriptions (default 0 = MaxNoOfTables).
- [MaxNoOfTables](#): Suggests a total number of NDB tables stored in database.
- [MaxNoOfTriggers](#): Total number of triggers that can be defined in system.
- [MaxNoOfUniqueHashIndexes](#): Total number of unique hash indexes that can be defined in the system.
- [MaxParallelCopyInstances](#): Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- [MaxParallelScansPerFragment](#): Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.

- [MaxReorgBuildBatchSize](#): Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- [MaxStartFailRetries](#): Maximum retries when data node fails on startup, requires `StopOnError = 0`. Setting to 0 causes start attempts to continue indefinitely.
- [MaxUIBuildBatchSize](#): Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- [MemReportFrequency](#): Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- [MinDiskWriteSpeed](#): Minimum number of bytes per second that can be written by LCP and backup.
- [MinFreePct](#): Percentage of memory resources to keep in reserve for restarts.
- [NodeGroup](#): Node group to which data node belongs; used only during initial start of cluster.
- [NodeGroupTransporters](#): Number of transporters to use between nodes in same node group.
- [NodeId](#): Number uniquely identifying data node among all nodes in cluster.
- [NoOfFragmentLogFiles](#): Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- [NoOfReplicas](#): Number of copies of all data in database.
- [Numa](#): (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- [ODirect](#): Use `O_DIRECT` file reads and writes when possible.
- [ODirectSyncFlag](#): `O_DIRECT` writes are treated as synchronized writes; ignored when `ODirect` is not enabled, `InitFragmentLogFiles` is set to `SPARSE`, or both.
- [RealtimeScheduler](#): When true, data node threads are scheduled as real-time threads. Default is false.
- [RecoveryWork](#): Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- [RedoBuffer](#): Number of bytes on each data node allocated for writing redo logs.
- [RedoOverCommitCounter](#): When `RedoOverCommitLimit` has been exceeded this many times, transactions are aborted, and operations are handled as specified by `DefaultOperationRedoProblemAction`.
- [RedoOverCommitLimit](#): Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to `RedoOverCommitCounter`.
- [ReservedConcurrentIndexOperations](#): Number of simultaneous index operations having dedicated resources on one data node.
- [ReservedConcurrentOperations](#): Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.
- [ReservedConcurrentScans](#): Number of simultaneous scans having dedicated resources on one data node.
- [ReservedConcurrentTransactions](#): Number of simultaneous transactions having dedicated resources on one data node.
- [ReservedFiredTriggers](#): Number of triggers having dedicated resources on one data node.

- [ReservedLocalScans](#): Number of simultaneous fragment scans having dedicated resources on one data node.
- [ReservedTransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.
- [RestartOnErrorInsert](#): Control type of restart caused by inserting an error (when [StopOnError](#) is enabled).
- [SchedulerExecutionTimer](#): Number of microseconds to execute in scheduler before sending.
- [SchedulerResponsiveness](#): Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- [SchedulerSpinTimer](#): Number of microseconds to execute in scheduler before sleeping.
- [ServerPort](#): Port used to set up transporter for incoming connections from API nodes.
- [SharedGlobalMemory](#): Total number of bytes on each data node allocated for any use.
- [SpinMethod](#): Determines spin method used by data node; see documentation for details.
- [StartFailRetryDelay](#): Delay in seconds after start failure prior to retry; requires [StopOnError](#) = 0.
- [StartFailureTimeout](#): Milliseconds to wait before terminating. (0=Wait forever).
- [StartNoNodeGroupTimeout](#): Time to wait for nodes without a nodegroup before trying to start (0=forever).
- [StartPartialTimeout](#): Milliseconds to wait before trying to start without all nodes. (0=Wait forever).
- [StartPartitionedTimeout](#): Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- [StartupStatusReportFrequency](#): Frequency of status reports during startup.
- [StopOnError](#): When set to 0, data node automatically restarts and recovers following node failures.
- [StringMemory](#): Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
- [TcpBind_INADDR_ANY](#): Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).
- [TimeBetweenEpochs](#): Time between epochs (synchronization used for replication).
- [TimeBetweenEpochsTimeout](#): Timeout for time between epochs. Exceeding will cause node shutdown.
- [TimeBetweenGlobalCheckpoints](#): Time between group commits of transactions to disk.
- [TimeBetweenGlobalCheckpointsTimeout](#): Minimum timeout for group commit of transactions to disk.
- [TimeBetweenInactiveTransactionAbortCheck](#): Time between checks for inactive transactions.
- [TimeBetweenLocalCheckpoints](#): Time between taking snapshots of database (expressed in base-2 logarithm of bytes).
- [TimeBetweenWatchDogCheck](#): Time between execution checks inside a data node.
- [TimeBetweenWatchDogCheckInitial](#): Time between execution checks inside a data node (early start phases when memory is allocated).

- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers..
- [TransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.
- [TransactionDeadlockDetectionTimeout](#): Time transaction can spend executing within a data node. This is time that transaction coordinator waits for each data node participating in transaction to execute a request. If data node takes more than this amount of time, transaction is aborted.
- [TransactionInactiveTimeout](#): Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.
- [TransactionMemory](#): Memory allocated for transactions on each data node.
- [TwoPassInitialNodeRestartCopy](#): Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- [UndoDataBuffer](#): Number of bytes on each data node allocated for writing data undo logs.
- [UndoIndexBuffer](#): Number of bytes on each data node allocated for writing index undo logs.
- [UseShm](#): Use shared memory connections between this data node and API node also running on this host.

The following parameters are specific to [ndbmtd](#):

- [MaxNoOfExecutionThreads](#): For ndbmtd only, specify maximum number of execution threads.
- [NoOfFragmentLogParts](#): Number of redo log file groups belonging to this data node.
- [ThreadConfig](#): Used for configuration of multithreaded data nodes (ndbmtd). Default is an empty string; see documentation for syntax and other information.

22.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the [\[ndb_mgmd\]](#) or [\[mgm\]](#) section of a [config.ini](#) file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 22.3.3.5, “Defining an NDB Cluster Management Server”](#).

- [ArbitrationDelay](#): When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
- [ArbitrationRank](#): If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- [DataDir](#): Data directory for this node.
- [ExecuteOnComputer](#): String referencing an earlier defined COMPUTER.
- [ExtraSendBufferMemory](#): Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- [HeartbeatIntervalMgmdMgmd](#): Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.
- [HeartbeatThreadPriority](#): Set heartbeat thread policy and priority for management nodes; see manual for allowed values.
- [HostName](#): Host name or IP address for this management node.
- [Id](#): Number identifying management node. Now deprecated; use NodeId instead.
- [LogDestination](#): Where to send log messages: console, system log, or specified log file.

- `NodeId`: Number uniquely identifying management node among all nodes in cluster.
- `PortNumber`: Port number to send commands to and fetch configuration from management server.
- `PortNumberStats`: Port number used to get statistical information from a management server.
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.
- `wan`: Use WAN TCP setting as default.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 22.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

22.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `ApiVerbose`: Enable NDB API debugging; for NDB development.
- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting.
- `ArbitrationRank`: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- `AutoReconnect`: Specifies whether an API node should reconnect fully when disconnected from cluster.
- `BatchByteSize`: Default batch size in bytes.
- `BatchSize`: Default batch size in number of records.
- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, `StartConnectBackoffMaxTime` is used instead.
- `ConnectionMap`: Specifies which data nodes to connect.
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- `DefaultOperationRedoProblemAction`: How operations are handled in event that `RedoOverCommitCounter` is exceeded.
- `ExecuteOnComputer`: String referencing an earlier defined COMPUTER.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by `TotalSendBufferMemory` or `SendBufferMemory`. Default (0) allows up to 16MB.
- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.

- **HostName**: Host name or IP address for this SQL or API node.
- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use **NodeId** instead.
- **MaxScanBatchSize**: Maximum collective batch size for one scan.
- **NodeId**: Number uniquely identifying SQL node or API node among all nodes in cluster.
- **StartConnectBackoffMaxTime**: Same as **ConnectBackoffMaxTime** except that this parameter is used in its place if no data nodes are connected to this API node.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **wan**: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

22.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, and `[shm]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see [Section 22.3.3.10, “NDB Cluster TCP/IP Connections”](#), or [Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”](#), as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- **HostName**: Host name or IP address of this computer.
- **Id**: A unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- **AllowUnresolvedHostNames**: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only.
- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors.
- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeId2**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of TCP connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and **Checksum** are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.

- [Proxy](#): .
- [ReceiveBufferMemory](#): Bytes of buffer for signals received by this node.
- [SendBufferMemory](#): Bytes of TCP buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- [TCP_MAXSEG_SIZE](#): Value used for TCP_MAXSEG.
- [TCP_RCV_BUF_SIZE](#): Value used for SO_RCVBUF.
- [TCP_SND_BUF_SIZE](#): Value used for SO_SNDBUF.
- [TcpBind_INADDR_ANY](#): Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the [config.ini](#) file's [\[shm\]](#) section:

- [Checksum](#): If checksum is enabled, all signals between nodes are checked for errors.
- [Group](#): Used for group proximity; smaller value is interpreted as being closer.
- [NodeId1](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeId2](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeIdServer](#): Set server side of SHM connection.
- [OverloadLimit](#): When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- [PreSendChecksum](#): If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- [SendBufferMemory](#): Bytes in shared memory buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files.
- [ShmKey](#): A shared memory key; when set to 1, this is calculated by NDB.
- [ShmSpinTime](#): When receiving, number of microseconds to spin before sleeping.
- [ShmSize](#): Size of shared memory segment.
- [Signal](#): Signal number to be used for signalling.

22.3.2.5 NDB Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.4, “Server Option, System Variable, and Status Variable Reference”](#).

- [Com_show_ndb_status](#): Count of SHOW NDB STATUS statements.
- [Handler_discover](#): Number of times that tables have been discovered.
- [ndb-batch-size](#): Size (in bytes) to use for NDB transaction batches.
- [ndb-blob-read-batch-bytes](#): Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- [ndb-blob-write-batch-bytes](#): Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- [ndb-cluster-connection-pool](#): Number of connections to the cluster used by MySQL.

- `ndb-cluster-connection-pool-nodeids`: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for `--ndb-cluster-connection-pool`.
- `ndb-connectstring`: Point to the management server that distributes the cluster configuration.
- `ndb-default-column-format`: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.
- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `ndb-log-apply-status`: Cause a MySQL server acting as a replica to log mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID. Effective only if the server is started with the `--ndbcluster` option.
- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when `--log-slave-updates` is enabled.
- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when `--log-slave-updates` is enabled.
- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- `ndb-log-fail-terminate`: Terminate mysqld process if complete logging of all found row events is not possible.
- `ndb-log-orig`: Log originating server id and epoch in mysql.ndb_binlog_index table.
- `ndb-log-transaction-id`: Write NDB transaction IDs in the binary log. Requires `--log-bin-v1-events=OFF`.
- `ndb-log-update-as-write`: Toggles logging of updates on the source between updates (OFF) and writes (ON).
- `ndb-mgmd-host`: Set the host (and port, if desired) for connecting to management server.
- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.
- `ndb-transid-mysql-connection-map`: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.
- `ndb-wait-connected`: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.
- `ndb-wait-setup`: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.
- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.
- `Ndb_api_bytes_received_count`: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_received_count_session`: Amount of data (in bytes) received from the data nodes in this client session.

- [Ndb_api_bytes_received_count_slave](#): Amount of data (in bytes) received from the data nodes by this replica.
- [Ndb_api_bytes_sent_count](#): Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).
- [Ndb_api_bytes_sent_count_session](#): Amount of data (in bytes) sent to the data nodes in this client session.
- [Ndb_api_bytes_sent_count_slave](#): Amount of data (in bytes) sent to the data nodes by this replica.
- [Ndb_api_event_bytes_count](#): Number of bytes of events received by this MySQL Server (SQL node).
- [Ndb_api_event_bytes_count_injector](#): Number of bytes of events received by the NDB binary log injector thread.
- [Ndb_api_event_data_count](#): Number of row change events received by this MySQL Server (SQL node).
- [Ndb_api_event_data_count_injector](#): Number of row change events received by the NDB binary log injector thread.
- [Ndb_api_event_nondata_count](#): Number of events received, other than row change events, by this MySQL Server (SQL node).
- [Ndb_api_event_nondata_count_injector](#): Number of events received, other than row change events, by the NDB binary log injector thread.
- [Ndb_api_pk_op_count](#): Number of operations based on or using primary keys by this MySQL Server (SQL node).
- [Ndb_api_pk_op_count_session](#): Number of operations based on or using primary keys in this client session.
- [Ndb_api_pk_op_count_slave](#): Number of operations based on or using primary keys by this replica.
- [Ndb_api_pruned_scan_count](#): Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).
- [Ndb_api_pruned_scan_count_session](#): Number of scans that have been pruned to a single partition in this client session.
- [Ndb_api_pruned_scan_count_slave](#): Number of scans that have been pruned to a single partition by this replica.
- [Ndb_api_range_scan_count](#): Number of range scans that have been started by this MySQL Server (SQL node).
- [Ndb_api_range_scan_count_session](#): Number of range scans that have been started in this client session.
- [Ndb_api_range_scan_count_slave](#): Number of range scans that have been started by this replica.
- [Ndb_api_read_row_count](#): Total number of rows that have been read by this MySQL Server (SQL node).
- [Ndb_api_read_row_count_session](#): Total number of rows that have been read in this client session.
- [Ndb_api_read_row_count_slave](#): Total number of rows that have been read by this replica.

- [Ndb_api_scan_batch_count](#): Number of batches of rows received by this MySQL Server (SQL node).
- [Ndb_api_scan_batch_count_session](#): Number of batches of rows received in this client session.
- [Ndb_api_scan_batch_count_slave](#): Number of batches of rows received by this replica.
- [Ndb_api_table_scan_count](#): Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- [Ndb_api_table_scan_count_session](#): Number of table scans that have been started, including scans of internal tables, in this client session.
- [Ndb_api_table_scan_count_slave](#): Number of table scans that have been started, including scans of internal tables, by this replica.
- [Ndb_api_trans_abort_count](#): Number of transactions aborted by this MySQL Server (SQL node).
- [Ndb_api_trans_abort_count_session](#): Number of transactions aborted in this client session.
- [Ndb_api_trans_abort_count_slave](#): Number of transactions aborted by this replica.
- [Ndb_api_trans_close_count](#): Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).
- [Ndb_api_trans_close_count_session](#): Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.
- [Ndb_api_trans_close_count_slave](#): Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this replica.
- [Ndb_api_trans_commit_count](#): Number of transactions committed by this MySQL Server (SQL node).
- [Ndb_api_trans_commit_count_session](#): Number of transactions committed in this client session.
- [Ndb_api_trans_commit_count_slave](#): Number of transactions committed by this replica.
- [Ndb_api_trans_local_read_row_count](#): Total number of rows that have been read by this MySQL Server (SQL node).
- [Ndb_api_trans_local_read_row_count_session](#): Total number of rows that have been read in this client session.
- [Ndb_api_trans_local_read_row_count_slave](#): Total number of rows that have been read by this replica.
- [Ndb_api_trans_start_count](#): Number of transactions started by this MySQL Server (SQL node).
- [Ndb_api_trans_start_count_session](#): Number of transactions started in this client session.
- [Ndb_api_trans_start_count_slave](#): Number of transactions started by this replica.
- [Ndb_api_uk_op_count](#): Number of operations based on or using unique keys by this MySQL Server (SQL node).
- [Ndb_api_uk_op_count_session](#): Number of operations based on or using unique keys in this client session.
- [Ndb_api_uk_op_count_slave](#): Number of operations based on or using unique keys by this replica.

- [Ndb_api_wait_exec_complete_count](#): Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).
- [Ndb_api_wait_exec_complete_count_session](#): Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.
- [Ndb_api_wait_exec_complete_count_slave](#): Number of times thread has been blocked while waiting for execution of an operation to complete by this replica.
- [Ndb_api_wait_meta_request_count](#): Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).
- [Ndb_api_wait_meta_request_count_session](#): Number of times thread has been blocked waiting for a metadata-based signal in this client session.
- [Ndb_api_wait_meta_request_count_slave](#): Number of times thread has been blocked waiting for a metadata-based signal by this replica.
- [Ndb_api_wait_nanos_count](#): Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).
- [Ndb_api_wait_nanos_count_session](#): Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.
- [Ndb_api_wait_nanos_count_slave](#): Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this replica.
- [Ndb_api_wait_scan_result_count](#): Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).
- [Ndb_api_wait_scan_result_count_session](#): Number of times thread has been blocked while waiting for a scan-based signal in this client session.
- [Ndb_api_wait_scan_result_count_slave](#): Number of times thread has been blocked while waiting for a scan-based signal by this replica.
- [ndb_autoincrement_prefetch_sz](#): NDB auto-increment prefetch size.
- [ndb_cache_check_time](#): Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache.
- [ndb_clear_apply_status](#): Causes RESET SLAVE to clear all rows from the `ndb_apply_status` table; ON by default.
- [Ndb_cluster_node_id](#): If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.
- [Ndb_config_from_host](#): The host name or IP address of the Cluster management server. Formerly `Ndb_connected_host`.
- [Ndb_config_from_port](#): The port for connecting to Cluster management server. Formerly `Ndb_connected_port`.
- [Ndb_conflict_fn_epoch](#): Number of rows that have been found in conflict by the `NDB$EPOCH()` conflict detection function.
- [Ndb_conflict_fn_epoch2](#): Number of rows that have been found in conflict by the `NDB$EPOCH2()` conflict detection function.
- [Ndb_conflict_fn_epoch2_trans](#): Number of rows that have been found in conflict by the `NDB$EPOCH2_TRANS()` conflict detection function.
- [Ndb_conflict_fn_epoch_trans](#): Number of rows that have been found in conflict by the `NDB$EPOCH_TRANS()` conflict detection function.

- [Ndb_conflict_fn_max](#): If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied.
- [Ndb_conflict_fn_old](#): If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied.
- [Ndb_conflict_last_conflict_epoch](#): Most recent NDB epoch on this replica in which a conflict was detected.
- [Ndb_conflict_last_stable_epoch](#): Number of rows found to be in conflict by a transactional conflict function.
- [Ndb_conflict_reflected_op_discard_count](#): Number of reflected operations that were not applied due an error during execution.
- [Ndb_conflict_reflected_op_prepare_count](#): Number of reflected operations received that have been prepared for execution.
- [Ndb_conflict_refresh_op_count](#): Number of refresh operations that have been prepared.
- [Ndb_conflict_trans_conflict_commit_count](#): Number of epoch transactions committed after requiring transactional conflict handling.
- [Ndb_conflict_trans_detect_iter_count](#): Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to [Ndb_conflict_trans_conflict_commit_count](#).
- [Ndb_conflict_trans_reject_count](#): Number of transactions rejected after being found in conflict by a transactional conflict function.
- [Ndb_conflict_trans_row_conflict_count](#): Number of rows found in conflict by a transactional conflict function. Includes any rows included in or dependent on conflicting transactions.
- [Ndb_conflict_trans_row_reject_count](#): Total number of rows realigned after being found in conflict by a transactional conflict function. Includes [Ndb_conflict_trans_row_conflict_count](#) and any rows included in or dependent on conflicting transactions.
- [ndb_data_node_neighbour](#): Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.
- [ndb_default_column_format](#): Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.
- [ndb_deferred_constraints](#): Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.
- [ndb_dbg_check_shares](#): Check for any lingering shares (debug builds only).
- [ndb-schema-dist-timeout](#): How long to wait before detecting timeout during schema distribution.
- [ndb_distribution](#): Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- [Ndb_epoch_delete_delete_count](#): Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).
- [ndb_eventbuffer_free_percent](#): Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by [ndb_eventbuffer_max_alloc](#).
- [ndb_eventbuffer_max_alloc](#): Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

- `Ndb_execute_count`: Provides the number of round trips to the NDB kernel made by operations.
- `ndb_extra_logging`: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log.
- `ndb_force_send`: Forces sending of buffers to NDB immediately, without waiting for other threads.
- `ndb_fully_replicated`: Whether new NDB tables are fully replicated.
- `ndb_index_stat_enable`: Use NDB index statistics in query optimization.
- `ndb_index_stat_option`: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces.
- `ndb_join_pushdown`: Enables pushing down of joins to data nodes.
- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB.
- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client.
- `ndb_log_apply_status`: Whether or not a MySQL server acting as a replica logs `mysql.ndb_apply_status` updates received from its immediate source in its own binary log, using its own server ID.
- `ndb_log_bin`: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with `--log-bin`.
- `ndb_log_binlog_index`: Insert mapping between epochs and binary log positions into the `ndb_binlog_index` table. Defaults to ON. Effective only if binary logging is enabled on the server.
- `ndb_log_empty_epochs`: When enabled, epochs in which there were no changes are written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.
- `ndb_log_empty_update`: When enabled, updates which produce no changes are written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.
- `ndb_log_exclusive_reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- `ndb_log_orig`: Whether the id and epoch of the originating server are recorded in the `mysql.ndb_binlog_index` table. Set using the `--ndb-log-orig` option when starting `mysqld`.
- `ndb_log_transaction_id`: Whether NDB transaction IDs are written into the binary log (Read-only.).
- `ndb-log-update-minimal`: Log updates in a minimal format.
- `ndb-log-updated-only`: Log complete rows (ON) or updates only (OFF).
- `ndb_metadata_check`: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.
- `Ndb_metadata_blacklist_size`: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as `Ndb_metadata_excluded_count`.
- `ndb_metadata_check_interval`: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.
- `Ndb_metadata_detected_count`: Number of times NDB metadata change monitor thread has detected changes.
- `Ndb_metadata_excluded_count`: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.

- [ndb_metadata_sync](#): Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes `ndb_metadata_check` and `ndb_metadata_check_interval` values to be ignored. Resets to false when synchronization is complete.
- [Ndb_metadata_synced_count](#): Number of NDB metadata objects which have been synchronized.
- [Ndb_number_of_data_nodes](#): If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.
- [ndb-optimization-delay](#): Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.
- [ndb_optimized_node_selection](#): Determines how an SQL node chooses a cluster data node to use as transaction coordinator.
- [Ndb_pruned_scan_count](#): Number of scans executed by NDB since the cluster was last started where partition pruning could be used.
- [Ndb_pushed_queries_defined](#): Number of joins that API nodes have attempted to push down to the data nodes.
- [Ndb_pushed_queries_dropped](#): Number of joins that API nodes have tried to push down, but failed.
- [Ndb_pushed_queries_executed](#): Number of joins successfully pushed down and executed on the data nodes.
- [Ndb_pushed_reads](#): Number of reads executed on the data nodes by pushed-down joins.
- [ndb_read_backup](#): Enable read from any replica for all NDB tables; use `NDB_TABLE=READ_BACKUP={0|1}` with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables.
- [ndb_recv_thread_activation_threshold](#): Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads).
- [ndb_recv_thread_cpu_mask](#): CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.
- [ndb_report_thresh_binlog_epoch_slip](#): NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.
- [ndb_report_thresh_binlog_mem_usage](#): This is a threshold on the percentage of free memory remaining before reporting binary log status.
- [ndb_row_checksum](#): When enabled, set row checksums; enabled by default.
- [Ndb_scan_count](#): The total number of scans executed by NDB since the cluster was last started.
- [ndb_schema_dist_lock_wait_timeout](#): Time during schema distribution to wait for lock before returning error.
- [ndb_schema_dist_timeout](#): Time to wait before detecting timeout during schema distribution.
- [ndb_schema_dist_upgrade_allowed](#): Allow schema distribution table upgrade when connecting to NDB.
- [ndb_show_foreign_key_mock_tables](#): Show the mock tables used to support `foreign_key_checks=0`.

- `ndb_slave_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- `Ndb_slave_max_replicated_epoch`: The most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- `Ndb_system_name`: Configured cluster system name; empty if server not connected to NDB.
- `ndb_table_no_logging`: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.
- `ndb_table_temporary`: NDB tables are not persistent on disk: no schema files are created and the tables are not logged.
- `Ndb_trans_hint_count_session`: Number of transactions using hints that have been started in this session.
- `ndb_use_copying_alter_table`: Use copying ALTER TABLE operations in NDB Cluster.
- `ndb_use_exact_count`: Use exact row count when planning queries.
- `ndb_use_transactions`: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.
- `ndb_version`: Shows build and NDB engine version as an integer.
- `ndb_version_string`: Shows build information including NDB engine version in ndb-x.y.z format.
- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.
- `ndbinfo`: Enable ndbinfo plugin, if supported.
- `ndbinfo_database`: The name used for the NDB information database; read only.
- `ndbinfo_max_bytes`: Used for debugging only.
- `ndbinfo_max_rows`: Used for debugging only.
- `ndbinfo_offline`: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views.
- `ndbinfo_show_hidden`: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.
- `ndbinfo_table_prefix`: The prefix to use for naming ndbinfo internal base tables.
- `ndbinfo_version`: The version of the ndbinfo engine; read only.
- `server_id_bits`: Sets the number of least significant bits in the `server_id` actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. `server_id` must be less than 2 to the power of this value.
- `skip-ndbcluster`: Disable the NDB Cluster storage engine.
- `slave_allow_batching`: Turns update batching on and off for a replica.
- `transaction_allow_batching`: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

22.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

Caching of configuration data. NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the `--initial` option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the `--reload` option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using `--config-cache=FALSE`.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

22.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 22.3.3.3, “NDB Cluster Connection Strings”](#).)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

If used, the `[ndbd default]` section must precede any `[ndbd]` sections in the configuration file. This is also true for `default` sections of any other type.

Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See [Section 22.3.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 22.3.3.4, “Defining Computers in an NDB Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 22.3.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 22.3.3.10, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define `default` values for each section. If used, a `default` section should come before any other sections of that type. For example, an `[ndbd default]` section should appear in the configuration file before any `[ndbd]` sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

22.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. As of NDB 8.0.19, it is also possible (but not required) to
# use more than 2 replicas, although 2 replicas are sufficient to provide
# high availability.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3456M

# The value provided for DataMemory assumes 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
```

```
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 144 inclusive and must be unique among all IDs specified for
# cluster nodes. (Previous to NDB 8.0.18, this range was 1 to 48 inclusive.)

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
```

```
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--optimizer-switch=engine_condition_pushdown=on`

22.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
```

```

host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[, ...]

host-definition:
  host_name[:port_number]

```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
 1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
 2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

22.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...

Restart Type	IS
------------------------------	----

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- [HostName](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

This is the computer's hostname or IP address.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.7 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- [Id](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for

addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144. (In NDB 8.0.17 and earlier, the maximum value for a data node ID was 48.)

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

As of NDB 8.0.18, data node IDs must be less than 145. (Previously, this was less than 49.) If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S
Deprecated	Yes (in NDB 7.5)

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- [PortNumber](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	1186
Range	0 - 64K
Restart Type	S

This is the port number on which the management server listens for configuration requests and management commands.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and [HostName](#) is not sufficient for distinguishing among processes. Intended for use in testing.

- [HostName](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than [localhost](#), either this parameter or [ExecuteOnComputer](#) is required.

- [LocationDomainId](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns a management node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `LogDestination`

Version (or later)	NDB 8.0.13
Type or units	{CONSOLE SYSLOG FILE}
Default	FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6
Range	...
Restart Type	N

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Version (or later)	NDB 8.0.13
--------------------	------------

Type or units	0-2
Default	1
Range	0 - 2
Restart Type	N

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. [ArbitrationRank](#) can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting [ArbitrationRank](#) to 0 on all management and SQL nodes, or by setting the [Arbitration](#) parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting [Arbitration](#) causes any settings for [ArbitrationRank](#) to be disregarded.

- [ArbitrationDelay](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- [DataDir](#)

Version (or later)	NDB 8.0.13
Type or units	path
Default	.
Range	...
Restart Type	N

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the [FILE](#) parameter for [LogDestination](#) as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- [PortNumberStats](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned

Default	[none]
Range	0 - 64K
Restart Type	N

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	S

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first out) or [RR](#) (round robin). The policy value is followed optionally by the priority (an integer).

- [ExtraSendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 32G
Restart Type	N

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [TotalSendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0

Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [HeartbeatIntervalMgmdMgmd](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1500
Range	100 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.8 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmtd\)](#). See also [Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

Identifying data nodes. The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `NodeId`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 48
Restart Type	IS
Version (or later)	NDB 8.0.18
Type or units	unsigned
Default	[none]
Range	1 - 144
Restart Type	IS

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. (In NDB 8.0.17 and earlier, this was 1 to 48 inclusive.) Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes.

- `ExecuteOnComputer`

Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S

Deprecated	Yes (in NDB 7.5)
------------	------------------

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes. Intended for use in testing.

- `HostName`

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	localhost
Range	...
Restart Type	N

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 64K
Restart Type	S

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [NodeGroup](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	0 - 65536
Restart Type	IS

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The [NodeGroup](#) parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a [NodeGroup](#) value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 22.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

- [LocationDomainId](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns a data node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [NoOfReplicas](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	2
Range	1 - 2

Restart Type	IS
Version (or later)	NDB 8.0.19
Type or units	integer
Default	2
Range	1 - 4
Restart Type	IS

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments, and prior to NDB 8.0.18, it was the maximum value supported. Beginning with NDB 8.0.19, setting this parameter's value to 3 or 4 is fully tested and supported in production.

Warning

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since $2/3$ and $2/4$ both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- [DataDir](#)

Version (or later)	NDB 8.0.13
Type or units	path
Default	.
Range	...
Restart Type	IN

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- [FileSystemPath](#)

Version (or later)	NDB 8.0.13
Type or units	path
Default	DataDir 3699

Range	...
Restart Type	IN

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by [DataDir](#).

Note

This directory must exist before the [ndbd](#) process is initiated.

The recommended directory hierarchy for NDB Cluster includes [/var/lib/mysql-cluster](#), under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named [ndb_2_fs](#).

- [BackupDataDir](#)

Version (or later)	NDB 8.0.13
Type or units	path
Default	FileSystemPath
Range	...
Restart Type	IN

This parameter specifies the directory in which backups are placed.

Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of [BackupDataDir](#) to [/var/lib/cluster-data](#), then all backups are stored under [/var/lib/cluster-data/BACKUP](#). This also means that the *effective* default backup location is the directory named [BACKUP](#) under the location specified by the [FileSystemPath](#) parameter.

Data Memory, Index Memory, and String Memory

[DataMemory](#) and [IndexMemory](#) are [\[ndbd\]](#) parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how [DataMemory](#) is used, as it usually needs to be updated to reflect actual usage by the cluster.

Note

[IndexMemory](#) is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- [DataMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	98M
Range	1M - 1T
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	bytes
Default	98M

Range	1M - 16T
Restart Type	N

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by [DataMemory](#) is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from [DataMemory](#). Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

As of NDB 8.0.18, the maximum record size is 30000 bytes. Previously, this was 14000 bytes.

Resources assigned to [DataMemory](#) are used for storing all data and indexes. (Any memory configured as [IndexMemory](#) is automatically added to that used by [DataMemory](#) to form a common resource pool.)

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free [DataMemory](#). This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can control the number of partitions per local data manager for a given table by setting the [NDB_TABLE](#) option [PARTITION_BALANCE](#) to one of the values [FOR_RA_BY_LDM](#), [FOR_RA_BY_LDM_X_2](#), [FOR_RA_BY_LDM_X_3](#), or [FOR_RA_BY_LDM_X_4](#), for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see [Section 13.1.20.10, "Setting NDB_TABLE Options"](#)).

Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the [MAX_ROWS](#) option for [CREATE TABLE](#). While still supported for backward compatibility, using [MAX_ROWS](#) for this purpose is deprecated; you should use [PARTITION_BALANCE](#) instead.

You can also use the [MinFreePct](#) configuration parameter to help avoid problems with node restarts.

The memory space allocated by [DataMemory](#) consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in [NoOfReplicas](#).

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that [DataMemory](#) pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The [DataMemory](#) memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the [DataMemory](#). There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted

upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	1M - 1T
Restart Type	N
Deprecated	Yes (in NDB 7.6)

The `IndexMemory` parameter is deprecated (and subject to future removal); any memory assigned to `IndexMemory` is allocated instead to the same pool as `DataMemory`, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of `IndexMemory` in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

```
size = ( (fragments * 32K) + (rows * 18) )
      * replicas
```

`fragments` is the number of fragments, `replicas` is the number of replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
```

/ sample_size

In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table *t1* has 1 million rows and an ordered index named *ix1* on two four-byte integers. Assume in addition that *IndexStatSaveSize* and *IndexStatSaveScale* are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ((1 * ~16.811) + 1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus $2 * 18 * 29182 = \sim 1050550$ bytes.

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

- **StringMemory**

Version (or later)	NDB 8.0.13
Type or units	% or bytes
Default	25
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	S

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 *Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error*, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns *a* and *b* consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with *b* as primary key and *a* as a

column. This other table consumes an additional 29 bytes of index memory per record in the [example](#) table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both [IndexMemory](#) and [DataMemory](#) is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that [DataMemory](#) and [IndexMemory](#) be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

[DataMemory](#) can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including [DataMemory](#) is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the [MinFreePct](#) data node configuration parameter (default 5).

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	5
Range	0 - 100
Restart Type	N

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few [\[ndbd\]](#) parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. [MaxNoOfConcurrentTransactions](#) sets the number of parallel transactions possible in a node. [MaxNoOfConcurrentOperations](#) sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially [MaxNoOfConcurrentOperations](#)) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

[MaxDMLOperationsPerTransaction](#) sets the maximum number of DML operations that can be performed in a given transaction.

- [MaxNoOfConcurrentTransactions](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	4096

Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	NDB 8.0.19

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
TotalNoOfConcurrentTransactions =
(maximum number of tables accessed in any single transaction + 1)
* number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then $10 * 11 = 110$ transaction records are required for this transaction, per MySQL server, or $110 * 10 = 1100$ transaction records total. Each data node can be expected to handle $\text{TotalNoOfConcurrentTransactions} / \text{number of data nodes}$. For an NDB Cluster having 4 data nodes, this would mean setting [MaxNoOfConcurrentTransactions](#) on each data node to $1100 / 4 = 275$. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's [MaxNoOfConcurrentTransactions](#) is sufficient to cover a number of transactions equal to $\text{TotalNoOfConcurrentTransactions} / \text{number of node groups}$. If this cluster has a single node group, then [MaxNoOfConcurrentTransactions](#) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for [MaxNoOfConcurrentTransactions](#) should always be no more than the value of [MaxNoOfConcurrentOperations](#).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	32K
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	N

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the

default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	UNDEFINED
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	NDB 8.0.19

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [MaxDMLOperationsPerTransaction](#)

Version (or later)	NDB 8.0.13
Type or units	operations (DML)
Default	4294967295
Range	32 - 4294967295
Restart Type	N

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

The value of this parameter cannot exceed that set for [MaxNoOfConcurrentOperations](#).

Transaction temporary storage. The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	8K
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	NDB 8.0.19

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [MaxNoOfFiredTriggers](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	4000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	NDB 8.0.19

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [TransactionBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	1M
Range	1K - 4294967039 (0xFFFFFFFF)
Restart Type	N

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF_FILESIZE](#) (found in [ndb/src/kernel/blocks/Dbtc/Dbtc.hpp](#)) set to 4000 × 128 bytes (500KB). A similar buffer for key information, [ZDATABUF_FILESIZE](#) (also in [Dbtc.hpp](#)) contains 4000 × 16 = 62.5KB of buffer space. [Dbtc](#) is the module that handles transaction coordination.

Transaction resource allocation parameters. The parameters in the following list are used to allocate transaction resources in the transaction coordinator ([DBTC](#)). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for [MaxDMLOperationsPerTransaction](#), [MaxNoOfConcurrentIndexOperations](#), [MaxNoOfConcurrentOperations](#), [MaxNoOfConcurrentScans](#), [MaxNoOfConcurrentTransactions](#), [MaxNoOfFiredTriggers](#),

[MaxNoOfLocalScans](#), or [TransactionBufferMemory](#) (see [Transaction parameters](#) and [Transaction temporary storage](#)).

- [ReservedConcurrentIndexOperations](#)

Version (or later)	NDB 8.0.16
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16

Number of simultaneous index operations having dedicated resources on one data node.

- [ReservedConcurrentOperations](#)

Version (or later)	NDB 8.0.16
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16

Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.

- [ReservedConcurrentScans](#)

Version (or later)	NDB 8.0.16

Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16

Number of simultaneous transactions having dedicated resources on one data node.

- [ReservedFiredTriggers](#)

Version (or later)	NDB 8.0.16
--------------------	------------

Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16

Number of triggers that have dedicated resources on one ndbd(DB) node.

- [ReservedLocalScans](#)

Version (or later)	NDB 8.0.16
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16

Number of simultaneous fragment scans having dedicated resources on one data node.

- [ReservedTransactionBufferMemory](#)

Version (or later)	NDB 8.0.16
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Added	NDB 8.0.16
Deprecated	NDB 8.0.19

Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.

- [TransactionMemory](#)

Version (or later)	NDB 8.0.19
Type or units	bytes
Default	0
Range	0 - 16384G
Restart Type	N
Added	NDB 8.0.19

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory can be handled in any one of the three ways listed here:

- A number of configuration parameters are incompatible with [TransactionMemory](#). If any of these are set, transaction memory is calculated as it was previous to NDB 8.0.19. You should be aware that it is not possible to set any of these parameters concurrently with [TransactionMemory](#); if you attempt to do so, the management server is unable to start (see [Parameters incompatible with TransactionMemory](#)).

- If [TransactionMemory](#) is set, this value is used for determining transaction memory.

- If neither any incompatible parameters are set nor `TransactionMemory` is set, transaction memory is set by `NDB` to 10% of the value of the `DataMemory` configuration parameter.

Parameters incompatible with `TransactionMemory`. The following parameters cannot be used concurrently with `TransactionMemory` and are deprecated as of NDB 8.0.19:

- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfLocalScans`

Explicitly setting any of the parameters just listed when `TransactionMemory` has also been set in the cluster configuration file (`config.ini`) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see [Section 22.3.3.13, “Data Node Memory Management”](#).

Scans and buffering. There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `BatchSizePerLocalScan`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	256
Range	1 - 992
Restart Type	N
Deprecated	NDB 8.0.19

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

Deprecated as of NDB 8.0.19.

- `LongMessageBuffer`

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	64M
Range	512K - 4294967039 (0xFFFFFFFF)
Restart Type	N

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- [MaxFKBuildBatchSize](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- [MaxNoOfConcurrentScans](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	256
Range	2 - 500
Restart Type	N

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

- [MaxNoOfLocalScans](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	4 * MaxNoOfConcurrentScans * [# of data nodes] + 2
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	NDB 8.0.19

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [MaxParallelCopyInstances](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 64
Restart Type	S

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- `MaxParallelScansPerFragment`

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	N

It is possible to configure the maximum number of parallel scans (`TUP` scans and `TUX` scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

- `MaxReorgBuildBatchSize`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- `MaxUIBuildBatchSize`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

Memory Allocation

`MaxAllocate`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	32M
Range	1M - 1G
Restart Type	N

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives *Out of memory* errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` that all available memory has not yet been used, you can increase the value of this parameter (or `MaxNoOfTables`, or both) to cause NDB to make sufficient memory available.

Multiple Transporters

Beginning with version 8.0.20, NDB allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the `NodeGroupTransporters` parameter introduced in that release.

NodeGroupTransporters

Version (or later)	NDB 8.0.20
Type or units	integer
Default	0
Range	0 - 32
Restart Type	N
Added	NDB 8.0.20

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting `NodeGroupTransporters` to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes NDB to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

Hash Map Size

DefaultHashMapSize

Version (or later)	NDB 8.0.13
Type or units	LDM threads
Default	240
Range	0 - 3840
Restart Type	N

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

Logging and checkpointing. The following `[ndbd]` parameters control log and checkpoint behavior.

- [FragmentLogFileSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	4M - 1G
Restart Type	IN

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitialNoOfOpenFiles](#)

Version (or later)	NDB 8.0.13
Type or units	files
Default	27
Range	20 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [InitFragmentLogFiles](#)

Version (or later)	NDB 8.0.13
Type or units	[see values]
Default	SPARSE
Range	SPARSE, FULL
Restart Type	IN

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. [InitFragmentLogFiles](#) takes either of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [EnablePartialLcp](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true

Range	...
Restart Type	N

When [true](#), enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If [EnablePartialLcp](#) is disabled ([false](#)), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled ([true](#)). The proportion of space used by partial LCPS can be modified by the setting for the [RecoveryWork](#) configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).

Setting this parameter to [false](#) also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- [LcpScanProgressTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	second
Default	60
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	second
Default	180
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the [LcpScanProgressTimeout](#) data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- [MaxNoOfOpenFiles](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	20 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [MaxNoOfSavedMessages](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	25
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 600
Restart Type	N

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [NoOfFragmentLogFiles](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	16
Range	3 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log

files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A **REDO** log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the **FragmentLogFileSize** parameter. In scenarios requiring a great many updates, the value for **NoOfFragmentLogFiles** may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (**Out of log file space temporarily**). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using **--initial**. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using **--initial** when starting each data node).

- **RecoveryWork**

Version (or later)	NDB 8.0.13
Type or units	integer
Default	60
Range	25 - 100
Restart Type	N

Percentage of storage overhead for LCP files. This parameter has an effect only when **EnablePartialLcp** is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for **RecoveryWork** means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting **RecoveryWork** to 60 means that the total size of an LCP is roughly $1 + 0.6 = 1.6$ times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at $1 + (1 / \text{RecoveryWork})$ times the rate of data changes during checkpoints—thus, when **RecoveryWork** = 60, it is necessary to write at approximately $1 + (1 / 0.6)$

= 2.67 times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- `InsertRecoveryWork`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	40
Range	0 - 70
Restart Type	N

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- `EnableRedoControl`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	...
Restart Type	N

Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

The parameter currently defaults to `false` (disabled) due to the fact that NDB is still deployed widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs). In settings such as these, the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated,

increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained IO subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors.

Metadata objects. The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	1000
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (*`greatest_number_of_attributes`*) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be $6 * \text{greatest_number_of_attributes} = 600$.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	128
Range	8 - 20320

Restart Type	N
--------------	---

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	128
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfUniqueHashIndexes`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	N
------------------------------	---

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the [USING HASH](#) option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed $2^{32} - 2$ (4294967294).

- [MaxNoOfTriggers](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	768
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfSubscriptions](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Each [NDB](#) table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for [MaxNoOfSubscriptions](#) is 0, which is treated as equal to [MaxNoOfTables](#). Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	N
--------------	---

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as $2 * \text{MaxNoOfTables}$; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to $3 * \text{MaxNoOfTables}$.

For more information, see [Section 22.6, “NDB Cluster Replication”](#).

- `MaxNoOfConcurrentSubOperations`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	256
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `CompressedLCP`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CrashOnCorruptedTuple`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	S

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- [Diskless](#)

Version (or later)	NDB 8.0.13
Type or units	true false (1 0)
Default	false
Range	true, false
Restart Type	IS

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run [ndbd](#) on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

[Diskless](#) is disabled by default.

- [LateAlloc](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	1
Range	0 - 1
Restart Type	N

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	0
Range	0 - 2

Restart Type

N

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

**Note**

In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats `true` or `false` for the value of this parameter as an error.

**Important**

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `ODirect`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false

Restart Type	N
--------------	---

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `ODirectSyncFlag`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

- `RestartOnErrorInsert`

Version (or later)	NDB 8.0.13
Type or units	error code
Default	2
Range	0 - 4
Restart Type	N

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `StopOnError`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	1
Range	0, 1

Restart Type	N
------------------------------	---

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and [StopOnError](#) is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when [StopOnError](#) equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- [UseShm](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of [\[ndbd\]](#) parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFFFF)
Restart Type	N

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- [TimeBetweenWatchDogCheckInitial](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFFFF)

Restart Type	N
------------------------------	---

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- [StartPartialTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	30000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If [StartPartitionedTimeout](#) is set to 0, the cluster waits indefinitely ($2^{32}-1$ ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

- [StartFailureTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a

data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [StartNoNodeGroupTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	15000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 22.5.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

- [HeartbeatIntervalDbDb](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	5000
Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	N

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- [HeartbeatIntervalDbApi](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1500
Range	100 - 4294967039 (0xFFFFFFFF)

Restart Type	N
------------------------------	---

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	0
Range	0 - 65535
Restart Type	S

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers [host1](#) and [host2](#), and that these data nodes make up 2 node groups, as shown in the following table:

Table 22.9 Four data nodes A, B, C, D running on two host computers [host1](#), [host2](#); each data node belongs to one of two node groups.

Node Group	Nodes Running on host1	Nodes Running on host2
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The [HeartbeatOrder](#) configuration parameter makes the order of heartbeat transmission user-configurable. The default value for [HeartbeatOrder](#) is zero; allowing the default value to be

used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Table 22.10 `HeartbeatOrder` values to force a heartbeat transition order of A->B->D->C->A.

Node	<code>HeartbeatOrder</code> Value
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- `TimeBetweenLocalCheckpoints`

Version (or later)	NDB 8.0.13
Type or units	number of 4-byte words, as a base-2 logarithm
Default	20
Range	0 - 31

Restart Type	N
------------------------------	---

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting [TimeBetweenLocalCheckpoints](#) to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	2000
Range	20 - 32000
Restart Type	N

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

In NDB 8.0.19 and later, it is recommended when using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that [MaxDiskDataLatency](#) is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenGlobalCheckpointsTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	120000
Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- [TimeBetweenEpochs](#)

Version (or later)	NDB 8.0.13
--------------------	------------

Type or units	milliseconds
Default	100
Range	0 - 32000
Restart Type	N

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 256000
Restart Type	N

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

Version (or later)	NDB 8.0.13
Type or units	epochs
Default	100
Range	0 - 100000
Restart Type	N

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	26214400
Range	26214400 (0x01900000) - 4294967039 (0xFFFFFFFF)
Restart Type	N

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1000
Range	1000 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	4294967039 (0xFFFFFFFF)
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1200
Range	50 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can

spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	4M
Range	32K - 4294967039 (0xFFFFFFFF)
Restart Type	N

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	20M
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	50M
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	200M
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	10M
Range	1M - 1024G
Restart Type	S

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters [MaxDiskWriteSpeed](#), [MaxDiskWriteSpeedOwnRestart](#), and [MaxDiskWriteSpeedOtherNodeRestart](#). See the descriptions of these parameters for more information.

- [ArbitrationTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	7500

Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

Version (or later)	NDB 8.0.13
Type or units	enumeration
Default	Default
Range	Default, Disabled, WaitExternal
Restart Type	N

The [Arbitration](#) parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the [ArbitrationRank](#) settings for the management and API nodes. This is the default value.
- **Disabled.** Setting [Arbitration](#) = [Disabled](#) in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting [ArbitrationRank](#) to 0 on all management and API nodes. When [Arbitration](#) is set in this way, any [ArbitrationRank](#) settings are ignored.
- **WaitExternal.** The [Arbitration](#) parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by [ArbitrationTimeout](#) has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting [Arbitration](#) = [WaitExternal](#) in the `[ndbd default]` section of the `config.ini` file. For best results with the [WaitExternal](#) setting, it is recommended that [ArbitrationTimeout](#) be 2 times as long as the interval required by the external cluster manager to perform arbitration.

Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when [Arbitration](#) is set to different values for individual data nodes.

- [RestartSubscriberConnectTimeout](#)

Version (or later)	NDB 8.0.13
Type or units	ms
Default	12000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	S

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set [RestartSubscriberConnectTimeout](#) to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

Buffering and logging. Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

- [UndoIndexBuffer](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	2M
Range	1M - 4294967039 (0xFFFFFFFF)
Restart Type	N

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [UndoDataBuffer](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	16M
Range	1M - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 ([Data UNDO buffers overloaded](#)).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [RedoBuffer](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32M
Range	1M - 4294967039 (0xFFFFFFFF)
Restart Type	N

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 ([REDO log buffers overloaded](#)). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

[ndbmt](#) allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an [ndbmt](#) data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of $4 * \text{RedoBuffer}$ bytes.

- [EventLogBufferSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	8192
Range	0 - 64K
Restart Type	S

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to [stdout](#). For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to [stdout](#); setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	1
Range	0 - 15
Restart Type	N

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- `LogLevelCheckpoint`

Version (or later)	NDB 8.0.13
Type or units	log level
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

Version (or later)	NDB 8.0.13
Type or units	level
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of [DataMemory](#), as set in the [config.ini](#) file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the [\[ndbd default\]](#) section of [config.ini](#), and can also be set or overridden for individual data nodes in the corresponding [\[ndbd\]](#) sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 22.5.3.2, “NDB Cluster Log Events”](#).

- [StartupStatusReportFrequency](#)

Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When a data node is started with the [--initial](#), it initializes the redo log file during Start Phase 4 (see [Section 22.5.4, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for [NoOfFragmentLogFiles](#), [FragmentLogFileSize](#), or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the [StartupStatusReportFrequency](#) configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
```

```
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- `DictTrace`

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	undefined
Range	0 - 100
Restart Type	N

It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional `DBDICT` debugging output.

- `WatchdogImmediateKill`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

Backup parameters. The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	512K - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	Yes (in NDB 7.6)

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, 3743

the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- [BackupDiskWriteSpeedPct](#)

Version (or later)	NDB 8.0.13
Type or units	percent
Default	50
Range	0 - 90
Restart Type	N

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by [MinDiskWriteSpeed](#) and [MaxDiskWriteSpeed](#). Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the [BackupDiskWriteSpeedPct](#) configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- [BackupLogBufferSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	2M - 4294967039 (0xFFFFFFFF)
Restart Type	N

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 22.5.8.3, “Configuration for NDB Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32M
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	Yes (in NDB 7.4)

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- [BackupReportFrequency](#)

Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256K
Range	32K - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	Yes (in NDB 7.6)

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	1M
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	Yes (in NDB 7.6)

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

- [CompressedBackup](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- [RequireEncryptedBackup](#)

Version (or later)	NDB 8.0.22
Type or units	integer
Default	0
Range	0 - 1
Restart Type	N
Added	NDB 8.0.22

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see [Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).

Added in NDB 8.0.22.

Note

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

Additional requirements. When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.

- [BuildIndexThreads](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	128
Range	0 - 128
Restart Type	S

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- [LockExecuteThreadToCPU](#)

Version (or later)	NDB 8.0.13
Type or units	set of CPU IDs
Default	0
Range	...
Restart Type	N

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- [LockMaintThreadsToCPU](#)

Version (or later)	NDB 8.0.13
Type or units	CPU ID
Default	0
Range	0 - 64K

Restart Type	N
--------------	---

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- `Numa`

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	1
Range	...
Restart Type	N

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmt`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmt`; this is because `ndbmt` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

- `RealtimeScheduler`

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`

Version (or later)	NDB 8.0.13
Type or units	µs

Default	50
Range	0 - 11000
Restart Type	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 μ sec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- [SchedulerResponsiveness](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	5
Range	0 - 10
Restart Type	S

Set the balance in the [NDB](#) scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- [SchedulerSpinTimer](#)

Version (or later)	NDB 8.0.13
Type or units	μ s
Default	0
Range	0 - 500
Restart Type	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

Starting with NDB 8.0.20, if [SpinMethod](#) is set, any setting for this parameter is ignored.

- [SpinMethod](#)

Version (or later)	NDB 8.0.20
Type or units	enumeration
Default	StaticSpinning
Range	CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning
Restart Type	N

Added	NDB 8.0.20
-------	------------

This parameter provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. **StaticSpinning** (default): Sets `EnableAdaptiveSpinning` to `false` and `SchedulerSpinTimer` to 0. (`SetAllowedSpinOverhead` is not relevant in this case.)
2. **CostBasedSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 100, and `SetAllowedSpinOverhead` to 200.
3. **LatencyOptimisedSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 200, and `SetAllowedSpinOverhead` to 1000.
4. **DatabaseMachineSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 500, and `SetAllowedSpinOverhead` to 10000. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by `SpinMethod` are described in the following list:

- **SchedulerSpinTimer**: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by `SpinMethod` overrides any value set in the `config.ini` file.
- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the `ndb_mgm` management client.
- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by `SpinMethod` should be satisfactory, but if it is necessary to change it directly, you can use `DUMP 104002 overhead` to do so, where `overhead` is a value ranging from 0 to 10000, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to 0 in all situations, and values for `SpinMethod` other than `StaticSpinning` are ignored.

- **TwoPassInitialNodeRestartCopy**

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	N

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

Multi-Threading Configuration Parameters (ndbmttd). `ndbmttd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter.

A second method, makes it possible to set up more complex rules for `ndbmt` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

Note

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more information, see [Section 22.5.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#), as well as [Section 22.4.23.2, “Restoring from a backup taken in parallel”](#).

- `MaxNoOfExecutionThreads`

Version (or later)	NDB 8.0.13
Type or units	integer
Default	2
Range	2 - 72
Restart Type	IS

This parameter directly controls the number of execution threads used by `ndbmt`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmt` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

Table 22.11 `MaxNoOfExecutionThreads` values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

<code>MaxNoOfExecutionThreads</code> Value	LDM Threads	TC Threads	Send Threads	Receive Threads
0 .. 3	1	0	0	1
4 .. 6	2	0	0	1
7 .. 8	4	0	0	1
9	4	2	0	1
10	4	2	1	1
11	4	3	1	1
12	6	2	1	1
13	6	3	1	1
14	6	3	1	2
15	6	3	2	2
16	8	3	1	2
17	8	4	1	2
18	8	4	2	2
19	8	5	2	2
20	10	4	2	2
21	10	5	2	2
22	10	5	2	3

66	32	17	7	8
67	32	17	8	8
68	32	18	8	8
69	32	18	8	9
70	32	19	8	9
71	32	20	8	9
72	32	20	8	10

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtl`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmtl`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See [Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see [ThreadConfig](#)).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use [ThreadConfig](#) instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread

- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (*N*) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is *not* required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- `NoOfFragmentLogParts`

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	4
Range	4, 6, 8, 10, 12, 16, 20, 24, 32
Restart Type	IN

Set the number of log file groups for redo logs belonging to this `ndbmtid`. The value of this parameter should be set equal to the number of LDM threads used by `ndbmtid` as determined by the setting for `MaxNoOfExecutionThreads`. A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of `MaxNoOfExecutionThreads` for more information.

- `ThreadConfig`

Version (or later)	NDB 8.0.13
Type or units	string
Default	"
Range	...
Restart Type	IS

This parameter is used with `ndbmtid` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type={param[,param[,...]]}

type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld

param := count=number
        | cpubind=cpu_list
        | cpuset=cpu_list
        | spintime=number
        | realtime={0|1}
        | nosend={0|1}
        | thread_prio={0..10}
        | cpubind_exclusive=cpu_list
```

```
| cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A *param* (parameter) specifies any or all of the following information:

- The number of threads of the given type (*count*).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of *cpubind* or *cpuset*. *cpubind* causes each thread to be bound (nonexclusively) to a CPU in the set; *cpuset* means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. *cpubind_exclusive* causes each thread to be bound exclusively to a CPU in the set; *cpuset_exclusive* means that each thread is bound exclusively to the set of CPUs specified.

Only one of *cpubind*, *cpuset*, *cpubind_exclusive*, or *cpuset_exclusive* can be provided in a single configuration.

- *spintime* determines the wait time in microseconds the thread spins before going to sleep.

The default value for *spintime* is the value of the *SchedulerSpinTimer* data node configuration parameter.

spintime does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- *realtime* can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that *thread_prio* cannot be set.

The *realtime* parameter is set by default to the value of the *RealtimeScheduler* data node configuration parameter.

realtime cannot be set for offline index build threads.

- By setting *nosend* to 1, you can prevent a *main*, *ldm*, *rep*, or *tc* thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.
- *thread_prio* is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

thread_prio settings and effects by platform. The implementation of *thread_prio* differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD:* We map *thread_prio* to a value to be supplied to the *nice* system call. Since a lower niceness value for a process indicates a higher process priority, increasing *thread_prio* has the effect of lowering the *nice* value.

Table 22.12 Mapping of thread_prio to nice values on Linux and FreeBSD

<i>thread_prio</i> value	<i>nice</i> value
0	19
1	16

<code>thread_prio</code> value	<code>nice</code> value
2	12
3	8
4	4
5	0
6	-4
7	-8
8	-12
9	-16
10	-20

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

- *Solaris*: Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

Table 22.13 Mapping of `thread_prio` to FX priority on Solaris

<code>thread_prio</code> value	Solaris FX priority
0	15
1	20
2	25
3	30
4	35
5	40
6	45
7	50
8	55
9	59
10	60

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- *Windows*: We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

Table 22.14 Mapping of `thread_prio` to Windows thread priority

<code>thread_prio</code> value	Windows thread priority
0 - 1	<code>THREAD_PRIORITY_LOWEST</code>
2 - 3	<code>THREAD_PRIORITY_BELOW_NORMAL</code>
4 - 5	<code>THREAD_PRIORITY_NORMAL</code>
6 - 7	<code>THREAD_PRIORITY_ABOVE_NORMAL</code>

<code>thread_prio</code> value	Windows thread priority
8 - 10	<code>THREAD_PRIORITY_HIGHEST</code>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- `ldm`: Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations, this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using `MaxNoOfExecutionThreads`.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0 - 32

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. This is always handled by a single dedicated thread.

Range: 1 only.

- `recv`: Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range: 1 - 16

- `send`: Send thread (`CMVMI` kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

In NDB 8.0.20 and later, due to changes in the multithreading implementation, using many send threads can have an adverse effect on scalability.

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range: 0 - 16

- `rep`: Replication thread (`SUMA` kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

Range: 1 only.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

- `watchdog`: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

- `idxbld`: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*N*) provided the following two conditions are met:
 - a. Each LDM thread handles a maximum of 8 fragments, and
 - b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

`NDB` can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.

ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.

Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}

ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of [ThreadConfig](#) offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting [IRQBALANCE_BANNED_CPUS](#) in [/etc/sysconfig/irqbalance](#) to [0xFFFFF0](#), and by using the [isolcpus](#) boot option in [grub.conf](#). For specific information, see your operating system or platform documentation.

Disk Data Configuration Parameters. Configuration parameters affecting Disk Data behavior include the following:

- [DiskPageBufferEntries](#)

Version (or later)	NDB 8.0.13
Type or units	32K pages
Default	10
Range	1 - 1000
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	bytes
Default	64MB
Range	4MB - 16TB
Restart Type	N

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in [DiskPageBufferMemory](#). The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- [DiskPageBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	64M
Range	4M - 1T
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	bytes
Default	64M
Range	4M - 16T
Restart Type	N

This determines the amount of space used for caching pages on disk, and is set in the [\[ndbd\]](#) or [\[ndbd default\]](#) section of the [config.ini](#) file.

Note

Previously, this parameter was specified as a number of 32 KB pages. Beginning with NDB 8.0.19, it is specified as a number of bytes.

If the value for [DiskPageBufferMemory](#) is set too low in conjunction with using more than the default number of LDM threads in [ThreadConfig](#) (for example [{ldm=6...}](#)), problems can arise

when trying to add a large (for example 500G) data file to a disk-based [NDB](#) table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase [DiskPageBufferMemory](#), or add smaller tablespace files. You may also need to adjust [DiskPageBufferEntries](#).

You can query the [ndbinfo.diskpagebuffer](#) table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 22.5.14.20, “The ndbinfo diskpagebuffer Table”](#), for more information.

- [SharedGlobalMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	128M
Range	0 - 64T
Restart Type	N

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, [UNDO](#) files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the [UNDO_BUFFER_SIZE](#) option used with [CREATE LOGFILE GROUP](#) and [ALTER LOGFILE GROUP](#) statements, including any default value implied for this options by the setting of the [InitialLogFileGroup](#) data node configuration parameter. [SharedGlobalMemory](#) can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `128M`.

- [DiskIOThreadPool](#)

Version (or later)	NDB 8.0.13
Type or units	threads
Default	2
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter determines the number of unbound threads used for Disk Data file access. Before [DiskIOThreadPool](#) was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With [DiskIOThreadPool](#), you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with

some or all of these sets of files, then you can (and should) set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

In NDB 8.0.19 and later, you should also disable `DiskDataUsingSameDisk` when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

Decreasing `TimeBetweenGlobalCheckpoints` is also recommended when using solid-state disk drives, in particular those using NVMe. See also [Disk Data latency parameters](#).

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.
- `FileSystemPathDD`

Version (or later)	NDB 8.0.13
Type or units	filename
Default	FileSystemPath
Range	...
Restart Type	IN

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

Version (or later)	NDB 8.0.13
Type or units	filename
Default	FileSystemPathDD
Range	...
Restart Type	IN

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles`

is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

Version (or later)	NDB 8.0.13
Type or units	filename
Default	FileSystemPathDD
Range	...
Restart Type	IN

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- `InitialLogFileGroup`

Version (or later)	NDB 8.0.13
Type or units	string
Default	[see documentation]
Range	...
Restart Type	S

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
file-specification-list:
    file-specification[; file-specification[; ...]]
file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`,

`FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

Version (or later)	NDB 8.0.13
Type or units	string
Default	[see documentation]
Range	...
Restart Type	S

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogFileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogFileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
```

```

EXTENT_SIZE 8M
INITIAL_SIZE 2G
ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;

```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.

- [MaxDiskDataLatency](#)

Version (or later)	NDB 8.0.19
Type or units	ms
Default	0
Range	0 - 8000
Restart Type	N
Added	NDB 8.0.19

This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, [NDB](#) begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use `0` to disable the latency check.

- [DiskDataUsingSameDisk](#)

Version (or later)	NDB 8.0.19
Type or units	boolean
Default	true
Range	...
Restart Type	N
Added	NDB 8.0.19

Set this parameter to `false` if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When [DiskDataUsingSameDisk](#) is `true`, [NDB](#) decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

Disk Data and GCP Stop errors. Errors encountered when using Disk Data tables such as [Node nodeid killed this node because GCP stop was detected](#) (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of [TimeBetweenGlobalCheckpoints](#) tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for [DiskPageBufferMemory](#) as explained previously, it is also very important that the [DiskIOThreadPool](#) configuration parameter be set correctly; having [DiskIOThreadPool](#) set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the [TimeBetweenEpochsTimeout](#) data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation. Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The [TotalSendBufferMemory](#) and [OverLoadLimit](#) data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as [SendBufferMemory](#)), see [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [ExtraSendBufferMemory](#)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [TotalSendBufferMemory](#)

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

See also [Section 22.5.7, “Adding NDB Cluster Data Nodes Online”](#).

Redo log over-commit handling. It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by [DefaultOperationRedoProblemAction](#). The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- [RedoOverCommitCounter](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	3
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	numeric
Default	3
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When [RedoOverCommitLimit](#) is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node

where any of these transactions originated handles the operations making up those transactions according to its value for [DefaultOperationRedoProblemAction](#) (by either queuing the operations to be re-tried, or aborting them).

- [RedoOverCommitLimit](#)

Version (or later)	NDB 8.0.13
Type or units	seconds
Default	20
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Version (or later)	NDB 8.0.19
Type or units	seconds
Default	20
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than [RedoOverCommitLimit](#), is kept and compared with [RedoOverCommitCounter](#), and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its [DefaultOperationRedoProblemAction](#) setting (it either queues the operations to be re-tried, or aborts them).

Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the [MaxStartFailRetries](#) and [StartFailRetryDelay](#) data node configuration parameters.

[MaxStartFailRetries](#) limits the total number of retries made before giving up on starting the data node, [StartFailRetryDelay](#) sets the number of seconds between retry attempts. These parameters are listed here:

- [StartFailRetryDelay](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and [MaxStartFailRetries](#) are ignored unless [StopOnError](#) is equal to 0.

- [MaxStartFailRetries](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	3
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	N
------------------------------	---

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and [StartFailRetryDelay](#) are ignored unless [StopOnError](#) is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- [IndexStatAutoCreate](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0, 1
Restart Type	S

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.

- [IndexStatAutoUpdate](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0, 1
Restart Type	S

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the [IndexStatTriggerPct](#) and [IndexStatTriggerScale](#) options.

- [IndexStatSaveSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32768
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

Maximum space in bytes allowed for the saved statistics of any given index in the [NDB](#) system tables and in the [mysqld](#) memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by [IndexStatSaveScale](#).

The size specified by [IndexStatSaveSize](#) is scaled by the value of [IndexStatTriggerPct](#) for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting [IndexStatTriggerPct](#) equal to 0 disables the scaling effect.

- [IndexStatSaveScale](#)

Version (or later)	NDB 8.0.13
--------------------	------------

Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

The size specified by [IndexStatSaveSize](#) is scaled by the value of [IndexStatTriggerPct](#) for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting [IndexStatTriggerPct](#) equal to 0 disables the scaling effect.

- [IndexStatTriggerPct](#)

Version (or later)	NDB 8.0.13
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

Percentage change in updates that triggers an index statistics update. The value is scaled by [IndexStatTriggerScale](#). You can disable this trigger altogether by setting [IndexStatTriggerPct](#) to 0.

- [IndexStatTriggerScale](#)

Version (or later)	NDB 8.0.13
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

Scale [IndexStatTriggerPct](#) by this amount times 0.01 for a large index. A value of 0 disables scaling.

- [IndexStatUpdateDelay](#)

Version (or later)	NDB 8.0.13
Type or units	seconds
Default	60
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	IN

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.15 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)

Symbol	Restart Type	Description
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

Note

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

• `Id`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

• `ConnectionMap`

Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	N

Specifies which data nodes to connect.

• `NodeId`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

The [NodeId](#) is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

[NodeId](#) is the preferred parameter name to use when identifying management nodes. An alias, [Id](#), was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- [ExecuteOnComputer](#)

Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S
Deprecated	Yes (in NDB 7.5)

This refers to the [Id](#) set for one of the computers (hosts) defined in a [\[computer\]](#) section of the configuration file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the [HostName](#) parameter instead.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and [HostName](#) is not sufficient for distinguishing among processes. Intended for use in testing.

- [HostName](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...

Restart Type	N
------------------------------	---

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or [ExecuteOnComputer](#) is required.

If no [HostName](#) or [ExecuteOnComputer](#) is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where [localhost](#) is assumed for [HostName](#) unless otherwise specified.*

- [LocationDomainId](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns an SQL or other API node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [ArbitrationRank](#)

Version (or later)	NDB 8.0.13
Type or units	0-2
Default	0
Range	0 - 2
Restart Type	N

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the

[Arbitration](#) parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- [ArbitrationDelay](#)

Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16K
Range	1K - 1M
Restart Type	N

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- [BatchSize](#)

Version (or later)	NDB 8.0.13
Type or units	records
Default	256
Range	1 - 992
Restart Type	N

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- [ExtraSendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	N
------------------------------	---

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [HeartbeatThreadPriority](#)

Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	S

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
    {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256K
Range	32K - 16M
Restart Type	N

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	N

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

Note

This parameter can be overridden using the NDB API. For more information, see [Ndb_cluster_connection::set_auto_reconnect\(\)](#), and [Ndb_cluster_connection::get_auto_reconnect\(\)](#).

- [DefaultOperationRedoProblemAction](#)

Version (or later)	NDB 8.0.13
Type or units	enumeration
Default	QUEUE
Range	ABORT, QUEUE
Restart Type	S

This parameter (along with [RedoOverCommitLimit](#) and [RedoOverCommitCounter](#)) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of [DefaultOperationRedoProblemAction](#), listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
 - **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when **P_TAIL_PROBLEM** errors occur.
- [DefaultHashMapSize](#)

Version (or later)	NDB 8.0.13
Type or units	buckets
Default	3840
Range	0 - 3840

Restart Type	N
------------------------------	---

The size of the table hash maps used by [NDB](#) is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 22.16 DefaultHashMapSize parameter values

Value	Description / Effect
0	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
240	Old default hash map size
3840	Hash map size used by default in NDB 8.0

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- [Wan](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Use WAN TCP setting as default.

- [ConnectBackoffMaxTime](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [ConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

- [StartConnectBackoffMaxTime](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [StartConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

API Node Debugging Parameters. You can use the [ApiVerbose](#) configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds [DBDICT](#) debugging output as well. (Bug #20638450) See also [DUMP 1229](#).

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using [SHOW STATUS](#) in the [mysql](#) client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 198.51.100.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see [NDB Cluster Status Variables](#).

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [\[mysqld\]](#) or [\[api\]](#) sections to the [config.ini](#) file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.17 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.8 Defining the System

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNode` are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- `ConfigGenerationNumber`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Configuration generation number. This parameter is currently unused.

- `Name`

Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	N

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- `PrimaryMGMNode`

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

Node ID of the primary management node. This parameter is currently unused.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.18 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see [Section 5.1, “The MySQL Server”](#).

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 22.3, “Configuration of NDB Cluster”](#).

MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.7, “Server Command Options”](#).

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#). For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 22.4, “NDB Cluster Programs”](#).

- `--ndbcluster`

Command-Line Format	<code>--ndbcluster[=value]</code>
Disabled by	<code>skip-ndbcluster</code>
Type	Enumeration
Default Value	<code>ON</code>
Valid Values	<code>OFF</code> <code>FORCE</code>

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

Command-Line Format	<code>--ndb-allow-copying-alter-table[={OFF ON}]</code>
---------------------	---

System Variable	<code>ndb_allow_copying_alter_table</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

Command-Line Format	<code>--ndb-batch-size</code>
System Variable	<code>ndb_batch_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>32768</code>
Minimum Value	<code>0</code>
Maximum Value	<code>31536000</code>

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

Command-Line Format	<code>--ndb-cluster-connection-pool</code>
System Variable	<code>ndb_cluster_connection_pool</code>
System Variable	<code>ndb_cluster_connection_pool</code>
Scope	Global
Scope	Global
Dynamic	No
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>1</code>
Minimum Value	<code>1</code>
Maximum Value	<code>63</code>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

Command-Line Format	<code>--ndb-cluster-connection-pool-nodeids</code>
System Variable	<code>ndb_cluster_connection_pool_nodeids</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=bytes`

Command-Line Format	<code>--ndb-blob-read-batch-bytes</code>
System Variable	<code>ndb_blob_read_batch_bytes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	65536
Minimum Value	0
Maximum Value	4294967295

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

Command-Line Format	<code>--ndb-blob-write-batch-bytes</code>
System Variable	<code>ndb_blob_write_batch_bytes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	65536
Minimum Value	0
Maximum Value	4294967295

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` write batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=connection_string`

Command-Line Format	<code>--ndb-connectstring</code>
Type	String

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), for syntax.

- `--ndb-default-column-format={FIXED|DYNAMIC}`

Command-Line Format	<code>--ndb-default-column-format={FIXED DYNAMIC}</code>
System Variable	<code>ndb_default_column_format</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>FIXED</code>
Valid Values	<code>FIXED</code> <code>DYNAMIC</code>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 13.1.20, “CREATE TABLE Statement”](#)). The default is `FIXED`.

- `--ndb-deferred-constraints=[0|1]`

Command-Line Format	<code>--ndb-deferred-constraints</code>
---------------------	---

System Variable	<code>ndb_deferred_constraints</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-schema-dist-timeout=#`

Command-Line Format	<code>--ndb-schema-dist-timeout=#</code>
Introduced	8.0.17-ndb-8.0.17
System Variable	<code>ndb_schema_dist_timeout</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	120
Minimum Value	5
Maximum Value	1200
Unit	seconds

Specifies the maximum time in seconds that this `mysqld` waits for a schema operation to complete before marking it as having timed out.

- `--ndb-distribution=[KEYHASH|LINHASH]`

Command-Line Format	<code>--ndb-distribution={KEYHASH LINHASH}</code>
System Variable	<code>ndb_distribution</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	KEYHASH
Valid Values	LINHASH KEYHASH

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-log-apply-status`

Command-Line Format	<code>--ndb-log-apply-status[={OFF ON}]</code>
System Variable	<code>ndb_log_apply_status</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

Command-Line Format	<code>--ndb-log-empty-epochs[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_epochs</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

Command-Line Format	<code>--ndb-log-empty-update[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_update</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Causes updates that produced no changes to be written to the [ndb_apply_status](#) and [ndb_binlog_index](#) tables, when [log_slave_updates](#) is enabled.

By default this option is disabled ([OFF](#)). Disabling [--ndb-log-empty-update](#) causes updates with no changes not to be written to the binary log.

- [--ndb-log-exclusive-reads={0|1}](#)

Command-Line Format	--ndb-log-exclusive-reads[={OFF ON}]
System Variable	ndb_log_exclusive_reads
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	0

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the [ndb_log_exclusive_reads](#) system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see [Read conflict detection and resolution](#).

- [--ndb-log-fail-terminate](#)

Command-Line Format	--ndb-log-fail-terminate
Introduced	8.0.21-ndb-8.0.21
System Variable	ndb_log_fail_terminate
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	FALSE

When this option is specified, and complete logging of all found row events is not possible, the [mysqld](#) process is terminated.

- [--ndb-log-orig](#)

Command-Line Format	--ndb-log-orig[={OFF ON}]
System Variable	ndb_log_orig
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Log the originating server ID and epoch in the `ndb_binlog_index` table.

Note

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see [Section 22.6.4, “NDB Cluster Replication Schema and Tables”](#).

- `--ndb-log-transaction-id`

Command-Line Format	<code>--ndb-log-transaction-id[={OFF ON}]</code>
System Variable	<code>ndb_log_transaction_id</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see [NDB \\$EPOCH_TRANS\(\)](#)). For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` when you use `--ndb-log-transaction-id`.

- `--ndb-log-update-minimal`

Command-Line Format	<code>--ndb-log-update-minimal[={OFF ON}]</code>
System Variable	<code>ndb_log_update_minimal</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than `NDB`.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	<code>--ndb-mgmd-host=host_name[:port_num]</code>
Type	String
Default Value	<code>localhost:1186</code>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Command-Line Format	<code>--ndb-nodeid=#</code>
Status Variable	<code>Ndb_cluster_node_id</code>
Scope	Global
Dynamic	No
Type	Integer
Minimum Value	1
Maximum Value	255
Maximum Value	63

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `--ndbinfo={ON|OFF|FORCE}`

Command-Line Format	<code>--ndbinfo[=value]</code> ($\geq 8.0.13$ -ndb-8.0.13)
Introduced	8.0.13-ndb-8.0.13
Type	Enumeration
Default Value	ON
Valid Values	OFF FORCE

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.

- `--ndb-optimization-delay=milliseconds`

Command-Line Format	<code>--ndb-optimization-delay=#</code>
System Variable	<code>ndb_optimization_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	100000

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

- `--ndb-transid-mysql-connection-map=state`

Command-Line Format	<code>--ndb-transid-mysql-connection-map[=state]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON OFF FORCE

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

Command-Line Format	<code>--ndb-wait-connected=#</code>
System Variable	<code>ndb_wait_connected</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	31536000

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- `--ndb-wait-setup=seconds`

Command-Line Format	<code>--ndb-wait-setup=#</code>
System Variable	<code>ndb_wait_setup</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Default Value	30
Default Value	15
Default Value	15

Minimum Value	0
Maximum Value	31536000

This variable shows the period of time that the MySQL server waits for the [NDB](#) storage engine to complete setup before timing out and treating [NDB](#) as unavailable. The time is specified in seconds. The default value is [30](#).

- [--skip-ndbcluster](#)

Command-Line Format	--skip-ndbcluster
---------------------	-----------------------------------

Disable the [NDBCLUSTER](#) storage engine. This is the default for binaries that were built with [NDBCLUSTER](#) storage engine support; the server allocates memory and other resources for this storage engine only if the [--ndbcluster](#) option is given explicitly. See [Section 22.3.1, “Quick Test Setup of NDB Cluster”](#), for an example.

NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the [NDB](#) storage engine. For system variables not specific to NDB Cluster, see [Section 5.1.8, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.9, “Using System Variables”](#).

- [ndb_autoincrement_prefetch_sz](#)

Command-Line Format	--ndb-autoincrement-prefetch-sz=#
System Variable	ndb_autoincrement_prefetch_sz
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (≥ 8.0.19-ndb-8.0.19)	512
Default Value (≤ 8.0.18-ndb-8.0.18)	1
Minimum Value	1
Maximum Value	65536

Determines the probability of gaps in an autoincremented column. Set it to [1](#) to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of [AUTO_INCREMENT](#) IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

Important

This variable does not affect inserts performed using [INSERT ... SELECT](#).

- [ndb_cache_check_time](#)

Command-Line Format	--ndb-cache-check-time=#
Deprecated	Yes
System Variable	ndb_cache_check_time

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

Note

The query cache `ndb_cache_check_time` are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- [ndb_clear_apply_status](#)

Command-Line Format	<code>--ndb-clear-apply-status[={OFF ON}]</code>
System Variable	ndb_clear_apply_status
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

By the default, executing `RESET SLAVE` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- [ndb_data_node_neighbour](#)

Command-Line Format	<code>--ndb-data-node-neighbour=#</code>
System Variable	ndb_data_node_neighbour
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	255

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that

the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See [Section 13.1.20.10, “Setting NDB_TABLE Options”](#), for further information.

Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- `ndb_dbg_check_shares`

Command-Line Format	<code>--ndb-dbg-check-shares=#</code>
Introduced	8.0.13-ndb-8.0.13
System Variable	<code>ndb_dbg_check_shares</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When set to 1, check that no shares are lingering. Available in debug builds only.

Added in NDB 8.0.13.

- `ndb_default_column_format`

Command-Line Format	<code>--ndb-default-column-format={FIXED DYNAMIC}</code>
System Variable	<code>ndb_default_column_format</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>FIXED</code>
Valid Values	<code>FIXED</code> <code>DYNAMIC</code>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 13.1.20, “CREATE TABLE Statement”](#)). The default is `FIXED`.

- `ndb_deferred_constraints`

Command-Line Format	<code>--ndb-deferred-constraints=#</code>
System Variable	<code>ndb_deferred_constraints</code>
Scope	Global, Session
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `ndb_distribution`

Command-Line Format	<code>--ndb-distribution={KEYHASH LINHASH}</code>
System Variable	<code>ndb_distribution</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	KEYHASH
Valid Values	LINHASH KEYHASH

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `ndb_eventbuffer_free_percent`

Command-Line Format	<code>--ndb-eventbuffer-free-percent=#</code>
System Variable	<code>ndb_eventbuffer_free_percent</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	1
Maximum Value	99

Sets the percentage of the maximum memory allocated to the event buffer (`ndb_eventbuffer_max_alloc`) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- `ndb_eventbuffer_max_alloc`

Command-Line Format	<code>--ndb-eventbuffer-max-alloc=#</code>
System Variable	<code>ndb_eventbuffer_max_alloc</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- `ndb_extra_logging`

Command-Line Format	<code>ndb_extra_logging=#</code>
System Variable	<code>ndb_extra_logging</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- `ndb_force_send`

Command-Line Format	<code>--ndb-force-send[={OFF ON}]</code>
System Variable	<code>ndb_force_send</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- `ndb_fully_replicated`

Command-Line Format	<code>--ndb-fully-replicated[={OFF ON}]</code>
System Variable	<code>ndb_fully_replicated</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 13.1.20.10, “Setting NDB_TABLE Options”](#), for syntax and other information.

- `ndb_index_stat_enable`

Command-Line Format	<code>--ndb-index-stat-enable[={OFF ON}]</code>
System Variable	<code>ndb_index_stat_enable</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Use NDB index statistics in query optimization. The default is ON.

- `ndb_index_stat_option`

Command-Line Format	<code>--ndb-index-stat-option=value</code>
System Variable	<code>ndb_index_stat_option</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M,cache_lowpct=90</code>

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

Table 22.19 `ndb_index_stat_option` options and values

Name	Description	Default/Units	Minimum/Maximum
<code>loop_enable</code>		1000 ms	0/4G
<code>loop_idle</code>	Time to sleep when idle	1000 ms	0/4G

Name	Description	Default/Units	Minimum/Maximum
<code>loop_busy</code>	Time to sleep when more work is waiting	100 ms	0/4G
<code>update_batch</code>		1	0/4G
<code>read_batch</code>		4	1/4G
<code>idle_batch</code>		32	1/4G
<code>check_batch</code>		8	1/4G
<code>check_delay</code>	How often to check for new statistics	10 m	1/4G
<code>delete_batch</code>		8	0/4G
<code>clean_delay</code>		1 m	0/4G
<code>error_batch</code>		4	1/4G
<code>error_delay</code>		1 m	1/4G
<code>evict_batch</code>		8	1/4G
<code>evict_delay</code>	Clean LRU cache, from read time	1 m	0/4G
<code>cache_limit</code>	Maximum amount of memory in bytes used for cached index statistics by this <code>mysqld</code> ; clean up the cache when this is exceeded.	32 M	0/4G
<code>cache_lowpct</code>		90	0/100
<code>zero_total</code>	Setting this to 1 resets all accumulating counters in <code>ndb_index_stat_status</code> to 0. This option value is also reset to 0 when this is done.	0	0/1

- `ndb_join_pushdown`

System Variable	<code>ndb_join_pushdown</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This variable controls whether joins on `NDB` tables are pushed down to the `NDB` kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with

a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

Conditions for NDB pushdown joins. In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type. This means that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

Previously, expressions such as `t1.a = t2.a + constant` could not be pushed down. This restriction is lifted in NDB 8.0.18 and later. The result of any operations on any column to be compared must yield the same type as the column itself.

Also beginning with NDB 8.0.18, expressions comparing columns from the same table can be pushed down. The columns (or the result of any operations on those columns) must be of exactly the same type, including the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the NDB storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
->      SELECT e.first_name, e.last_name, t.title, d.dept_name
->      FROM employees e
->      JOIN dept_emp de ON e.emp_no=de.emp_no
->      JOIN departments d ON d.dept_no=de.dept_no
->      JOIN titles t ON e.emp_no=t.emp_no\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: d
         type: ALL
possible_keys: PRIMARY
         key: NULL
        key_len: NULL
         ref: NULL
         rows: 9
      Extra: Parent of 4 pushed join@1
***** 2. row *****
```

```

        id: 1
        select_type: SIMPLE
        table: de
        type: ref
possible_keys: PRIMARY,emp_no,dept_no
        key: dept_no
        key_len: 4
        ref: employees.d.dept_no
        rows: 5305
        Extra: Child of 'd' in pushed join@1
***** 3. row *****
        id: 1
        select_type: SIMPLE
        table: e
        type: eq_ref
possible_keys: PRIMARY
        key: PRIMARY
        key_len: 4
        ref: employees.de.emp_no
        rows: 1
        Extra: Child of 'de' in pushed join@1
***** 4. row *****
        id: 1
        select_type: SIMPLE
        table: t
        type: ref
possible_keys: PRIMARY,emp_no
        key: emp_no
        key_len: 4
        ref: employees.de.emp_no
        rows: 19
        Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)

```

Note

If inner joined child tables are joined by [ref](#), and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables [Ndb_pushed_queries_defined](#), [Ndb_pushed_queries_dropped](#), [Ndb_pushed_queries_executed](#), and [Ndb_pushed_reads](#).
2. The counters in the [ndbinfo.counters](#) table that belong to the [DBSPJ](#) kernel block. See [Section 22.5.14.10, “The ndbinfo counters Table”](#), for information about these counters. See also [The DBSPJ Block](#), in the *NDB Cluster API Developer Guide*.

- [ndb_log_apply_status](#)

Command-Line Format	<code>--ndb-log-apply-status[={OFF ON}]</code>
System Variable	ndb_log_apply_status
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

Command-Line Format	<code>--ndb-log-bin[={OFF ON}]</code>
System Variable	<code>ndb_log_bin</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value (≥ 8.0.16-ndb-8.0.16)	<code>OFF</code>
Default Value (≤ 8.0.15-ndb-8.0.15)	<code>ON</code>

Causes updates to `NDB` tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0.16 and later, `ndb_log_bin` defaults to 0 (FALSE).

- `ndb_log_binlog_index`

Command-Line Format	<code>--ndb-log-binlog-index[={OFF ON}]</code>
System Variable	<code>ndb_log_binlog_index</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_empty_epochs`

Command-Line Format	<code>--ndb-log-empty-epochs[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_epochs</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `ndb_log_empty_update`

Command-Line Format	<code>--ndb-log-empty-update[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_update</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When this variable is set to [ON](#) (1), update transactions with no changes are written to the binary log, even when [log_slave_updates](#) is enabled.

- [ndb_log_exclusive_reads](#)

Command-Line Format	<code>--ndb-log-exclusive-reads[={OFF ON}]</code>
System Variable	ndb_log_exclusive_reads
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	0

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of [ndb_log_exclusive_reads](#) to 1. 0, which disables such locking, is the default.

For more information, see [Read conflict detection and resolution](#).

- [ndb_log_orig](#)

Command-Line Format	<code>--ndb-log-orig[={OFF ON}]</code>
System Variable	ndb_log_orig
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Shows whether the originating server ID and epoch are logged in the [ndb_binlog_index](#) table. Set using the `--ndb-log-orig` server option.

- [ndb_log_transaction_id](#)

System Variable	ndb_log_transaction_id
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This read-only, Boolean system variable shows whether a replica [mysqld](#) writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with [NDB](#)).

`$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 8.0.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_metadata_check`

Command-Line Format	<code>--ndb-metadata-check[={OFF ON}]</code>
Introduced	8.0.16-ndb-8.0.16
System Variable	<code>ndb_metadata_check</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Beginning with NDB 8.0.16, NDB uses a background thread to check for metadata changes each `ndb_metadata_check_interval` seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting `ndb_metadata_check` to `OFF`. The thread is enabled by default.

- `ndb_metadata_check_interval`

Command-Line Format	<code>--ndb-metadata-check-interval=#</code>
Introduced	8.0.16-ndb-8.0.16
System Variable	<code>ndb_metadata_check_interval</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>60</code>
Minimum Value	<code>0</code>
Maximum Value	<code>31536000</code>
Unit	<code>seconds</code>

In NDB 8.0.16 and later, NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of `ndb_metadata_check_interval`. To enable or disable the thread, use `ndb_metadata_check`.

- `ndb_metadata_sync`

Introduced	8.0.19-ndb-8.0.19
System Variable	<code>ndb_metadata_sync</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	false
---------------	-------

Setting this variable causes the change monitor thread to override any values set for `ndb_metadata_check` or `ndb_metadata_check_interval`, and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. `ndb_metadata_sync` is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for `ndb_metadata_check` and `ndb_metadata_check_interval`.

In NDB 8.0.22 and later, setting this variable to `true` causes the list of excluded objects to be cleared, and setting it to `false` clears the list of objects to be retried.

- `ndb_optimized_node_selection`

Command-Line Format	<code>--ndb-optimized-node-selection=#</code>
System Variable	<code>ndb_optimized_node_selection</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	3

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- `1`: Proximity to the SQL node is used to determine the transaction coordinator.
- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.
- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

Command-Line Format	<code>--ndb-read-backup[= { OFF ON }]</code>
System Variable	<code>ndb_read_backup</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value (≥ 8.0.19-ndb-8.0.19)	<code>ON</code>
Default Value (≤ 8.0.18-ndb-8.0.18)	<code>OFF</code>

Enable read from any replica for any `NDB` table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

To enable or disable read from any replica for an individual table, you can set the `NDB_TABLE` option `READ_BACKUP` for the table accordingly, in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 13.1.20.10, “Setting NDB_TABLE Options”](#), for more information.

- `ndb_recv_thread_activation_threshold`

Command-Line Format	<code>--ndb-recv-thread-activation-threshold=#</code>
System Variable	<code>ndb_recv_thread_activation_threshold</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0 (<code>MIN_ACTIVATION_THRESHOLD</code>)
Maximum Value	16 (<code>MAX_ACTIVATION_THRESHOLD</code>)

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- `ndb_recv_thread_cpu_mask`

Command-Line Format	<code>--ndb-recv-thread-cpu-mask=mask</code>
---------------------	--

System Variable	ndb_recv_thread_cpu_mask
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Bitmap
Default Value	[empty]

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting [ndb_recv_thread_cpu_mask](#) to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- [ndb_report_thresh_binlog_epoch_slip](#)

Command-Line Format	<code>--ndb-report-thresh-binlog-epoch-slip=#</code>
System Variable	ndb_report_thresh_binlog_epoch_slip
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	256

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with [BUFFERED_EPOCHS_OVER_THRESHOLD](#) supplied as the reason (see [Section 22.5.2.3, “Event Buffer Reporting in the Cluster Log”](#)). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the [Ndb::setEventBufferQueueEmptyEpoch\(\)](#) method from the NDB API.

- [ndb_report_thresh_binlog_mem_usage](#)

Command-Line Format	<code>--ndb-report-thresh-binlog-mem-usage=#</code>
System Variable	ndb_report_thresh_binlog_mem_usage
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	10

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- `ndb_row_checksum`

System Variable	<code>ndb_row_checksum</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	1

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- `ndb_schema_dist_lock_wait_timeout`

Command-Line Format	<code>--ndb-schema-dist-lock-wait-timeout=value</code>
Introduced	8.0.18-ndb-8.0.18
System Variable	<code>ndb_schema_dist_lock_wait_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	1200
Unit	seconds

Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- `ndb_schema_dist_timeout`

Command-Line Format	<code>--ndb-schema-dist-timeout=value</code>
Introduced	8.0.16-ndb-8.0.16
System Variable	<code>ndb_schema_dist_timeout</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	120
Minimum Value	5
Maximum Value	1200

Unit	seconds
------	---------

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- `ndb_schema_dist_upgrade_allowed`

Command-Line Format	<code>--ndb-schema-dist-upgrade-allowed=value</code>
Introduced	8.0.17-ndb-8.0.17
System Variable	<code>ndb_schema_dist_upgrade_allowed</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>true</code>

Allow upgrading of the schema distribution table when connecting to NDB. When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

Note

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- `ndb_show_foreign_key_mock_tables`

Command-Line Format	<code>--ndb-show-foreign-key-mock-tables[={OFF ON}]</code>
System Variable	<code>ndb_show_foreign_key_mock_tables</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Show the mock tables used by NDB to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- `ndb_slave_conflict_role`

Command-Line Format	<code>--ndb-slave-conflict-role=value</code>
System Variable	<code>ndb_slave_conflict_role</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NONE</code>
Valid Values	<code>NONE</code>

	PRIMARY
	SECONDARY
	PASS

Determine the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The replica SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_table_no_logging`

System Variable	<code>ndb_table_no_logging</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and `B` was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

System Variable	<code>ndb_table_temporary</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When set to `ON` or `1`, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

System Variable	<code>ndb_use_copying_alter_table</code>
Scope	Global, Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Forces NDB to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

System Variable	<code>ndb_use_exact_count</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`

Command-Line Format	<code>--ndb-use-transactions[={OFF ON}]</code>
System Variable	<code>ndb_use_transactions</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

You can disable NDB transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- `ndb_version`

System Variable	<code>ndb_version</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	

NDB engine version, as a composite integer.

- `ndb_version_string`

System Variable	<code>ndb_version_string</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	

NDB engine version in `ndb-x.y.z` format.

- `server_id_bits`

Command-Line Format	<code>--server-id-bits=#</code>
System Variable	<code>server_id_bits</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	7
Maximum Value	32

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to

mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- `slave_allow_batching`

Command-Line Format	<code>--slave-allow-batching[={OFF ON}]</code>
System Variable	<code>slave_allow_batching</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether or not batched updates are enabled on NDB Cluster replicas.

Setting this variable has an effect only when using replication with the `NDB` storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Section 22.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

- `transaction_allow_batching`

System Variable	<code>transaction_allow_batching</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

Important

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

System Variable	ndbinfo_database
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	ndbinfo

Shows the name used for the [NDB](#) information database; the default is [ndbinfo](#). This is a read-only variable whose value is determined at compile time; you can set it by starting the server using [--ndbinfo-database=name](#), which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- [ndbinfo_max_bytes](#)

Command-Line Format	--ndbinfo-max-bytes=#
System Variable	ndbinfo_max_bytes
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

Used in testing and debugging only.

- [ndbinfo_max_rows](#)

Command-Line Format	--ndbinfo-max-rows=#
System Variable	ndbinfo_max_rows
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10

Used in testing and debugging only.

- [ndbinfo_offline](#)

System Variable	ndbinfo_offline
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Place the [ndbinfo](#) database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in [NDB](#). No rows are returned from such tables (or views).

- [ndbinfo_show_hidden](#)

Command-Line Format	<code>--ndbinfo-show-hidden[={OFF ON}]</code>
System Variable	<code>ndbinfo_show_hidden</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix`

Command-Line Format	<code>--ndbinfo-table-prefix=name</code>
System Variable	<code>ndbinfo_table_prefix</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>ndb\$</code>

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

System Variable	<code>ndbinfo_version</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	

Shows the version of the `ndbinfo` engine in use; read-only.

NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see [Section 5.1.10, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_bytes_sent_count_session`

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_slave`

Amount of data (in bytes) sent to the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count`

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_session`

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_slave`

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count_injector`

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count`

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_session`

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_slave`

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_session`

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_slave`

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count`

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_session`

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_slave`

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count`

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_slave`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_session`

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_slave`

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count`

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_session`

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_slave`

The number of table scans that have been started by this replica, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_slave`

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_slave`

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count`

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_session`

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_slave`

The number of transactions committed by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count`

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_slave`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_session`

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_slave`

The number of transactions started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count`

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_session`

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_slave`

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_session`

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_slave`

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_slave`

The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_cluster_node_id`

If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_conflict_fn_max_del_win`

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_old`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2`

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the source designated as the primary since the last time it was restarted.

For more information, see [NDB\\$EPOCH2\(\)](#).

- `Ndb_conflict_fn_epoch_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [NDB\\$EPOCH2_TRANS\(\)](#).

- `Ndb_conflict_last_conflict_epoch`

The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_discard_count`

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_prepare_count`

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_refresh_op_count`

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_last_stable_epoch`

Number of rows found to be in conflict by a transactional conflict function

See [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_trans_row_conflict_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_detect_iter_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_conflict_commit_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_epoch_delete_delete_count`

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

Provides the number of round trips to the `NDB` kernel made by operations.

- `Ndb_last_commit_epoch_server`

The epoch most recently committed by `NDB`.

- `Ndb_last_commit_epoch_session`

The epoch most recently committed by this `NDB` client.

- `Ndb_metadata_detected_count`

The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

Added in NDB 8.0.16.

- `Ndb_metadata_excluded_count`

The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.

Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table`, `SELECT * FROM table`, or any other statement that would trigger table discovery.

Added in NDB 8.0.18. Prior to NDB 8.0.22, this variable was named `Ndb_metadata_blacklist_size`.

- `Ndb_metadata_synced_count`

The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

Added in NDB 8.0.18.

- `Ndb_number_of_data_nodes`

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

Note

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- `Ndb_pushed_queries_dropped`

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- `Ndb_pushed_queries_executed`

The number of joins successfully pushed down to `NDB` and executed there.

- `Ndb_pushed_reads`

The number of rows returned to `mysql` from the NDB kernel by joins that were pushed down.

Note

Executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- `Ndb_slave_max_replicated_epoch`

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_system_name`

If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- `Ndb_trans_hint_count_session`

The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints. Added in NDB 8.0.17.

22.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

Note

For an exception to this rule, see [Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `AllowUnresolvedHostNames`

Version (or later)	NDB 8.0.22
Type or units	boolean
Default	false
Range	true, false

Restart Type	N
Added	NDB 8.0.22

By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the global configuration file (usually named `config.ini`), in which case failure to resolve a host name is treated as a warning and `ndb_mgmd` startup continues uninterrupted.

- [Checksum](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [Group](#)

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- [HostName1](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- [NodeId2](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- [OverloadLimit](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- [PreSendChecksum](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [ReceiveBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	2M
Range	16K - 4294967039 (0xFFFFFFFF)
Restart Type	N

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- [SendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	2M
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	N

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false (debug builds: true)
Range	true, false
Restart Type	N

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to [Y](#), message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [TcpBind_INADDR_ANY](#)

Setting this parameter to [TRUE](#) or [1](#) binds [IP_ADDR_ANY](#) so that connections can be made from anywhere (for autogenerated connections). The default is [FALSE](#) ([0](#)).

- [TcpSpinTime](#)

Version (or later)	NDB 8.0.20
--------------------	------------

Type or units	µsec
Default	0
Range	0 - 2000
Restart Type	N
Added	NDB 8.0.20

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

- [TCP_MAXSEG_SIZE](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- [TCP_RCV_BUF_SIZE](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP_SND_BUF_SIZE](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.20 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)

Symbol	Restart Type	Description
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

22.3.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to `1`, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```

Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (`config.ini`) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in μ s to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.
- `Checksum`: Indicates that a checksum is included in each signal sent through the transporter.
- `PreSendChecksum`: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. `10.0.0.0`: The management server
2. `10.0.0.1`: A data node and an SQL node
3. `10.0.0.2`: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the `config.ini` file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1
```

```

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]

```

Parameters affecting all shared memory transporters are set in the `[shm default]` section; these can be overridden on a per-connection basis in one or more `[shm]` sections. Each such section must be associated with a given SHM connection using `NodeId1` and `NodeId2`; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using `HostName1` and `HostName2`, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the `[tcp default]` section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (`ShmSpinTime` parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

- [Checksum](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	N

This parameter is a boolean ([Y/N](#)) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [Group](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	35
Range	0 - 200
Restart Type	N

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- [HostName1](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeId2](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255

Restart Type	N
------------------------------	---

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeIdServer](#)

Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 63
Restart Type	N

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- [OverloadLimit](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), and [Section 22.5.14.47, “The ndbinfo transporters Table”](#), for more information.

- [PreSendChecksum](#)

Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [SendBufferMemory](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	2M
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	N

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- [SendSignalId](#)

Version (or later)	NDB 8.0.13
--------------------	------------

Type or units	boolean
Default	false
Range	true, false
Restart Type	N

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to [Y](#) causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [ShmKey](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If [UseShm](#) is enabled, the shared memory key is calculated automatically by [NDB](#).

- [ShmSize](#)

Version (or later)	NDB 8.0.13
Type or units	bytes
Default	4M
Range	64K - 4294967039 (0xFFFFFFFF)
Restart Type	N

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 4MB.

- [ShmSpinTime](#)

Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 2000
Restart Type	S

When receiving, the time to wait before sleeping, in microseconds.

- [SigNum](#)

Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	N
Deprecated	Yes (in NDB 7.6)

This parameter was used formerly to override operating system signal numbers; in NDB 8.0, it is no longer used, and any setting for it is ignored.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.21 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

22.3.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The NDB memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory ([DataMemory](#))
- Redo log buffers ([RedoBuffer](#))
- Job buffers
- Send buffers ([SendBufferMemory](#), [TotalSendBufferMemory](#), [ExtraSendBufferMemory](#), [ReservedSendBufferMemory](#))

- Disk Data record page cache ([DiskPageBufferMemory](#), [DiskPageBufferEntries](#))
- Transaction memory ([TransactionMemory](#))
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the [SharedGlobalMemory](#) configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the [DataMemory](#) configuration parameter, whose maximum is 16384 GB. [DataMemory](#) is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the [RedoBuffer](#) configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by [NDB](#), based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the [TotalSendBufferMemory](#) configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for [SendBufferMemory](#) for a data node connection is 2 MByte, this works out to 26 MB total.
2. To obtain the total reserved size for the send buffer, the value of the [ExtraSendBufferMemory](#) configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if [TotalSendBufferMemory](#) has been set, the send buffer size is [TotalSendBufferMemory](#) + [ExtraSendBufferMemory](#); otherwise, the size of the send buffer is equal to $([number\ of\ node\ connections] * SendBufferMemory) + ExtraSendBufferMemory$.

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the [DiskPageBufferMemory](#) configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the [DiskPageBufferEntries](#) configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by [NDB](#), or is set explicitly using the [TransactionMemory](#) configuration parameter introduced in NDB 8.0.19 (in previous releases, this value was always calculated by [NDB](#)); transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

In NDB 8.0.16 and earlier, operational records used dedicated resources whose sizes were controlled by a number of configuration parameters. Beginning with NDB 8.0.17, these are all allocated from a common transaction memory resource and can also use resources from global shared memory. In NDB 8.0.19 and later, the size of this resource can be controlled using a single [TransactionMemory](#) configuration parameter.

Reserved memory for undo log buffers can be set using the [InitialLogFileGroup](#) configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If [TransactionMemory](#) is not set, it is calculated based on the following parameters:

- [MaxNoOfConcurrentOperations](#)
- [MaxNoOfConcurrentTransactions](#)
- [MaxNoOfFiredTriggers](#)
- [MaxNoOfLocalOperations](#)
- [MaxNoOfConcurrentIndexOperations](#)
- [MaxNoOfConcurrentScans](#)
- [MaxNoOfLocalScans](#)
- [BatchSizePerLocalScan](#)
- [TransactionBufferMemory](#)

When [TransactionMemory](#) is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters [MaxNoOfConcurrentIndexOperations](#), [MaxNoOfFiredTriggers](#), [MaxNoOfLocalOperations](#), and [MaxNoOfLocalScans](#) are incompatible with [TransactionMemory](#) and cannot be set concurrently with it; if [TransactionMemory](#) is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start. These four parameters are deprecated in NDB 8.0.19, and will be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- [ReservedConcurrentIndexOperations](#)
- [ReservedFiredTriggers](#)
- [ReservedConcurrentOperations](#)
- [ReservedLocalScans](#)
- [ReservedConcurrentTransactions](#)
- [ReservedConcurrentScans](#)

- [ReservedTransactionBufferMemory](#)

If the parameters just listed are not set, the reserved setting is 25% of transaction memory. The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set [TransactionMemory](#) alone, and to allow the number of records in pools to be governed by its value.

[MaxNoOfConcurrentScans](#) limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

[MaxNoOfConcurrentOperations](#) limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that [MaxNoOfConcurrentOperations](#) be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the [\[ndbd default\]](#) section of the [config.ini](#) global configuration file). While its value can be increased using a rolling restart (see [Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the [MaxDMLOperationsPerTransaction](#) parameter. If this is not set, the size of one transaction is limited by [MaxNoOfConcurrentOperations](#) since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

- [MaxNoOfSubscriptions](#)
- [MaxNoOfSubscribers](#)
- [MaxNoOfConcurrentSubOperations](#)
- [MaxNoOfAttributes](#)
- [MaxNoOfTables](#)
- [MaxNoOfOrderedIndexes](#)
- [MaxNoOfUniqueHashIndexes](#)
- [MaxNoOfTriggers](#)

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

22.3.3.14 Configuring NDB Cluster Send Buffer Parameters

The [NDB](#) kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the [\[ndbd\]](#), [\[mgm\]](#), and [\[api\]](#) (or [\[mysql\]](#)) sections of the [config.ini](#) file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Table 22.22 Transporter types with maximum send buffer sizes

Transporter	Maximum Send Buffer Size (bytes)
TCP	<code>SendBufferMemory</code> (default = 2M)
SHM	20K

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (*Send Buffers overloaded in NDB kernel*) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

22.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 22.3.3.10, “NDB Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See [Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*.

Note

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, NDB attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

22.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py`, used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that [Section 22.4.26, “ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster”](#), contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see [The NDB Cluster Auto-Installer \(NDB 7.5\) \(DEPRECATED\)](#).

For information about using `mysqld` as an NDB Cluster process, see [Section 22.5.9, “MySQL Server Usage for NDB Cluster”](#).

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

22.4.1 `ndbd` — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbd`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.23 Command-line options for the `ndbd` program

Format	Description	Added, Deprecated, or Removed
<code>--bind-address=name</code>	Local bind address	(Supported in all MySQL 8.0 based releases)
<code>--connect-delay=#</code>	Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts	(Supported in all MySQL 8.0 based releases)
<code>--connect-retries=#</code>	Set the number of times to retry a connection before giving up;	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--connect-retry-delay=#</code>	0 means 1 attempt only (and no retries) Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts	(Supported in all MySQL 8.0 based releases)
<code>--daemon,</code> <code>-d</code> <code>--foreground</code>	Start ndbd as daemon (default); override with <code>--nodaemon</code> Run ndbd in foreground, provided for debugging purposes (implies <code>--nodaemon</code>)	(Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases)
<code>--initial</code>	Perform initial start of ndbd, including file system cleanup; consult documentation before using this option	(Supported in all MySQL 8.0 based releases)
<code>--initial-start</code>	Perform partial initial start (requires <code>--nowait-nodes</code>)	(Supported in all MySQL 8.0 based releases)
<code>--install[=name]</code>	Used to install data node process as Windows service; does not apply on other platforms	(Supported in all MySQL 8.0 based releases)
<code>--logbuffer-size=#</code>	Control size of log buffer; for use when debugging with many log messages being generated; default is sufficient for normal operations	(Supported in all MySQL 8.0 based releases)
<code>--nodaemon</code>	Do not start ndbd as daemon; provided for testing purposes	(Supported in all MySQL 8.0 based releases)
<code>--nostart,</code> <code>-n</code> <code>--nowait-nodes=list</code>	Do not start ndbd immediately; ndbd waits for command to start from <code>ndb_mgm</code> Do not wait for these data nodes to start (takes comma-separated list of node IDs); requires <code>--ndb-nodeid</code>	(Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases)
<code>--remove[=name]</code>	Used to remove data node process that was previously installed as Windows service; does not apply on other platforms	(Supported in all MySQL 8.0 based releases)
<code>--verbose,</code> <code>-v</code>	Write extra debugging information to node log	(Supported in all MySQL 8.0 based releases)

**Note**

All of these options also apply to the multithreaded version of this program (`ndbmtd`) and you may substitute “`ndbmtd`” for “`ndbd`” wherever the latter occurs in this section.

- `--bind-address`

Command-Line Format	<code>--bind-address=name</code>
---------------------	----------------------------------

Type	String
Default Value	

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- `--connect-delay=#`

Command-Line Format	<code>--connect-delay=#</code>
Deprecated	Yes
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	3600

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- `--connect-retries=#`

Command-Line Format	<code>--connect-retries=#</code>
Type	Numeric
Default Value	12
Minimum Value	0
Maximum Value	65535

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

- `--connect-retry-delay=#`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	4294967295

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

- `--daemon, -d`

Command-Line Format	<code>--daemon</code>
Type	Boolean

Default Value	TRUE
---------------	------

Instructs `ndbd` or `ndbmt` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--foreground`

Command-Line Format	<code>--foreground</code>
Type	Boolean
Default Value	FALSE

Causes `ndbd` or `ndbmt` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--initial`

Command-Line Format	<code>--initial</code>
Type	Boolean
Default Value	FALSE

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

Important

This option does *not* affect backup files that have already been created by the affected node.

Prior to NDB 8.0.21, the `--initial` option also did not affect any Disk Data files. In NDB 8.0.21 and later, when used to perform an initial restart

of the cluster, the option causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see [Section 22.5.10, “NDB Cluster Disk Data Tables”](#)).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with `--initial`, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Command-Line Format	<code>--initial-start</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndbd</code>

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—

together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--logbuffer-size=#`

Command-Line Format	<code>--logbuffer-size=#</code>
Type	Integer
Default Value	32768
Minimum Value	2048
Maximum Value	4294967295

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- `--nodaemon`

Command-Line Format	<code>--nodaemon</code>
Type	Boolean
Default Value	FALSE

Prevents `ndbd` or `ndbmt` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--nostart, -n`

Command-Line Format	<code>--nostart</code>
Type	Boolean
Default Value	FALSE

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 22.5.1, “Commands in the NDB Cluster Management Client”](#)).

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

Command-Line Format	<code>--nowait-nodes=list</code>
Type	String
Default Value	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4

connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--remove[=name]`

Command-Line Format	<code>--remove[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndbd</code>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--verbose, -v`

Causes extra debug output to be written to the node log.

You can also use `NODELOG DEBUG ON` and `NODELOG DEBUG OFF` to enable and disable this extra logging while the data node is running.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [Data Node Error Messages](#).

Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), for additional information about this issue. [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), describes other command-line options which can be used with `ndbd`. For information about data node configuration parameters, see [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#).

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See [Section 22.1.7, “Known Limitations of NDB Cluster”](#).

22.4.2 ndbinfo_select_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database

Not all `ndbinfo` tables available in the `mysql` client can be read by this program. In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type      log_id  log_part      total  used   high
5       0          0        0      33554432    262144  0
6       0          0        0      33554432    262144  0
7       0          0        0      33554432    262144  0
8       0          0        0      33554432    262144  0
== logspaces ==
node_id log_type      log_id  log_part      total  used   high
5       0          0        0      268435456     0      0
5       0          0        1      268435456     0      0
5       0          0        2      268435456     0      0
5       0          0        3      268435456     0      0
6       0          0        0      268435456     0      0
6       0          0        1      268435456     0      0
6       0          0        2      268435456     0      0
6       0          0        3      268435456     0      0
7       0          0        0      268435456     0      0
7       0          0        1      268435456     0      0
7       0          0        2      268435456     0      0
7       0          0        3      268435456     0      0
8       0          0        0      268435456     0      0
8       0          0        1      268435456     0      0
8       0          0        2      268435456     0      0
8       0          0        3      268435456     0      0
shell>
```

The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbinfo_select_all`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.24 Command-line options for the `ndbinfo_select_all` program

Format	Description	Added, Deprecated, or Removed
<code>--delay=#</code>	Set delay in seconds between loops	(Supported in all MySQL 8.0 based releases)
<code>--loops=#,</code> <code>-l</code>	Set number of times to perform select	(Supported in all MySQL 8.0 based releases)
<code>--database=db_name,</code> <code>-d</code>	Name of database where table is located	(Supported in all MySQL 8.0 based releases)
<code>--parallelism=#,</code> <code>-p</code>	Set degree of parallelism	(Supported in all MySQL 8.0 based releases)

- `--delay=seconds`

Command-Line Format	<code>--delay=#</code>
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	<code>MAX_INT</code>

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--loops=number, -l number`

Command-Line Format	<code>--loops=#</code>
Type	Numeric
Default Value	1
Minimum Value	0
Maximum Value	<code>MAX_INT</code>

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

22.4.3 ndbmtbd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmtbd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmtbd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmtbd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmtbd` differs from `ndbd`, and you should consult [Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmtbd`. For more information about these options and parameters, see [Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), and [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#), respectively.

`ndbmtbd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmtbd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmtbd` to run in multithreaded fashion.) Similarly, an `ndbmtbd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmtbd` differs from using `ndbd` in two key respects:

1. Because `ndbmtbd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see [Multi-Threading Configuration Parameters \(ndbmtbd\)](#).
2. Trace files are generated by critical errors in `ndbmtbd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmtbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtbd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtbd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of

the failure of an `ndbmtid` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtid`. See [Data Node Error Messages](#), for a listing of these.

Note

It is possible to use `ndbd` and `ndbmtid` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

22.4.4 `ndb_mgmd` — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.25 Command-line options for the `ndb_mgmd` program

Format	Description	Added, Deprecated, or Removed
<code>--bind-address=host</code>	Local bind address	(Supported in all MySQL 8.0 based releases)
<code>--config-cache[=TRUE FALSE]</code>	Enable management server configuration cache; true by default	(Supported in all MySQL 8.0 based releases)
<code>--config-file=file,</code> <code>-f</code>	Specify cluster configuration file; also specify <code>--reload</code> or <code>--initial</code> to override configuration cache if present	(Supported in all MySQL 8.0 based releases)
<code>--configdir=directory,</code> <code>--config-dir=directory</code>	Specify cluster management server configuration cache directory	(Supported in all MySQL 8.0 based releases)
<code>--daemon,</code> <code>-d</code>	Run <code>ndb_mgmd</code> in daemon mode (default)	(Supported in all MySQL 8.0 based releases)
<code>--initial</code>	Causes management server to reload configuration data from configuration file, bypassing configuration cache	(Supported in all MySQL 8.0 based releases)
<code>--install[=name]</code>	Used to install management server process as Windows service; does not apply on other platforms	(Supported in all MySQL 8.0 based releases)
<code>--interactive</code>	Run <code>ndb_mgmd</code> in interactive mode (not officially supported in	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--log-name=name</code>	production; for testing purposes only) Name to use when writing cluster log messages applying to this node	(Supported in all MySQL 8.0 based releases)
<code>--mycnf</code>	Read cluster configuration data from my.cnf file	(Supported in all MySQL 8.0 based releases)
<code>--no-nodeid-checks</code>	Do not provide any node ID checks	(Supported in all MySQL 8.0 based releases)
<code>--nodaemon</code>	Do not run ndb_mgmd as a daemon	(Supported in all MySQL 8.0 based releases)
<code>--nowait-nodes=list</code>	Do not wait for management nodes specified when starting this management server; requires <code>--ndb-nodeid</code> option	(Supported in all MySQL 8.0 based releases)
<code>--print-full-config,</code> <code>-P</code>	Print full configuration and exit	(Supported in all MySQL 8.0 based releases)
<code>--reload</code>	Causes management server to compare configuration file with configuration cache	(Supported in all MySQL 8.0 based releases)
<code>--remove[=name]</code>	Used to remove management server process that was previously installed as Windows service, optionally specifying name of service to be removed; does not apply on other platforms	(Supported in all MySQL 8.0 based releases)
<code>--verbose,</code> <code>-v</code>	Write additional information to log	(Supported in all MySQL 8.0 based releases)

- `--bind-address=host`

Command-Line Format	<code>--bind-address=host</code>
Type	String
Default Value	<code>[none]</code>

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--config-cache`

Command-Line Format	<code>--config-cache[=TRUE FALSE]</code>
Type	Boolean
Default Value	<code>TRUE</code>

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 22.3.3, “NDB Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`

- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

Command-Line Format	<code>--config-file=file</code>
Type	File name
Default Value	<code>[none]</code>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 22.3.3, “NDB Cluster Configuration Files”](#), for more information.

- `--configdir=dir_name`

Command-Line Format	<code>--configdir=directory</code> <code>--config-dir=directory</code>
---------------------	---

Type	File name
Default Value	<code>\$INSTALLDIR/mysql-cluster</code>

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- `--daemon, -d`

Command-Line Format	<code>--daemon</code>
Type	Boolean
Default Value	<code>TRUE</code>

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--initial`

Command-Line Format	<code>--initial</code>
Type	Boolean
Default Value	<code>FALSE</code>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 22.3.3, “NDB Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndb_mgmd</code>

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them

together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

Command-Line Format	<code>--interactive</code>
Type	Boolean
Default Value	<code>FALSE</code>

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--log-name=name`

Command-Line Format	<code>--log-name=name</code>
Type	String
Default Value	<code>MgmtSrvr</code>

Provides a name to be used for this node in the cluster log.

- `--mycnf`

Command-Line Format	<code>--mycnf</code>
Type	Boolean
Default Value	<code>FALSE</code>

Read configuration data from the `my.cnf` file.

- `--no-nodeid-checks`

Command-Line Format	<code>--no-nodeid-checks</code>
Type	Boolean
Default Value	<code>FALSE</code>

Do not perform any checks of node IDs.

- `--nodaemon`

Command-Line Format	<code>--nodaemon</code>
Type	Boolean
Default Value	<code>FALSE</code>

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--nowait-nodes`

Command-Line Format	<code>--nowait-nodes=list</code>
Type	Numeric
Default Value	
Minimum Value	1
Maximum Value	255

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without

restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtl` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config, -P`

Command-Line Format	<code>--print-full-config</code>
Type	Boolean
Default Value	<code>FALSE</code>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

Command-Line Format	<code>--reload</code>
Type	Boolean
Default Value	<code>FALSE</code>

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 22.3.3, “NDB Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store

against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See [Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for additional information.

- `--remove[=name]`

Command-Line Format	<code>--remove[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndb_mgmd</code>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>FALSE</code>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), for information about using connection strings. [Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 22.3, “Configuration of NDB Cluster”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 22.5, “Management of NDB Cluster”](#).

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

22.4.5 ndb_mgm — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgm`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.26 Command-line options for the `ndb_mgm` program

Format	Description	Added, Deprecated, or Removed
<code>--connect-retries=#</code>	Set number of times to retry connection before giving up; 0 means 1 attempt only (and no retries)	(Supported in all MySQL 8.0 based releases)
<code>--try-reconnect=#</code> , <code>-t</code>	Set number of times to retry connection before giving up; synonym for <code>--connect-retries</code>	(Supported in all MySQL 8.0 based releases)
<code>--execute=name</code> , <code>-e</code>	Execute command and exit	(Supported in all MySQL 8.0 based releases)

- `--connect-retries=#`

Command-Line Format	<code>--connect-retries=#</code>
Type	Numeric
Default Value	3
Minimum Value	0

Maximum Value	4294967295
---------------	------------

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

The default for this option this option differs from its default when used with other NDB programs. See [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), for more information.

- `--execute=command`, `-e command`

Command-Line Format	<code>--execute=name</code>
---------------------	-----------------------------

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"

shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.2.1, “Using Options on the Command Line”](#).

Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

Command-Line Format	<code>--try-reconnect=#</code>
Deprecated	Yes
Type	Numeric
Type	Integer
Default Value	12
Default Value	3
Minimum Value	0
Maximum Value	4294967295

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

Additional information about using `ndb_mgm` can be found in [Section 22.5.1, “Commands in the NDB Cluster Management Client”](#).

22.4.6 **ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for ndb_blob_tool is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the --help option, you must specify an action to be performed by including one or more of the options --check-orphans, --delete-orphans, or --dump-file. These options cause ndb_blob_tool to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking ndb_blob_tool. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table's BLOB and TEXT columns. If you need to specify a database, use the --database (-d) option.

The --verbose option provides additional information in the output about the tool's progress.

The following table includes options that are specific to ndb_blob_tool. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_blob_tool), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.27 Command-line options for the ndb_blob_tool program

Format	Description	Added, Deprecated, or Removed
--add-missing	Write dummy blob parts to take place of those which are missing	ADDED: NDB 8.0.20
--check-missing	Check for blobs having inline parts but missing one or more parts from parts table	ADDED: NDB 8.0.20
--check-orphans	Check for blob parts having no corresponding inline parts	(Supported in all MySQL 8.0 based releases)
--database=db_name, -d	Database to find the table in	(Supported in all MySQL 8.0 based releases)
--delete-orphans	Delete blob parts having no corresponding inline parts	(Supported in all MySQL 8.0 based releases)
--dump-file=file	Write orphan keys to specified file	(Supported in all MySQL 8.0 based releases)
--verbose, -v	Verbose output	(Supported in all MySQL 8.0 based releases)

- --add-missing

Command-Line Format	--add-missing
Introduced	8.0.20-ndb-8.0.20
Type	Boolean
Default Value	FALSE

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- `--check-missing`

Command-Line Format	<code>--check-missing</code>
Introduced	8.0.20-ndb-8.0.20
Type	Boolean
Default Value	<code>FALSE</code>

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- `--check-orphans`

Command-Line Format	<code>--check-orphans</code>
Type	Boolean
Default Value	<code>FALSE</code>

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- `--database=db_name, -d`

Command-Line Format	<code>--database=db_name</code>
Type	String
Default Value	<code>[none]</code>

Specify the database to find the table in.

- `--delete-orphans`

Command-Line Format	<code>--delete-orphans</code>
Type	Boolean
Default Value	<code>FALSE</code>

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- `--dump-file=file`

Command-Line Format	<code>--dump-file=file</code>
Type	File name
Default Value	<code>[none]</code>

Writes a list of orphaned BLOB column parts to *file*. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--verbose`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>FALSE</code>

Provide extra information in the tool's output regarding its progress.

Example

First we create an NDB table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;
```

```
CREATE TABLE btest (
  c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c1 TEXT,
  c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no NDB BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an NDB table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by NDB for this column. See [Section 11.7, “Data Type Storage Requirements”](#), for more information.

22.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_config`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.28 Command-line options for the ndb_config program

Format	Description	Added, Deprecated, or Removed
<code>--config-file=file_name</code>	Set the path to config.ini file	(Supported in all MySQL 8.0 based releases)
<code>--config-from-node=#</code>	Obtain configuration data from the node having this ID (must be a data node)	(Supported in all MySQL 8.0 based releases)
<code>--configinfo</code>	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output	(Supported in all MySQL 8.0 based releases)
<code>--connections</code>	Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--nodes</code>	(Supported in all MySQL 8.0 based releases)
<code>--diff-default</code>	Print only configuration parameters that have non-default values	(Supported in all MySQL 8.0 based releases)
<code>--fields=string,</code> <code>-f</code>	Field separator	(Supported in all MySQL 8.0 based releases)
<code>--host=name</code>	Specify host	(Supported in all MySQL 8.0 based releases)
<code>--mycnf</code>	Read configuration data from my.cnf file	(Supported in all MySQL 8.0 based releases)
<code>--nodeid</code>	Get configuration of node with this ID	(Supported in all MySQL 8.0 based releases)
<code>--nodes</code>	Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--connections</code>	(Supported in all MySQL 8.0 based releases)
<code>-c</code>	Short form for <code>--ndb-connectstring</code>	(Supported in all MySQL 8.0 based releases)
<code>--query=string,</code> <code>-q</code>	One or more query options (attributes)	(Supported in all MySQL 8.0 based releases)
<code>--query-all,</code> <code>-a</code>	Dumps all parameters and values to a single comma-delimited string	(Supported in all MySQL 8.0 based releases)
<code>--rows=string,</code> <code>-r</code>	Row separator	(Supported in all MySQL 8.0 based releases)
<code>--system</code>	Print SYSTEM section information only (see <code>ndb_config --configinfo</code> output). Cannot be used with <code>--nodes</code> or <code>--connections</code>	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--type=name</code>	Specify node type	(Supported in all MySQL 8.0 based releases)
<code>--configinfo --xml</code>	Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values	(Supported in all MySQL 8.0 based releases)

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMDNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...
```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

Command-Line Format	<code>--config-file=file_name</code>
Type	File name

Default Value	
---------------	--

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config-from-node=#`

Command-Line Format	<code>--config-from-node=#</code>
Type	Numeric
Default Value	<code>none</code>
Minimum Value	<code>1</code>
Maximum Value	<code>48</code>

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

Command-Line Format	<code>--connections</code>
Type	Boolean
Default Value	<code>FALSE</code>

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see [Section 22.3.3.10, “NDB Cluster TCP/IP Connections”](#), and [Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”](#), for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--diff-default`

Command-Line Format	<code>--diff-default</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print only configuration parameters that have non-default values.

- `--fields=delimiter, -f delimiter`

Command-Line Format	<code>--fields=string</code>
Type	String
Default Value	

Specifies a `delimiter` string used to separate the fields in the result. The default is `,` (the comma character).

Note

If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--host=hostname`

Command-Line Format	<code>--host=name</code>
Type	String
Default Value	

Specifies the host name of the node for which configuration information is to be obtained.

Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--mycnf`

Command-Line Format	<code>--mycnf</code>
Type	Boolean
Default Value	<code>FALSE</code>

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string, -c connection_string`

Command-Line Format	<code>--ndb-connectstring=connection_string</code> <code>--connect-string=connection_string</code>
Type	String
Default Value	<code>localhost:1186</code>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), and defaults to `localhost:1186`.

- `--nodeid=node_id`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Numeric
Default Value	<code>0</code>

Specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

Command-Line Format	<code>--nodes</code>
Type	Boolean
Default Value	<code>FALSE</code>

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#)).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--query=query-options, -q query-options`

Command-Line Format	<code>--query=string</code>
Type	String
Default Value	

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all, -a`

Command-Line Format	<code>--query-all</code>
Type	String
Default Value	

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

- `--rows=separator, -r separator`

Command-Line Format	<code>--rows=string</code>
Type	String
Default Value	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--system`

Command-Line Format	<code>--system</code>
Type	Boolean
Default Value	<code>FALSE</code>

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for

them. They can be seen (prefixed with `***** SYSTEM *****`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

Command-Line Format	<code>--type=name</code>
Type	Enumeration
Default Value	<code>[none]</code>
Valid Values	<code>ndbd</code> <code>mysqld</code> <code>ndb_mgmd</code>

Filters results so that only configuration values applying to nodes of the specified *node_type* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--usage`, `--help`, or `-?`

Command-Line Format	<code>--help</code> <code>--usage</code>
---------------------	---

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

Command-Line Format	<code>--configinfo --xml</code>
Type	Boolean
Default Value	<code>false</code>

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.32-ndb-7.5.20"
    ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
    ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
      default="false"/>
    <param name="HostName" comment="Name of computer for this node"
      type="string" default="" />
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
```

```

        min="1" max="255" deprecated="true"/>
<param name="NodeId" comment="Number identifying application node (mysqld(API))"
        type="unsigned" mandatory="true" min="1" max="255"/>
<param name="ExecuteOnComputer" comment="HostName" type="string"
        deprecated="true"/>

...

</section>

...

</configvariables>

```

Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```

<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
        restart="system" initial="true"/>

```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```

<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
        type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>

```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```

<param name="NodeId"
        comment="Number identifying application node (mysqld(API))"

```

```
type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=nodeid,type --fields=: --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysql
7:mysql
8:mysql
9:mysql
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

22.4.8 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.29 Command-line options for the `ndb_delete_all` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname,</code> <code>-d</code>	Name of the database in which the table is found	(Supported in all MySQL 8.0 based releases)
<code>--transactional,</code> <code>-t</code>	Perform the delete in a single transaction (may run out of operations)	(Supported in all MySQL 8.0 based releases)
<code>--tupscan</code>	Run tup scan	(Supported in all MySQL 8.0 based releases)
<code>--diskscan</code>	Run disk scan	(Supported in all MySQL 8.0 based releases)

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

Prior to NDB 8.0.18, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

22.4.9 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

```
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag var sized memory      Extent_spa
0              2              2              32768              32768              0
1              4              4              32768              32768              0

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see [NDB Schema Object Versions](#).

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
+-----+-----+-----+
| Level | Code | Message
```

Level	Code	Message
Warning	1296	Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not i

```
1 row in set (0.00 sec)
```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; NDB sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish\G
***** 1. row *****
      Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag varsized memory      Extent_space
NDBT_ProgramExit: 0 - OK
```

For more information about these table properties, see [Section 13.1.20.10, “Setting NDB_TABLE Options”](#).

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
```

```

    UNDO_BUFFER_SIZE 2M
    ENGINE NDB;

ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDB;

CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDB;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDB;

```

(For more information on the statements just shown and the objects created by them, see [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#), as well as [Section 13.1.16, “CREATE LOGFILE GROUP Statement”](#), and [Section 13.1.21, “CREATE TABLESPACE Statement”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```

DROP TABLE IF EXISTS fish;

CREATE TABLE fish (
    id INT NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT NOT NULL,
    weight_gm INT NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);

```

When run against this version of the table, `ndb_desc` displays the following output:

```

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 1001
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
Tablespace id: 16

```

```

Tablespace: ts_1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(80;utf8mb4_0900_ai_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag varsized memory      Extent_space
0              2              2              32768              32768              1048576
1              4              4              32768              32768              1048576

NDBT_ProgramExit: 0 - OK

```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as [Free extent_space](#) is available for storing on-disk column data from the [fish](#) table only; for this reason, it is not visible when selecting from the [INFORMATION_SCHEMA.FILES](#) table.

[Tablespace id](#) and [Tablespace](#) are displayed for Disk Data tables beginning with NDB 8.0.21.

For fully replicated tables, [ndb_desc](#) shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the [mysql](#) client, from the [table_distribution_status](#), [table_fragments](#), [table_info](#), and [table_replicas](#) tables in the [ndbinfo](#) database.

The following table includes options that are specific to [ndb_desc](#). Additional descriptions follow the table. For options common to most NDB Cluster programs (including [ndb_desc](#)), see [Section 22.4.32](#), “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.30 Command-line options for the [ndb_desc](#) program

Format	Description	Added, Deprecated, or Removed
--auto-inc ,	Show next value for	ADDED: NDB 8.0.21
-a	AUTO_INCREMENT oolumn if table has one	
--blob-info ,	Include partition information for	(Supported in all MySQL 8.0 based releases)
-b	BLOB tables in output. Requires that the -p option also be used	
--context ,	Show extra information for table	ADDED: NDB 8.0.21
-x	such as database, schema, name, internal ID	
--database=dbname ,	Name of database containing table	(Supported in all MySQL 8.0 based releases)
-d		
--extra-node-info ,	Include partition-to-data-node mappings in output. Requires that	(Supported in all MySQL 8.0 based releases)
-n	the -p option also be used	
--extra-partition-info ,	Display information about partitions	(Supported in all MySQL 8.0 based releases)
-p		
--retries=# ,	Number of times to retry the connection (once per second)	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>-r</code> <code>--table=tbl_name,</code> <code>-t</code> <code>--unqualified,</code> <code>-u</code>	<p>Specify the table in which to find an index. When this option is used, <code>-p</code> and <code>-n</code> have no effect and are ignored</p> <p>Use unqualified table names</p>	<p>(Supported in all MySQL 8.0 based releases)</p> <p>(Supported in all MySQL 8.0 based releases)</p>

- `--auto-inc, -a`

Show the next value for a table's `AUTO_INCREMENT` column, if it has one.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--context, -x`

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--database=db_name, -d`

Specify the database in which the table should be found.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--retries=#, -r`

Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name, -t`

Specify the table in which to look for an index.

- `--unqualified, -u`

Use unqualified table names.

Table indexes listed in the output are ordered by ID.

22.4.10 ndb_drop_index — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an `NDB` table. *It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.*

Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_index`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.31 Command-line options for the `ndb_drop_index` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname,</code> <code>-d</code>	Name of database in which table is found	(Supported in all MySQL 8.0 based releases)

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 22.4.11, “ndb_drop_table — Drop an NDB Table”](#)) to drop the table.

22.4.11 `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error `723: No such table exists.`) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.32 Command-line options for the `ndb_drop_table` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname,</code> <code>-d</code>	Name of database in which table is found	(Supported in all MySQL 8.0 based releases)

Prior to NDB 8.0.17, an NDB table dropped using this utility persisted in the MySQL data dictionary but could not be dropped using `DROP TABLE` in the `mysql` client. In NDB 8.0.17 and later, such “orphan” tables can be dropped using `DROP TABLE`. (Bug #29125206, Bug #93672)

22.4.12 `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_error_reporter`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.33 Command-line options for the `ndb_error_reporter` program

Format	Description	Added, Deprecated, or Removed
<code>--connection-timeout=timeout</code>	Number of seconds to wait when connecting to nodes before timing out	(Supported in all MySQL 8.0 based releases)
<code>--dry-scp</code>	Disable scp with remote hosts; used only for testing	(Supported in all MySQL 8.0 based releases)
<code>--fs</code>	Include file system data in error report; can use a large amount of disk space	(Supported in all MySQL 8.0 based releases)
<code>--skip-nodegroup=nodegroup_id</code>	Skip all nodes in the node group having this ID	(Supported in all MySQL 8.0 based releases)

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster’s data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where `YYYYMMDDhhmmss` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

Command-Line Format	<code>--connection-timeout=timeout</code>
Type	Integer
Default Value	0

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

Command-Line Format	<code>--dry-scp</code>
Type	Boolean
Default Value	TRUE

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--fs`

Command-Line Format	<code>--fs</code>
Type	Boolean
Default Value	FALSE

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodegroup=nodegroup_id`

Command-Line Format	<code>--connection-timeout=timeout</code>
Type	Integer
Default Value	0

Skip all nodes belong to the node group having the supplied node group ID.

22.4.13 ndb_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section. `ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused `[api]` slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after

this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing InnoDB table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

```
mysql> USE myinnodb;

mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
>   FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
>   LINES TERMINATED BY '\n'
>   FROM myinnodbttable;

mysql> CREATE DATABASE myndb;

mysql> USE myndb;

mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;

mysql> ALTER TABLE myndb_table ENGINE=NDB;

mysql> EXIT;
Bye
shell>
```

Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir

shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \
--fields-terminated-by="," --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
shell>
```

The following table includes options that are specific to `ndb_import`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_import`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.34 Command-line options for the `ndb_import` program

Format	Description	Added, Deprecated, or Removed
<code>--abort-on-error</code>	Dump core on any fatal error; used for debugging	(Supported in all MySQL 8.0 based releases)
<code>--ai-increment=#</code>	For table with hidden PK, specify autoincrement increment. See <code>mysqld</code>	(Supported in all MySQL 8.0 based releases)
<code>--ai-offset=#</code>	For table with hidden PK, specify autoincrement offset. See <code>mysqld</code>	(Supported in all MySQL 8.0 based releases)
<code>--ai-prefetch-sz=#</code>	For table with hidden PK, specify number of autoincrement values that are prefetched. See <code>mysqld</code>	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--connections=#</code>	Number of cluster connections to create	(Supported in all MySQL 8.0 based releases)
<code>--continue</code>	When job fails, continue to next job	(Supported in all MySQL 8.0 based releases)
<code>--db-workers=#</code>	Number of threads, per data node, executing database operations	(Supported in all MySQL 8.0 based releases)
<code>--errins-type=name</code>	Error insert type, for testing purposes; use "list" to obtain all possible values	(Supported in all MySQL 8.0 based releases)
<code>--errins-delay=#</code>	Error insert delay in milliseconds; random variation is added	(Supported in all MySQL 8.0 based releases)
<code>--fields-enclosed-by=char</code>	Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by	(Supported in all MySQL 8.0 based releases)
<code>--fields-escaped-by=name</code>	Same as FIELDS ESCAPED BY option for LOAD DATA statements	(Supported in all MySQL 8.0 based releases)
<code>--fields-optionally-enclosed-by=char</code>	Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements	(Supported in all MySQL 8.0 based releases)
<code>--fields-terminated-by=char</code>	Same as FIELDS TERMINATED BY option for LOAD DATA statements	(Supported in all MySQL 8.0 based releases)
<code>--idlesleep=#</code>	Number of milliseconds to sleep waiting for more to do	(Supported in all MySQL 8.0 based releases)
<code>--idlespin=#</code>	Number of times to re-try before idlesleep	(Supported in all MySQL 8.0 based releases)
<code>--ignore-lines=#</code>	Ignore first # lines in input file. Used to skip a non-data header	(Supported in all MySQL 8.0 based releases)
<code>--input-type=name</code>	Input type: random or csv	(Supported in all MySQL 8.0 based releases)
<code>--input-workers=#</code>	Number of threads processing input. Must be 2 or more if --input-type is csv	(Supported in all MySQL 8.0 based releases)
<code>--keep-state</code>	State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead	(Supported in all MySQL 8.0 based releases)
<code>--lines-terminated-by=name</code>	Same as LINES TERMINATED BY option for LOAD DATA statements	(Supported in all MySQL 8.0 based releases)
<code>--max-rows=#</code>	Import only this number of input data rows; default is 0, which imports all rows	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--monitor=#</code>	Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit	(Supported in all MySQL 8.0 based releases)
<code>--no-asynch</code>	Run database operations as batches, in single transactions	(Supported in all MySQL 8.0 based releases)
<code>--no-hint</code>	Do not use distribution key hint to select data node (TC)	(Supported in all MySQL 8.0 based releases)
<code>--opbatch=#</code>	A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of asynch transactions. Value 0 is not valid	(Supported in all MySQL 8.0 based releases)
<code>--opbytes=#</code>	Limit bytes in execution batch (default 0 = no limit)	(Supported in all MySQL 8.0 based releases)
<code>--output-type=name</code>	Output type: ndb is default, null used for testing	(Supported in all MySQL 8.0 based releases)
<code>--output-workers=#</code>	Number of threads processing output or relaying database operations	(Supported in all MySQL 8.0 based releases)
<code>--pagesize=#</code>	Align I/O buffers to given size	(Supported in all MySQL 8.0 based releases)
<code>--pagecnt=#</code>	Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer	(Supported in all MySQL 8.0 based releases)
<code>--polltimeout=#</code>	Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs	(Supported in all MySQL 8.0 based releases)
<code>--rejects=#</code>	Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej	(Supported in all MySQL 8.0 based releases)
<code>--resume</code>	If job aborted (temporary error, user interrupt), resume with rows not yet processed	(Supported in all MySQL 8.0 based releases)
<code>--rowbatch=#</code>	Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random	(Supported in all MySQL 8.0 based releases)
<code>--rowbytes=#</code>	Limit bytes in row queues (0 = no limit)	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--state-dir=name</code>	Where to write state files; current directory is default	(Supported in all MySQL 8.0 based releases)
<code>--stats</code>	Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used	(Supported in all MySQL 8.0 based releases)
<code>--tempdelay=#</code>	Number of milliseconds to sleep between temporary errors	(Supported in all MySQL 8.0 based releases)
<code>--temperrors=#</code>	Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file	(Supported in all MySQL 8.0 based releases)
<code>--verbose,</code> <code>-v</code>	Enable verbose output	(Supported in all MySQL 8.0 based releases)

- `--abort-on-error`

Command-Line Format	<code>--abort-on-error</code>
Type	Boolean
Default Value	<code>FALSE</code>

Dump core on any fatal error; used for debugging only.

- `--ai-increment=#`

Command-Line Format	<code>--ai-increment=#</code>
Type	Integer
Default Value	<code>1</code>
Minimum Value	<code>1</code>
Maximum Value	<code>4294967295</code>

For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- `--ai-offset=#`

Command-Line Format	<code>--ai-offset=#</code>
Type	Integer
Default Value	<code>1</code>
Minimum Value	<code>1</code>
Maximum Value	<code>4294967295</code>

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- `--ai-prefetch-sz=#`

Command-Line Format	<code>--ai-prefetch-sz=#</code>
Type	Integer
Default Value	1024
Minimum Value	1
Maximum Value	4294967295

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- `--connections=#`

Command-Line Format	<code>--connections=#</code>
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

Number of cluster connections to create.

- `--continue`

Command-Line Format	<code>--continue</code>
Type	Boolean
Default Value	FALSE

When a job fails, continue to the next job.

- `--db-workers=#`

Command-Line Format	<code>--db-workers=#</code>
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	4294967295

Number of threads, per data node, executing database operations.

- `--errins-type=name`

Command-Line Format	<code>--errins-type=name</code>
Type	Enumeration
Default Value	[none]
Valid Values	stopjob stopall sighup sigint

	<code>list</code>
--	-------------------

Error insert type; use `list` as the `name` value to obtain all possible values. This option is used for testing purposes only.

- `--errins-delay=#`

Command-Line Format	<code>--errins-delay=#</code>
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295
Unit	ms

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- `--fields-enclosed-by=char`

Command-Line Format	<code>--fields-enclosed-by=char</code>
Type	String
Default Value	[none]

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- `--fields-escaped-by=name`

Command-Line Format	<code>--fields-escaped-by=name</code>
Type	String
Default Value	\

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

- `--fields-optionally-enclosed-by=char`

Command-Line Format	<code>--fields-optionally-enclosed-by=char</code>
Type	String
Default Value	[none]

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- `--fields-terminated-by=char`

Command-Line Format	<code>--fields-terminated-by=char</code>
Type	String

Default Value	<code>\t</code>
---------------	-----------------

This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- `--idlesleep=#`

Command-Line Format	<code>--idlesleep=#</code>
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295
Unit	ms

Number of milliseconds to sleep waiting for more work to perform.

- `--idlespin=#`

Command-Line Format	<code>--idlespin=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Number of times to retry before sleeping.

- `--ignore-lines=#`

Command-Line Format	<code>--ignore-lines=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Cause `ndb_import` to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- `--input-type=name`

Command-Line Format	<code>--input-type=name</code>
Type	Enumeration
Default Value	csv
Valid Values	random csv

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only. .

- `--input-workers=#`

Command-Line Format	<code>--input-workers=#</code>	3889
Type	Integer	

Default Value	4
Minimum Value	1
Maximum Value	4294967295

Set the number of threads processing input.

- `--keep-state`

Command-Line Format	<code>--keep-state</code>
Type	Boolean
Default Value	<code>false</code>

By default, `ndb_import` removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- `--lines-terminated-by=name`

Command-Line Format	<code>--lines-terminated-by=name</code>
Type	String
Default Value	<code>\n</code>

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- `--log-level=#`

Command-Line Format	<code>--log-level=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- `--max-rows=#`

Command-Line Format	<code>--max-rows=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Import only this number of input data rows; the default is 0, which imports all rows.

- `--monitor=#`

Command-Line Format	<code>--monitor=#</code>
Type	Integer
Default Value	2

Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--no-async`

Command-Line Format	<code>--no-async</code>
Type	Boolean
Default Value	<code>FALSE</code>

Run database operations as batches, in single transactions.

- `--no-hint`

Command-Line Format	<code>--no-hint</code>
Type	Boolean
Default Value	<code>FALSE</code>

Do not use distribution key hinting to select a data node.

- `--opbatch=#`

Command-Line Format	<code>--opbatch=#</code>
Type	Integer
Default Value	256
Minimum Value	1
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- `--opbytes=#`

Command-Line Format	<code>--opbytes=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- `--output-type=name`

Command-Line Format	<code>--output-type=name</code>
Type	Enumeration
Default Value	<code>ndb</code>

Valid Values	<code>null</code>
--------------	-------------------

Set the output type. `ndb` is the default. `null` is used only for testing.

- `--output-workers=#`

Command-Line Format	<code>--output-workers=#</code>
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	4294967295

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

Command-Line Format	<code>--pagesize=#</code>
Type	Integer
Default Value	4096
Minimum Value	1
Maximum Value	4294967295
Unit	bytes

Align I/O buffers to the given size.

- `--pagecnt=#`

Command-Line Format	<code>--pagecnt=#</code>
Type	Integer
Default Value	64
Minimum Value	1
Maximum Value	4294967295

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

Command-Line Format	<code>--polltimeout=#</code>
Type	Integer
Default Value	1000
Minimum Value	1
Maximum Value	4294967295
Unit	ms

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- `--rejects=#`

Command-Line Format	<code>--rejects=#</code>
Type	Integer

Default Value	0
Minimum Value	0
Maximum Value	4294967295

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the `.rej` file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using `--resume` is considered a “new” run for this purpose.

- `--resume`

Command-Line Format	<code>--resume</code>
Type	Boolean
Default Value	<code>FALSE</code>

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- `--rowbatch=#`

Command-Line Format	<code>--rowbatch=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	rows

Set a limit on the number of rows per row queue. Use 0 for no limit.

- `--rowbytes=#`

Command-Line Format	<code>--rowbytes=#</code>
Type	Integer
Default Value	262144
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- `--stats`

Command-Line Format	<code>--stats</code>
Type	Boolean
Default Value	<code>false</code>

Save information about options related to performance and other internal statistics in files named `*.sto` and `*.stt`. These files are always kept on successful completion (even if `--keep-state` is not also specified).

- `--state-dir=name`

Command-Line Format	<code>--state-dir=name</code>
Type	String
Default Value	<code>.</code>

Where to write the state files (`tbl_name.map`, `tbl_name.rej`, `tbl_name.res`, and `tbl_name.stt`) produced by a run of the program; the default is the current directory.

- `--tempdelay=#`

Command-Line Format	<code>--tempdelay=#</code>
Type	Integer
Default Value	<code>10</code>
Minimum Value	<code>0</code>
Maximum Value	<code>4294967295</code>
Unit	<code>ms</code>

Number of milliseconds to sleep between temporary errors.

- `--temperrors=#`

Command-Line Format	<code>--temperrors=#</code>
Type	Integer
Default Value	<code>0</code>
Minimum Value	<code>0</code>
Maximum Value	<code>4294967295</code>

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>false</code>

Enable verbose output.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

`ndb_import` was added in NDB 7.6.2.

22.4.14 ndb_index_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database` (`-d`) option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

If the only output from the program is `NDBT_ProgramExit: 0 - OK`, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke

`ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including `ndb_index_stat`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.35 Command-line options for the `ndb_index_stat` program

Format	Description	Added, Deprecated, or Removed
<code>--database=name,</code> <code>-d</code>	Name of database containing table	(Supported in all MySQL 8.0 based releases)
<code>--delete</code>	Delete index statistics for table, stopping any auto-update previously configured	(Supported in all MySQL 8.0 based releases)
<code>--update</code>	Update index statistics for table, restarting any auto-update previously configured	(Supported in all MySQL 8.0 based releases)
<code>--dump</code>	Print query cache	(Supported in all MySQL 8.0 based releases)
<code>--query=#</code>	Perform random range queries on first key attr (must be int unsigned)	(Supported in all MySQL 8.0 based releases)
<code>--sys-drop</code>	Drop any statistics tables and events in NDB kernel (all statistics are lost)	(Supported in all MySQL 8.0 based releases)
<code>--sys-create</code>	Create all statistics tables and events in NDB kernel, if none of them already exist	(Supported in all MySQL 8.0 based releases)
<code>--sys-create-if-not-exist</code>	Create any statistics tables and events in NDB kernel that do not already exist	(Supported in all MySQL 8.0 based releases)
<code>--sys-create-if-not-valid</code>	Create any statistics tables or events that do not already exist in the NDB kernel, after dropping any that are invalid	(Supported in all MySQL 8.0 based releases)
<code>--sys-check</code>	Verify that NDB system index statistics and event tables exist	(Supported in all MySQL 8.0 based releases)
<code>--sys-skip-tables</code>	Do not apply sys-* options to tables	(Supported in all MySQL 8.0 based releases)
<code>--sys-skip-events</code>	Do not apply sys-* options to events	(Supported in all MySQL 8.0 based releases)
<code>--verbose,</code> <code>-v</code>	Turn on verbose output	(Supported in all MySQL 8.0 based releases)
<code>--loops=#</code>	Set the number of times to perform given command; default is 0	(Supported in all MySQL 8.0 based releases)

ndb_index_stat statistics options. The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see [ndb_index_stat system options](#)).

- `--database=name, -d name`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	<code>[none]</code>
Minimum Value	
Maximum Value	

The name of the database that contains the table being queried.

- `--delete`

Command-Line Format	<code>--delete</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`

Command-Line Format	<code>--update</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--dump`

Command-Line Format	<code>--dump</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Dump the contents of the query cache.

- `--query=#`

Command-Line Format	<code>--query=#</code>
Type	Numeric
Default Value	<code>0</code>
Minimum Value	<code>0</code>

Maximum Value	MAX_INT
---------------	---------

Perform random range queries on first key attribute (must be int unsigned).

ndb_index_stat system options. The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb_index_stat statistics options](#)).

- `--sys-drop`

Command-Line Format	<code>--sys-drop</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

Command-Line Format	<code>--sys-create</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

Command-Line Format	<code>--sys-create-if-not-exist</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

Command-Line Format	<code>--sys-create-if-not-valid</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

Command-Line Format	<code>--sys-check</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

Command-Line Format	<code>--sys-skip-tables</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

Command-Line Format	<code>--sys-skip-events</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Do not apply any `--sys-*` options to any events.

- `--verbose`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>false</code>
Minimum Value	
Maximum Value	

Turn on verbose output.

- `--loops=#`

Command-Line Format	<code>--loops=#</code>
Type	Numeric
Default Value	<code>0</code>
Minimum Value	<code>0</code>
Maximum Value	<code>MAX_INT</code>

Repeat commands this number of times (for use in testing).

22.4.15 ndb_move_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to `ndb_move_data`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_move_data`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.36 Command-line options for the `ndb_move_data` program

Format	Description	Added, Deprecated, or Removed
<code>--abort-on-error</code>	Dump core on permanent error (debug option)	(Supported in all MySQL 8.0 based releases)
<code>--character-sets-dir=name</code>	Directory where character sets are	(Supported in all MySQL 8.0 based releases)
<code>--database=dbname,</code> <code>-d</code>	Name of database in which table is found	(Supported in all MySQL 8.0 based releases)
<code>--drop-source</code>	Drop source table after all rows have been moved	(Supported in all MySQL 8.0 based releases)
<code>--error-insert</code>	Insert random temporary errors (testing option)	(Supported in all MySQL 8.0 based releases)
<code>--exclude-missing-columns</code>	Ignore extra columns in source or target table	(Supported in all MySQL 8.0 based releases)
<code>--lossy-conversions,</code> <code>-l</code>	Allow attribute data to be truncated when converted to smaller type	(Supported in all MySQL 8.0 based releases)
<code>--promote-attributes,</code> <code>-A</code>	Allow attribute data to be converted to larger type	(Supported in all MySQL 8.0 based releases)
<code>--staging-tries=x[,y[,z]]</code>	Specify tries on temporary errors; format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)	(Supported in all MySQL 8.0 based releases)
<code>--verbose</code>	Enable verbose messages	(Supported in all MySQL 8.0 based releases)

- `--abort-on-error`

Command-Line Format	<code>--abort-on-error</code>
Type	Boolean
Default Value	<code>FALSE</code>

Dump core on permanent error (debug option).

- `--character-sets-dir=name`

Command-Line Format	<code>--character-sets-dir=name</code>
Type	String
Default Value	<code>[none]</code>

Directory where character sets are.

- `--database=dbname, -d`

Command-Line Format	<code>--database=dbname</code>
Type	String
Default Value	<code>TEST_DB</code>

Name of the database in which the table is found.

- `--drop-source`

Command-Line Format	<code>--drop-source</code>
Type	Boolean
Default Value	<code>FALSE</code>

Drop source table after all rows have been moved.

- `--error-insert`

Command-Line Format	<code>--error-insert</code>
Type	Boolean
Default Value	<code>FALSE</code>

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

Command-Line Format	<code>--exclude-missing-columns</code>
Type	Boolean
Default Value	<code>FALSE</code>

Ignore extra columns in source or target table.

- `--lossy-conversions, -l`

Command-Line Format	<code>--lossy-conversions</code>
Type	Boolean
Default Value	<code>FALSE</code>

Allow attribute data to be truncated when converted to a smaller type.

- `--promote-attributes, -A`

Command-Line Format	<code>--promote-attributes</code>
Type	Boolean
Default Value	<code>FALSE</code>

Allow attribute data to be converted to a larger type.

- `--staging-tries=x[,y[,z]]`

Command-Line Format	<code>--staging-tries=x[,y[,z]]</code>
Type	String

Default Value	0,1000,60000
---------------	--------------

Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- `--verbose`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable verbose messages.

22.4.16 **ndb_perror** — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for `perror --ndb`.

Usage

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.

`ndb_perror` replaces `perror --ndb`, which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on `perror` for obtaining NDB error information, `ndb_perror` supports its own “dummy” `--ndb` option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program `ndb_perror`. Additional descriptions follow the table.

Table 22.37 Command-line options for the `ndb_perror` program

Format	Description	Added, Deprecated, or Removed
<code>--help</code> , <code>-?</code>	Display help text	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--ndb</code>	For compatibility with applications depending on old versions of <code>pererror</code> ; does nothing	(Supported in all MySQL 8.0 based releases)
<code>--silent</code> , <code>-s</code>	Show error message only	(Supported in all MySQL 8.0 based releases)
<code>--version</code> , <code>-V</code>	Print program version information and exit	(Supported in all MySQL 8.0 based releases)
<code>--verbose</code> , <code>-v</code>	Verbose output; disable with <code>--silent</code>	(Supported in all MySQL 8.0 based releases)

Additional Options

- `--help`, `-?`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>TRUE</code>

Display program help text and exit.

- `--ndb`

Command-Line Format	<code>--ndb</code>
Type	Boolean
Default Value	<code>TRUE</code>

For compatibility with applications depending on old versions of `pererror` that use that program's `--ndb` option. The option when used with `ndb_perror` does nothing, and is ignored by it.

- `--silent`, `-s`

Command-Line Format	<code>--silent</code>
Type	Boolean
Default Value	<code>TRUE</code>

Show error message only.

- `--version`, `-V`

Command-Line Format	<code>--version</code>
Type	Boolean
Default Value	<code>TRUE</code>

Print program version information and exit.

- `--verbose`, `-v`

Command-Line Format	<code>--verbose</code>
Type	Boolean

Default Value	TRUE
---------------	------

Verbose output; disable with `--silent`.

22.4.17 ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage

```
ndb_print_backup_file [-P password] file_name
```

file_name is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 22.5.8.1, “NDB Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0.17 and later, this program can also be used to read undo log files.

Beginning with NDB 8.0.22, this program can read encrypted backups. To do this, supply the `-P` option together with the password used to encrypt the backup.

Additional Options

None.

22.4.18 ndb_print_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

Usage

```
ndb_print_file [-v] [-q] file_name+
```

file_name is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).

- `--help`, `-h`, `-?`: Print help message.

For more information, see [Section 22.5.10, “NDB Cluster Disk Data Tables”](#).

22.4.19 ndb_print_frag_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

Usage

```
ndb_print_frag_file file_name
```

`file_name` is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `X` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

Sample Output

```
shell> ndb_print_frag_file /usr/local/mysqlld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqlld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
```

22.4.20 ndb_print_schema_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.21 `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBD IH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.22 `ndb_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program `ndb_redo_log_reader`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_redo_log_reader`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.38 Command-line options for the ndb_redo_log_reader program

Format	Description	Added, Deprecated, or Removed
<code>-dump</code>	Print dump info	(Supported in all MySQL 8.0 based releases)
<code>-filedescriptors</code>	Print file descriptors only	(Supported in all MySQL 8.0 based releases)
<code>--help</code>	Print usage information	(Supported in all MySQL 8.0 based releases)
<code>-lap</code>	Provide lap info, with max GCI started and completed	(Supported in all MySQL 8.0 based releases)
<code>-mbyte #</code>	Starting megabyte	(Supported in all MySQL 8.0 based releases)
<code>-mbyteheaders</code>	Show only first page header of each megabyte in file	(Supported in all MySQL 8.0 based releases)
<code>-nocheck</code>	Do not check records for errors	(Supported in all MySQL 8.0 based releases)
<code>-noprint</code>	Do not print records	(Supported in all MySQL 8.0 based releases)
<code>-page #</code>	Start with this page	(Supported in all MySQL 8.0 based releases)
<code>-pageheaders</code>	Show page headers only	(Supported in all MySQL 8.0 based releases)
<code>-pageindex #</code>	Start with this page index	(Supported in all MySQL 8.0 based releases)
<code>-twiddle</code>	Bit-shifted dump	(Supported in all MySQL 8.0 based releases)

Usage

```
ndb_redo_log_reader file_name [options]
```

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (*DataDir*); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#.FragLog`. *nodeid* is the data node's node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see [NDB Cluster Data Node File System Directory](#).

The name of the file to be read may be followed by one or more of the options listed here:

- `-dump`

Command-Line Format	<code>-dump</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print dump info.

- | | |
|---------------------|-------------------------------|
| Command-Line Format | <code>-filedescriptors</code> |
| Type | Boolean |

Default Value	FALSE
---------------	-------

`-filedescriptors`: Print file descriptors only.

- Command-Line Format `--help`

`--help`: Print usage information.

- `-lap`

Command-Line Format	<code>-lap</code>
Type	Boolean
Default Value	FALSE

Provide lap info, with max GCI started and completed.

- Command-Line Format `-mbyte #`
- | | |
|---------------|---------|
| Type | Numeric |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 15 |

`-mbyte #`: Starting megabyte.

`#` is an integer in the range 0 to 15, inclusive.

- Command-Line Format `-mbyteheaders`
- | | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

`-mbyteheaders`: Show only the first page header of every megabyte in the file.

- Command-Line Format `-noprint`
- | | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

`-noprint`: Do not print the contents of the log file.

- Command-Line Format `-nocheck`
- | | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

`-nocheck`: Do not check the log file for errors.

- Command-Line Format `-page #`
- | | |
|---------------|---------|
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 31 |

`-page #`: Start at this page.

`#` is an integer in the range 0 to 31, inclusive.

Command-Line Format	<code>-pageheaders</code>
Type	Boolean
Default Value	<code>FALSE</code>

`-pageheaders`: Show page headers only.

Command-Line Format	<code>-pageindex #</code>
Type	Integer
Default Value	<code>12</code>
Minimum Value	<code>12</code>
Maximum Value	<code>8191</code>

`-pageindex #`: Start at this page index.

`#` is an integer between 12 and 8191, inclusive.

- `-twiddle`

Command-Line Format	<code>-twiddle</code>
Type	Boolean
Default Value	<code>FALSE</code>

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

22.4.23 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

Note

Beginning with NDB 8.0.17, this program no longer prints `NDBT_ProgramExit: ...` when it finishes its run. Applications depending on this behavior should be modified accordingly when upgrading from NDB 8.0.16 or earlier to a NDB 8.0 later release.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 22.5.6, “NDB Cluster Single User Mode”](#), for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most NDB

Cluster programs (including `ndb_restore`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.39 Command-line options for the `ndb_restore` program

Format	Description	Added, Deprecated, or Removed
<code>--allow-pk-changes[=0 1]</code>	Allow changes to set of columns making up table's primary key	ADDED: NDB 8.0.21
<code>--append</code>	Append data to tab-delimited file	(Supported in all MySQL 8.0 based releases)
<code>--backup-password=string</code>	Supply a password for decrypting an encrypted backup with <code>--decrypt</code> ; see documentation for allowed values	ADDED: NDB 8.0.22
<code>--backup-path=dir_name</code>	Path to backup files directory	(Supported in all MySQL 8.0 based releases)
<code>--backupid=#,</code> <code>-b</code>	Restore from backup having this ID	(Supported in all MySQL 8.0 based releases)
<code>--connect,</code> <code>-c</code>	Alias for <code>--connectstring</code>	(Supported in all MySQL 8.0 based releases)
<code>--decrypt</code>	Decrypt an encrypted backup; requires <code>--backup-password</code>	ADDED: NDB 8.0.22
<code>--disable-indexes</code>	Causes indexes from backup to be ignored; may decrease time needed to restore data	(Supported in all MySQL 8.0 based releases)
<code>--dont-ignore-systab=0,</code> <code>-f</code>	Do not ignore system table during restore; experimental only; not for production use	(Supported in all MySQL 8.0 based releases)
<code>--exclude-databases=db-list</code>	List of one or more databases to exclude (includes those not named)	(Supported in all MySQL 8.0 based releases)
<code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code>	If TRUE (default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations	(Supported in all MySQL 8.0 based releases)
<code>--exclude-missing-columns</code>	Causes columns from backup version of table that are missing from version of table in database to be ignored	(Supported in all MySQL 8.0 based releases)
<code>--exclude-missing-tables</code>	Causes tables from backup that are missing from database to be ignored	(Supported in all MySQL 8.0 based releases)
<code>--exclude-tables=table-list</code>	List of one or more tables to exclude (includes those in same database that are not named); each table reference must include database name	(Supported in all MySQL 8.0 based releases)
<code>--fields-enclosed-by=char</code>	Fields are enclosed by this character	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--fields-optionally-enclosed-by</code>	Fields are optionally enclosed by this character	(Supported in all MySQL 8.0 based releases)
<code>--fields-terminated-by=char</code>	Fields are terminated by this character	(Supported in all MySQL 8.0 based releases)
<code>--hex</code>	Print binary types in hexadecimal format	(Supported in all MySQL 8.0 based releases)
<code>--ignore-extended-pk-updates[=0 1]</code>	Ignore log entries containing updates to columns now included in extended primary key	ADDED: NDB 8.0.21
<code>--include-databases=db-list</code>	List of one or more databases to restore (excludes those not named)	(Supported in all MySQL 8.0 based releases)
<code>--include-stored-grants</code>	Restore shared users and grants to <code>ndb_sql_metadata</code> table	ADDED: NDB 8.0.19
<code>--include-tables=table-list</code>	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include database name	(Supported in all MySQL 8.0 based releases)
<code>--lines-terminated-by=char</code>	Lines are terminated by this character	(Supported in all MySQL 8.0 based releases)
<code>--lossy-conversions,</code> <code>-L</code>	Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup	(Supported in all MySQL 8.0 based releases)
<code>--no-binlog</code>	If mysqld is connected and using binary logging, do not log restored data	(Supported in all MySQL 8.0 based releases)
<code>--no-restore-disk-objects,</code> <code>-d</code>	Do not restore objects relating to Disk Data	(Supported in all MySQL 8.0 based releases)
<code>--no-upgrade,</code> <code>-u</code>	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	(Supported in all MySQL 8.0 based releases)
<code>--ndb-nodegroup-map=map,</code> <code>-z</code>	Nodegroup map for NDBCLUSTER storage engine; syntax: list of (source_nodegroup, destination_nodegroup)	(Supported in all MySQL 8.0 based releases)
<code>--nodeid=#,</code> <code>-n</code>	ID of node where backup was taken	(Supported in all MySQL 8.0 based releases)
<code>--num-slices=#</code>	Number of slices to apply when restoring by slice	ADDED: NDB 8.0.20
<code>--parallelism=#,</code> <code>-p</code>	Number of parallel transactions to use while restoring data	(Supported in all MySQL 8.0 based releases)
<code>--preserve-trailing-spaces,</code>	Allow preservation of trailing spaces (including padding) when	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
-P	promoting fixed-width string types to variable-width types	
--print	Print metadata, data, and log to stdout (equivalent to --print-meta --print-data --print-log)	(Supported in all MySQL 8.0 based releases)
--print-data	Print data to stdout	(Supported in all MySQL 8.0 based releases)
--print-log	Print log to stdout	(Supported in all MySQL 8.0 based releases)
--print-meta	Print metadata to stdout	(Supported in all MySQL 8.0 based releases)
--print-sql-log	Write SQL log to stdout; default is FALSE	(Supported in all MySQL 8.0 based releases)
--progress-frequency=#	Print status of restore each given number of seconds	(Supported in all MySQL 8.0 based releases)
--promote-attributes, -A	Allow attributes to be promoted when restoring data from backup	(Supported in all MySQL 8.0 based releases)
--rebuild-indexes	Causes multithreaded rebuilding of ordered indexes found in backup; number of threads used is determined by setting BuildIndexThreads	(Supported in all MySQL 8.0 based releases)
--remap-column=[db]. [tbl].[col]:[fn]:[args]	Apply offset to value of specified column using indicated function and arguments	ADDED: NDB 8.0.21
--restore-data, -r	Restore table data and logs into NDB Cluster using NDB API	(Supported in all MySQL 8.0 based releases)
--restore-epoch, -e	Restore epoch info into status table; useful on replica cluster for starting replication; updates or inserts row in mysql.ndb_apply_status with ID 0	(Supported in all MySQL 8.0 based releases)
--restore-meta, -m	Restore metadata to NDB Cluster using NDB API	(Supported in all MySQL 8.0 based releases)
--restore-privilege- tables	Restore MySQL privilege tables that were previously moved to NDB	DEPRECATED: NDB 8.0.16
--rewrite- database=olddb,newdb	Restore to differently named database	(Supported in all MySQL 8.0 based releases)
--skip-broken-objects	Ignore missing blob tables in backup file	(Supported in all MySQL 8.0 based releases)
--skip-table-check, -s	Skip table structure check during restore	(Supported in all MySQL 8.0 based releases)
--skip-unknown-objects	Causes schema objects not recognized by ndb_restore to be ignored when restoring backup	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--slice-id=#</code>	made from newer NDB version to older version Slice ID, when restoring by slices	ADDED: NDB 8.0.20
<code>--tab=dir_name,</code>	Creates a tab-separated .txt file for each table in path provided	(Supported in all MySQL 8.0 based releases)
<code>-T dir_name</code>		
<code>--verbose=#</code>	Level of verbosity in output	(Supported in all MySQL 8.0 based releases)

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
  [-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup-path` options.

Prior to NDB 8.0.19, when `ndb_restore` was used to restore any tables containing unique indexes, it was necessary to include `--disable-indexes` or `--rebuild-indexes`. Beginning with NDB 8.0.19, when automatic metadata synchronization is enabled, this is no longer necessary.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see [Section 22.3.3.3, “NDB Cluster Connection Strings”](#)). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#)).

In NDB 8.0.22 and later, `ndb_restore` can decrypt an encrypted backup using `--decrypt` and `--backup-password`. Both options must be specified to perform decryption. See the documentation for the `START BACKUP` management client command for information on creating encrypted backups.

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

More detailed information about all options used by `ndb_restore` can be found in the following list:

- `--allow-pk-changes`

Command-Line Format	<code>--allow-pk-changes[=0 1]</code>
Introduced	8.0.21-ndb-8.0.21
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When this option is set to `1`, `ndb_restore` allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears

that performing the restore operation using `ndb_restore` is simpler or more efficient than issuing many `ALTER TABLE` statements after restoring table schemas and data.

The following changes in primary key definitions are supported by `--allow-pk-changes`:

- **Extending the primary key:** A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

Important

When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by `ndb_restore` cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the `--ignore-extended-pk-updates` option; see the description of this option for more information.

- **Contracting the primary key (1):** A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.
- **Contracting the primary key (2):** A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel. (Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

- `--append`

Command-Line Format	<code>--append</code>
---------------------	-----------------------

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- `--backup-path=dir_name`

Command-Line Format	<code>--backup-path=dir_name</code>
---------------------	-------------------------------------

Type	Directory name
Default Value	<code>./</code>

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.20 to a cluster running NDB Cluster 7.4.30, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.20 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backup-password=password`

Command-Line Format	<code>--backup-password=string</code>
Introduced	8.0.22-ndb-8.0.22
Type	String
Default Value	<code>[none]</code>

This option specifies a password to be used when decrypting an encrypted backup with the `--decrypt` option. This must be the same password that was used to encrypt the backup.

The password can be up to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for `!`, `'`, `"`, `$`, `%`, `\`, and `^`.

- `--backupid=#, -b`

Command-Line Format	<code>--backupid=#</code>
Type	Numeric
Default Value	<code>none</code>

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed

upon completion of a backup. (See [Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

In NDB 8.0.15 and later, this option is required.

- `--connect, -c`

Command-Line Format	<code>--connect</code>
Type	String
Default Value	<code>localhost:1186</code>

Alias for `--ndb-connectstring`.

- `--decrypt`

Command-Line Format	<code>--decrypt</code>
Introduced	8.0.22-ndb-8.0.22

Decrypt an encrypted backup using the password supplied by the `--backup-password` option.

- `--disable-indexes`

Command-Line Format	<code>--disable-indexes</code>
---------------------	--------------------------------

Disable restoration of indexes during restoration of the data from a native [NDB](#) backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

- `--dont-ignore-systab-0, -f`

Command-Line Format	<code>--dont-ignore-systab-0</code>
---------------------	-------------------------------------

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the [NDB](#) system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

Command-Line Format	<code>--exclude-databases=db-list</code>
Type	String
Default Value	

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

Command-Line Format	<code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code>
Type	Boolean
Default Value	<code>TRUE</code>

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- `--exclude-missing-columns`

Command-Line Format	<code>--exclude-missing-columns</code>
---------------------	--

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

Command-Line Format	<code>--exclude-missing-tables</code>
---------------------	---------------------------------------

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- `--exclude-tables=table-list`

Command-Line Format	<code>--exclude-tables=table-list</code>
Type	String
Default Value	

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` usng `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

Table 22.40 Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.

Option	Result
<code>--exclude-databases=db1</code>	All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored
<code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>)	All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored

Option	Result
<code>--exclude-tables=db1.t1</code>	All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored
<code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>)	All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

Command-Line Format	<code>--fields-enclosed-by=char</code>
Type	String
Default Value	

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

Command-Line Format	<code>--fields-optionally-enclosed-by</code>
Type	String
Default Value	

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

Command-Line Format	<code>--fields-terminated-by=char</code>
Type	String
Default Value	<code>\t</code> (tab)

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

Command-Line Format	<code>--hex</code>
---------------------	--------------------

If this option is used, all binary values are output in hexadecimal format.

- `--ignore-extended-pk-updates`

Command-Line Format	<code>--ignore-extended-pk-updates[=0 1]</code>
Introduced	8.0.21-ndb-8.0.21
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When using `--allow-pk-changes`, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

Important

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.

- `--include-databases=db-list`

Command-Line Format	<code>--include-databases=db-list</code>
Type	String
Default Value	

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-stored-grants`

Command-Line Format	<code>--include-stored-grants</code>
Introduced	8.0.19-ndb-8.0.19
Type	Boolean

Default Value	FALSE
---------------	-------

In NDB 8.0.19 and later, `ndb_restore` does not by default restore shared users and grants (see [Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#)) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- `--include-tables=table-list`

Command-Line Format	<code>--include-tables=table-list</code>
Type	String
Default Value	

Comma-delimited list of tables to restore; each table reference must include the database name.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

Table 22.41 Several invocations of `ndb_restore` using `--include-*` options, and their effects on restoring from an NDB Cluster backup.

Option	Result
<code>--include-databases=db1</code>	Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored
<code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code>)	Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored
<code>--include-tables=db1.t1</code>	Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored
<code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>)	Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...]] | tbl_name[,tbl_name][,...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

- `--lines-terminated-by=char`

Command-Line Format	<code>--lines-terminated-by=char</code>
Type	String
Default Value	<code>\n</code> (linebreak)

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--lossy-conversions, -L`

Command-Line Format	<code>--lossy-conversions</code>
Type	Boolean
Default Value	<code>FALSE</code> (If option is not used)

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see [Replication of Columns Having Different Data Types](#), for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`

Command-Line Format	<code>--no-binlog</code>
---------------------	--------------------------

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-restore-disk-objects, -d`

Command-Line Format	<code>--no-restore-disk-objects</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 22.5.10, “NDB Cluster Disk Data Tables”](#), for more information about these.

- `--no-upgrade, -u`

Command-Line Format	<code>--no-upgrade</code>
---------------------	---------------------------

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--ndb-nodegroup-map=map, -z`

Command-Line Format	<code>--ndb-nodegroup-map=map</code>
---------------------	--------------------------------------

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

- `--nodeid=#, -n`

Command-Line Format	<code>--nodeid=#</code>
Type	Numeric
Default Value	<code>none</code>

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See [Section 22.4.23.1, “Restoring to a different number of data nodes”](#), for additional information and examples.

In NDB 8.0.15 and later, this option is required.

- `--num-slices=#`

Command-Line Format	<code>--num-slices=#</code>
Introduced	8.0.20-ndb-8.0.20
Type	Integer
Default Value	<code>1</code>
Minimum Value	<code>1</code>
Maximum Value	<code>1024</code>

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of `ndb_restore` to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the `--slice-id` option. The two options must always be used together, and the value set by `--slice-id` must always be less than the number of slices.

`ndb_restore` encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a `BLOB` table, the slice to which a given fragment belongs is determined using the formula shown here:

```
[slice_ID] = [fragment_counter] % [number_of_slices]
```

For a `BLOB` table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the `BLOB` table (recall that `NDB` stores `BLOB` values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

```
[slice_ID] =
([main_table_ID] + [fragment_ID]) % [number_of_slices]
```

Thus, restoring by *N* slices means running *N* instances of `ndb_restore`, all with `--num-slices=N` (along with any other necessary options) and one each with `--slice-id=1`, `--slice-id=2`, `--slice-id=3`, and so on through `slice-id=N-1`.

Example. Assume that you want to restore a backup named `BACKUP-1`, found in the default directory `/var/lib/mysql-cluster/BACKUP/BACKUP-3` on the node file system on each data

node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using `ndb_restore` as shown here:

```
shell> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
```

2. Restore the cluster data to the data nodes invoking `ndb_restore` as shown here:

```
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/1

shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/1

shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/1

shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/1
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/1
```

All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the `--backup-path` option).

3. Restore indexes as usual, as shown here:

```
shell> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```
shell> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a *single* `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism` causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMs.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

- `--parallelism=#, -p`

Command-Line Format	<code>--parallelism=#</code>
Type	Numeric
Default Value	128
Minimum Value	1
Maximum Value	1024

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces, -P`

Command-Line Format	<code>--preserve-trailing-spaces</code>
---------------------	---

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

Command-Line Format	<code>--print</code>
Type	Boolean
Default Value	<code>FALSE</code>

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

Note

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- `--print-data`

Command-Line Format	<code>--print-data</code>
Type	Boolean

Default Value	FALSE
---------------	-------

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

`TEXT` and `BLOB` column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- `--print-log`

Command-Line Format	<code>--print-log</code>
Type	Boolean
Default Value	FALSE

Cause `ndb_restore` to output its log to `stdout`.

- `--print-meta`

Command-Line Format	<code>--print-meta</code>
Type	Boolean
Default Value	FALSE

Print all metadata to `stdout`.

- `print-sql-log`

Command-Line Format	<code>--print-sql-log</code>
Type	Boolean
Default Value	FALSE

Log SQL statements to `stdout`. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by `NDB` cannot be converted to valid SQL.

This option does not work with tables having `BLOB` columns.

- `--progress-frequency=N`

Command-Line Format	<code>--progress-frequency=#</code>
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	65535

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- `--promote-attributes, -A`

Command-Line Format	<code>--promote-attributes</code>
---------------------	-----------------------------------

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be

restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Replication of Columns Having Different Data Types](#), for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$Stnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- `--rebuild-indexes`

Command-Line Format	<code>--rebuild-indexes</code>
---------------------	--------------------------------

Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMS.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMS by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--remap-column=db.tbl.col:fn:args`

Command-Line Format	<code>--remap-column=[db].[tbl].[col]:[fn]:[args]</code>
Introduced	8.0.21-ndb-8.0.21
Type	String
Default Value	<code>[none]</code>

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- `db`: Database name, following any renames performed by `--rewrite-database`.
- `tbl`: Table name.
- `col`: Name of the column to be updated. This column must be of type `INT` or `BIGINT`. The column can also be but is not required to be `UNSIGNED`.
- `fn`: Function name; currently, the only supported name is `offset`.
- `args`: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an `INT` column, then the allowed range of the argument passed to the `offset` function is `-2147483648` to `2147483647` (see [Section 11.1.2, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#)).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a `BIGINT`, and the option attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since $4294967291 + 8 = 4294967299 > 4294967295$.

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see [Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
--remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
```

```
--remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can be obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

- `--restore-data, -r`

Command-Line Format	<code>--restore-data</code>
Type	Boolean
Default Value	<code>FALSE</code>

Output [NDB](#) table data and logs.

- `--restore-epoch, -e`

Command-Line Format	<code>--restore-epoch</code>
---------------------	------------------------------

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).)

- `--restore-meta, -m`

Command-Line Format	<code>--restore-meta</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option causes `ndb_restore` to print [NDB](#) table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore-meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 8.0, when restoring metadata, this is no longer an issue; `ndb_restore` now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option in NDB 8.0.16 or later, it is recommended that auto synchronization be disabled by setting `ndb_metadata_check=OFF` until `ndb_restore` has completed restoring the

metadata, after which it can be turned on again to synchronize objects newly created in the NDB dictionary.

Note

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--restore-privilege-tables`

Command-Line Format	<code>--restore-privilege-tables</code>
Deprecated	8.0.16-ndb-8.0.16
Type	Boolean
Default Value	<code>FALSE</code> (If option is not used)

`ndb_restore` does not by default restore distributed MySQL privilege tables created in releases of NDB Cluster prior to version 8.0, which does not support distributed privileges as implemented in NDB 7.6 and earlier. This option causes `ndb_restore` to restore them.

In NDB 8.0.16 and later, such tables are not used for access control; as part of the MySQL server's upgrade process, the server creates `InnoDB` copies of these tables local to itself. For more information, see [Section 22.2.7, “Upgrading and Downgrading NDB Cluster”](#), as well as [Section 6.2.3, “Grant Tables”](#).

- `--rewrite-database=olddb,newdb`

Command-Line Format	<code>--rewrite-database=olddb,newdb</code>
Type	String
Default Value	<code>none</code>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is

not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

Command-Line Format	<code>--skip-broken-objects</code>
---------------------	------------------------------------

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check, -s`

Command-Line Format	<code>--skip-table-check</code>
---------------------	---------------------------------

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings
- `--skip-unknown-objects`

Command-Line Format	<code>--skip-unknown-objects</code>
---------------------	-------------------------------------

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

Command-Line Format	<code>--slice-id=#</code>
Introduced	8.0.20-ndb-8.0.20
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1023

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name, -T dir_name`

Command-Line Format	<code>--tab=dir_name</code>
Type	Directory name

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--verbose=#`

Command-Line Format	<code>--verbose=#</code>
Type	Numeric
Default Value	1
Minimum Value	0
Maximum Value	255

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Error reporting.

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

Important

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

Restoring a backup to a previous version of NDB Cluster. You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. For example, tables created in NDB 8.0 by default use the `utf8mb4_ai_ci` character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an `ndb_restore` binary from one of these earlier versions.

22.4.23.1 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:

```
[ndbd]
NodeId=2
HostName=host2
```

```
[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
HostName=host8
```

We assume that each data node was originally started with `ndbmtbd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See [Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for information about how to do this.
3. The files created by the backup on each data node are listed here, where *N* is the node ID and *B* is the backup ID.

- `BACKUP-B-0.N.Data`
- `BACKUP-B.Nctl`
- `BACKUP-B.N.log`

These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```
[ndbd]
NodeId=3
hostname=host3

[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmtbd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- `BACKUP-1-0.2.Data`
- `BACKUP-1.2ctl`
- `BACKUP-1.2.log`
- `BACKUP-1-0.6.Data`
- `BACKUP-1.6ctl`
- `BACKUP-1.6.log`

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

- BACKUP-1-0.4.Data
- BACKUP-1.4.ctl
- BACKUP-1.4.log
- BACKUP-1-0.8.Data
- BACKUP-1.8.ctl
- BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Restoring to More Nodes Than the Original

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be known or calculated when performing the backup.

Note

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. *Create the backup of the data.* You can do this by invoking the `ndb_mgm` client `START BACKUP` command from the system shell, like this:

```
shell> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. *Create a backup of the schema.* This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

Important

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.

- Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- `BACKUP-1-0.1.Data`
- `BACKUP-1.1.ct1`
- `BACKUP-1.1.log`

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

- Restore the schema.*

- If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:

```
shell> mysql < myschema.sql
```

When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.

- If you did *not* need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:

```
shell> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP-1
```

`ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

- Restore the data.* This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

```
ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1 --disable-indexes
```

These can be run in parallel.

Be sure to add the `--ndb-connectstring` option as needed.

- Rebuild the indexes.* These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

```
shell> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
```

As mentioned previously, you may need to add the `--ndb-connectstring` option, so that `ndb_restore` can contact the management server.

22.4.23.2 Restoring from a backup taken in parallel

Beginning with NDB Cluster 8.0.16, it is possible to take parallel backups on each data node using `ndbmtd` with multiple LDMs (see [Section 22.5.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#)). The next two sections describe how to restore backups that were taken in this fashion.

Restoring a parallel backup in parallel

Restoring a parallel backup in parallel requires an `ndb_restore` binary from an NDB Cluster distribution version 8.0.16 or later. The process is not substantially different from that outlined in the general usage section under the description of the `ndb_restore` program, and consists of executing `ndb_restore` twice, similarly to what is shown here:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
shell> ndb_restore -n 1 -b 1 -r --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
```

`backup_id` is the ID of the backup to be restored. In the general case, no additional special arguments are required; `ndb_restore` always checks for the existence of parallel subdirectories under the directory indicated by the `--backup-path` option and restores the metadata (serially) and then the table data (in parallel).

Restoring a parallel backup serially

It is possible to restore a backup that was made using parallelism on the data nodes in serial fashion. To do this, invoke `ndb_restore` with `--backup-path` pointing to the subdirectories created by each LDM under the main backup directory, once to any one of the subdirectories to restore the metadata (it does not matter which one, since each subdirectory contains a complete copy of the metadata), then to each of the subdirectories in turn to restore the data. Suppose that we want to restore the backup having backup ID 100 that was taken with four LDMs, and that the `BackupDataDir` is `/opt`. To restore the metadata in this case, we can invoke `ndb_restore` like this:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
```

To restore the table data, execute `ndb_restore` four times, each time using one of the subdirectories in turn, as shown here:

```
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-2-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-3-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-4-OF-4
```

You can employ the same technique to restore a parallel backup to an older version of NDB Cluster (prior to NDB 8.0.16) that does not support parallel backups, using the `ndb_restore` binary supplied with the older version of the NDB Cluster software.

22.4.24 ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_all`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.42 Command-line options for the `ndb_select_all` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname,</code>	Name of database in which table is found	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>-d</code> <code>--parallelism=#,</code> <code>-p</code> <code>--lock=#,</code> <code>-l</code> <code>--order=index,</code> <code>-o</code> <code>--descending,</code> <code>-z</code> <code>--header,</code> <code>-h</code> <code>--useHexFormat,</code> <code>-x</code> <code>--delimiter=char,</code> <code>-D</code> <code>--disk</code> <code>--rowid</code> <code>--gci</code> <code>--gci64</code> <code>--tupscan,</code> <code>-t</code> <code>--nodata</code>	Degree of parallelism Lock type Sort resultset according to index having this name Sort resultset in descending order (requires --order) Print header (set to 0 FALSE to disable headers in output) Output numbers in hexadecimal format Set column delimiter Print disk references (useful only for Disk Data tables having nonindexed columns) Print row ID Include GCI in output Include GCI and row epoch in output Scan in tup order Do not print table column data	(Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases) (Supported in all MySQL 8.0 based releases)

- `--database=dbname`, `-d dbname`

Name of the database in which the table is found. The default value is `TEST_DB`.

- `parallelism=#`, `-p #`

Specifies the degree of parallelism.

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`.

Note

This is the name of an index, not of a column; the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

Excludes column headers from the output.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See [Section 22.1, “NDB Cluster Overview”](#), and [Section 22.5.3.2, “NDB Cluster Log Events”](#), for more information about checkpoints.

- `--gci64`

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--tupscan, -t`

Scan the table in the order of the tuples.

- `--nodata`

Causes any table data to be omitted.

Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name  |
+----+-----+
| 3  | shark |
| 6  | puffer|
| 2  | tuna  |
| 4  | manta ray |
| 5  | grouper|
| 1  | guppy |
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets (`[...]`) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name      breed      DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]    [Mutt]      [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian]  [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]     [Collie]    [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

22.4.25 ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_count`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.43 Command-line options for the `ndb_select_count` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname,</code> <code>-d</code>	Name of database in which table is found	(Supported in all MySQL 8.0 based releases)
<code>--parallelism=#,</code> <code>-p</code>	Degree of parallelism	(Supported in all MySQL 8.0 based releases)
<code>--lock=#,</code> <code>-l</code>	Lock type	(Supported in all MySQL 8.0 based releases)

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

22.4.26 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster

`ndb_setup.py` starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

Important

This program is intended to be invoked as a normal user, and not with the `mysql`, system `root` or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when `ndb_setup.py` is invoked, see [The NDB Cluster Auto-Installer \(NDB 7.5\) \(DEPRECATED\)](#).

Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

Table 22.44 Command-line options for the `ndb_setup.py` program

Format	Description	Added, Deprecated, or Removed
<code>--browser-start-page=filename,</code> <code>-s</code>	Page that web browser opens when starting	(Supported in all MySQL 8.0 based releases)
<code>--ca-certs-file=filename,</code> <code>-a</code>	File containing list of client certificates allowed to connect to server	(Supported in all MySQL 8.0 based releases)
<code>--cert-file=filename,</code> <code>-c</code>	File containing X509 certificate identifying server	(Supported in all MySQL 8.0 based releases)
<code>--debug-level=level,</code> <code>-d</code>	Python logging module debug level; one of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL	(Supported in all MySQL 8.0 based releases)
<code>--help,</code> <code>-h</code>	Print help message	(Supported in all MySQL 8.0 based releases)
<code>--key-file=file,</code> <code>-k</code>	Specify file containing private key (if not included in <code>--cert-file</code>)	(Supported in all MySQL 8.0 based releases)
<code>--no-browser,</code> <code>-n</code>	Do not open start page in browser, merely start tool	(Supported in all MySQL 8.0 based releases)
<code>--port=#,</code> <code>-p</code>	Specify port used by web server	(Supported in all MySQL 8.0 based releases)
<code>--server-log-file=file,</code> <code>-o</code>	Log requests to this file; use '-' to force logging to stderr instead	(Supported in all MySQL 8.0 based releases)
<code>--server-name=name,</code> <code>-N</code>	Name of server to connect to	(Supported in all MySQL 8.0 based releases)
<code>--use-http,</code> <code>-H</code>	Use unencrypted (HTTP) client/server connection	(Supported in all MySQL 8.0 based releases)
<code>--use-https,</code> <code>-S</code>	Use encrypted (HTTPS) client/server connection	(Supported in all MySQL 8.0 based releases)

- `--browser-start-page=file, -s`

Command-Line Format	<code>--browser-start-page=filename</code>
---------------------	--

Type	String
Default Value	<code>index.html</code>

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=file, -a`

Command-Line Format	<code>--ca-certs-file=filename</code>
Type	File name
Default Value	<code>[none]</code>

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=file, -c`

Command-Line Format	<code>--cert-file=filename</code>
Type	File name
Default Value	<code>/usr/share/mysql/mcc/cfg.pem</code>

Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`

Command-Line Format	<code>--debug-level=level</code>
Type	Enumeration
Default Value	<code>WARNING</code>
Valid Values	<code>WARNING</code> <code>DEBUG</code> <code>INFO</code> <code>ERROR</code> <code>CRITICAL</code>

Set the Python logging module debug level. This is one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, or `CRITICAL`. `WARNING` is the default.

- `--help, -h`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Print a help message.

- `--key-file=file, -d`

Command-Line Format	<code>--key-file=file</code>
Type	File name
Default Value	<code>[none]</code>

Specify a file containing the private key if this is not included in the X509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser, -n`

Command-Line Format	<code>--no-browser</code>
---------------------	---------------------------

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#, -p`

Command-Line Format	<code>--port=#</code>
Type	Numeric
Default Value	8081
Minimum Value	1
Maximum Value	65535

Set the port used by the web server. The default is 8081.

- `--server-log-file=file, -o`

Command-Line Format	<code>--server-log-file=file</code>
Type	File name
Default Value	<code>ndb_setup.log</code>
Valid Values	<code>ndb_setup.log</code> - (Log to stderr)

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a - (dash character) for the file name.

- `--server-name=host, -N`

Command-Line Format	<code>--server-name=name</code>
Type	String
Default Value	<code>localhost</code>

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.

- `--use-http, -H`

Command-Line Format	<code>--use-http</code>
---------------------	-------------------------

Make the browser use HTTP to connect with the server. This means that the connection is unencrypted and not secured in any way.

- `--use-https, -S`

Command-Line Format	<code>--use-https</code>
---------------------	--------------------------

Make the browser use a secure (HTTPS) connection with the server.

22.4.27 ndb_show_tables — Display List of NDB Tables

3942

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_show_tables`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.45 Command-line options for the `ndb_show_tables` program

Format	Description	Added, Deprecated, or Removed
<code>--database=string,</code> <code>-d</code>	Specifies database in which table is found; database name must be followed by table name	(Supported in all MySQL 8.0 based releases)
<code>--loops=#,</code> <code>-l</code>	Number of times to repeat output	(Supported in all MySQL 8.0 based releases)
<code>--parsable,</code> <code>-p</code>	Return output suitable for MySQL LOAD DATA statement	(Supported in all MySQL 8.0 based releases)
<code>--show-temp-status</code>	Show table temporary flag	(Supported in all MySQL 8.0 based releases)
<code>--type=#,</code> <code>-t</code>	Limit output to objects of this type	(Supported in all MySQL 8.0 based releases)
<code>--unqualified,</code> <code>-u</code>	Do not qualify table names	(Supported in all MySQL 8.0 based releases)

Usage

```
ndb_show_tables [-c connection_string]
```

- `--database, -d`

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table

- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- --unqualified, -u

If specified, this causes unqualified object names to be displayed.

Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 22.4.24, “ndb_select_all — Print Rows from an NDB Table”](#)).

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

22.4.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the NDB Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_size.pl`), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.46 Command-line options for the `ndb_size.pl` program

Format	Description	Added, Deprecated, or Removed
<code>--database=dbname</code>	Database or databases to examine; a comma-delimited list; default is ALL (use all databases found on server)	(Supported in all MySQL 8.0 based releases)
<code>--hostname[:port]</code>	Specify host and optional port as host[:port]	(Supported in all MySQL 8.0 based releases)
<code>--socket=file_name</code>	Specify socket to connect to	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--user=string</code>	Specify MySQL user name	(Supported in all MySQL 8.0 based releases)
<code>--password=string</code>	Specify MySQL user password	(Supported in all MySQL 8.0 based releases)
<code>--format=string</code>	Set output format (text or HTML)	(Supported in all MySQL 8.0 based releases)
<code>--excludetables=tbl_list</code>	Skip any tables in comma-separated list	(Supported in all MySQL 8.0 based releases)
<code>--excludedbs=db_list</code>	Skip any databases in comma-separated list	(Supported in all MySQL 8.0 based releases)
<code>--savequeries=file</code>	Saves all queries on database into file specified	(Supported in all MySQL 8.0 based releases)
<code>--loadqueries=file</code>	Loads all queries from file specified; does not connect to database	(Supported in all MySQL 8.0 based releases)
<code>--real_table_name=table</code>	Designates table to handle unique index size calculations	(Supported in all MySQL 8.0 based releases)

Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
  [--user=user] [--password=password] \
  [--help|-h] [--format={html|text}] \
  [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost:mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1
-----

DataMemory for Columns (* means var sized DataMemory):
  Column Name      Type  Varsized  Key  4.1  5.0  5.1
  -----

Fixedsize DataMemory (KB)	0	0	0	
Rows/32kb Varsize DM Page	0	0	2040	
Varsize DataMemory (KB)	0	0	0	
Rows/8kb IM Page	248	512	512	
IndexMemory (KB)	0	0	0	
Parameter Minimum Requirements				

* indicates greater than default				
Parameter	Default	4.1	5.0	5.1
DataMemory (KB)	81920	0	0	0
NoOfOrderedIndexes	128	1	1	1
NoOfTables	128	1	1	1
IndexMemory (KB)	18432	0	0	0
NoOfUniqueHashIndexes	64	0	0	0
NoOfAttributes	1000	3	3	3
NoOfTriggers	768	5	5	5

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

22.4.29 ndb_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host` (`-h`) and `--port` (`-t`). To specify a MySQL user and password, use the `--user` (`-u`) and `--passwd` (`-p`) options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see [Section 6.2, “Access Control and Account Management”](#).

Output is available as plain text or an ASCII graph; you can specify this using the `--text` (`-x`) and `--graph` (`-g`) options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort`, `-r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load` (`-m`) and `--os-load` (`-o`) options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id` (`-n`) option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time` (`-s`).

Note

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

Table 22.47 Command-line options for the `ndb_top` program

Format	Description	Added, Deprecated, or Removed
<code>--color</code> , <code>-c</code>	Show ASCII graphs in color; use <code>--skip-colors</code> to disable	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--graph,</code> <code>-g</code>	Display data using graphs; use <code>--skip-graphs</code> to disable	(Supported in all MySQL 8.0 based releases)
<code>--help,</code> <code>-?</code>	Show program usage information	(Supported in all MySQL 8.0 based releases)
<code>--host[=name],</code> <code>-h</code>	Host name or IP address of MySQL Server to connect to	(Supported in all MySQL 8.0 based releases)
<code>--measured-load,</code> <code>-m</code>	Show measured load by thread	(Supported in all MySQL 8.0 based releases)
<code>--node-id[=#],</code> <code>-n</code>	Watch node having this node ID	(Supported in all MySQL 8.0 based releases)
<code>--os-load,</code> <code>-o</code>	Show load measured by operating system	(Supported in all MySQL 8.0 based releases)
<code>--password[=password],</code> <code>-p</code>	Connect using this password	(Supported in all MySQL 8.0 based releases)
<code>--port[=#],</code> <code>-P (>=7.6.6)</code>	Port number to use when connecting to MySQL Server	(Supported in all MySQL 8.0 based releases)
<code>--sleep-time[=seconds],</code> <code>-s</code>	Time to wait between display refreshes, in seconds	(Supported in all MySQL 8.0 based releases)
<code>--socket,</code> <code>-S</code>	Socket file to use for connection	(Supported in all MySQL 8.0 based releases)
<code>--sort,</code> <code>-r</code>	Sort threads by usage; use <code>--skip-sort</code> to disable	(Supported in all MySQL 8.0 based releases)
<code>--text,</code> <code>-t (>=7.6.6)</code>	Display data using text	(Supported in all MySQL 8.0 based releases)
<code>--user[=name],</code> <code>-u</code>	Connect as this MySQL user	(Supported in all MySQL 8.0 based releases)

In NDB 7.6.6 and later, `ndb_top` also supports the common NDB program options `--defaults-file`, `--defaults-extra-file`, `--print-defaults`, `--no-defaults`, and `--defaults-group-suffix`. (Bug #86614, Bug #26236298)

Additional Options

- `--color, -c`

Command-Line Format	<code>--color</code>
Type	Boolean
Default Value	<code>TRUE</code>

Show ASCII graphs in color; use `--skip-colors` to disable.

- `--graph, -g`

Command-Line Format	<code>--graph</code>
Type	Boolean
Default Value	<code>TRUE</code>

Display data using graphs; use `--skip-graphs` to disable. This option or `--text` must be true; both options may be true.

- `--help, -?`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>TRUE</code>

Show program usage information.

- `--host[=name], -h`

Command-Line Format	<code>--host[=name]</code>
Type	String
Default Value	<code>localhost</code>

Host name or IP address of MySQL Server to connect to.

- `--measured-load, -m`

Command-Line Format	<code>--measured-load</code>
Type	Boolean
Default Value	<code>FALSE</code>

Show measured load by thread. This option or `--os-load` must be true; both options may be true.

- `--node-id[=#], -n`

Command-Line Format	<code>--node-id[=#]</code>
Type	Integer
Default Value	<code>1</code>

Watch the data node having this node ID.

- `--os-load, -o`

Command-Line Format	<code>--os-load</code>
Type	Boolean
Default Value	<code>TRUE</code>

Show load measured by operating system. This option or `--measured-load` must be true; both options may be true.

- `--passwd[=password], -p`

Command-Line Format	<code>--passwd[=password]</code>
Type	Boolean

Default Value	NULL
---------------	------

Connect using this password.

This option is deprecated in NDB 7.6.4. It is removed in NDB 7.6.6, where it is replaced by the `--password` option. (Bug #26907833)

- `--password[=password], -p`

Command-Line Format	<code>--password[=password]</code>
Type	Boolean
Default Value	NULL

Connect using this password.

This option was added in NDB 7.6.6 as a replacement for the `--passwd` option used previously. (Bug #26907833)

- `--port[=#], -t` (NDB 7.6.6 and later: `-P`)

Command-Line Format	<code>--port[=#]</code>
Type	Integer
Default Value	3306

Port number to use when connecting to MySQL Server.

Beginning with NDB 7.6.6, the short form for this option is `-P`, and `-t` is repurposed as the short form for the `--text` option. (Bug #26907833)

- `--sleep-time[=seconds], -s`

Command-Line Format	<code>--sleep-time[=seconds]</code>
Type	Integer
Default Value	1

Time to wait between display refreshes, in seconds.

- `--socket=path/to/file, -S`

Command-Line Format	<code>--socket</code>
Type	Path name
Default Value	[none]

Use the specified socket file for the connection.

Added in NDB 7.6.6. (Bug #86614, Bug #26236298)

- `--sort, -r`

Command-Line Format	<code>--sort</code>
Type	Boolean
Default Value	TRUE

Sort threads by usage; use `--skip-sort` to disable.

- `--text, -t`

Command-Line Format	<code>--text</code>
Type	Boolean
Default Value	<code>FALSE</code>

Display data using text. This option or `--graph` must be true; both options may be true.

The short form for this option was `-x` in previous versions of NDB Cluster, but this is no longer supported.

- `--user[=name]`, `-u`

Command-Line Format	<code>--user[=name]</code>
Type	String
Default Value	<code>root</code>

Connect as this MySQL user.

Sample Output. The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmt` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

Figure 22.26 `ndb_top` Running in Terminal

Beginning with NDB 8.0.20, `ndb_top` also shows spin times for threads, displayed in green.

22.4.30 `ndb_waiter` — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.

- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's **RESTART** command.
- **STARTING**: The node's **ndbd** process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.
- **SINGLE_USER_MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program **ndb_waiter**. Additional descriptions follow the table. For options common to most NDB Cluster programs (including **ndb_waiter**), see [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

Table 22.48 Command-line options for the **ndb_waiter program**

Format	Description	Added, Deprecated, or Removed
<code>--no-contact,</code> <code>-n</code>	Wait for cluster to reach NO CONTACT state	(Supported in all MySQL 8.0 based releases)
<code>--not-started</code>	Wait for cluster to reach NOT STARTED state	(Supported in all MySQL 8.0 based releases)
<code>--single-user</code>	Wait for cluster to enter single user mode	(Supported in all MySQL 8.0 based releases)
<code>--timeout=#,</code> <code>-t</code>	Wait this many seconds, then exit whether or not cluster has reached desired state	(Supported in all MySQL 8.0 based releases)
<code>--nowait-nodes=list</code>	List of nodes not to be waited for	(Supported in all MySQL 8.0 based releases)
<code>--wait-nodes=list,</code> <code>-w</code>	List of nodes to be waited for	(Supported in all MySQL 8.0 based releases)

Usage

```
ndb_waiter [-c connection_string]
```

Additional Options

- `--no-contact, -n`

Instead of waiting for the **STARTED** state, **ndb_waiter** continues running until the cluster reaches **NO_CONTACT** status before exiting.

- `--not-started`

Instead of waiting for the **STARTED** state, **ndb_waiter** continues running until the cluster reaches **NOT_STARTED** status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

Important

Do *not* use this option together with the `--wait-nodes` option.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

Important

Do *not* use this option together with the `--nowait-nodes` option.

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by ...) are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...
```

```

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

```

Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

22.4.31 ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The `ndbxfrm` utility, introduced in NDB 8.0.22, can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

Table 22.49 Command-line options for the `ndbxfrm` program

Format	Description	Added, Deprecated, or Removed
<code>--compress,</code> <code>-c</code>	Compress file	ADDED: NDB 8.0.22
<code>--decrypt-</code> <code>password=string</code>	Use this password to decrypt file	ADDED: NDB 8.0.22
<code>--encrypt-kdf-iter-</code> <code>count=#,</code>	Number of iterations used in key definition	ADDED: NDB 8.0.22
<code>-k</code> <code>--encrypt-</code> <code>password=string</code>	Use this password to encrypt file	ADDED: NDB 8.0.22
<code>--help,</code>	Print usage information	ADDED: NDB 8.0.22
<code>-?</code> <code>--info,</code>	Print file information	ADDED: NDB 8.0.22
<code>-i</code> <code>--usage,</code>	Prints usage information; synonym for <code>--help</code>	ADDED: NDB 8.0.22
<code>-?</code> <code>--version,</code>	Output version information	ADDED: NDB 8.0.22
<code>-V</code>		

Usage

```
ndbxfrm --info file[ file ...]

ndbxfrm --compress input_file output_file

ndbxfrm --decrypt-password=password input_file output_file

ndbxfrm [--encrypt-ldf-iter-count=#] --encrypt-password=password input_file output_file
```

Options

- `--compress, -c`

Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup file that is not encrypted, it is necessary only to invoke `ndbxfrm` using the names of the compressed file and an output file (with no options required).

- `--decrypt-password=password`

Decrypts a file encrypted by NDB using the password supplied.

- `--encrypt-kdf-iter-count=#, -k #`

When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the `--encrypt-password` option.

- `--encrypt-password=password`

Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

- Uses any of the printable ASCII characters except `!`, `'`, `"`, `$`, `%`, `\`, and `^`
- Contains at least 1 character but is no more than 256 characters in length
- Is enclosed by single or double quotation marks

Because `ndbxfrm` expects to find a secret key in any files to be encrypted or decrypted, it can perform these tasks only with backup files created using NDB Cluster 8.0.22 or later.

- `--help, -?`

Prints usage information for the program.

- `--info, -i`

Prints the following information about one or more input files:

- The name of the file
- Whether the file is compressed (`compression=yes` or `compression=no`)
- Whether the file is encrypted (`encryption=yes` or `encryption=no`)

Example:

```
shell> ndbxfrm -i BACKUP-10-0.5.Data BACKUP-10.5.ctl BACKUP-10.5.log
File=BACKUP-10-0.5.Data, compression=no, encryption=yes
File=BACKUP-10.5.ctl, compression=no, encryption=yes
File=BACKUP-10.5.log, compression=no, encryption=yes
```

- `--usage, -?`

Synonym for `--help`.

- `--version`, `-V`

Prints out version information.

Note

`ndbxfrm` does not take any of the options shown in [Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), other than those explicitly listed in this section (that is, `--help`, `--usage`, and `--version`).

22.4.32 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`

Note

Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with `mysqld`. You can use the `--help` option with any NDB Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

Table 22.50 Command-line options common to all MySQL NDB Cluster programs

Format	Description	Added, Deprecated, or Removed
<code>--character-sets-dir=dir_name</code>	Directory where character sets are installed	(Supported in all MySQL 8.0 based releases)
<code>--connect-retries=#</code>	Set the number of times to retry a connection before giving up	(Supported in all MySQL 8.0 based releases)
<code>--connect-retry-delay=#</code>	Time to wait between attempts to contact a management server, in seconds	(Supported in all MySQL 8.0 based releases)
<code>--core-file</code>	Write core on errors (defaults to TRUE in debug builds)	(Supported in all MySQL 8.0 based releases)
<code>--debug=options</code>	Enable output from debug calls. Can be used only for versions compiled with debugging enabled	(Supported in all MySQL 8.0 based releases)
<code>--defaults-extra-file=filename</code>	Read this file after global option files are read	(Supported in all MySQL 8.0 based releases)

Format	Description	Added, Deprecated, or Removed
<code>--defaults-file=filename</code>	Read default options from this file	(Supported in all MySQL 8.0 based releases)
<code>--defaults-group-suffix</code>	Also read groups with names ending in this suffix	(Supported in all MySQL 8.0 based releases)
<code>--help,</code> <code>--usage,</code> <code>-?</code>	Display help message and exit	(Supported in all MySQL 8.0 based releases)
<code>--login-path=path</code>	Read this path from the login file	(Supported in all MySQL 8.0 based releases)
<code>--ndb-connectstring=connectstring,</code> <code>--connect-string=connectstring,</code> <code>-c</code>	Set connection string for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=<id>;]</code> <code>[host=]<hostname>[:<port>]</code> . Overrides entries specified in <code>NDB_CONNECTSTRING</code> or <code>my.cnf</code>	(Supported in all MySQL 8.0 based releases)
<code>--ndb-mgmd-host=host[:port]</code>	Set the host (and port, if desired) for connecting to management server	(Supported in all MySQL 8.0 based releases)
<code>--ndb-nodeid=#</code>	Set node id for this node	(Supported in all MySQL 8.0 based releases)
<code>--ndb-optimized-node-selection</code>	Select nodes for transactions in a more optimal way	(Supported in all MySQL 8.0 based releases)
<code>--no-defaults</code>	Do not read default options from any option file other than login file	(Supported in all MySQL 8.0 based releases)
<code>--print-defaults</code>	Print the program argument list and exit	(Supported in all MySQL 8.0 based releases)
<code>--version,</code> <code>-V</code>	Output version information and exit	(Supported in all MySQL 8.0 based releases)

For options specific to individual NDB Cluster programs, see [Section 22.4, “NDB Cluster Programs”](#).

See [MySQL Server Options for NDB Cluster](#), for `mysqld` options relating to NDB Cluster.

- `--character-sets-dir=name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name
Default Value	

Tells the program where to find character set information.

- `--connect-retries=#`

Command-Line Format	<code>--connect-retries=#</code>
Type	Numeric
Default Value	12
Minimum Value	0

Maximum Value	4294967295
---------------	------------

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

Note

When used with `ndb_mgm`, this option has 3 as its default. See [Section 22.4.5, “ndb_mgm — The NDB Cluster Management Client”](#), for more information.

- `--connect-retry-delay=#`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Numeric
Default Value	5
Minimum Value	1
Minimum Value	0
Maximum Value	4294967295

This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
Type	Boolean
Default Value	<code>FALSE</code>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

Command-Line Format	<code>--debug=options</code>
Type	String
Default Value	<code>d:t:0,/tmp/ndb_restore.trace</code>

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--defaults-extra-file=filename`

Command-Line Format	<code>--defaults-extra-file=filename</code>
Type	String
Default Value	<code>[none]</code>

Read this file after global option files are read.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=filename`

Command-Line Format	<code>--defaults-file=filename</code>
Type	String
Default Value	<code>[none]</code>

Read default options from this file.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix</code>
Type	String
Default Value	<code>[none]</code>

Also read groups with names ending in this suffix.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--help`, `--usage`, `-?`

Command-Line Format	<code>--help</code> <code>--usage</code>
---------------------	---

Prints a short list with descriptions of the available command options.

- `--login-path=path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read this path from the login file.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--ndb-connectstring=connection_string`, `--connect-string=connection_string`, `-c connection_string`

Command-Line Format	<code>--ndb-connectstring=connectstring</code> <code>--connect-string=connectstring</code>
Type	String

Default Value	<code>localhost:1186</code>
---------------	-----------------------------

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 22.3.3.3, “NDB Cluster Connection Strings”](#).

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	<code>--ndb-mgmd-host=host[:port]</code>
Type	String
Default Value	<code>localhost:1186</code>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Numeric
Default Value	0

Sets this node's NDB Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the NDB Cluster software version.* See [Section 22.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#), for more information.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
Type	Boolean
Default Value	TRUE

Do not read default options from any option file other than login file.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
Type	Boolean
Default Value	TRUE

Optimize selection of nodes for transactions. Enabled by default.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
Type	Boolean

Default Value	TRUE
---------------	------

Print the program argument list and exit.

For additional information about this and other option-file options, see [Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster.

See [Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)), for more information.

22.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in [Section 22.3, “Configuration of NDB Cluster”](#), and [Section 22.4, “NDB Cluster Programs”](#).

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see [Section 22.5.17, “NDB Cluster Security Issues”](#).

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. MySQL Cluster Manager version 1.4.8 provides experimental support for NDB 8.0. See [MySQL™ Cluster Manager 1.4.8 User Manual](#), for more information.

22.5.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 22.5.3, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 22.5.8, “Online Backup of NDB Cluster”](#).

Using `ndb_mgm` with MySQL Cluster Manager. MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

Displays information on all available commands.

- `CONNECT connection-string`

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `SHOW`

Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`). In NDB 8.0.17 and later, it also indicates which API or SQL node has exclusive access when this mode is in effect; this works only when all data nodes and management nodes connected to the cluster are version 8.0.17 or later.

- `node_id START`

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

Important

To use this command to bring a data node online, the data node must have been started using `--nostream` or `-n`.

- `node_id STOP [-a] [-f]`

Stops the data or management node identified by `node_id`.

**Note**

`ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

**Warning**

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- `node_id RESTART [-n] [-i] [-a] [-f]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

**Note**

Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.

- `node_id` `REPORT` *report-type*

Displays a report of type *report-type* for the data node identified by *node_id*, or for all data nodes using `ALL`.

Currently, there are three accepted values for *report-type*:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

report-type is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `ENTER SINGLE USER MODE` *node_id*

Enters single user mode, whereby only the MySQL server identified by the node ID *node_id* is permitted to access the database.

Beginning with NDB 8.0.17, the `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:

```
ndb_mgm> ENTER SINGLE USER MODE 100
Single user mode entered
Access is granted for API node 100 only.
```

Also in NDB 8.0.17 and later, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=5 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0, *)
id=6 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=50 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17)

[mysqld(API)] 2 node(s)
id=100 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, allowed single user)
id=101 (not connected, accepting connect from any host)
```

Note

All data and management nodes must be running version 8.0.17 of the NDB Cluster software for this feature to be enabled.

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT`, `EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 22.5.7, “Adding NDB Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the NDB Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3      @10.100.2.67  (8.0.22-ndb-8.0.22, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 22.5.7, “Adding NDB Cluster Data Nodes Online”](#).

- `PROMPT [prompt]`

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:'
'mymgm:' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
jon@valhaj:~/bin>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

- `node_id NODELOG DEBUG {ON|OFF}`

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

Additional commands. A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see [Section 22.5.8, “Online Backup of NDB Cluster”](#).
- The `CLUSTERLOG` command is used to perform various logging functions. See [Section 22.5.3, “Event Reports Generated in NDB Cluster”](#), for more information and examples. `NODELOG DEBUG` activates or deactivates debug printouts in node logs, as described previously in this section.
- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see [MySQL NDB Cluster Internals Manual](#).

22.5.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

22.5.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see [Section 22.5.3, “Event Reports Generated in NDB Cluster”](#). These

log messages also correspond to log event types in the MGM API; see [The Ndb_logevent_type Type](#), for related information of interest to Cluster API developers.

Table 22.51 Common NDB cluster log messages

Log Message	Description	Event Name	Event Type	Priority	Severity
Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Connected	The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i>).	Connected	Connection	8	INFO
Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Disconnected	The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i>).	Disconnected	Connection	8	ALERT
Node <i>data_node_id</i> : Communication to Node <i>api_node_id</i> closed	The API node or SQL node having node ID <i>api_node_id</i> is no longer communicating with data node <i>data_node_id</i> .	CommunicationClosed	Connection	8	INFO
Node <i>data_node_id</i> : Communication to Node <i>api_node_id</i> opened	The API node or SQL node having node ID <i>api_node_id</i> is now communicating with data node <i>data_node_id</i> .	CommunicationOpened	Connection	8	INFO
Node <i>mgm_node_id</i> : Node <i>api_node_id</i> : API version	The API node having node ID <i>api_node_id</i> has connected to management node <i>mgm_node_id</i> using NDB API version <i>version</i> (generally the same as the MySQL version number).	ConnectedApiVersion	Connection	8	INFO
Node <i>node_id</i> : Global checkpoint <i>gci</i> started	A global checkpoint with the ID <i>gci</i> has been started; node <i>node_id</i> is the master responsible for this global checkpoint.	GlobalCheckpointStart	Checkpoint	9	INFO

Log Message	Description	Event Name	Event Type	Priority	Severity
Node <i>node_id</i> : Global checkpoint <i>gci</i> completed	The global checkpoint having the ID <i>gci</i> has been completed; node <i>node_id</i> was the master responsible for this global checkpoint.	GlobalCheckpointCompleted	Checkpoint	10	INFO
Node <i>node_id</i> : Local checkpoint <i>lcp</i> started. Keep GCI = <i>current_gci</i> oldest restorable GCI = <i>old_gci</i>	The local checkpoint having sequence ID <i>lcp</i> has been started on node <i>node_id</i> . The most recent GCI that can be used has the index <i>current_gci</i> , and the oldest GCI from which the cluster can be restored has the index <i>old_gci</i> .	LocalCheckpointStarted	Checkpoint	7	INFO
Node <i>node_id</i> : Local checkpoint <i>lcp</i> completed	The local checkpoint having sequence ID <i>lcp</i> on node <i>node_id</i> has been completed.	LocalCheckpointCompleted	Checkpoint	8	INFO
Node <i>node_id</i> : Local Checkpoint stopped in CALCULATED_KEEP_GCI	The node was unable to determine the most recent usable GCI.	LCPStoppedInCalcKeepGCI	Checkpoint	0	ALERT
Node <i>node_id</i> : Table ID = <i>table_id</i> , fragment ID = <i>fragment_id</i> has completed LCP on Node <i>node_id</i> maxGciStarted: <i>started_gci</i> maxGciCompleted: <i>completed_gci</i>	A table fragment has been checkpointed to disk on node <i>node_id</i> . The GCI in progress has the index <i>started_gci</i> , and the most recent GCI to have been completed has the index <i>completed_gci</i> .	LCPFragmentCompleted	Checkpoint	11	INFO
Node <i>node_id</i> : ACC Blocked <i>num_1</i> and TUP Blocked <i>num_2</i> times last second	Undo logging is blocked because the log buffer is close to overflowing.	UndoLogBlocked	Checkpoint	7	INFO

22.5.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [all: %s connected: %s no-wait: %s]
- Waiting until nodes: %s connects, nodes [all: %s connected: %s no-wait: %s]
- Waiting %u sec for nodes %s to connect, nodes [all: %s connected: %s no-wait: %s]
- Waiting for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]
- Waiting %u sec for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]
- Initial start with nodes %s [missing: %s no-wait: %s]
- Start with all nodes %s
- Start with nodes %s [missing: %s no-wait: %s]
- Start potentially partitioned with nodes %s [missing: %s no-wait: %s]
- Unknown startreport: 0x%x [%s %s %s %s]

22.5.2.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each `Ndb` object subscribing to table events, which means that there are usually two buffers for each `mysqld` performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- *node_id*: ID of the node where the report originated.
- *object_id*: ID of the `Ndb` object where the report originated.
- *bytes_used*: Number of bytes used by the buffer.
- *percent_used*: Percentage of allocated bytes used.

- `bytes_allocated`: Number of bytes allocated to this buffer.
- `percent_alloc`: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- `bytes_available`: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- `latest_consumed_epoch`: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- `latest_buffered_epoch`: The epoch most recently buffered (completely) in the event buffer.
- `report_reason`: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- `ENOUGH_FREE_EVENTBUFFER`: The event buffer has sufficient space.

`LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- `BUFFERED_EPOCHS_OVER_THRESHOLD`: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- `PARTIALLY_DISCARDING`: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.
- `COMPLETELY_DISCARDING`: No epochs are buffered.
- `PARTIALLY_BUFFERING`: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.
- `COMPLETELY_BUFFERING`: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

22.5.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

0x00	<code>TE_NO_ERROR</code>
	No error
0x01	<code>TE_ERROR_CLOSING_SOCKET</code>
	Error found during closing of socket
0x02	<code>TE_ERROR_IN_SELECT_BEFORE_ACCEPT</code>

	Error found before accept. The transporter will retry
0x03	TE_INVALID_MESSAGE_LENGTH
	Error found in message (invalid message length)
0x04	TE_INVALID_CHECKSUM
	Error found in message (checksum)
0x05	TE_COULD_NOT_CREATE_SOCKET
	Error found while creating socket(can't create socket)
0x06	TE_COULD_NOT_BIND_SOCKET
	Error found while binding server socket
0x07	TE_LISTEN_FAILED
	Error found while listening to server socket
0x08	TE_ACCEPT_RETURN_ERROR
	Error found during accept(accept return error)
0x0b	TE_SHM_DISCONNECT
	The remote node has disconnected
0x0c	TE_SHM_IPC_STAT
	Unable to check shm segment
0x0d	TE_SHM_UNABLE_TO_CREATE_SEGMENT
	Unable to create shm segment
0x0e	TE_SHM_UNABLE_TO_ATTACH_SEGMENT
	Unable to attach shm segment
0x0f	TE_SHM_UNABLE_TO_REMOVE_SEGMENT
	Unable to remove shm segment
0x10	TE_TOO_SMALL_SIGID
	Sig ID too small
0x11	TE_TOO_LARGE_SIGID
	Sig ID too large
0x12	TE_WAIT_STACK_FULL
	Wait stack was full
0x13	TE_RECEIVE_BUFFER_FULL
	Receive buffer was full

0x14	TE_SIGNAL_LOST_SEND_BUFFER_FULL Send buffer was full, and trying to force send fails
0x15	TE_SIGNAL_LOST Send failed for unknown reason(signal lost)
0x16	TE_SEND_BUFFER_FULL The send buffer was full, but sleeping for a while solved
0x21	TE_SHM_IPC_PERMANENT Shm ipc Permanent error

**Note**

Transporter error codes [0x17](#) through [0x20](#) and [0x22](#) are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

22.5.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *node_id* is the node ID of the management server) in the management server's `DataDir`.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 22.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *node_id* is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level:** This can be any one of the following values: [ALERT](#), [CRITICAL](#), [ERROR](#), [WARNING](#), [INFO](#), or [DEBUG](#).

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Index usage is 1%(24 8K pages of total 2336)

2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9: API 8.0.22-ndb-8.0.22
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9: API 8.0.22-ndb-8.0.22
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9: API 8.0.22-ndb-8.0.22
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9: API 8.0.22-ndb-8.0.22
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

22.5.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, `node_id` denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`
Turns the cluster log on.
- `CLUSTERLOG OFF`
Turns the cluster log off.
- `CLUSTERLOG INFO`
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`
Logs `category` events with priority less than or equal to `threshold` in the cluster log.
- `CLUSTERLOG FILTER severity_level`

Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

Table 22.52 Cluster log categories, with default threshold setting

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The *STATISTICS* category can provide a great deal of useful data. See [Section 22.5.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a *STARTUP* event with a priority of 3 is not logged unless the threshold for *STARTUP* is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix *syslog* levels, except for *LOG_EMERG* and *LOG_NOTICE*, which are not used or mapped.

Table 22.53 Event severity levels

Severity Level Value	Severity	Description
1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for <i>NDBCLUSTER</i> development

Event severity levels can be turned on or off (using *CLUSTERLOG FILTER*—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

22.5.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Table 22.54 Events associated with connections between cluster nodes

Event	Priority	Severity Level	Description
<code>Connected</code>	8	INFO	Data nodes connected
<code>Disconnected</code>	8	ALERT	Data nodes disconnected
<code>CommunicationClosed</code>	8	INFO	SQL node or data node connection closed
<code>CommunicationOpened</code>	8	INFO	SQL node or data node connection open
<code>ConnectedApiVersion</code>	8	INFO	Connection using API version

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Table 22.55 Events associated with checkpoints

Event	Priority	Severity Level	Description
<code>GlobalCheckpointStarted</code>	9	INFO	Start of GCP: REDO log is written to disk
<code>GlobalCheckpointCompleted</code>	10	INFO	GCP finished
<code>LocalCheckpointStarted</code>	7	INFO	Start of LCP: data written to disk
<code>LocalCheckpointCompleted</code>	7	INFO	LCP completed normally
<code>LCPStoppedInCalcKeepGci</code>	0	ALERT	LCP stopped
<code>LCPFragmentCompleted</code>	11	INFO	LCP on a fragment has been completed

Event	Priority	Severity Level	Description
UndoLogBlocked	7	INFO	UNDO logging blocked; buffer near overflow
RedoStatus	7	INFO	Redo status

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Table 22.56 Events relating to the startup of a node or cluster

Event	Priority	Severity Level	Description
NDBStartStarted	1	INFO	Data node start phases initiated (all nodes starting)
NDBStartCompleted	1	INFO	Start phases completed, all data nodes
STTORRYRecieved	15	INFO	Blocks received after completion of restart
StartPhaseCompleted	4	INFO	Data node start phase <i>x</i> completed
CM_REGCONF	3	INFO	Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID
CM_REGREF	8	INFO	Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
FIND_NEIGHBOURS	8	INFO	Shows neighboring data nodes
NDBStopStarted	1	INFO	Data node shutdown initiated
NDBStopCompleted	1	INFO	Data node shutdown complete
NDBStopForced	1	ALERT	Forced shutdown of data node
NDBStopAborted	1	INFO	Unable to shut down data node normally
StartREDOLog	4	INFO	New redo log started; GCI keep <i>x</i> , newest restorable GCI <i>y</i>
StartLog	10	INFO	New log started; log part <i>x</i> , start MB <i>y</i> , stop MB <i>z</i>
UNDORecordsExecuted	15	INFO	Undo records executed
StartReport	4	INFO	Report started
LogFileInitStatus	7	INFO	Log file initialization status
LogFileInitCompStatus	7	INFO	Log file completion status
StartReadLCP	10	INFO	Start read for local checkpoint
ReadLCPComplete	10	INFO	Read for local checkpoint completed
RunRedo	8	INFO	Running the redo log
RebuildIndex	10	INFO	Rebuilding indexes

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Table 22.57 Events relating to restarting a node

Event	Priority	Severity Level	Description
NR_CopyDict	7	INFO	Completed copying of dictionary information
NR_CopyDistr	7	INFO	Completed copying distribution information
NR_CopyFragStarted	7	INFO	Starting to copy fragments
NR_CopyFragDone	10	INFO	Completed copying a fragment
NR_CopyFragCompleted	7	INFO	Completed copying all fragments
NodeFailCompleted	8	ALERT	Node failure phase completed
NODE_FAILREP	8	ALERT	Reports that a node has failed
ArbitState	6	INFO	<p>Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here:</p> <ul style="list-style-type: none"> • Management server restarts arbitration thread [state=<i>x</i>] • Prepare arbitrator node <i>x</i> [ticket=<i>y</i>] • Receive arbitrator node <i>x</i> [ticket=<i>y</i>] • Started arbitrator node <i>x</i> [ticket=<i>y</i>] • Lost arbitrator node <i>x</i> - process failure [state=<i>y</i>] • Lost arbitrator node <i>x</i> - process exit [state=<i>y</i>] • Lost arbitrator node <i>x</i> <error msg> [state=<i>y</i>]
ArbitResult	2	ALERT	<p>Report arbitrator results; there are eight different possible results for arbitration attempts, listed here:</p> <ul style="list-style-type: none"> • Arbitration check failed: less than 1/2 nodes left • Arbitration check succeeded: node group majority • Arbitration check failed: missing node group • Network partitioning: arbitration required • Arbitration succeeded: affirmative response from node <i>x</i> • Arbitration failed: negative response from node <i>x</i> • Network partitioning: no arbitrator available • Network partitioning: no arbitrator configured

Event	Priority	Severity Level	Description
GCP_TakeoverStarted	7	INFO	GCP takeover started
GCP_TakeoverCompleted	7	INFO	GCP takeover complete
LCP_TakeoverStarted	7	INFO	LCP takeover started
LCP_TakeoverCompleted	7	INFO	LCP takeover complete (state = <i>x</i>)
ConnectCheckStarted	6	INFO	Connection check started
ConnectCheckCompleted	6	INFO	Connection check completed
NodeFailRejected	6	ALERT	Node failure phase failed

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Table 22.58 Events of a statistical nature

Event	Priority	Severity Level	Description
TransReportCounters	8	INFO	Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
OperationReportCounters	8	INFO	Number of operations
TableCreated	7	INFO	Report number of tables created
JobStatistic	9	INFO	Mean internal job scheduling statistics
ThreadConfigLoop	9	INFO	Number of thread configuration loops
SendBytesStatistic	9	INFO	Mean number of bytes sent to node <i>x</i>
ReceiveBytesStatistic	9	INFO	Mean number of bytes received from node <i>x</i>
MemoryUsage	5	INFO	Data and index memory usage (80%, 90%, and 100%)
MTSignalStatistics	9	INFO	Multithreaded signals

SCHEMA Events

These events relate to NDB Cluster schema operations.

Table 22.59 Events relating to NDB Cluster schema operations

Event	Priority	Severity Level	Description
CreateSchemaObject	8	INFO	Schema object created
AlterSchemaObject	8	INFO	Schema object updated
DropSchemaObject	8	INFO	Schema object dropped

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Table 22.60 Events relating to cluster errors and warnings

Event	Priority	Severity Level	Description
<code>TransporterError</code>	2	ERROR	Transporter error
<code>TransporterWarning</code>	8	WARNING	Transporter warning
<code>MissedHeartbeat</code>	8	WARNING	Node <i>X</i> missed heartbeat number <i>Y</i>
<code>DeadDueToHeartbeat</code>	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
<code>WarningEvent</code>	2	WARNING	General warning event
<code>SubscriptionStatus</code>	4	WARNING	Change in subscription status

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Table 22.61 Information events

Event	Priority	Severity Level	Description
<code>SentHeartbeat</code>	12	INFO	Sent heartbeat
<code>CreateLogBytes</code>	11	INFO	Create log: Log part, log file, size in MB
<code>InfoEvent</code>	2	INFO	General informational event
<code>EventBufferStatus</code>	7	INFO	Event buffer status
<code>EventBufferStatus2</code>	7	INFO	Improved event buffer status information

Note

`SentHeartbeat` events are available only if NDB Cluster was compiled with `VM_TRACE` enabled.

SINGLEUSER Events

These events are associated with entering and exiting single user mode.

Table 22.62 Events relating to single user mode

Event	Priority	Severity Level	Description
<code>SingleUser</code>	7	INFO	Entering or exiting single user mode

BACKUP Events

These events provide information about backups being created or restored.

Table 22.63 Backup events

Event	Priority	Severity Level	Description
<code>BackupStarted</code>	7	INFO	Backup started
<code>BackupStatus</code>	7	INFO	Backup status
<code>BackupCompleted</code>	7	INFO	Backup completed

Event	Priority	Severity Level	Description
BackupFailedToStart	7	ALERT	Backup failed to start
BackupAborted	7	ALERT	Backup aborted by user
RestoreStarted	7	INFO	Started restoring from backup
RestoreMetaData	7	INFO	Restoring metadata
RestoreData	7	INFO	Restoring data
RestoreLog	7	INFO	Restoring log files
RestoreCompleted	7	INFO	Completed restoring from backup
SavedEvent	7	INFO	Event saved

22.5.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's [CLUSTERLOG STATISTICS](#) command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

Note

You can determine which TC selection method is used for transactions started from a given SQL node using the [ndb_optimized_node_selection](#) system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for [Commit count](#) to be greater than [Trans count](#).
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

**Note**

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in [AttrInfoCount](#).

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that [Concurrent Operations](#) can have is the maximum number of operations that a TC block can support; currently, this is $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$. (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 22.3.3.6, “Defining NDB Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, [Abort count](#) can sometimes be greater than [Trans count](#).
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the [LOCAL_READS](#) counter in the [ndbinfo.counters](#) table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the [LOCAL_WRITES](#) counter in the [ndbinfo.counters](#) table.

Local query handler statistics (Operations). There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

**Note**

A single transaction may operate on data stored in multiple LQH blocks.

The [Operations](#) statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and

delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see [Section 22.5.3.1, “NDB Cluster Logging Management Commands”](#).

22.5.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](#), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 22.5.1, “Commands in the NDB Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

Start types. There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

**Note**

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNT` blocks start (see [NDB Kernel Blocks](#)). Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

**Note**

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNT` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.

- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as *Started*. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by *DBDIH*).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

22.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

NDB Cluster software upgrade or downgrade. To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

Change on node host. To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

System reset (cluster reset).

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (*ndbd* or possibly *ndbmtdd*) with the *--initial* option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

Beginning with NDB 8.0.21, this also forces the removal of all Disk Data objects and files associated with those objects.

- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 22.5.8, “Online Backup of NDB Cluster”](#), and [Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

Resource Recovery.

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers](#).)
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmt` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

Note

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see [Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”](#)).

The type of restart required is indicated in the documentation for each node configuration parameter. See [Section 22.3.3, “NDB Cluster Configuration Files”](#).

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade.

Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 22.5.14.30, “The ndbinfo nodes Table”](#).

22.5.6 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 22.5.14.30, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is,

waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes

- Method 2:

Restart storage nodes prior to entering single user mode.

22.5.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

Important

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

22.5.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Table 22.64 Data node failure handling during node group creation and table reorganization

Failure during	Failure in “Old” data node	Failure in “New” data node	System Failure
Node group creation	<ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back 	<ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back 	<ul style="list-style-type: none"> • If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without. • If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When restarted, the cluster does not include the new node group.
Table reorganization	<ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table reorganization is rolled back. 	<ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table reorganization is rolled back. 	<ul style="list-style-type: none"> • If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using the “new” data nodes. • If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes.

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since

there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

22.5.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmt` binaries for the data node processes. For a more detailed example, see [Section 22.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.
5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes will belong.
7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

Exception: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is

deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 13.1.20.10](#), “Setting `NDB_TABLE Options`”, for more information.

Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory `NDB` tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

22.5.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new `NDB` Cluster data nodes online, starting with an `NDB` Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21 @198.51.100.21 (8.0.22-ndb-8.0.22)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address VARCHAR(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
```

```
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO      -- NDB Cluster Management Server. 8.0.22-ndb-8.0.22
2008-12-08 17:29:23 [MgmSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1   @198.51.100.1  (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2   @198.51.100.2  (8.0.22-ndb-8.0.22, Nodegroup: 0)
id=3   (not connected, accepting connect from 198.51.100.3)
id=4   (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10  @198.51.100.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20  @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21  @198.51.100.21 (8.0.22-ndb-8.0.22)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 8.0.22)
Node 1: Started (version 8.0.22)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
```

```
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 8.0.22)

ndb_mgm> Node 2: Started (version 8.0.22)
```

Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 198.51.100.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.22-ndb-8.0.22, no nodegroup)
id=4 @198.51.100.4 (8.0.22-ndb-8.0.22, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21 @198.51.100.21 (8.0.22-ndb-8.0.22)
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.22-ndb-8.0.22, Nodegroup: 1)
id=4 @198.51.100.4 (8.0.22-ndb-8.0.22, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21 @198.51.100.21 (8.0.22-ndb-8.0.22)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
```

```
-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag var sized memory
0          26086    26086         1572864           557056
1          26329    26329         1605632           557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDB` table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

Important

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 13.1.20.10, “Setting NDB_TABLE Options”](#), for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR

type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag var sized memory
0          12981    52296         1572864           557056
1          13236    52515         1605632           557056
2          13105    13105          819200           294912
3          13093    13093          819200           294912

NDBT_ProgramExit: 0 - OK
```

Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set

of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 13.1.9, “ALTER TABLE Statement”](#).

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1
```

```
[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

22.5.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore`

and its use in restoring NDB Cluster backups, see [Section 22.4.23, “`ndb_restore` — Restore an NDB Cluster Backup](#)”.

Starting with NDB 8.0.16, it is possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See [Section 22.5.8.5, “Taking an NDB Backup with Parallel Data Nodes](#)”.

22.5.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_idctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

22.5.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 22.5.8.3, “Configuration for NDB Cluster Backups](#)”.)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id]
  [encryption_option]
  [wait_option]
  [snapshot_option]

encryption_option:
ENCRYPT PASSWORD=password

password:
{ 'password_string' | "password_string" }

wait_option:
```

```
WAIT {STARTED | COMPLETED} | NOWAIT
```

```
snapshot_option:  
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

NDB 8.0.22 and later supports the creation of encrypted backups using `ENCRYPT PASSWORD=password`; the `password` must meet all of the following requirements:

- Uses any of the printable ASCII characters except `!`, `'`, `"`, `$`, `%`, `\`, and `^`
- Contains at least 1 character but is no more than 256 characters in length
- Is enclosed by single or double quotation marks

An encrypted backup can be decrypted using `ndb_restore --decrypt --backup-password=password`.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT  
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED  
Waiting for started, this may take several minutes  
Node 2: Backup 3 started from node 1  
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
```

```
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

backup_id is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given *backup_id* are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

Cancelling backups. To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

22.5.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.

- [BackupMemory](#)

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- [BackupWriteSize](#)

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- [BackupMaxWriteSize](#)

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, [CompressedBackup](#) causes NDB to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the [BackupDataDir](#) configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

In NDB 8.0.22 and later, you can enforce encryption of backup files by enabling [RequireEncryptedBackup](#). When this parameter is set to 1, backups cannot be created without specifying `ENCRYPT PASSWORD=password` as part of a `START BACKUP` command.

22.5.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set [BackupDataBufferSize](#) and [BackupLogBufferSize](#) and their sum is greater than 4MB, then you must also set [BackupMemory](#) as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

22.5.8.5 Taking an NDB Backup with Parallel Data Nodes

Beginning with NDB 8.0.16, it is possible to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmtd` (`ndbnd` is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; `ndbmtd` by default runs in single-threaded mode. You can cause them to use multiple LDMs this by choosing an appropriate setting for one of the multi-threaded data node configuration parameters [MaxNoOfExecutionThreads](#) or [ThreadConfig](#). Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart.

Depending on the number of LDMs and other factors, you may also need to increase [NoOfFragmentLogParts](#). If you are using large Disk Data tables, you may also need to increase

`DiskPageBufferMemory`. As with single-threaded backups, you also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see [Backup parameters](#)).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmtl` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/BACKUP-backup_id/` (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-backup_id-PART-1-OF-N/`, `BACKUP-backup_id-PART-2-OF-N/`, and so on, up to `BACKUP-backup_id-PART-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-backup_id-0.node_id.Data`, `BACKUP-backup_id.node_idctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

In NDB 8.0.16 and later, `ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see [Section 22.4.23.2, “Restoring from a backup taken in parallel”](#).

22.5.9 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the `NDB` storage engine, as it is in the precompiled binaries available from <https://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for `NDB`.

For more information about compiling NDB Cluster from source, see [Section 22.2.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 22.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see [Section 22.3.3.9, “MySQL Server Options and Variables for NDB Cluster”](#).)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 22.3.3.3, “NDB Cluster Connection Strings”](#), for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
      Id: 1
     User: system user
      Host:
       db:
Command: Daemon
      Time: 1
     State: Waiting for event from ndbcluster
      Info: NULL
```

Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

22.5.10 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#).

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [Disk Data Configuration Parameters](#), and [Disk Data and GCP Stop errors](#).

Beginning with NDB 8.0.19, you should also set the `DiskDataUsingSameDisk` data node configuration parameter to `false` when using separate disks for Disk Data files.

See also [Disk Data file system parameters](#).

NDB 8.0.19 (and later) provides improved support when using Disk Data tables with solid-state drives, in particular those using NVMe. See the following documentation for more information:

- [Disk Data latency parameters](#)
- [Section 22.5.14.21, “The ndbinfo diskstat Table”](#)
- [Section 22.5.14.22, “The ndbinfo diskstats_1sec Table”](#)
- [Section 22.5.14.32, “The ndbinfo pgman_time_track_stats Table”](#)

22.5.10.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- *Tablespace*: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- *Data file*: Stores column data. A data file is assigned directly to a tablespace.
- *Undo log file*: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- *log file group*: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `ddl`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
```

```
ADD UNDOFILE 'undo_1.log'
INITIAL_SIZE 16M
UNDO_BUFFER_SIZE 2M
ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
ADD UNDOFILE 'undo_2.log'
INITIAL_SIZE 12M
ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We employ it merely to make the log files easily recognizable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
 - `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
 - See [Section 13.1.16, “CREATE LOGFILE GROUP Statement”](#), and [Section 13.1.6, “ALTER LOGFILE GROUP Statement”](#), for more information about these statements.
2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. We want the tablespace to contain two data files, named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
ADD DATAFILE 'data_1.dat'
USE LOGFILE GROUP lg_1
INITIAL_SIZE 32M
ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
ADD DATAFILE 'data_2.dat'
INITIAL_SIZE 48M;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace `ts_1`:

```
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

`TABLESPACE ts_1 STORAGE DISK` tells the NDB storage engine to use tablespace `ts_1` for data storage on disk.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 13.1.20, “CREATE TABLE Statement”](#), for more information.

You can obtain information about the **NDB** disk data files and undo log files just created by querying the **FILES** table in the **INFORMATION SCHEMA** database, as shown here:

```
mysql> SELECT
        FILE_NAME AS File, FILE_TYPE AS Type,
        TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
        LOGFILE_GROUP_NAME AS 'File group',
        FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total
FROM INFORMATION_SCHEMA.FILES
WHERE ENGINE='ndbcluster';
```

File	Type	Tablespace	Name	File group	Free	Total
./undo_1.log	UNDO LOG	lg_1	NULL	lg_1	0	4194304
./undo_2.log	UNDO LOG	lg_1	NULL	lg_1	0	3145728
./data_1.dat	DATAFILE	ts_1	NULL	lg_1	32	32
./data_2.dat	DATAFILE	ts_1	NULL	lg_1	48	48

4 rows in set (0.00 sec)

For more information and examples, see [Section 25.15, “The INFORMATION_SCHEMA FILES Table”](#).

Indexing of columns implicitly stored on disk. For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which *implicitly* uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```
mysql> CREATE TABLE ti (
->     c1 INT PRIMARY KEY,
->     c2 INT,
->     c3 INT,
->     c4 INT
-> )
->     STORAGE DISK
->     TABLESPACE ts_1
->     ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```
mysql> SHOW CREATE TABLE ti\G
***** 1. row *****
      Table: ti
Create Table: CREATE TABLE `ti` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`),
  KEY `i1` (`c2`),
  KEY `i2` (`c3`)
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
shell> ./ndb_desc -d test t1
```

```

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with [ADD UNDOFILE](#) and [ADD DATAFILE](#); relative paths are calculated with respect to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;
```

```
mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

22.5.10.2 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 11.7, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 25.15, “The INFORMATION_SCHEMA FILES Table”](#).

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

22.5.11 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using the standard `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT | INPLACE | COPY`), and described elsewhere.

Note

Some older releases of NDB Cluster used a syntax specific to `NDB` for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of `NDB` tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see [Limitations of NDB online operations](#), later in this section). Such operations do not require single user mode for `NDB` table

alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on NDB tables. Online renaming of NDB tables is also supported.

Previously, columns of NDB tables could not be renamed online; this limitation is removed in NDB 8.0.18.

Currently you cannot add disk-based columns to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
>     c1 INT NOT NULL PRIMARY KEY,
>     c2 VARCHAR(30)
> )
>     TABLESPACE ts1 STORAGE DISK
>     ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER TABLE t1
>     ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
>     ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER TABLE t1
>     ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
>     ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

**Note**

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no `partition_names INTO (partition_definitions)` option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does *not* perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see [Section 22.5.7, “Adding NDB Cluster Data Nodes Online”](#).

Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.
- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE ADD COLUMN`, `ADD INDEX`, or `DROP INDEX` operation (or `CREATE INDEX` or `DROP INDEX` statement) is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.
- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.
- The storage engine used by the table cannot be changed online.
- The tablespace used by the table cannot be changed online. Beginning with NDB 8.0.21, a statement such as `ALTER TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace` is specifically disallowed. (Bug #99269, Bug #31180526)
- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the `BLOB` or `TEXT` type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.
- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t2 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
>   ADD COLUMN c2 INT,
>   ADD COLUMN c3 INT,
>   ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
```

```

Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the `FIRST` keyword, the statement fails with an error.
- Existing table columns cannot be reordered online.

For online `ALTER TABLE` operations on `NDB` tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the `CREATE TABLE` and `ALTER TABLE` statements just shown for the sake of clarity):

```

mysql> CREATE TABLE t2 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
>   ADD COLUMN c2 INT,
>   ADD COLUMN c3 INT,
>   ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
***** 2. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)

```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```

mysql> CREATE TABLE t3 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
> ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)

```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see [Section 13.1.20, “CREATE TABLE Statement”](#).

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #2196004)

22.5.12 Distributed MySQL Privileges with NDB_STORED_USER

NDB 8.0.18 introduces a new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes connected to an NDB Cluster. This can be enabled by granting the `NDB_STORED_USER` privilege. See the description of the privilege for usage information.

`NDB_STORED_USER` is printed in the output of `SHOW GRANTS` as with any other privilege. To verify that privileges are shared, use the `ndb_select_all` utility supplied with the NDB Cluster distribution, as shown here (some output wrapped to preserve formatting):

```
shell> ndb_select_all -d mysql ndb_sql_metadata
type  name      seq    note      sql_ddl_text
11     ''jon'@'localhost'  0      4      "CREATE USER 'jon'@'localhost'
IDENTIFIED WITH 'caching_sha2_password' AS
'$A$005${B};3!?tI\".EFy\ZA5K5DQHrWiBvuRNYTIME00YeBlPpZotFRPjVtYzTA5b0' REQUIRE
NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD
REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT"
12     ''jon'@'localhost'  0      [NULL]  "GRANT USAGE ON *.* TO `jon`@`localhost`"
12     ''jon'@'localhost'  3      [NULL]  "GRANT ALL PRIVILEGES ON `test`.* TO `jon`@`localhost`"
12     ''jon'@'localhost'  2      [NULL]  "GRANT ALL PRIVILEGES ON `mydb`.* TO `jon`@`localhost`"
12     ''jon'@'localhost'  1      [NULL]  "GRANT NDB_STORED_USER ON *.* TO `jon`@`localhost`"
5 rows returned
```

`ndb_sql_metadata` is a special NDB table that is not visible using the `mysql` or other MySQL client.

A statement granting the `NDB_STORED_USER` privilege, such as `GRANT NDB_STORED_USER ON *.* TO 'cluster_app_user'@'localhost'`, works by directing NDB to create a snapshot using the queries `SHOW CREATE USER cluster_app_user@localhost` and `SHOW GRANTS FOR cluster_app_user@localhost`, then storing the results in `ndb_sql_metadata`. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored `CREATE USER` and `GRANT` statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the `NDBCLUSTER` storage engine; this is done within a security environment equivalent to that of the MySQL replication replica applier thread.

You should be aware that changes to users with `NDB_STORED_USER` are distributed asynchronously. Because distributed schema change operations are performed synchronously, the next distributed schema change following a change to any distributed user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a `DROP DATABASE` statement follows a `DROP USER` of a distributed user, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple `GRANT`, `REVOKE`, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing `GRANT NDB_STORED_USER` for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

NDB Cluster 8.0 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by converting the MySQL privilege tables to use the NDB storage engine, as implemented in NDB 7.6 and earlier releases (see [Distributed Privileges Using Shared Grant Tables](#)). For information about the impact of this change on upgrades to NDB 8.0 from a previous release, see [Section 22.2.7, "Upgrading and Downgrading NDB Cluster"](#).

22.5.13 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received

by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the Performance Schema `session_status` or `global_status` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	0

```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `session_status` or the `global_status` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Replica counters (global)*

This set of counters relates to the `Ndb` objects used by the replica SQL thread, if any. If this `mysqld` does not act as a replica, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the replica SQL thread (if any), the binary log injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	2
Ndb_api_wait_scan_result_count_session	0
Ndb_api_wait_meta_request_count_session	1
Ndb_api_wait_nanos_count_session	8144375
Ndb_api_bytes_sent_count_session	68
Ndb_api_bytes_received_count_session	84
Ndb_api_trans_start_count_session	1
Ndb_api_trans_commit_count_session	1
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	1
Ndb_api_pk_op_count_session	1

```

| Ndb_api_uk_op_count_session          | 0 |
| Ndb_api_table_scan_count_session    | 0 |
| Ndb_api_range_scan_count_session    | 0 |
| Ndb_api_pruned_scan_count_session   | 0 |
| Ndb_api_scan_batch_count_session    | 0 |
| Ndb_api_read_row_count_session      | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.50 sec)

```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```

mysql> SELECT * FROM performance_schema.session_status
      -> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----+-----+
| VARIABLE_NAME                | VARIABLE_VALUE |
+-----+-----+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT   | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT  | 28             |
| NDB_API_WAIT_NANOS_COUNT         | 53756398      |
| NDB_API_BYTES_SENT_COUNT         | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT     | 9724           |
| NDB_API_TRANS_START_COUNT        | 3              |
| NDB_API_TRANS_COMMIT_COUNT       | 2              |
| NDB_API_TRANS_ABORT_COUNT        | 0              |
| NDB_API_TRANS_CLOSE_COUNT        | 3              |
| NDB_API_PK_OP_COUNT              | 2              |
| NDB_API_UK_OP_COUNT              | 0              |
| NDB_API_TABLE_SCAN_COUNT         | 1              |
| NDB_API_RANGE_SCAN_COUNT         | 0              |
| NDB_API_PRUNED_SCAN_COUNT        | 0              |
| NDB_API_SCAN_BATCH_COUNT         | 0              |
| NDB_API_READ_ROW_COUNT           | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT         | 0              |
| NDB_API_EVENT_NONDATA_COUNT      | 0              |
| NDB_API_EVENT_BYTES_COUNT        | 0              |
+-----+-----+
21 rows in set (0.09 sec)

```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```

mysql> SHOW STATUS LIKE 'ndb_api%event%';
+-----+-----+
| Variable_name                | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0      |
| Ndb_api_event_nondata_count_injector | 0      |
| Ndb_api_event_bytes_count_injector  | 0      |
| Ndb_api_event_data_count           | 0      |
| Ndb_api_event_nondata_count         | 0      |
| Ndb_api_event_bytes_count           | 0      |
+-----+-----+
6 rows in set (0.00 sec)

```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```

mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-----+-----+
| Variable_name                | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0      |
| Ndb_api_event_nondata_count_injector | 0      |
| Ndb_api_event_bytes_count_injector  | 0      |
+-----+-----+
3 rows in set (0.00 sec)

```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Table 22.65 NDB API statistics counters

Counter Name	Description	Status Variables (by statistic type):
		<ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server
<code>WaitExecCompleteCount</code>	Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.	<ul style="list-style-type: none"> • <code>Ndb_api_wait_exec_complete_count_session</code> • <code>Ndb_api_wait_exec_complete_count_slave</code> • [none] • <code>Ndb_api_wait_exec_complete_count_server</code>
<code>WaitScanResultCount</code>	Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.	<ul style="list-style-type: none"> • <code>Ndb_api_wait_scan_result_count_session</code> • <code>Ndb_api_wait_scan_result_count_slave</code> • [none] • <code>Ndb_api_wait_scan_result_count_server</code>
<code>WaitMetaRequestCount</code>	Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).	<ul style="list-style-type: none"> • <code>Ndb_api_wait_meta_request_count_session</code> • <code>Ndb_api_wait_meta_request_count_slave</code> • [none] • <code>Ndb_api_wait_meta_request_count_server</code>
<code>WaitNanosCount</code>	Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.	<ul style="list-style-type: none"> • <code>Ndb_api_wait_nanos_count_session</code> • <code>Ndb_api_wait_nanos_count_slave</code> • [none] • <code>Ndb_api_wait_nanos_count_server</code>
<code>BytesSentCount</code>	Amount of data (in bytes) sent to the data nodes	<ul style="list-style-type: none"> • <code>Ndb_api_bytes_sent_count_session</code> • <code>Ndb_api_bytes_sent_count_slave</code> • [none] • <code>Ndb_api_bytes_sent_count_server</code>
<code>BytesRecvdCount</code>	Amount of data (in bytes) received from the data nodes	<ul style="list-style-type: none"> • <code>Ndb_api_bytes_received_count_session</code> • <code>Ndb_api_bytes_received_count_slave</code> • [none] • <code>Ndb_api_bytes_received_count_server</code>
<code>TransStartCount</code>	Number of transactions started.	<ul style="list-style-type: none"> • <code>Ndb_api_trans_start_count_session</code>

Counter Name	Description	Status Variables (by statistic type):
		<ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server
		<ul style="list-style-type: none"> • <code>Ndb_api_trans_start_count_sl</code> • <code>[none]</code> • <code>Ndb_api_trans_start_count</code>
<code>TransCommitCount</code>	Number of transactions committed.	<ul style="list-style-type: none"> • <code>Ndb_api_trans_commit_count_s</code> • <code>Ndb_api_trans_commit_count_sl</code> • <code>[none]</code> • <code>Ndb_api_trans_commit_count</code>
<code>TransAbortCount</code>	Number of transactions aborted.	<ul style="list-style-type: none"> • <code>Ndb_api_trans_abort_count_se</code> • <code>Ndb_api_trans_abort_count_sl</code> • <code>[none]</code> • <code>Ndb_api_trans_abort_count</code>
<code>TransCloseCount</code>	Number of transactions aborted. (This value may be greater than the sum of <code>TransCommitCount</code> and <code>TransAbortCount</code> .)	<ul style="list-style-type: none"> • <code>Ndb_api_trans_close_count_se</code> • <code>Ndb_api_trans_close_count_sl</code> • <code>[none]</code> • <code>Ndb_api_trans_close_count</code>
<code>PkOpCount</code>	Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients.	<ul style="list-style-type: none"> • <code>Ndb_api_pk_op_count_session</code> • <code>Ndb_api_pk_op_count_slave</code> • <code>[none]</code> • <code>Ndb_api_pk_op_count</code>
<code>UkOpCount</code>	Number of operations based on or using unique keys.	<ul style="list-style-type: none"> • <code>Ndb_api_uk_op_count_session</code> • <code>Ndb_api_uk_op_count_slave</code> • <code>[none]</code> • <code>Ndb_api_uk_op_count</code>
<code>TableScanCount</code>	Number of table scans that have been started. This includes scans of internal tables.	<ul style="list-style-type: none"> • <code>Ndb_api_table_scan_count_ses</code> • <code>Ndb_api_table_scan_count_sla</code> • <code>[none]</code> • <code>Ndb_api_table_scan_count</code>
<code>RangeScanCount</code>	Number of range scans that have been started.	<ul style="list-style-type: none"> • <code>Ndb_api_range_scan_count_ses</code>

Counter Name	Description	Status Variables (by statistic type):
		<ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server
		<ul style="list-style-type: none"> • Ndb_api_range_scan_count_slave • [none] • Ndb_api_range_scan_count
PrunedScanCount	Number of scans that have been pruned to a single partition.	<ul style="list-style-type: none"> • Ndb_api_pruned_scan_count_session • Ndb_api_pruned_scan_count_slave • [none] • Ndb_api_pruned_scan_count
ScanBatchCount	Number of batches of rows received. (A <i>batch</i> in this context is a set of scan results from a single fragment.)	<ul style="list-style-type: none"> • Ndb_api_scan_batch_count_session • Ndb_api_scan_batch_count_slave • [none] • Ndb_api_scan_batch_count
ReadRowCount	Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.	<ul style="list-style-type: none"> • Ndb_api_read_row_count_session • Ndb_api_read_row_count_slave • [none] • Ndb_api_read_row_count
TransLocalReadRowCount	Number of rows read from the data same node on which the transaction was being run.	<ul style="list-style-type: none"> • Ndb_api_trans_local_read_row_count • Ndb_api_trans_local_read_row_count_slave • [none] • Ndb_api_trans_local_read_row_count
DataEventsRecvdCount	Number of row change events received.	<ul style="list-style-type: none"> • [none] • [none] • Ndb_api_event_data_count_injector • Ndb_api_event_data_count
NondataEventsRecvdCount	Number of events received, other than row change events.	<ul style="list-style-type: none"> • [none] • [none] • Ndb_api_event_nondata_count_injector • Ndb_api_event_nondata_count
EventBytesRecvdCount	Number of bytes of events received.	<ul style="list-style-type: none"> • [none] • [none]

Counter Name	Description	Status Variables (by statistic type):
		<ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server
		<ul style="list-style-type: none"> • <code>Ndb_api_event_bytes_count_in</code> • <code>Ndb_api_event_bytes_count</code>

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave   | 0 |
| Ndb_api_trans_commit_count         | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session   | 0 |
| Ndb_api_wait_meta_request_count_session  | 3 |
| Ndb_api_wait_nanos_count_session         | 820705 |
| Ndb_api_bytes_sent_count_session         | 132 |
| Ndb_api_bytes_received_count_session     | 372 |
| Ndb_api_trans_start_count_session        | 1 |
| Ndb_api_trans_commit_count_session       | 1 |
| Ndb_api_trans_abort_count_session        | 0 |
| Ndb_api_trans_close_count_session        | 1 |
| Ndb_api_pk_op_count_session              | 1 |
| Ndb_api_uk_op_count_session              | 0 |
| Ndb_api_table_scan_count_session         | 0 |
| Ndb_api_range_scan_count_session         | 0 |
| Ndb_api_pruned_scan_count_session        | 0 |
| Ndb_api_scan_batch_count_session         | 0 |
| Ndb_api_read_row_count_session           | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	8
Ndb_api_wait_scan_result_count_session	0
Ndb_api_wait_meta_request_count_session	17
Ndb_api_wait_nanos_count_session	706871709
Ndb_api_bytes_sent_count_session	2376
Ndb_api_bytes_received_count_session	3844
Ndb_api_trans_start_count_session	4
Ndb_api_trans_commit_count_session	4
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	4
Ndb_api_pk_op_count_session	6
Ndb_api_uk_op_count_session	0
Ndb_api_table_scan_count_session	0
Ndb_api_range_scan_count_session	0
Ndb_api_pruned_scan_count_session	0
Ndb_api_scan_batch_count_session	0
Ndb_api_read_row_count_session	2
Ndb_api_trans_local_read_row_count_session	1

18 rows in set (0.00 sec)

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	11
Ndb_api_wait_scan_result_count_session	6
Ndb_api_wait_meta_request_count_session	20
Ndb_api_wait_nanos_count_session	707370418
Ndb_api_bytes_sent_count_session	2724
Ndb_api_bytes_received_count_session	4116
Ndb_api_trans_start_count_session	7
Ndb_api_trans_commit_count_session	6
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	7
Ndb_api_pk_op_count_session	8
Ndb_api_uk_op_count_session	0
Ndb_api_table_scan_count_session	1
Ndb_api_range_scan_count_session	0
Ndb_api_pruned_scan_count_session	0
Ndb_api_scan_batch_count_session	0
Ndb_api_read_row_count_session	3
Ndb_api_trans_local_read_row_count_session	2

18 rows in set (0.00 sec)

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.
- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer ($706871709 - 820705 = 706051004$ nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` ($707370418 - 706871709 = 498709$ ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

22.5.14 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G

10 rows in set (0.00 sec)

```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```

mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| ndbinfo |
| performance_schema |
| sys |
+-----+
5 rows in set (0.04 sec)

```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```

mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| arbitrator_validity_detail |
| arbitrator_validity_summary |
| blocks |
| cluster_locks |
| cluster_operations |
| cluster_transactions |
| config_nodes |
+-----+

```

```

| config_params
| config_values
| counters
| cpustat
| cpustat_1sec
| cpustat_20sec
| cpustat_50ms
| dict_obj_info
| dict_obj_types
| disk_write_speed_aggregate
| disk_write_speed_aggregate_node
| disk_write_speed_base
| diskpagebuffer
| error_messages
| locks_per_fragment
| logbuffers
| logspaces
| membership
| memory_per_fragment
| memoryusage
| nodes
| operations_per_fragment
| processes
| resources
| restart_info
| server_locks
| server_operations
| server_transactions
| table_distribution_status
| table_fragments
| table_info
| table_replicas
| tc_time_track_stats
| threadblocks
| threads
| threadstat
| transporters
+-----+
44 rows in set (0.00 sec)

```

In NDB 8.0, all `ndbinfo` tables use the `NDB` storage engine; however, an `ndbinfo` entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```

mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+-----+-----+
| node_id | memory_type | used | used_pages | total | total_pages |
+-----+-----+-----+-----+-----+-----+
| 5 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 5 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 5 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
| 6 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 6 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 6 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
+-----+-----+-----+-----+-----+-----+
6 rows in set (0.02 sec)

```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```

mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE memory_type = 'Data memory';
+-----+
| Data Memory Used, All Nodes |
+-----+
| 6460 |
+-----+
1 row in set (0.37 sec)

```

```
mysql> SELECT SUM(max) as 'Total IndexMemory Available'
> FROM memoryusage
> WHERE memory_type = 'Index memory';
+-----+
| Total IndexMemory Available |
+-----+
| 25664 |
+-----+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 13602 | STARTED | 0 |
| 2 | 16 | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or [Section 22.5.15, "INFORMATION_SCHEMA Tables for NDB Cluster"](#).

22.5.14.1 The `ndbinfo` `arbitrator_validity_detail` Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The `arbitrator_validity_detail` table contains the following columns:

- `node_id`
This node's node ID
- `arbitrator`
Node ID of arbitrator
- `arb_ticket`
Internal identifier used to track arbitration
- `arb_connected`
Whether this node is connected to the arbitrator; either of `Yes` or `No`
- `arb_state`
Arbitration state

Notes

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitorator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitorator`.

22.5.14.2 The `ndbinfo` `arbitorator_validity_summary` Table

The `arbitorator_validity_summary` table provides a composite view of the arbitorator with regard to the cluster's data nodes.

The `arbitorator_validity_summary` table contains the following columns:

- `arbitorator`
Node ID of arbitorator
- `arb_ticket`
Internal identifier used to track arbitration
- `arb_connected`
Whether this arbitorator is connected to the cluster
- `consensus_count`
Number of data nodes that see this node as arbitorator; either of `Yes` or `No`

Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitorator, or all nodes are connected, but do not agree on the same arbitorator.

The `arbitorator` column shows the arbitorator's node ID.

`arb_ticket` is the internal identifier used by this arbitorator.

`arb_connected` shows whether this node is connected to the cluster as an arbitorator.

22.5.14.3 The `ndbinfo` `blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The `blocks` table contains the following columns:

- `block_number`
Block number
- `block_name`
Block name

Notes

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

22.5.14.4 The `ndbinfo` `cluster_locks` Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to `cluster_operations`. Information obtain from the `cluster_locks` table may be useful in investigating stalls and deadlocks.

The `cluster_locks` table contains the following columns:

- `node_id`
ID of reporting node
- `block_instance`
ID of reporting LDM instance
- `tableid`
ID of table containing this row
- `fragmentid`
ID of fragment containing locked row
- `rowid`
ID of locked row
- `transid`
Transaction ID
- `mode`
Lock request mode
- `state`
Lock state
- `detail`
Whether this is first holding lock in row lock queue
- `op`
Operation type
- `duration_millis`
Milliseconds spent waiting or holding lock
- `lock_num`
ID of lock object
- `waiting_for`
Waiting for lock with this ID

Notes

The table ID (`tableid` column) is assigned internally, and is the same as that used in other `ndbinfo` tables. It is also shown in the output of `ndb_show_tables`.

The transaction ID (`transid` column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode; this is always one of `S` (indicating a shared lock) or `X` (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

When the `detail` column contains a `*` (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

The lock state is shown in the `lock_state` column; if this is `W`, the lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, the `waiting_for` column is empty. `waiting_for` can refer only to locks on the same row, as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`.

22.5.14.5 The `ndbinfo cluster_operations` Table

The `cluster_operations` table provides a per-operation (stateful primary key `op`) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see [The DBLQH Block](#)).

The `cluster_operations` table contains the following columns:

- `node_id`
Node ID of reporting LQH block
- `block_instance`
LQH block instance
- `transid`
Transaction ID
- `operation_type`
Operation type (see text for possible values)
- `state`
Operation state (see text for possible values)
- `tableid`
Table ID
- `fragmentid`
Fragment ID

- `client_node_id`
Client node ID
- `client_block_ref`
Client block reference
- `tc_node_id`
Transaction coordinator node ID
- `tc_block_no`
Transaction coordinator block number
- `tc_block_instance`
Transaction coordinator block instance

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

22.5.14.6 The `ndbinfo cluster_transactions` Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- `node_id`

Node ID of transaction coordinator

- [block_instance](#)

TC block instance

- [transid](#)

Transaction ID

- [state](#)

Operation state (see text for possible values)

- [count_operations](#)

Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)

- [outstanding_operations](#)

Operations still being executed in local data management blocks

- [inactive_seconds](#)

Time spent waiting for API

- [client_node_id](#)

Client node ID

- [client_block_ref](#)

Client block reference

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's [getTransactionId\(\)](#) method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

[block_instance](#) refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the [threadblocks](#) table.

The [state](#) column can have any one of the values [CS_ABORTING](#), [CS_COMMITTING](#), [CS_COMMIT_SENT](#), [CS_COMPLETE_SENT](#), [CS_COMPLETING](#), [CS_CONNECTED](#), [CS_DISCONNECTED](#), [CS_FAIL_ABORTED](#), [CS_FAIL_ABORTING](#), [CS_FAIL_COMMITTED](#), [CS_FAIL_COMMITTING](#), [CS_FAIL_COMPLETED](#), [CS_FAIL_PREPARED](#), [CS_PREPARE_TO_COMMIT](#), [CS_RECEIVING](#), [CS_REC_COMMITTING](#), [CS_RESTART](#), [CS_SEND_FIRE_TRIG_REQ](#), [CS_STARTED](#), [CS_START_COMMITTING](#), [CS_START_SCAN](#), [CS_WAIT_ABORT_CONF](#), [CS_WAIT_COMMIT_CONF](#), [CS_WAIT_COMPLETE_CONF](#), [CS_WAIT_FIRE_TRIG_REQ](#). (If the MySQL Server is running with [ndbinfo_show_hidden](#) enabled, you can view this list of states by selecting from the [ndb](#) [\\$dbtc_apiconnect_state](#) table, which is normally hidden.)

In [client_node_id](#) and [client_block_ref](#), [client](#) refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The [tc_block_instance](#) column provides the [DBTC](#) block instance number. You can use this along with the block name to obtain information about specific threads from the [threadblocks](#) table.

22.5.14.7 The ndbinfo config_nodes Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the `nodes` and `processes` table.

The `config_nodes` table contains the following columns:

- `node_id`
The node's ID
- `node_type`
The type of node
- `node_hostname`
The name or IP address of the host on which the node resides

Notes

The `node_id` column shows the node ID used in the `config.ini` file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API node; this includes SQL nodes.

The `node_hostname` column shows the node host as specified in the `config.ini` file. This can be empty for an API node, if `HostName` has not been set in the cluster configuration file. If `HostName` has not been set for a data node in the configuration file, `localhost` is used here. `localhost` is also used if `HostName` has not been specified for a management node.

22.5.14.8 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters. This table can also be used in conjunction with the `config_values` table for obtaining realtime information about node configuration parameters.

The `config_params` table contains the following columns:

- `param_number`
The parameter's internal ID number
- `param_name`
The name of the parameter
- `param_description`
A brief description of the parameter
- `param_type`
The parameter's data type

- `param_default`
The parameter's default value, if any
- `param_min`
The parameter's maximum value, if any
- `param_max`
The parameter's minimum value, if any
- `param_mandatory`
This is 1 if the parameter is required, otherwise 0
- `param_status`
Currently unused

Notes

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

22.5.14.9 The `ndbinfo config_values` Table

The `config_values` table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

The `config_values` table contains the following columns:

- `node_id`
ID of the node in the cluster
- `config_param`
The parameter's internal ID number
- `config_value`
Current value of the parameter

Notes

This table's `config_param` column and the `config_params` table's `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT    v.node_id AS 'Node Id',
          p.param_name AS 'Parameter',
          v.config_value AS 'Value'
FROM      config_values v
JOIN      config_params p
ON        v.config_param=p.param_number
WHERE     p.param_name NOT LIKE '\_\'
ORDER BY  v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

Node Id	Parameter	Value
2	Arbitration	1
2	ArbitrationTimeout	7500
2	BackupDataBufferSize	16777216
2	BackupDataDir	/home/jon/data
2	BackupDiskWriteSpeedPct	50
2	BackupLogBufferSize	16777216
...		
3	TotalSendBufferMemory	0
3	TransactionBufferMemory	1048576
3	TransactionDeadlockDetectionTimeout	1200
3	TransactionInactiveTimeout	4294967039
3	TwoPassInitialNodeRestartCopy	0
3	UndoDataBuffer	16777216
3	UndoIndexBuffer	2097152

248 rows in set (0.02 sec)

The `WHERE` clause filters out parameters whose names begin with a double underscore (`__`); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the `NodeId`, `NoOfReplicas`, `HostName`, `DataMemory`, `IndexMemory`, and `TotalSendBufferMemory` parameters as currently set for all data nodes in the cluster:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name
        IN ('NodeId', 'NoOfReplicas', 'HostName',
            'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')\G
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here (NDB 8.0.18 and later):

```

22.5.14.10 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- `node_id`

The data node ID

- `block_name`

Name of the associated NDB kernel block (see [NDB Kernel Blocks](#)).

- `block_instance`

Block instance

- `counter_id`

The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- `counter_name`

The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- `val`

The counter's value

Notes

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block. A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITTS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block.

`LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

`ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See [NDB Protocol Messages](#), for more information about `ATTRINFO` messages in the `NDB` kernel.

The `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters are associated with the `DBSPJ` (select push-down join) kernel block.

The `block_name` and `block_instance` columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the `threadblocks` table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload
- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded
- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.
- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded
- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.
- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

22.5.14.11 The `ndbinfo cpustat` Table

The `cpustat` table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The `cpustat` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user`
OS user time
- `OS_system`
OS system time
- `OS_idle`
OS idle time
- `thread_exec`
Thread execution time
- `thread_sleeping`
Thread sleep time
- `thread_spinning`
Thread spin time

- `thread_send`
Thread send time
- `thread_buffer_full`
Thread buffer full time
- `elapsed_time`
Elapsed time

22.5.14.12 The `ndbinfo cpustat_50ms` Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_50ms` provides 1 second of history.

The `cpustat_50ms` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user_time`
OS user time
- `OS_system_time`
OS system time
- `OS_idle_time`
OS idle time
- `exec_time`
Thread execution time
- `sleep_time`
Thread sleep time
- `spin_time`
Thread spin time
- `send_time`
Thread send time
- `buffer_full_time`
Thread buffer full time
- `elapsed_time`

Elapsed time

22.5.14.13 The ndbinfo cpustat_1sec Table

The `cpustat_1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The `cpustat_1sec` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user_time`
OS user time
- `OS_system_time`
OS system time
- `OS_idle_time`
OS idle time
- `exec_time`
Thread execution time
- `sleep_time`
Thread sleep time
- `spin_time`
Thread spin time
- `send_time`
Thread send time
- `buffer_full_time`
Thread buffer full time
- `elapsed_time`
Elapsed time

22.5.14.14 The ndbinfo cpustat_20sec Table

The `cpustat_20sec` table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_1sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_20sec` provides 400 seconds of history.

The `cpustat_20sec` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user_time`
OS user time
- `OS_system_time`
OS system time
- `OS_idle_time`
OS idle time
- `exec_time`
Thread execution time
- `sleep_time`
Thread sleep time
- `spin_time`
Thread spin time
- `send_time`
Thread send time
- `buffer_full_time`
Thread buffer full time
- `elapsed_time`
Elapsed time

22.5.14.15 The `ndbinfo dict_obj_info` Table

The `dict_obj_info` table provides information about NDB data dictionary (`DICT`) objects such as tables and indexes. (The `dict_obj_types` table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The `dict_obj_info` table contains the following columns:

- `type`
Type of `DICT` object; join on `dict_obj_types` to obtain the name
- `id`
Object identifier; for Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables

- `version`

Object version

- `state`

Object state

- `parent_obj_type`

Parent object's type (a `dict_obj_types` type ID); 0 indicates that the object has no parent

- `parent_obj_id`

Parent object ID (such as a base table); 0 indicates that the object has no parent

- `fq_name`

Fully qualified object name; for a table, this has the form `database_name/def/table_name`, for a primary key, the form is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`

22.5.14.16 The `ndbinfo dict_obj_types` Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The `dict_obj_types` table contains the following columns:

- `type_id`

The type ID for this type

- `type_name`

The name of this type

22.5.14.17 The `ndbinfo disk_write_speed_base` Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_base` table contains the following columns:

- `node_id`

Node ID of this node

- `thr_no`

Thread ID of this LDM thread

- `millis_ago`

Milliseconds since this reporting period ended

- `millis_passed`

Milliseconds elapsed in this reporting period

- `backup_lcp_bytes_written`

Number of bytes written to disk by local checkpoints and backup processes during this period

- `redo_bytes_written`

Number of bytes written to REDO log during this period

- `target_disk_write_speed`

Actual speed of disk writes per LDM thread (base data)

22.5.14.18 The `ndbinfo disk_write_speed_aggregate` Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- `node_id`

Node ID of this node

- `thr_no`

Thread ID of this LDM thread

- `backup_lcp_speed_last_sec`

Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`

Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_10sec`

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `std_dev_redo_speed_last_10sec`

Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_60sec`

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `std_dev_redo_speed_last_60sec`

Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

- `slowdowns_due_to_io_lag`

Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

- `slowdowns_due_to_high_cpu`

Number of seconds since last node start that disk writes were slowed due to high CPU usage

- `disk_write_speed_set_to_min`

Number of seconds since last node start that disk write speed was set to minimum

- `current_target_disk_write_speed`

Actual speed of disk writes per LDM thread (aggregated)

22.5.14.19 The `ndbinfo disk_write_speed_aggregate_node` Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` table contains the following columns:

- `node_id`

Node ID of this node

- `backup_lcp_speed_last_sec`

Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`

Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

22.5.14.20 The `ndbinfo diskpagebuffer` Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- `node_id`

The data node ID

- `block_instance`

Block instance

- `pages_written`

Number of pages written to disk.

- `pages_written_lcp`

Number of pages written by local checkpoints.

- `pages_read`

Number of pages read from disk

- `log_waits`

Number of page writes waiting for log to be written to disk

- `page_requests_direct_return`

Number of requests for pages that were available in buffer

- `page_requests_wait_queue`

Number of requests that had to wait for pages to become available in buffer

- `page_requests_wait_io`

Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

Notes

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
    AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

node_id	hit_ratio
5	97.6744
6	97.6879
7	98.1776
8	98.1343

4 rows in set (0.00 sec)

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

Note

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using `LIMIT 1` to limit the output to a single thread is shown here:

```
mysql> SELECT
>   node_id, thr_no, block_name, thread_name, pages_written,
>   pages_written_lcp, pages_read, log_waits,
>   page_requests_direct_return, page_requests_wait_queue,
>   page_requests_wait_io
> FROM ndbinfo.diskpagebuffer
>   INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
>   INNER JOIN ndbinfo.threads USING (node_id, thr_no)
> WHERE block_name = 'PGMAN' LIMIT 1\G
***** 1. row *****
      node_id: 1
      thr_no: 1
    block_name: PGMAN
    thread_name: rep
    pages_written: 0
    pages_written_lcp: 0
      pages_read: 1
      log_waits: 0
page_requests_direct_return: 4
    page_requests_wait_queue: 0
    page_requests_wait_io: 1
1 row in set (0.01 sec)
```

22.5.14.21 The ndbinfo diskstat Table

The `diskstat` table provides information about writes to Disk Data tablespaces during the past 1 second.

The `diskstat` table contains the following columns:

- `node_id`
Node ID of this node
- `block_instance`
ID of reporting instance of `PGMAN`
- `pages_made_dirty`
Number of pages made dirty during the past second
- `reads_issued`
Reads issued during the past second
- `reads_completed`
Reads completed during the past second

- `writes_issued`
Writes issued during the past second
- `writes_completed`
Writes completed during the past second
- `log_writes_issued`
Number of times a page write has required a log write during the past second
- `log_writes_completed`
Number of log writes completed during the last second
- `get_page_calls_issued`
Number of `get_page()` calls issued during the past second
- `get_page_reqs_issued`
Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the past second
- `get_page_reqs_completed`
Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the past second

Notes

Each row in this table corresponds to an instance of `PGMAN`; there is one such instance per LDM thread plus an additional instance for each data node.

The `diskstat` table was added in NDB 8.0.19.

22.5.14.22 The `ndbinfo diskstats_1sec` Table

The `diskstats_1sec` table provides information about writes to Disk Data tablespaces over the past 20 seconds.

The `diskstat` table contains the following columns:

- `node_id`
Node ID of this node
- `block_instance`
ID of reporting instance of `PGMAN`
- `pages_made_dirty`
Pages made dirty during the designated 1-second interval
- `reads_issued`
Reads issued during the designated 1-second interval
- `reads_completed`
Reads completed during the designated 1-second interval

- `writes_issued`
Writes issued during the designated 1-second interval
- `writes_completed`
Writes completed during the designated 1-second interval
- `log_writes_issued`
Number of times a page write has required a log write during the designated 1-second interval
- `log_writes_completed`
Number of log writes completed during the designated 1-second interval
- `get_page_calls_issued`
Number of `get_page()` calls issued during the designated 1-second interval
- `get_page_reqs_issued`
Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the designated 1-second interval
- `get_page_reqs_completed`
Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the designated 1-second interval
- `seconds_ago`
Number of 1-second intervals in the past of the interval to which this row applies

Notes

Each row in this table corresponds to an instance of `PGMAN` during a 1-second interval occurring from 0 to 19 seconds ago; there is one such instance per LDM thread plus an additional instance for each data node.

The `diskstats_1sec` table was added in NDB 8.0.19.

22.5.14.23 The `ndbinfo error_messages` Table

The `error_messages` table provides information about

The `error_messages` table contains the following columns:

- `error_code`
Numeric error code
- `error_description`
Description of error
- `error_status`
Error status code
- `error_classification`
Error classification code

Notes

`error_code` is a numeric NDB error code. This is the same error code that can be supplied to `ndb_perror` (or, prior to NDB 8.0.13, to `perror --ndb`).

`error_description` provides a basic description of the condition causing the error.

The `error_status` column provides status information relating to the error. Possible values for this column are listed here:

- No error
- Illegal connect string
- Illegal server handle
- Illegal reply from server
- Illegal number of nodes
- Illegal node status
- Out of memory
- Management server not connected
- Could not connect to socket
- Start failed
- Stop failed
- Restart failed
- Could not start backup
- Could not abort backup
- Could not enter single user mode
- Could not exit single user mode
- Failed to complete configuration change
- Failed to get configuration
- Usage error
- Success
- Permanent error
- Temporary error
- Unknown result
- Temporary error, restart node
- Permanent error, external action needed
- Ndbd file system error, restart node initial
- Unknown

The `error_classification` column shows the error classification. See [NDB Error Classifications](#), for information about classification codes and their meanings.

22.5.14.24 The `ndbinfo locks_per_fragment` Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The `locks_per_fragment` table contains the following columns:

- `fq_name`
Fully qualified table name
- `parent_fq_name`
Fully qualified name of parent object
- `type`
Table type; see text for possible values
- `table_id`
Table ID
- `node_id`
Reporting node ID
- `block_instance`
LDM instance ID
- `fragment_num`
Fragment identifier
- `ex_req`
Exclusive lock requests started
- `ex_imm_ok`
Exclusive lock requests immediately granted
- `ex_wait_ok`
Exclusive lock requests granted following wait
- `ex_wait_fail`
Exclusive lock requests not granted
- `sh_req`
Shared lock requests started
- `sh_imm_ok`
Shared lock requests immediately granted

- `sh_wait_ok`

Shared lock requests granted following wait

- `sh_wait_fail`

Shared lock requests not granted

- `wait_ok_millis`

Time spent waiting for lock requests that were granted, in milliseconds

- `wait_fail_millis`

Time spent waiting for lock requests that failed, in milliseconds

Notes

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

`fq_name` is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.

`parent_fq_name` is the fully qualified name of this object's parent object (table).

`table_id` is the table's internal ID generated by NDB. This is the same internal table ID shown in other `ndbinfo` tables; it is also visible in the output of `ndb_show_tables`.

The `type` column shows the type of table. This is always one of `System table`, `User table`, `Unique hash index`, `Hash index`, `Unique ordered index`, `Ordered index`, `Hash index trigger`, `Subscription trigger`, `Read only constraint`, `Index trigger`, `Reorganize trigger`, `Tablespace`, `Log file group`, `Data file`, `Undo file`, `Hash map`, `Foreign key definition`, `Foreign key parent trigger`, `Foreign key child trigger`, or `Schema transaction`.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
```

```
sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
  ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
```

```
[shared lock requests in progress] =
  sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

```
[aborts while waiting for locks] = ex_wait_fail + sh_wait_fail
```

22.5.14.25 The `ndbinfo logbuffers` Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The `logbuffers` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

Type of log. One of: `REDO`, `DD-UNDO`, `BACKUP-DATA`, or `BACKUP-LOG`.

- `log_id`

The log ID; for Disk Data undo log files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table as well as the value shown for the `log_id` column of the `ndbinfo logspaces` table

- `log_part`

The log part number

- `total`

Total space available for this log

- `used`

Space used by this log

Notes

`logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

22.5.14.26 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The `logspaces` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

Type of log; one of: `REDO` or `DD-UNDO`.

- `node_id`

The log ID; for Disk Data undo log files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table, as well as the value shown for the `log_id` column of the `ndbinfo logbuffers` table

- `log_part`

The log part number.

- `total`

Total space available for this log.

- `used`

Space used by this log.

22.5.14.27 The `ndbinfo` membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The `membership` table contains the following columns:

- `node_id`

This node's node ID

- `group_id`

Node group to which this node belongs

- `left_node`

Node ID of the previous node

- `right_node`

Node ID of the next node

- `president`

President's node ID

- `successor`

Node ID of successor to president

- `succession_order`

Order in which this node succeeds to presidency

- `Conf_HB_order`

-

- `arbitrator`

Node ID of arbitrator

- `arb_ticket`

Internal identifier used to track arbitration

- `arb_state`

Arbitration state

- `arb_connected`

Whether this node is connected to the arbitrator; either of `Yes` or `No`

- `connected_rank1_arbs`

Connected arbitrators of rank 1

- `connected_rank2_arbs`

Connected arbitrators of rank 1

Notes

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

Figure 22.27 Circular Arrangement of NDB Cluster Nodes

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
-> FROM ndbinfo.membership;
```

node_id	left_node	right_node
5	15	6
6	5	7
7	6	8
8	7	12
12	8	13
13	12	14
14	13	15
15	14	5

8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see [NDB Cluster Start Phases](#)). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's arbitrator.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

Note

Both management nodes and API nodes are eligible to become arbitrators.

22.5.14.28 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The `memoryusage` table contains the following columns:

- `node_id`

The node ID of this data node.

- `memory_type`

One of `Data memory`, `Index memory`, or `Long message buffer`.

- `used`

Number of bytes currently used for data memory or index memory by this data node.

- `used_pages`

Number of pages currently used for data memory or index memory by this data node; see text.

- `total`

Total number of bytes of data memory or index memory available for this data node; see text.

- `total_pages`

Total number of memory pages available for data memory or index memory on this data node; see text.

Notes

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
+-----+-----+-----+
| node_id | memory_type | total |
+-----+-----+-----+
| 5 | Data memory | 1073741824 |
| 5 | Index memory | 1074003968 |
| 5 | Long message buffer | 67108864 |
| 6 | Data memory | 1073741824 |
| 6 | Index memory | 1074003968 |
| 6 | Long message buffer | 67108864 |
+-----+-----+-----+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

22.5.14.29 The ndbinfo memory_per_fragment Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The `memory_per_fragment` table contains the following columns:

- `fq_name`
Name of this fragment
- `parent_fq_name`
Name of this fragment's parent
- `type`
Type of object; see text for possible values
- `table_id`
Table ID for this table
- `node_id`
Node ID for this node
- `block_instance`
Kernel block instance ID
- `fragment_num`
Fragment ID (number)
- `fixed_elem_alloc_bytes`
Number of bytes allocated for fixed-sized elements
- `fixed_elem_free_bytes`
Free bytes remaining in pages allocated to fixed-size elements
- `fixed_elem_size_bytes`

Length of each fixed-size element in bytes

- `fixed_elem_count`

Number of fixed-size elements

- `fixed_elem_free_count`

Number of free rows for fixed-size elements

- `var_elem_alloc_bytes`

Number of bytes allocated for variable-size elements

- `var_elem_free_bytes`

Free bytes remaining in pages allocated to variable-size elements

- `var_elem_count`

Number of variable-size elements

- `hash_index_alloc_bytes`

Number of bytes allocated to hash indexes

Notes

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition

- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

22.5.14.30 The `ndbinfo` nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- `node_id`
The data node's unique node ID in the cluster.
- `uptime`
Time since the node was last started, in seconds.
- `status`
Current status of the data node; see text for possible values.
- `start_phase`
If the data node is starting, the current start phase.
- `config_generation`
The version of the cluster configuration file in use on this data node.

Notes

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmt` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 22.5.6, “NDB Cluster Single User Mode”](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 22.5.1, “Commands in the NDB Cluster Management Client”](#)). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see [Section 22.5.4, “Summary of NDB Cluster Start Phases”](#).

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make

changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
1	10462	STARTED	0	6
2	10460	STARTED	0	6
3	10457	STARTED	0	5
4	10455	STARTED	0	6

```
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
1	11776	STARTED	0	6
2	11774	STARTED	0	6
3	11771	STARTED	0	6
4	11769	STARTED	0	6

```
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
1	11807	STARTED	0	6
3	11802	STARTED	0	6
4	11800	STARTED	0	6

```
3 rows in set (0.02 sec)
```

22.5.14.31 The ndbinfo operations_per_fragment Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The `operations_per_fragment` table contains the following columns:

- `fq_name`
Name of this fragment
- `parent_fq_name`
Name of this fragment's parent

- `type`
Type of object; see text for possible values
- `table_id`
Table ID for this table
- `node_id`
Node ID for this node
- `block_instance`
Kernel block instance ID
- `fragment_num`
Fragment ID (number)
- `tot_key_reads`
Total number of key reads for this fragment replica
- `tot_key_inserts`
Total number of key inserts for this fragment replica
- `tot_key_updates`
total number of key updates for this fragment replica
- `tot_key_writes`
Total number of key writes for this fragment replica
- `tot_key_deletes`
Total number of key deletes for this fragment replica
- `tot_key_refs`
Number of key operations refused
- `tot_key_attrinfo_bytes`
Total size of all `attrinfo` attributes
- `tot_key_keyinfo_bytes`
Total size of all `keyinfo` attributes
- `tot_key_prog_bytes`
Total size of all interpreted programs carried by `attrinfo` attributes
- `tot_key_inst_exec`
Total number of instructions executed by interpreted programs for key operations
- `tot_key_bytes_returned`
Total size of all data and metadata returned from key read operations
- `tot_frag_scans`

Total number of scans performed on this fragment replica

- `tot_scan_rows_examined`

Total number of rows examined by scans

- `tot_scan_rows_returned`

Total number of rows returned to client

- `tot_scan_bytes_returned`

Total size of data and metadata returned to the client

- `tot_scan_prog_bytes`

Total size of interpreted programs for scan operations

- `tot_scan_bound_bytes`

Total size of all bounds used in ordered index scans

- `tot_scan_inst_exec`

Total number of instructions executed for scans

- `tot_qd_frag_scans`

Number of times that scans of this fragment replica have been queued

- `conc_frag_scans`

Number of scans currently active on this fragment replica (excluding queued scans)

- `conc_qd_frag_scans`

Number of scans currently queued for this fragment replica

- `tot_commits`

Total number of row changes committed to this fragment replica

Notes

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: `DbName/def/TblName`
- BLOB table: `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- Ordered index: `sys/def/BaseTblId/IndexName`
- Unique index: `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysql`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- Base table: `mydb/def/t1`
- BLOB table: `mydb/def/NDB$BLOB_11_2`
- Ordered index (primary key): `sys/def/11/PRIMARY`
- Unique index: `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

Note

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the NDB implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see [The NDB Communication Protocol](#)) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can be limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

22.5.14.32 The `ndbinfo pgman_time_track_stats` Table

This table provides information regarding the latency of disk operations for NDB Cluster Disk Data tablespaces.

The `pgman_time_track_stats` table contains the following columns:

- `node_id`
Unique node ID of this node in the cluster
- `block_number`
Block number (from `blocks` table)
- `block_instance`
Block instance number
- `upper_bound`
Upper bound
- `page_reads`
Page read latency (ms)
- `page_writes`
Page write latency (ms)
- `log_waits`
Log wait latency (ms)
- `get_page`
Latency of `get_page()` calls (ms)

Notes

The read latency (`page_reads` column) measures the time from when the read request is sent to the file system thread until the read is complete and has been reported back to the execution thread. The write latency (`page_writes`) is calculated in a similar fashion. The size of the page read to or written from a Disk Data tablespace is always 32 KB.

Log wait latency (`log_waits` column) is the length of time a page write must wait for the undo log to be flushed, which must be done prior to each page write.

The `pgman_time_track_stats` table was added in NDB 8.0.19.

22.5.14.33 The ndbinfo processes Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain information about nodes that are configured but not connected to the cluster from the [nodes](#) and [config_nodes](#) tables.

The [processes](#) table contains the following columns:

- [node_id](#)
The node's unique node ID in the cluster
- [node_type](#)
Type of node (management, data, or API node; see text)
- [node_version](#)
Version of the [NDB](#) software program running on this node.
- [process_id](#)
This node's process ID
- [angel_process_id](#)
Process ID of this node's angel process
- [process_name](#)
Name of the executable
- [service_URI](#)
Service URI of this node (see text)

Notes

[node_id](#) is the ID assigned to this node in the cluster.

The [node_type](#) column displays one of the following three values:

- [MGM](#): Management node.
- [NDB](#): Data node.
- [API](#): API or SQL node.

For an executable shipped with the NDB Cluster distribution, [node_version](#) shows the software Cluster version string, such as `8.0.22-ndb-8.0.22`.

[process_id](#) is the node executable's process ID as shown by the host operating system using a process display application such as [top](#) on Linux, or the Task Manager on Windows platforms.

[angel_process_id](#) is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is [NULL](#).

The [process_name](#) column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmtbd` (multithreaded). For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

`service_URI` shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*`, `0.0.0.0`, or `::`.

Additional path information may be included in the `service_URI` value for an SQL node reflecting various configuration options. For example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

22.5.14.34 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The `resources` table contains the following columns:

- `node_id`

The unique node ID of this data node.

- `resource_name`

Name of the resource; see text.

- `reserved`

The amount reserved for this resource.

- `used`

The amount actually used by this resource.

- `max`

The maximum amount of this resource used, since the node was last started.

Notes

The `resource_name` can be any one of the names shown in the following table:

- `RESERVED`: Reserved by the system; cannot be overridden.
- `DISK_OPERATIONS`: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.
- `DISK_RECORDS`: Records allocated for Disk Data operations.
- `DATA_MEMORY`: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.
- `JOBBUFFER`: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.

- **FILE_BUFFERS**: Used by the redo log handler in the **DBLQH** kernel block; cannot be overallocated. Size is **NoOfFragmentLogParts** * **RedoBuffer**, plus 1 MB per log file part.
- **TRANSPORTER_BUFFERS**: Used for send buffers by **ndbmt**; the sum of **TotalSendBufferMemory** and **ExtraSendBufferMemory**. This resource that can be overallocated by up to 25 percent. **TotalSendBufferMemory** is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. **ExtraSendBufferMemory** is used by **ndbmt** and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, **ExtraSendBufferMemory** is 10 * 2 MB. Overallocation of this resource can be performed by setting the **SharedGlobalMemory** data node configuration parameter.
- **DISK_PAGE_BUFFER**: Used for the disk page buffer; determined by the **DiskPageBufferMemory** configuration parameter. Cannot be overallocated.
- **QUERY_MEMORY**: Used by the **DBSPJ** kernel block.
- **SCHEMA_TRANS_MEMORY**: Minimum is 2 MB; can be overallocated to use any remaining available memory.

22.5.14.35 The ndbinfo restart_info Table

The **restart_info** table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The **restart_info** table contains the following columns:

- **node_id**
Node ID in the cluster
- **node_restart_status**
Node status; see text for values. Each of these corresponds to a possible value of **node_restart_status_int**.
- **node_restart_status_int**
Node status code; see text for values.
- **secs_to_complete_node_failure**
Time in seconds to complete node failure handling
- **secs_to_allocate_node_id**
Time in seconds from node failure completion to allocation of node ID
- **secs_to_include_in_heartbeat_protocol**
Time in seconds from allocation of node ID to inclusion in heartbeat protocol
- **secs_until_wait_for_ndbcntr_master**
Time in seconds from being included in heartbeat protocol until waiting for **NDBCNTR** master began
- **secs_wait_for_ndbcntr_master**
Time in seconds spent waiting to be accepted by **NDBCNTR** master for starting
- **secs_to_get_start_permitted**

Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node

- [secs_to_wait_for_lcp_for_copy_meta_data](#)

Time in seconds spent waiting for LCP completion before copying meta data

- [secs_to_copy_meta_data](#)

Time in seconds required to copy metadata from master to newly starting node

- [secs_to_include_node](#)

Time in seconds waited for GCP and inclusion of all nodes into protocols

- [secs_starting_node_to_request_local_recovery](#)

Time in seconds that the node just starting spent waiting to request local recovery

- [secs_for_local_recovery](#)

Time in seconds required for local recovery by node just starting

- [secs_restore_fragments](#)

Time in seconds required to restore fragments from LCP files

- [secs_undo_disk_data](#)

Time in seconds required to execute undo log on disk data part of records

- [secs_exec_redo_log](#)

Time in seconds required to execute redo log on all restored fragments

- [secs_index_rebuild](#)

Time in seconds required to rebuild indexes on restored fragments

- [secs_to_synchronize_starting_node](#)

Time in seconds required to synchronize starting node from live nodes

- [secs_wait_lcp_for_restart](#)

Time in seconds required for LCP start and completion before restart was completed

- [secs_wait_subscription_handover](#)

Time in seconds spent waiting for handover of replication subscriptions

- [total_restart_secs](#)

Total number of seconds from node failure until node is started again

Notes

The following list contains values defined for the [node_restart_status_int](#) column with their internal status names (in parentheses), and the corresponding messages shown in the [node_restart_status](#) column:

- 0 ([ALLOCATED_NODE_ID](#))

Allocated node id

- 1 (INCLUDED_IN_HB_PROTOCOL)
Included in heartbeat protocol
- 2 (NDBCNTR_START_WAIT)
Wait for NDBCNTR master to permit us to start
- 3 (NDBCNTR_STARTED)
NDBCNTR master permitted us to start
- 4 (START_PERMITTED)
All nodes permitted us to start
- 5 (WAIT_LCP_TO_COPY_DICT)
Wait for LCP completion to start copying metadata
- 6 (COPY_DICT_TO_STARTING_NODE)
Copying metadata to starting node
- 7 (INCLUDE_NODE_IN_LCP_AND_GCP)
Include node in LCP and GCP protocols
- 8 (LOCAL_RECOVERY_STARTED)
Restore fragments ongoing
- 9 (COPY_FRAGMENTS_STARTED)
Synchronizing starting node with live nodes
- 10 (WAIT_LCP_FOR_RESTART)
Wait for LCP to ensure durability
- 11 (WAIT_SUMA_HANOVER)
Wait for handover of subscriptions
- 12 (RESTART_COMPLETED)
Restart completed
- 13 (NODE_FAILED)
Node failed, failure handling in progress
- 14 (NODE_FAILURE_COMPLETED)
Node failure handling completed
- 15 (NODE_GETTING_PERMIT)
All nodes permitted us to start
- 16 (NODE_GETTING_INCLUDED)

Include node in LCP and GCP protocols

- 17 (NODE_GETTING_SYNCED)

Synchronizing starting node with live nodes

- 18 (NODE_GETTING_LCP_WAITED)

[none]

- 19 (NODE_ACTIVE)

Restart completed

- 20 (NOT_DEFINED_IN_CLUSTER)

[none]

- 21 (NODE_NOT_RESTARTED_YET)

Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also [Section 22.5.4, “Summary of NDB Cluster Start Phases”](#).

22.5.14.36 The ndbinfo server_locks Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysqld` instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The `server_locks` table contains the following columns:

- `mysql_connection_id`

MySQL connection ID

- `node_id`

ID of reporting node

- `block_instance`

ID of reporting LDM instance

- `tableid`

ID of table containing this row

- `fragmentid`

ID of fragment containing locked row

- `rowid`

ID of locked row

- `transid`
Transaction ID
- `mode`
Lock request mode
- `state`
Lock state
- `detail`
Whether this is first holding lock in row lock queue
- `op`
Operation type
- `duration_millis`
Milliseconds spent waiting or holding lock
- `lock_num`
ID of lock object
- `waiting_for`
Waiting for lock with this ID

Notes

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `tableid` is assigned to the table by `NDB`; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains a `*` (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

22.5.14.37 The `ndbinfo server_operations` Table

The `server_operations` table contains entries for all ongoing `NDB` operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- `mysql_connection_id`
MySQL Server connection ID
- `node_id`
Node ID
- `block_instance`
Block instance
- `transid`
Transaction ID
- `operation_type`
Operation type (see text for possible values)
- `state`
Operation state (see text for possible values)
- `tableid`
Table ID
- `fragmentid`
Fragment ID
- `client_node_id`
Client node ID
- `client_block_ref`
Client block reference
- `tc_node_id`
Transaction coordinator node ID
- `tc_block_no`
Transaction coordinator block number
- `tc_block_instance`
Transaction coordinator block instance

Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

22.5.14.38 The ndbinfo server_transactions Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`
MySQL Server connection ID
- `node_id`
Transaction coordinator node ID
- `block_instance`
Transaction coordinator block instance
- `transid`

Transaction ID

- `state`

Operation state (see text for possible values)

- `count_operations`

Number of stateful operations in the transaction

- `outstanding_operations`

Operations still being executed by local data management layer (LQH blocks)

- `inactive_seconds`

Time spent waiting for API

- `client_node_id`

Client node ID

- `client_block_ref`

Client block reference

Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

22.5.14.39 The ndbinfo table_distribution_status Table

The `table_distribution_status` table provides information about the progress of table distribution for `NDB` tables.

The `table_distribution_status` table contains the following columns:

- `node_id`

Node id

- `table_id`

Table ID

- `tab_copy_status`

Status of copying of table distribution data to disk; one of `IDLE`, `SR_PHASE1_READ_PAGES`, `SR_PHASE2_READ_TABLE`, `SR_PHASE3_COPY_TABLE`, `REMOVE_NODE`, `LCP_READ_TABLE`, `COPY_TAB_REQ`, `COPY_NODE_STATE`, `ADD_TABLE_MASTER`, `ADD_TABLE_SLAVE`, `INVALIDATE_NODE_LCP`, `ALTER_TABLE`, `COPY_TO_SAVE`, or `GET_TABINFO`

- `tab_update_status`

Status of updating of table distribution data; one of `IDLE`, `LOCAL_CHECKPOINT`, `LOCAL_CHECKPOINT_QUEUED`, `REMOVE_NODE`, `COPY_TAB_REQ`, `ADD_TABLE_MASTER`, `ADD_TABLE_SLAVE`, `INVALIDATE_NODE_LCP`, or `CALLBACK`

- `tab_lcp_status`

Status of table LCP; one of `ACTIVE` (waiting for local checkpoint to be performed), `WRITING_TO_FILE` (checkpoint performed but not yet written to disk), or `COMPLETED` (checkpoint performed and persisted to disk)

- `tab_status`

Table internal status; one of `ACTIVE` (table exists), `CREATING` (table is being created), or `DROPPING` (table is being dropped)

- `tab_storage`

Table recoverability; one of `NORMAL` (fully recoverable with redo logging and checkpointing), `NOLOGGING` (recoverable from node crash, empty following cluster crash), or `TEMPORARY` (not recoverable)

- `tab_partitions`

Number of partitions in table

- `tab_fragments`

Number of fragments in table; normally same as `tab_partitions`; for fully replicated tables equal to `tab_partitions * [number of node groups]`

- `current_scan_count`

Current number of active scans

- `scan_count_wait`

Current number of scans waiting to be performed before `ALTER TABLE` can complete.

- `is_reorg_ongoing`

Whether the table is currently being reorganized (1 if true)

22.5.14.40 The ndbinfo table_fragments Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of `NDB` tables.

The `table_fragments` table contains the following columns:

- `node_id`
Node ID (DIH master)
- `table_id`
Table ID
- `partition_id`
Partition ID
- `fragment_id`
Fragment ID (same as partition ID unless table is fully replicated)
- `partition_order`
Order of fragment in partition
- `log_part_id`
Log part ID of fragment
- `no_of_replicas`
Number of replicas
- `current_primary`
Current primary node ID
- `preferred_primary`
Preferred primary node ID
- `current_first_backup`
Current first backup node ID
- `current_second_backup`
Current second backup node ID
- `current_third_backup`
Current third backup node ID
- `num_alive_replicas`
Current number of live replicas
- `num_dead_replicas`
Current number of dead replicas
- `num_lcp_replicas`
Number of replicas remaining to be checkpointed

22.5.14.41 The `ndbinfo table_info` Table

The `table_info` table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The `table_info` table contains the following columns:

- `table_id`

Table ID

- `logged_table`

Whether table is logged (1) or not (0)

- `row_contains_gci`

Whether table rows contain GCI (1 true, 0 false)

- `row_contains_checksum`

Whether table rows contain checksum (1 true, 0 false)

- `read_backup`

If backup replicas are read this is 1, otherwise 0

- `fully_replicated`

If table is fully replicated this is 1, otherwise 0

- `storage_type`

Table storage type; one of `MEMORY` or `DISK`

- `hashmap_id`

Hashmap ID

- `partition_balance`

Partition balance (fragment count type) used for table; one of `FOR_RP_BY_NODE`, `FOR_RA_BY_NODE`, `FOR_RP_BY_LDM`, or `FOR_RA_BY_LDM`

- `create_gci`

GCI in which table was created

22.5.14.42 The ndbinfo table_replicas Table

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The `table_replicas` table contains the following columns:

- `node_id`

ID of the node from which data is fetched (`DIH` master)

- `table_id`

Table ID

- `fragment_id`

Fragment ID

- `initial_gci`
Initial GCI for table
- `replica_node_id`
ID of node where replica is stored
- `is_lcp_ongoing`
Is 1 if LCP is ongoing on this fragment, 0 otherwise
- `num_crashed_replicas`
Number of crashed replica instances
- `last_max_gci_started`
Highest GCI started in most recent LCP
- `last_max_gci_completed`
Highest GCI completed in most recent LCP
- `last_lcp_id`
ID of most recent LCP
- `prev_lcp_id`
ID of previous LCP
- `prev_max_gci_started`
Highest GCI started in previous LCP
- `prev_max_gci_completed`
Highest GCI completed in previous LCP
- `last_create_gci`
Last Create GCI of last crashed replica instance
- `last_replica_gci`
Last GCI of last crashed replica instance
- `is_replica_alive`
1 if this replica is alive, 0 otherwise

22.5.14.43 The `ndbinfo tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the `DBTC` block (TC) instances in the data nodes, through API nodes access `NDB`. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The `tc_time_track_stats` table contains the following columns:

- `node_id`

Requesting node ID

- `block_number`

TC block number

- `block_instance`

TC block instance number

- `comm_node_id`

Node ID of communicating API or data node

- `upper_bound`

Upper bound of interval (in microseconds)

- `scans`

Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_errors`

Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_fragments`

Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them

- `scan_fragment_errors`

Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them

- `transactions`

Based on duration of successful transactions from beginning until sending of commit `ACK`, tracked against the API or data nodes requesting them. Stateless transactions are not included.

- `transaction_errors`

Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

- [read_key_ops](#)

Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

- [write_key_ops](#)

Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

- [index_key_ops](#)

Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

- [key_op_errors](#)

Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

Notes

The [block_instance](#) column provides the [DBTC](#) kernel block instance number. You can use this together with the block name to obtain information about specific threads from the [threadblocks](#) table.

22.5.14.44 The ndbinfo threadblocks Table

The [threadblocks](#) table associates data nodes, threads, and instances of [NDB](#) kernel blocks.

The [threadblocks](#) table contains the following columns:

- [node_id](#)

Node ID

- [thr_no](#)

Thread ID

- [block_name](#)

Block name

- [block_instance](#)

Block instance number

Notes

The value of the [block_name](#) in this table is one of the values found in the [block_name](#) column when selecting from the [ndbinfo.blocks](#) table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The [block_instance](#) column provides the kernel block instance number.

22.5.14.45 The ndbinfo threads Table

The [threads](#) table provides information about threads running in the [NDB](#) kernel.

The [threads](#) table contains the following columns:

- [node_id](#)

ID of the node where the thread is running

- `thr_no`

Thread ID (specific to this node)

- `thread_name`

Thread name (type of thread)

- `thread_description`

Thread (type) description

Notes

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
```

node_id	thr_no	thread_name	thread_description
5	0	main	main thread, schema and distribution handling
5	1	rep	rep thread, asynch replication and proxy block handling
5	2	ldm	ldm thread, handling a set of data partitions
5	3	recv	receive thread, performing receive and polling for new receives
6	0	main	main thread, schema and distribution handling
6	1	rep	rep thread, asynch replication and proxy block handling
6	2	ldm	ldm thread, handling a set of data partitions
6	3	recv	receive thread, performing receive and polling for new receives

```
8 rows in set (0.01 sec)
```

22.5.14.46 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the [NDB](#) kernel.

The `threadstat` table contains the following columns:

- `node_id`

Node ID

- `thr_no`

Thread ID

- `thr_nm`

Thread name

- `c_loop`

Number of loops in main loop

- `c_exec`

Number of signals executed

- `c_wait`

Number of times waiting for additional input

- `c_l_sent_prioa`

Number of priority A signals sent to own node

- `c_l_sent_priob`

Number of priority B signals sent to own node

- `c_r_sent_prioa`

Number of priority A signals sent to remote node

- `c_r_sent_priob`

Number of priority B signals sent to remote node

- `os_tid`

OS thread ID

- `os_now`

OS time (ms)

- `os_ru_utime`

OS user CPU time (µs)

- `os_ru_stime`

OS system CPU time (µs)

- `os_ru_minflt`

OS page reclaims (soft page faults)

- `os_ru_majflt`

OS page faults (hard page faults)

- `os_ru_nvcsw`

OS voluntary context switches

- `os_ru_nivcsw`

OS involuntary context switches

Notes

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see [Section 24.4, "Using the Event Scheduler"](#).

22.5.14.47 The ndbinfo transporters Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- `node_id`
This data node's unique node ID in the cluster
- `remote_node_id`
The remote data node's node ID
- `status`
Status of the connection
- `remote_address`
Name or IP address of the remote host
- `bytes_sent`
Number of bytes sent using this connection
- `bytes_received`
Number of bytes received using this connection
- `connect_count`
Number of times connection established on this transporter
- `overloaded`
1 if this transporter is currently overloaded, otherwise 0
- `overload_count`
Number of times this transporter has entered overload state since connecting
- `slowdown`
1 if this transporter is in slowdown state, otherwise 0
- `slowdown_count`
Number of times this transporter has entered slowdown state since connecting

Notes

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```

ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.100.10.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2 @10.100.10.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (8.0.22-ndb-8.0.22)
id=21 @10.100.10.21 (8.0.22-ndb-8.0.22)

```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```

mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+
| node_id | remote_node_id | status |
+-----+
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
| 2 | 1 | CONNECTED |
| 2 | 2 | DISCONNECTED |
| 2 | 10 | CONNECTED |
| 2 | 20 | CONNECTED |
| 2 | 21 | CONNECTED |
+-----+
10 rows in set (0.04 sec)

```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```

mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+
| node_id | remote_node_id | status |
+-----+
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTING |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
+-----+
5 rows in set (0.02 sec)

```

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The *overload* state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OVERloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, $0.8 * 2097152 = 1677721$ bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The *slowdown* state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to $0.6 *$

2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in [TEXT](#) columns or [BLOB](#) columns (or both types of columns)
- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient [SendBufferMemory](#)
- Hardware issues such as insufficient RAM or poor network connectivity

See also [Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

22.5.15 INFORMATION_SCHEMA Tables for NDB Cluster

Two [INFORMATION_SCHEMA](#) tables provide information that is of particular use when managing an NDB Cluster. The [FILES](#) table provides information about NDB Cluster Disk Data files (see [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#)). The [ndb_transid_mysql_connection_map](#) table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the [ndbinfo](#) database. For information about these tables, see [Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

22.5.16 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- [SHOW ENGINE NDB STATUS](#), [SHOW ENGINE NDBCLUSTER STATUS](#)

The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

See [Section 13.7.7.15, “SHOW ENGINE Statement”](#), for a usage example and more detailed information.

- [SHOW ENGINES](#)

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 13.7.7.16, “SHOW ENGINES Statement”](#), for more detailed information.

Note

This statement does not support a [LIKE](#) clause. However, you can use [LIKE](#) to filter queries against the [INFORMATION_SCHEMA.ENGINES](#) table, as discussed in the next item.

- [SELECT * FROM INFORMATION_SCHEMA.ENGINES \[WHERE ENGINE LIKE 'NDB%'\]](#)

This is the equivalent of [SHOW ENGINES](#), but uses the [ENGINES](#) table of the [INFORMATION_SCHEMA](#) database. Unlike the case with the [SHOW ENGINES](#) statement, it is possible to filter the results using a [LIKE](#) clause, and to select specific columns to obtain information that may

be of use in scripts. For example, the following query shows whether the server was built with [NDB](#) support and, if so, whether it is enabled:

```
mysql> SELECT ENGINE, SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
```

ENGINE	SUPPORT
ndbcluster	YES
ndbinfo	YES

If [NDB](#) support is not enabled, the preceding query returns an empty set. See [Section 25.13, “The INFORMATION_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the [NDB](#) storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
```

Variable_name	Value
ndb_allow_copying_alter_table	ON
ndb_autoincrement_prefetch_sz	512
ndb_batch_size	32768
ndb_blob_read_batch_bytes	65536

ndbinfo_version	524308

See [Section 5.1.8, “Server System Variables”](#), for more information.

- `SELECT * FROM performance_schema.global_variables WHERE VARIABLE_NAME LIKE 'NDB%'`

This statement is the equivalent of the `SHOW VARIABLES` statement described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME LIKE 'NDB%';
```

VARIABLE_NAME	VARIABLE_VALUE
ndb_allow_copying_alter_table	ON
ndb_autoincrement_prefetch_sz	512
ndb_batch_size	32768
ndb_blob_read_batch_bytes	65536
ndb_blob_write_batch_bytes	65536
ndb_clear_apply_status	ON
ndb_cluster_connection_pool	1
ndb_cluster_connection_pool_nodeids	
ndb_connectstring	127.0.0.1
ndb_data_node_neighbour	0

ndb_index_stat_option	loop_enable=1000ms,loop_idle=1000ms,
loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_batch=8,	
check_delay=10m,delete_batch=8,clean_delay=1m,error_batch=4,error_delay=1m,	
evict_batch=8,evict_delay=1m,cache_limit=32M,cache_lowpct=90,zero_total=0	
ndb_join_pushdown	ON
ndb_log_apply_status	OFF
ndb_log_bin	OFF
ndb_log_binlog_index	ON
ndb_log_empty_epochs	OFF
ndb_log_empty_update	OFF
ndb_log_exclusive_reads	OFF
ndb_log_orig	OFF
ndb_log_transaction_id	OFF
ndb_log_update_as_write	ON
ndb_log_update_minimal	OFF

ndb_log_updated_only	ON
ndb_metadata_check	ON
ndb_metadata_check_interval	60
ndb_metadata_sync	OFF
ndb_mgmd_host	127.0.0.1
ndb_nodeid	0
ndb_optimization_delay	10
ndb_optimized_node_selection	3
ndb_read_backup	ON
ndb_rcv_thread_activation_threshold	8
ndb_rcv_thread_cpu_mask	
ndb_report_thresh_binlog_epoch_slip	10
ndb_report_thresh_binlog_mem_usage	10
ndb_row_checksum	1
ndb_schema_dist_lock_wait_timeout	30
ndb_schema_dist_timeout	120
ndb_schema_dist_upgrade_allowed	ON
ndb_show_foreign_key_mock_tables	OFF
ndb_slave_conflict_role	NONE
ndb_table_no_logging	OFF
ndb_table_temporary	OFF
ndb_use_copying_alter_table	OFF
ndb_use_exact_count	OFF
ndb_use_transactions	ON
ndb_version	524308
ndb_version_string	ndb-8.0.20
ndb_wait_connected	30
ndb_wait_setup	30
ndbinfo_database	ndbinfo
ndbinfo_max_bytes	0
ndbinfo_max_rows	10
ndbinfo_offline	OFF
ndbinfo_show_hidden	OFF
ndbinfo_table_prefix	ndb\$
ndbinfo_version	524308

Unlike the case with the `SHOW VARIABLES` statement, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
-> FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME = 'ndb_force_send';
```

VARIABLE_VALUE
ON

A more useful query is shown here:

```
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
> FROM performance_schema.global_variables
> WHERE VARIABLE_NAME
> IN ('version', 'ndb_version',
>     'ndb_version_string', 'ndbinfo_version');
```

Name	Value
ndb_version	524308
ndb_version_string	ndb-8.0.20
ndbinfo_version	524308
version	8.0.20-cluster

4 rows in set (0.00 sec)

For more information, see [Section 26.12.15, “Performance Schema Status Variable Tables”](#), and [Section 5.1.8, “Server System Variables”](#).

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

Variable_name	Value

If the MySQL server was built with [NDB](#) support, but it is not currently connected to a cluster, every row in the output of this statement contains a zero or an empty string for the [Value](#) column.

See also [Section 13.7.7.37, “SHOW STATUS Statement”](#).

- `SELECT * FROM performance_schema.global_status WHERE VARIABLE_NAME LIKE 'NDB%'`

This statement provides similar output to the `SHOW STATUS` statement discussed in the previous item. Unlike the case with `SHOW STATUS`, it is possible using `SELECT` statements to extract values in SQL for use in scripts for monitoring and automation purposes.

For more information, see [Section 26.12.15, “Performance Schema Status Variable Tables”](#).

- `SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'`

This statement displays information from the `INFORMATION_SCHEMA.PLUGINS` table about plugins associated with NDB Cluster, such as version, author, and license, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS
> WHERE PLUGIN_NAME LIKE 'NDB%'\G
***** 1. row *****
      PLUGIN_NAME: ndbcluster
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 80020.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: Oracle Corporation
      PLUGIN_DESCRIPTION: Clustered, fault-tolerant tables
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
***** 2. row *****
      PLUGIN_NAME: ndbinfo
      PLUGIN_VERSION: 0.1
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 80020.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: Oracle Corporation
      PLUGIN_DESCRIPTION: MySQL Cluster system information storage engine
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
***** 3. row *****
      PLUGIN_NAME: ndb_transid_mysql_connection_map
      PLUGIN_VERSION: 0.1
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: INFORMATION SCHEMA
      PLUGIN_TYPE_VERSION: 80020.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: Oracle Corporation
      PLUGIN_DESCRIPTION: Map between MySQL connection ID and NDB transaction ID
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
```

You can also use the `SHOW PLUGINS` statement to display this information, but the output from that statement cannot easily be filtered. See also [The MySQL Plugin API](#), which describes where and how the information in the `PLUGINS` table is obtained.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See [Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

22.5.17 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues

- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

22.5.17.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 22.5.17.2, “NDB Cluster and MySQL Privileges”](#), for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 22.3.1, “Quick Test Setup of NDB Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

Figure 22.28 NDB Cluster with Hardware Firewall

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 6.1.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type

of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

Figure 22.29 NDB Cluster with Software Firewalls

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Table 22.66 Node types in a host-based firewall cluster configuration

Node Type	Permitted Traffic
SQL or API node	<ul style="list-style-type: none"> It originates from the IP address of a management or data node (using any TCP or UDP port). It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node	<ul style="list-style-type: none"> It originates from the IP address of a management or data node (using any TCP or UDP port).

Node Type	Permitted Traffic
	<ul style="list-style-type: none"> It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

- It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

Figure 22.30 NDB Cluster with a Combination of Hardware and Software Firewalls

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the

management client to access the management server safely, from within the cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

22.5.17.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see [Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#), for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=management_host` and access this NDB Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all NDB databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
 - `SELECT * FROM some_table` to read all the data from any table
 - `DELETE FROM some_table` to delete all the data from a table

- `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
- `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster's distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the `NDB` storage engine manually. Use the stored procedure provided for this purpose instead; see [Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#).

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.
3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

22.5.17.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root      10467  0.0  0.1   3616  1380 pts/3    S      11:53   0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl     11:53   0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+     11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 22.5.17.2, “NDB Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
->   SET Password=PASSWORD('secure_password')
->   WHERE User='root';

mysql> DELETE FROM mysql.user
->   WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 22.4, “NDB Cluster Programs”](#), for more information about these utilities.

22.6 NDB Cluster Replication

NDB Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 17, Replication](#)).

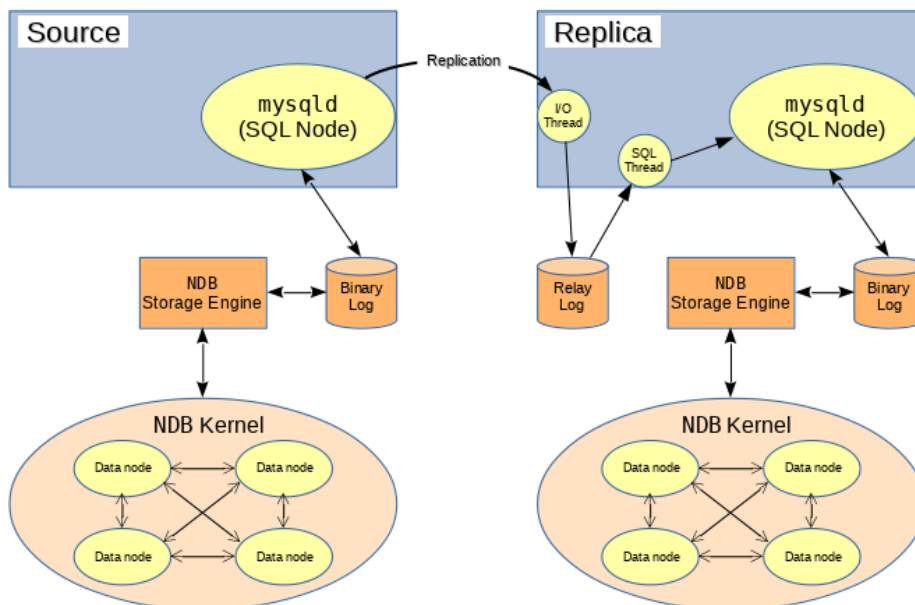

Note

NDB Cluster does not support replication using GTIDs; semisynchronous replication and group replication are also not supported by the NDB storage engine.

Normal (non-clustered) replication involves a source server (formerly called a “master”) and a replica server (formerly referred to as a “slave”), the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the replica's copies of the replicated tables (see [Replication from NDB to other storage engines](#)). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

Figure 22.31 NDB Cluster-to-Cluster Replication Layout

In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see [Section 22.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”](#).

NDB API replica status variables. NDB API counters can provide enhanced monitoring capabilities on replica clusters. These counters are implemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the Performance Schema `session_status` or `global_status` table in a `mysql` client session connected to a MySQL Server that is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting NDB Cluster Replication. [Section 22.5.13, “NDB API Statistics Counters and Variables”](#), provides additional information.

Replication from NDB to non-NDB tables. It is possible to replicate NDB tables from an NDB Cluster acting as the replication source to tables using other MySQL storage engines such as `InnoDB` or `MyISAM` on a replica `mysqld`. This is subject to a number of conditions; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

22.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and replica clusters, and to processes and commands run on the clusters or cluster nodes:

Table 22.67 Abbreviations used throughout this section referring to source and replica clusters, and to processes and commands run on cluster nodes

Symbol or Abbreviation	Description (Refers to...)
<code>S</code>	The cluster serving as the (primary) replication source
<code>R</code>	The cluster acting as the (primary) replica
<code>shellS></code>	Shell command to be issued on the source cluster
<code>mysqlS></code>	MySQL client command issued on a single MySQL server running as an SQL node on the source cluster
<code>mysqlS*></code>	MySQL client command to be issued on all SQL nodes participating in the replication source cluster
<code>shellR></code>	Shell command to be issued on the replica cluster
<code>mysqlR></code>	MySQL client command issued on a single MySQL server running as an SQL node on the replica cluster
<code>mysqlR*></code>	MySQL client command to be issued on all SQL nodes participating in the replica cluster
<code>C</code>	Primary replication channel
<code>C'</code>	Secondary replication channel
<code>S'</code>	Secondary replication source
<code>R'</code>	Secondary replica

22.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 22.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 17.2.1, “Replication Formats”](#).

Important

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the source cluster and the `epoch` column of the `ndb_apply_status` table on the replica cluster are not updated (see [Section 22.6.4, “NDB Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.

The default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see [Section 17.5.2, “Replication Compatibility Between MySQL Versions”](#)). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 8.0 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all source and replica `mysqld` binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

22.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

Loss of connection between source and replica. A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The source SQL node issues a “gap” event when connecting or reconnecting to the source cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about what to do in such circumstances.

Important

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#), and [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#).

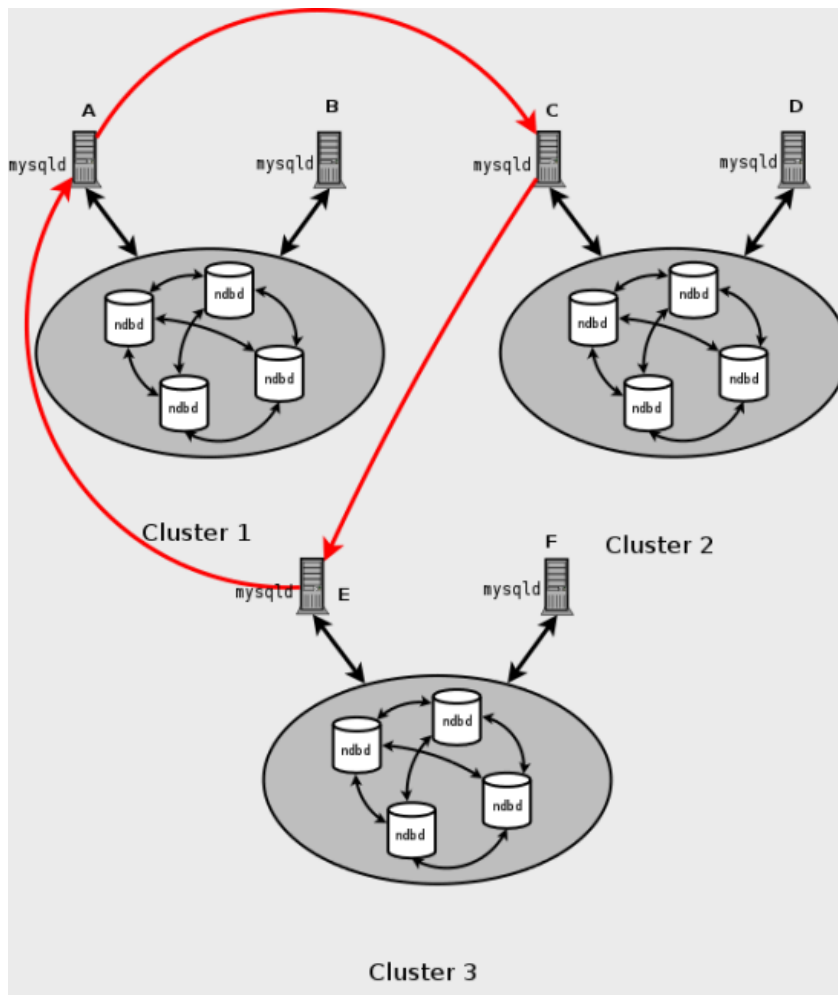

If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

Circular replication. NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all source and replica clusters are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

Figure 22.32 NDB Cluster Circular Replication With All Sources As Replicas

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:

Figure 22.33 NDB Cluster Circular Replication Where Not All Sources Are Replicas

In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Note

The NDB storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

NDB Cluster replication and primary keys. In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have explicit primary keys.

NDB Cluster Replication and Unique Keys. In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by [NDB](#). Thus, updates of unique keys when replicating from [NDB](#) to a different storage engine such as [InnoDB](#) or [MyISAM](#) are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using [NDB](#) table such as [t](#), is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following [UPDATE](#) statement on [t](#) succeeds on the source, since the rows affected are processed in the order determined by the [ORDER BY](#) option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

Note

Every [NDB](#) table is implicitly partitioned by key when it is created. See [Section 23.2.5, “KEY Partitioning”](#), for more information.

GTIDs not supported. Replication using global transaction IDs is not compatible with the [NDB](#) storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

Multithreaded replicas not supported. NDB Cluster does not support multithreaded replicas, and setting related system variables such as [slave_parallel_workers](#), [slave_checkpoint_group](#), and [slave_checkpoint_group](#) (or the equivalent [mysqld](#) startup options) has no effect.

This is because the replica may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the [NDB](#) storage engine involves at least two databases—the target database and the [mysql](#) system database—due to the requirement for updating the [mysql.ndb_apply_status](#) table (see [Section 22.6.4, “NDB Cluster Replication Schema and Tables”](#)). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

Restarting with `--initial`. Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the [RESET MASTER](#) and [RESET SLAVE](#) statements to clear the invalid [ndb_binlog_index](#) and [ndb_apply_status](#) tables, respectively.

Replication from NDB to other storage engines. It is possible to replicate an [NDB](#) table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the [NDB](#) storage engine for this to work).
- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.
- Use of a nontransactional storage engine for tables on the replica also requires special handling.
- The source [mysqld](#) must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

Multiple sources not supported when replicating NDB to other storage engines. For replication from [NDB](#) to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between [NDB](#) and a different storage engine. (An NDB Cluster database *can* simultaneously replicate to multiple NDB Cluster databases.) If the source uses [NDB](#) tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

Replicating NDB tables to a storage engine that does not perform binary logging. If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the replica. It is safe to do this when using a storage engine other than [NDB](#) on the replica, since you do not need to worry about keeping multiple replicas synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the replica.** This can be done by starting the replica with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See [Replication and binary log filtering rules with replication between NDB Clusters](#), for details.

Replication from NDB to a nontransactional storage engine. When replicating from [NDB](#) to a nontransactional storage engine such as [MyISAM](#), you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes, rather than as updates.

Replication and binary log filtering rules with replication between NDB Clusters. If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, you must take care not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should

also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

- Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

- Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.4.4, “The Binary Log”](#).

If you are replicating an NDB Cluster to a replica that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

NDB Cluster Replication and IPv6. Beginning with NDB 8.0.22, all types of NDB Cluster nodes support IPv6; this includes management nodes, data nodes, and API or SQL nodes.

Prior to NDB 8.0.22, the NDB API and MGM API (and thus data nodes and management nodes) do not support IPv6, although MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. In versions of NDB Cluster prior to 8.0.22, you can replicate between clusters using IPv6 to connect the SQL nodes acting as source and replica as shown by the dotted arrow in the following diagram:

Figure 22.34 Replication Between SQL Nodes Connected Using IPv6

Prior to NDB 8.0.22, all connections originating *within* the NDB Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. In NDB 8.0.22 and later, these restrictions no

longer apply; in addition, any applications written using the NDB and MGM APIs can be written and deployed assuming an IPv6-only environment.

Attribute promotion and demotion. NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see [Row-based replication: attribute promotion and demotion](#).

NDB, unlike InnoDB or MyISAM, does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

22.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster. These tables are created during the MySQL installation process, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the InnoDB storage engine. This means that it must be created separately on each `mysqld` participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` INT(10) UNSIGNED NOT NULL,
  `updates` INT(10) UNSIGNED NOT NULL,
  `deletes` INT(10) UNSIGNED NOT NULL,
  `schemaops` INT(10) UNSIGNED NOT NULL,
  `orig_server_id` INT(10) UNSIGNED NOT NULL,
  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
  `gci` INT(10) UNSIGNED NOT NULL,
  `next_position` bigint(20) unsigned NOT NULL,
  `next_file` varchar(255) NOT NULL,
  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

Note

If you are upgrading from an older release (prior to NDB 7.5.2), perform the MySQL upgrade procedure and ensure that the system tables are upgraded. (As of MySQL 8.0.16, start the server with the `--upgrade=FORCE` option. Prior to MySQL 8.0.16, invoke `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to InnoDB. If this becomes an issue, you may be able to conserve space by using an InnoDB tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see [Section 13.1.21, “CREATE TABLESPACE Statement”](#), and [Section 13.1.20, “CREATE TABLE Statement”](#), as well as [Section 15.6.3, “Tablespaces”](#).

The size of the `ndb_binlog_index` table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs

resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

$$[\text{number of epochs per file}] = [\text{time spent per file}] / \text{TimeBetweenEpochs}$$

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see [Section 22.6.10, “NDB Cluster Replication: Bidirectional and Circular Replication”](#)) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover times by adding an index to these columns, as shown here:

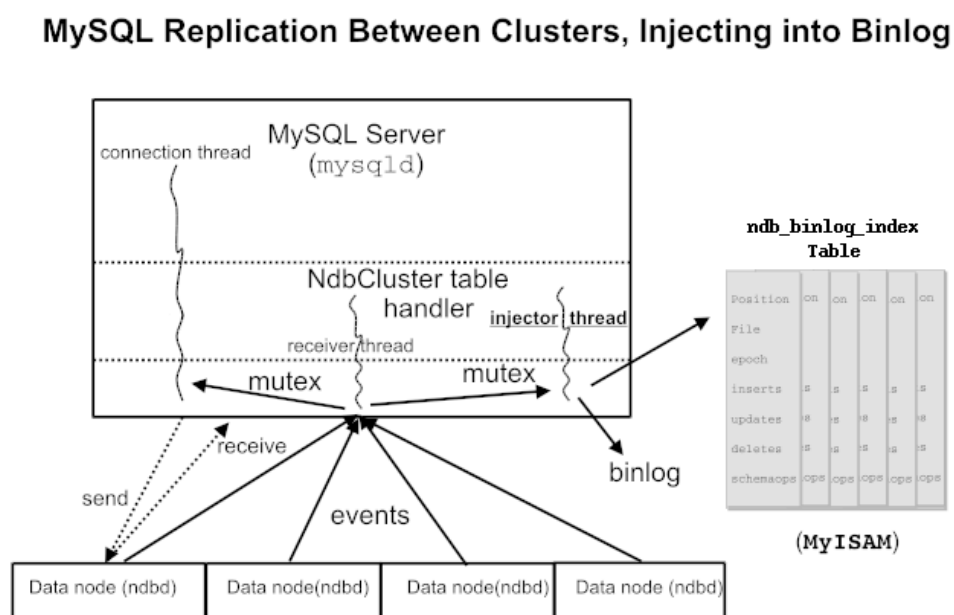

```
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single source to a single replica, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

Figure 22.35 The Replication Source Cluster

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the source to the replica. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (replica) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos` BIGINT(20) UNSIGNED NOT NULL,
  `end_pos` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any `DataMemory` to `ndb_apply_status` there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating `ndb_apply_status`, or that prevent the source from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between NDB Clusters](#).

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both are maintained by the `NDB` binary log (binlog) injector thread. This keeps the source `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB binlog injector thread` receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The replica I/O thread transfers the events from the source's binary log to the replica's relay log.

Even though `ndb_binlog_index` and `ndb_apply_status` are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the source. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the source or replica SQL node. (See [Section 13.7.7.2, “SHOW BINLOG EVENTS Statement”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

Note

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table does not exist on the replica, `ndb_restore` re-creates it.

Conflict resolution for NDB Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see [Section 22.6.11, “NDB Cluster Replication Conflict Resolution”](#).

22.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 22.6.2, “General Requirements for NDB Cluster Replication”](#)).
2. Create a replication account on the source Cluster with the appropriate privileges, using the following two SQL statements:

```
mysqlS> CREATE USER 'replica_user'@'replica_host'
-> IDENTIFIED BY 'replica_password';

mysqlS> GRANT REPLICATION SLAVE ON *.*
-> TO 'replica_user'@'replica_host';
```

In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following `CREATE USER` and `GRANT` statements:

```
mysqlS> CREATE USER 'myreplica'@'replica-host'
-> IDENTIFIED BY '53cr37';

mysqlS> GRANT REPLICATION SLAVE ON *.*
-> TO 'myreplica'@'replica-host';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3. Set up the replica to use the source. Using the `mysql` client, this can be accomplished with the the following `CHANGE MASTER TO` statement:

```
mysqlR> CHANGE MASTER TO
-> MASTER_HOST='source_host',
-> MASTER_PORT=source_port,
-> MASTER_USER='replica_user',
-> MASTER_PASSWORD='replica_password';
```

In the previous statement, `source_host` is the host name or IP address of the replication source, `source_port` is the port for the replica to use when connecting to the source, `replica_user` is the user name set up for the replica on the source, and `replica_password` is the password set for that user account in the previous step.

For example, to tell the replica to use the MySQL server whose host name is `rep-source` with the replication account created in the previous step, use the following statement:

```
mysqlR> CHANGE MASTER TO
-> MASTER_HOST='rep-source',
-> MASTER_PORT=3306,
-> MASTER_USER='myreplica',
-> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#).

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the replica's `my.cnf` file prior to starting the replication process. See [Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#), for details.

For additional options that can be set in `my.cnf` for replicas, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

4. If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup

and restore procedure described in [Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using NDB Cluster on the replica, you can create a backup with this command on the source:

```
shellS> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the `mysql` client to import the data from the dumpfile into the replica database as shown here, where *dump_file* is the name of the file that was generated using `mysqldump` on the source, and *db_name* is the name of the database to be replicated:

```
shellR> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Note

If you copy the data to the replica in this fashion, you should make sure that the replica is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the replica's `my.cnf` file to keep it from trying to connect to the source to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See [Section 17.2.1, “Replication Formats”](#).) In addition, we recommend enabling the `slave_allow_batching` system variable, and possibly increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. All of these options can be set either in the source server's `my.cnf` file, or on the command line when starting the source `mysqld` process. See [Section 22.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#), for more information.

22.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command:

```
shellS> mysqld --ndbcluster --server-id=id \
--log-bin --ndb-log-bin &
```

In the previous statement, *id* is this server's unique ID (see [Section 22.6.2, “General Requirements for NDB Cluster Replication”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format. It is also necessary in NDB 8.0 to enable logging of updates to NDB tables explicitly, using the `--ndb-log-bin` option; this is a change from previous versions of NDB Cluster, in which this option was enabled by default.

Note

You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see [Section 22.6.2, “General Requirements for NDB Cluster Replication”](#)).

2. Start the MySQL replica server as shown here:

```
shellR> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *id* is the replica server's unique ID. It is not necessary to enable logging on the replica.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the replica server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

```
mysqlR> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the replica to begin reading the source server's binary log from the log's starting point. Otherwise—that is, if you are loading data from the source using a backup—see [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the `mysql` client on the replica:

```
mysqlR> START SLAVE;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#).

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the replicas' `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
```

```
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

22.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Table 22.68 NDB Cluster replication servers described in the text

Server ID	Description
1	Source - primary replication channel (S)
2	Source - secondary replication channel (S')
3	Replica - primary replication channel (R)
4	replica - secondary replication channel (R')

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START SLAVE` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:

```
shellS> mysqld --ndbcluster --server-id=1 \
            --log-bin &
```

2. Start the secondary replication source:

```
shellS'> mysqld --ndbcluster --server-id=2 \
            --log-bin &
```

3. Start the primary replica server:

```
shellR> mysqld --ndbcluster --server-id=3 \
            --skip-slave-start &
```

4. Start the secondary replica server:

```
shellR'> mysqld --ndbcluster --server-id=4 \
            --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary replica as shown here:

```
mysqlR> START SLAVE;
```

Warning

Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary replication channel fails, as described in [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

22.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the replica cluster, which can be found using the following query:

```
mysqlR'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the replicas' binary logs. This means that the `ndb_apply_status` table contains information for the replica on this host as well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this replica. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list from the `CHANGE MASTER TO` statement used to prepare this replica's source are also considered to be from local servers, in addition to those having the replica's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for `ignore_server_ids` in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

```
mysqlR'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the source cluster.

You can use the following query to obtain the needed records from the `ndb_binlog_index` table on the source:

```
mysqlS'> SELECT
-> @file:=SUBSTRING_INDEX(next_file, '/', -1),
-> @pos:=next_position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch >= @latest
-> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or by an application.

Important

You must ensure that the replica `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

- Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```
mysqlR'> CHANGE MASTER TO
->     MASTER_LOG_FILE='@file',
->     MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

- You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary replica `mysqld`:

```
mysqlR'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from `S` to `R'`, or from `S'` to `R`.

22.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 22.6.5, “Preparing the NDB Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

- There are two different methods by which the backup may be started.
 - Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the

following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the source cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 22.2.3, “Initial Configuration of NDB Cluster”](#), for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication source:

```
shellS> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellS> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 22.6.5, “Preparing the NDB Cluster for Replication”](#)), this would be executed as follows:

```
shellS> ndb_mgm rep-source:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the replica that is being brought on line. Each system running an `ndbd` process for the source cluster will have cluster backup files located on it, and *all* of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica's management host resides, as long as the MySQL and NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

While it is not necessary that the replica cluster have the same number of `ndbd` processes (data nodes) as the source, it is highly recommended this number be the same. It *is* necessary that the replica be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the `mysql` client:

```
mysqlR> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

```
shellR> ndb_restore -c replica_host:port -n node-id \
-b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a source cluster with four data nodes (as shown in the figure in [Section 22.6, “NDB Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shellR> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \
-r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 3 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 4 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \
-r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See [Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#)):

```
mysqlR> SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source using the query shown here:

```
mysqlS> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch >= @latest
-> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the replica's `mysql` client:

```
mysqlR> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

- Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```
mysqlR> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 22.5.8, “Online Backup of NDB Cluster”](#).

22.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see [Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#)). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

22.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native [NDB](#) data backup (taken by issuing [CREATE BACKUP](#) in the [ndb_mgm](#) client) and restoring the [ndb_binlog_index](#) table (from a dump made using [mysqldump](#)).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all [NDB](#) databases in the cluster, using the [START BACKUP](#) command in the [ndb_mgm](#) client (see [Section 22.5.8](#), “Online Backup of NDB Cluster”).
2. At some later point, prior to restoring the cluster, make a backup of the [mysql.ndb_binlog_index](#) table. It is probably simplest to use [mysqldump](#) for this task. Also back up the binary log files at this time.

This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)
4. Locate the last known good backup.
5. Clear the data node file systems (using [ndbd --initial](#) or [ndbmtd --initial](#)).

**Note**

Beginning with NDB 8.0.21, Disk Data tablespace and log files are removed by `--initial`. Previously, it was necessary to delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore-epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”](#), for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LATEST_EPOCH:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
FROM mysql.ndb_binlog_index
WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#), for more information about the binary log, replication, and incremental recovery.

22.6.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all sources and replicas are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

Figure 22.36 NDB Cluster Circular Replication with All Sources As Replicas

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:

Figure 22.37 NDB Cluster Circular Replication Where Not All Sources Are Replicas

In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Using NDB-native backup and restore to initialize a replica cluster. When setting up circular replication, it is possible to initialize the replica cluster by using the management client `BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster's SQL node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`. This is a known issue.

Multi-source failover example. In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

Figure 22.38 NDB Cluster Multi-Master Replication With 3 Sources

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

Figure 22.39 NDB Cluster Multi-Source Replication, With MySQL Servers

MySQL servers acting as replicas must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

Note

Using the `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

Note

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See [Section 22.6.4, “NDB Cluster Replication Schema and Tables”](#), for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC'
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#), and [Section 13.7.7.36, “SHOW SLAVE | REPLICA STATUS Statement”](#). For information about how this option interacts with the `ndb_log_apply_status` variable, see [Section 22.6.8, “Implementing Failover with NDB Cluster Replication”](#).

22.6.11 NDB Cluster Replication Conflict Resolution

When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the replica when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see [The ndb_replication system table](#)).

Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

See [Section 17.5.1.20, “Replication and max_allowed_packet”](#), for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see [The ndb_replication system table](#)).
- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see [Read conflict detection and resolution](#).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (`INTEGER`) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

Source column control. We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source’s binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

Logging Full or Partial Rows (--ndb-log-updated-only Option)

Command-Line Format	<code>--ndb-log-updated-only[={OFF ON}]</code>
System Variable	<code>ndb_log_updated_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Boolean
Default Value	ON

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or OFF.

`--ndb-log-update-as-write` Option: Logging Changed Data as Updates

Command-Line Format	<code>--ndb-log-update-as-write[={OFF ON}]</code>
System Variable	<code>ndb_log_update_as_write</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows. This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.

To disable the option, start the source `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the source, the replica, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple source-replica setup where data can also be changed locally on the replica this is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
```

```
PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db, table_name);
```

The columns in this table are described in the next few paragraphs.

db. The name of the database containing the table to be replicated. You may employ either or both of the wildcards `_` and `%` as part of the database name. Matching is similar to what is implemented for the `LIKE` operator.

table_name. The name of the table to be replicated. The table name may include either or both of the wildcards `_` and `%`. Matching is similar to what is implemented for the `LIKE` operator.

server_id. The unique server ID of the MySQL instance (SQL node) where the table resides.

binlog_type. The type of binary logging to be employed. This is determined as shown in the following table:

Table 22.69 binlog_type values, with internal values and descriptions

Value	Internal Value	Description
0	<code>NBT_DEFAULT</code>	Use server default
1	<code>NBT_NO_LOGGING</code>	Do not log this table in the binary log
2	<code>NBT_UPDATED_ONLY</code>	Only updated attributes are logged
3	<code>NBT_FULL</code>	Log full row, even if not updated (MySQL server default behavior)
4	<code>NBT_USE_UPDATE</code>	(For generating <code>NBT_UPDATED_ONLY_USE_UPDATE</code> and <code>NBT_FULL_USE_UPDATE</code> values only—not intended for separate use)
5	<code>[Not used]</code>	---
6	<code>NBT_UPDATED_ONLY</code> (equal to <code>NBT_UPDATED_ONLY</code> <code>NBT_USE_UPDATE</code>)	Use updated attributes, even if values are unchanged
7	<code>NBT_FULL_USE_UPDATE</code> (equal to <code>NBT_FULL</code> <code>NBT_USE_UPDATE</code>)	Use full row, even if values are unchanged

conflict_fn. The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- `NDB$OLD(column_name)`
- `NDB$MAX(column_name)`
- `NDB$MAX_DELETE_WIN()`
- `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`
- `NDB$EPOCH_TRANS()`
- `NDB$EPOCH2()`
- `NDB$EPOCH2_TRANS()`
- `NULL`: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

NDB\$OLD(column_name). If the value of `column_name` is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (source_old_column_value == replica_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.

Important

The column value from the source’s “before” image is used by this function.

NDB\$MAX(column_name). If the “timestamp” column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```
if (source_new_column_value > replica_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

Important

The column value from the source’s “after” image is used by this function.

NDB\$MAX_DELETE_WIN(). This is a variation on `NDB$MAX()`. Due to the fact that no timestamp is available for a delete operation, a delete using `NDB$MAX()` is in fact processed as `NDB$OLD`, but for some use cases, this is not optimal. For `NDB$MAX_DELETE_WIN()`, if the “timestamp” column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```
if ( (source_new_column_value > replica_current_column_value)
    ||
    operation.type == "delete")
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

Note

As with `NDB$MAX()`, the column value from the source’s “after” image is the value used by this function.

NDB\$EPOCH() and NDB\$EPOCH_TRANS(). The `NDB$EPOCH()` function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of `NDB$EPOCH()` also applies to `NDB$EPOCH_TRANS()`. Any exceptions are noted in the text.

`NDB$EPOCH()` is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as

the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). You must create any exceptions table before creating the data table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see [The ndb_replication system table](#)). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the `server_id` entries of the primary and secondary replicas.

A conflict between `DELETE` operations alone is not sufficient to trigger a conflict using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`, and the relative placement within epochs does not matter. (Bug #18459944)

Conflict detection status variables. Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this replica was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans` show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

For more information, see [NDB Cluster Status Variables](#).

Limitations on NDB\$EPOCH(). The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to $2 * (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$. This implies that—assuming the default for `TimeBetweenEpochs` and ignoring any latency between clusters (as well as any queueing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.
- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.
- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a bidirectional “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.
- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

NDB\$EPOCH_TRANS(). `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see [NDB\\$EPOCH\(\)](#) and [NDB\\$EPOCH_TRANS\(\)](#)) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that all transaction IDs are recorded in the secondary's binary log (the `--ndb-log-transaction-id` option), which adds a variable overhead (up to 13 bytes per row). The deprecated

`log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` with `NDB$EPOCH_TRANS()`.

See `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

Status information. A server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

NDB\$EPOCH2(). The `NDB$EPOCH2()` function is similar to `NDB$EPOCH()`, except that `NDB$EPOCH2()` provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each source (usually one each of `PRIMARY`, `SECONDARY`). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

NDB\$EPOCH2_TRANS(). `NDB$EPOCH2_TRANS()` extends the `NDB$EPOCH2()` function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, `NDB$EPOCH2()` realigns individual conflicting rows on the secondary, while `NDB$EPOCH_TRANS()` realigns conflicting transactions.

Where `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

`NDB$EPOCH2()` bypasses the issue just described—storing information about deleted rows on the `PRIMARY`—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using `NDB$EPOCH2()`, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary's following changes immediately. Because of this, the secondary's state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary's logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count`

and `Ndb_conflict_reflected_op_discard_count` status variables. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must *not* exist.
- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of the conditions are not met, the reflected operation is discarded by the secondary.

Conflict resolution exceptions table. To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX (
  [NDB$]server_id INT UNSIGNED,
  [NDB$]source_server_id INT UNSIGNED,
  [NDB$]source_epoch BIGINT UNSIGNED,
  [NDB$]count INT UNSIGNED,

  [NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL,]
  [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]
  [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]

  original_table_pk_columns,

  [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]

  [additional_columns,]

  PRIMARY KEY([NDB$]server_id, [NDB$]source_server_id, [NDB$]source_epoch, [NDB$]count)
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `source_server_id`, `source_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.

The exceptions table must use the NDB storage engine. (An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be `NOT NULL`. NDB Cluster supports three additional, predefined optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, and `NDB$ORIG_TRANSID`, which are described in the next few paragraphs.

`NDB$OP_TYPE`: This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
                'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` operation types represent user-initiated operations. `REFRESH_ROW` operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. `READ_ROW` operations are user-initiated read tracking operations defined with exclusive row locks.

`NDB$CFT_CAUSE`: You can define an optional column `NDB$CFT_CAUSE` which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
                  'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

`ROW_DOES_NOT_EXIST` can be reported as the cause for `UPDATE_ROW` and `WRITE_ROW` operations; `ROW_ALREADY_EXISTS` can be reported for `WRITE_ROW` events. `DATA_IN_CONFLICT` is reported when a row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

`NDB$ORIG_TRANSID`: The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a value for a given reference column that is not a primary key, the exceptions table row contains either `NULL`, or a defined default value for that column.

Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in [Section 22.6.5, “Preparing the NDB Cluster for Replication”](#), and [Section 22.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

`NDB$MAX()` example. Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the source `mysqld` with `--ndb-log-update-as-write=OFF`.

2. On the source, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns
) ENGINE=NDB;
```

Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the replica.

Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE`—should be used to control logging on the source using the `ndb_replication` table rather than by using command-line options.

NDB\$OLD() example. Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  columns,
  mycol INT UNSIGNED NOT NULL,
  columns,
  PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
  server_id INT UNSIGNED,
  source_server_id INT UNSIGNED,
  source_epoch BIGINT UNSIGNED,
  count INT UNSIGNED,
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,

  [additional_columns,]

  PRIMARY KEY(server_id, source_server_id, source_epoch, count)
```

```
) ENGINE=NDB;
```

We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

```
CREATE TABLE test.t2$EX (
  NDB$server_id INT UNSIGNED,
  NDB$source_server_id INT UNSIGNED,
  NDB$source_epoch BIGINT UNSIGNED,
  NDB$count INT UNSIGNED,
  a INT UNSIGNED NOT NULL,

  NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL,
  NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
  NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,

  [additional_columns,]

  PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
) ENGINE=NDB;
```

Note

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

Read conflict detection and resolution. NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster A) while the replica cluster (hereafter B) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```
# Employee table
CREATE TABLE employee (
  id INT PRIMARY KEY,
  name VARCHAR(2000),
  dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (
  id INT PRIMARY KEY,
  name VARCHAR(2000),
  members INT
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
+-----+-----+-----+
| id   | name  | dept |
+-----+-----+-----+
```

```

...
| 998 | Mike | 3 |
| 999 | Joe | 3 |
| 1000 | Mary | 3 |
...
+-----+-----+-----+

mysql> SELECT id, name, members FROM department;
+-----+-----+-----+
| id | name | members |
+-----+-----+-----+
...
| 3 | Old project | 24 |
...
+-----+-----+-----+

```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table's primary key), the optional columns for operation type and cause, and the original table's primary key column, created using the SQL statement shown here:

```

CREATE TABLE employee$EX (
    NDB$server_id INT UNSIGNED,
    NDB$source_server_id INT UNSIGNED,
    NDB$source_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,

    NDB$OP_TYPE ENUM( 'WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
        'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST',
        'ROW_ALREADY_EXISTS',
        'DATA_IN_CONFLICT',
        'TRANS_IN_CONFLICT') NOT NULL,

    id INT NOT NULL,

    PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
)
ENGINE=NDB;

```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster A, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```

BEGIN;
INSERT INTO department VALUES (4, "New project", 1);
UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;

```

At the same time, on cluster B, another transaction reads from `employee`, as shown here:

```

BEGIN;
SELECT name FROM employee WHERE id = 999;
UPDATE department SET members = members - 1 WHERE id = 3;
commit;

```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. You can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster B is tracked and sent to cluster A for resolution; the conflict on the employee row is subsequently detected and the transaction on cluster B is aborted.

The conflict is registered in the exceptions table (on cluster A) as a `READ_ROW` operation (see [Conflict resolution exceptions table](#), for a description of operation types), as shown here:

```

mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-----+-----+-----+

```

id	NDB\$OP_TYPE	NDB\$CFT_CAUSE
...		
999	READ_ROW	TRANS_IN_CONFLICT

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster *A* and a read of multiple rows on cluster *B* from the same table in simultaneous transactions. The transaction executed on cluster *A* is shown here:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster *B*:

```
SET ndb_log_exclusive_reads = 1; # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-----+-----+-----+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE |
+-----+-----+-----+
| ...   |             |                |
| 998   | READ_ROW    | TRANS_IN_CONFLICT |
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
| 1000  | READ_ROW    | TRANS_IN_CONFLICT |
| ...   |             |                |
+-----+-----+-----+
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are *found* and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

22.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 8.0 release at [NDB 8.0 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

Chapter 23 Partitioning

Table of Contents

23.1 Overview of Partitioning in MySQL	4152
23.2 Partitioning Types	4155
23.2.1 RANGE Partitioning	4156
23.2.2 LIST Partitioning	4160
23.2.3 COLUMNS Partitioning	4163
23.2.4 HASH Partitioning	4170
23.2.5 KEY Partitioning	4173
23.2.6 Subpartitioning	4175
23.2.7 How MySQL Partitioning Handles NULL	4176
23.3 Partition Management	4180
23.3.1 Management of RANGE and LIST Partitions	4181
23.3.2 Management of HASH and KEY Partitions	4187
23.3.3 Exchanging Partitions and Subpartitions with Tables	4188
23.3.4 Maintenance of Partitions	4195
23.3.5 Obtaining Information About Partitions	4196
23.4 Partition Pruning	4198
23.5 Partition Selection	4201
23.6 Restrictions and Limitations on Partitioning	4207
23.6.1 Partitioning Keys, Primary Keys, and Unique Keys	4213
23.6.2 Partitioning Limitations Relating to Storage Engines	4216
23.6.3 Partitioning Limitations Relating to Functions	4217

This chapter discusses *user-defined partitioning*.

Note

Table partitioning differs from partitioning as used by window functions. For information about window functions, see [Section 12.21, “Window Functions”](#).

In MySQL 8.0, partitioning support is provided by the [InnoDB](#) and [NDB](#) storage engines.

MySQL 8.0 does not currently support partitioning of tables using any storage engine other than [InnoDB](#) or [NDB](#), such as [MyISAM](#). An attempt to create a partitioned tables using a storage engine that does not supply native partitioning support fails with [ER_CHECK_NOT_IMPLEMENTED](#).

MySQL 8.0 Community binaries provided by Oracle include partitioning support provided by the [InnoDB](#) and [NDB](#) storage engines. For information about partitioning support offered in MySQL Enterprise Edition binaries, see [Chapter 29, MySQL Enterprise Edition](#).

If you are compiling MySQL 8.0 from source, configuring the build with [InnoDB](#) support is sufficient to produce binaries with partition support for [InnoDB](#) tables. For more information, see [Section 2.9, “Installing MySQL from Source”](#).

Nothing further needs to be done to enable partitioning support by [InnoDB](#) (for example, no special entries are required in the [my.cnf](#) file).

It is not possible to disable partitioning support by the [InnoDB](#) storage engine.

See [Section 23.1, “Overview of Partitioning in MySQL”](#), for an introduction to partitioning and partitioning concepts.

Several types of partitioning are supported, as well as subpartitioning; see [Section 23.2, “Partitioning Types”](#), and [Section 23.2.6, “Subpartitioning”](#).

[Section 23.3, “Partition Management”](#), covers methods of adding, removing, and altering partitions in existing partitioned tables.

[Section 23.3.4, “Maintenance of Partitions”](#), discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 25.21, “The INFORMATION_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 23.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 8.0, see [Section 23.6, “Restrictions and Limitations on Partitioning”](#).

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

23.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 8.0.

For information on partitioning restrictions and feature limitations, see [Section 23.6, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace (see [Section 15.6.3, “Tablespaces”](#)), and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 8.12.2, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value,

a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of [RANGE](#), [LIST](#), and [\[LINEAR\] HASH](#) partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either [NULL](#) or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

([MAXVALUE](#) is used to represent the least upper bound for the type of integer in question. [-MAXVALUE](#) represents the greatest lower bound.)

For [\[LINEAR\] KEY](#), [RANGE COLUMNS](#), and [LIST COLUMNS](#) partitioning, the partitioning expression consists of a list of one or more columns.

For [\[LINEAR\] KEY](#) partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 23.2, “Partitioning Types”](#), as well as [Section 13.1.20, “CREATE TABLE Statement”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 23.6.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 8.0 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For creating partitioned tables, you must use a storage engine that supports them. In MySQL 8.0, all partitions of the same partitioned table must use the same storage engine. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

In MySQL 8.0, the only storage engines that support partitioning are [InnoDB](#) and [NDB](#). Partitioning cannot be used with storage engines that do not support it; these include the [MyISAM](#), [MERGE](#), [CSV](#), and [FEDERATED](#) storage engines.

Partitioning by [KEY](#) or [LINEAR KEY](#) is possible with [NDB](#), but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an [NDB](#) table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the [PARTITION BY KEY](#) or [PARTITION BY LINEAR KEY](#) clause of the [CREATE TABLE](#) or [ALTER TABLE](#) statement used to create or modify a user-partitioned [NDB](#) table, then the table is not required to have an explicit primary key. For more information, see [Section 22.1.7.1, “Noncompliance with SQL Syntax in NDB Cluster”](#).

When creating a partitioned table, the default storage engine is used just as when creating any other table; to override this behavior, it is necessary only to use the [\[STORAGE\] ENGINE](#) option just as you would for a table that is not partitioned. The target storage engine must provide native partitioning support, or the statement fails. You should keep in mind that [\[STORAGE\] ENGINE](#) (and other table options) need to be listed *before* any partitioning options are used in a [CREATE TABLE](#) statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine (regardless of the value of `default_storage_engine`):

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each [PARTITION](#) clause can include a [\[STORAGE\] ENGINE](#) option, but in MySQL 8.0 this has no effect.

Unless otherwise specified, the remaining examples in this discussion assume that `default_storage_engine` is `InnoDB`.

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables. As of MySQL 8.0.21, the directory specified in a `DATA DIRECTORY` clause must be known to `InnoDB`. For more information, see [Using the DATA DIRECTORY Clause](#).

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
  id INT NOT NULL AUTO_INCREMENT,
  ref BIGINT NOT NULL,
  name VARCHAR(255),
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See [Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 23.3, “Partition Management”](#), for more information on these options.

The `MAX_ROWS` option can also be useful for creating NDB Cluster tables with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as [Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 23.4, “Partition Pruning”](#).

In addition, MySQL supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that

match the [WHERE](#) condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and [LOAD DATA](#), [LOAD XML](#). See the descriptions of these statements for more information and examples.

23.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 8.0. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 23.2.1, “RANGE Partitioning”](#). For information about an extension to this type, [RANGE COLUMNS](#), see [Section 23.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by [RANGE](#), except that the partition is selected based on columns matching one of a set of discrete values. See [Section 23.2.2, “LIST Partitioning”](#). For information about an extension to this type, [LIST COLUMNS](#), see [Section 23.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, [LINEAR HASH](#), is also available. See [Section 23.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by [HASH](#), except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, [LINEAR KEY](#), is also available. See [Section 23.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 8.0. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 8.0, it is also possible to use a [DATE](#) or [DATETIME](#) column as the partitioning column using [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning.

Other partitioning types require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
```

```

username VARCHAR(16) NOT NULL,
email VARCHAR(35),
joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 23.2.1, “RANGE Partitioning”](#)
- [Section 23.2.4, “HASH Partitioning”](#)
- [Section 23.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 23.4, “Partition Pruning”](#)
- [Section 23.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 12.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```

mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart

```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; for this information, see [Section 13.1.20, “CREATE TABLE Statement”](#).

23.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but

not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

Note

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see [Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
```

```
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

(As with the other examples in this chapter, we assume that the default storage engine is [InnoDB](#).)

Note

Another way to avoid an error when no matching value is found is to use the [IGNORE](#) keyword as part of the [INSERT](#) statement. For an example, see [Section 23.2.2, “LIST Partitioning”](#). Also see [Section 13.2.6, “INSERT Statement”](#), for general information about [IGNORE](#).

[MAXVALUE](#) represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose [store_id](#) column value is greater than or equal to 16 (the highest value defined) are stored in partition [p3](#). At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an [ALTER TABLE](#) statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 23.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of [job_code](#) column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition [p0](#), those relating to office and support staff in [p1](#), and those relating to managers in partition [p2](#).

It is also possible to use an expression in [VALUES LESS THAN](#) clauses. However, MySQL must be able to evaluate the expression's return value as part of a [LESS THAN \(<\)](#) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two [DATE](#) columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of [YEAR\(separated\)](#). An example of a [CREATE TABLE](#) statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
```

```
PARTITION p2 VALUES LESS THAN (2001),
PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by [RANGE](#), based on the value of a [TIMESTAMP](#) column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
  PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving [TIMESTAMP](#) values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.9, “ALTER TABLE Statement”](#), and [Section 23.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990`;
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 23.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning is [RANGE COLUMNS](#) partitioning. Partitioning by [RANGE COLUMNS](#) makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 23.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 8.0, you have two options:

1. Partition the table by [RANGE](#), and for the partitioning expression, employ a function operating on a [DATE](#), [TIME](#), or [DATETIME](#) column and returning an integer value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
```

```

username VARCHAR(16) NOT NULL,
email VARCHAR(35),
joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

In MySQL 8.0, it is also possible to partition a table by [RANGE](#) based on the value of a [TIMESTAMP](#) column, using the [UNIX_TIMESTAMP\(\)](#) function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

In MySQL 8.0, any other expressions involving [TIMESTAMP](#) values are not permitted. (See Bug #42849.)

Note

It is also possible in MySQL 8.0 to use [UNIX_TIMESTAMP\(timestamp_column\)](#) as a partitioning expression for tables that are partitioned by [LIST](#). However, it is usually not practical to do so.

2. Partition the table by [RANGE COLUMNS](#), using a [DATE](#) or [DATETIME](#) column as the partitioning column. For example, the [members](#) table could be defined using the [joined](#) column directly, as shown here:

```

CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Note

The use of partitioning columns employing date or time types other than [DATE](#) or [DATETIME](#) is not supported with [RANGE COLUMNS](#).

23.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where *expr* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where *value_list* is a comma-separated list of integers.

Note

In MySQL 8.0, it is possible to match against only a list of integers (and possibly `NULL`—see [Section 23.2.7, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 13.1.20, “CREATE TABLE Statement”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 23.2.1, “RANGE Partitioning”](#). As with the other partitioning examples, we assume that the `default_storage_engine` is `InnoDB`.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
```

```
PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 8.0, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 23.2.6, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (1, 4, 7),
->   PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement into a single [InnoDB](#) table, [InnoDB](#) considers the statement a single transaction, so that the presence of any unmatched values causes the statement to fail completely, and so no rows are inserted.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 7 | 5 |
| 1 | 9 |
| 2 | 5 |
+-----+-----+
3 rows in set (0.00 sec)
```

MySQL 8.0 also provides support for [LIST COLUMNS](#) partitioning, a variant of [LIST](#) partitioning that enables you to use columns of types other than integer types for partitioning columns, and to use multiple columns as partitioning keys. For more information, see [Section 23.2.3.2, “LIST COLUMNS partitioning”](#).

23.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on *RANGE* and *LIST* partitioning. *COLUMNS* partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both *RANGE COLUMNS* partitioning and *LIST COLUMNS* partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: *TINYINT*, *SMALLINT*, *MEDIUMINT*, *INT* (*INTEGER*), and *BIGINT*. (This is the same as with partitioning by *RANGE* and *LIST*.)

Other numeric data types (such as *DECIMAL* or *FLOAT*) are not supported as partitioning columns.

- *DATE* and *DATETIME*.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: *CHAR*, *VARCHAR*, *BINARY*, and *VARBINARY*.

TEXT and *BLOB* columns are not supported as partitioning columns.

The discussions of *RANGE COLUMNS* and *LIST COLUMNS* partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 23.2.1, “RANGE Partitioning”](#), and [Section 23.2.2, “LIST Partitioning”](#), respectively.

23.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

RANGE COLUMNS partitioning differs significantly from *RANGE* partitioning in the following ways:

- *RANGE COLUMNS* does not accept expressions, only names of columns.
- *RANGE COLUMNS* accepts a list of one or more columns.

RANGE COLUMNS partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in *RANGE COLUMNS* partitions is also based on comparisons between tuples; this is discussed further later in this section.

- *RANGE COLUMNS* partitioning columns are not restricted to integer columns; string, *DATE* and *DATETIME* columns can also be used as partitioning columns. (See [Section 23.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by *RANGE COLUMNS* is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    ...]
)

column_list:
    column_name[, column_name][, ...]

value_list:
```

```
value[, value][, ...]
```

**Note**

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 13.1.20, “CREATE TABLE Statement”](#).

In the syntax just shown, *column_list* is a list of one or more columns (sometimes called a *partitioning column list*), and *value_list* is a list of values (that is, it is a *partition definition value list*). A *value_list* must be supplied for each partition definition, and each *value_list* must have the same number of values as the *column_list* has columns. Generally speaking, if you use *N* columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->     a INT,
->     b INT,
->     c CHAR(3),
->     d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->     PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->     PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
->     PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
  a INT,
  b INT
)
PARTITION BY RANGE (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
       -> FROM INFORMATION_SCHEMA.PARTITIONS
       -> WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             |            0 |
| p1             |            3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rc1 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
       -> FROM INFORMATION_SCHEMA.PARTITIONS
       -> WHERE TABLE_NAME = 'rc1';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             |            2 |
| p             | p1             |            1 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1               | 1               | 0               |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 13.2.11.5, “Row Subqueries”](#).

For a table partitioned by [RANGE COLUMNS](#) using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by [RANGE](#). The following [CREATE TABLE](#) statement creates a table partitioned by [RANGE COLUMNS](#) using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             | 0           |
| p             | p1             | 3           |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by [RANGE COLUMNS](#) where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following [CREATE TABLE](#) statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```
CREATE TABLE rc4 (
  a INT,
```

```

    b INT,
    c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
    PARTITION p0 VALUES LESS THAN (0,25,50),
    PARTITION p1 VALUES LESS THAN (10,20,100),
    PARTITION p2 VALUES LESS THAN (10,30,50)
    PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);

```

When designing tables partitioned by **RANGE COLUMNS**, you can always test successive partition definitions by comparing the desired tuples using the **mysql** client, like this:

```

mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)

```

If a **CREATE TABLE** statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```

mysql> CREATE TABLE rcf (
->     a INT,
->     b INT,
->     c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
->     PARTITION p0 VALUES LESS THAN (0,25,50),
->     PARTITION p1 VALUES LESS THAN (20,20,100),
->     PARTITION p2 VALUES LESS THAN (10,30,50),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition

```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition **p2** because the tuple used to define it is not less than the tuple used to define partition **p3**, as shown here:

```

mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)

```

It is also possible for **MAXVALUE** to appear for the same column in more than one **VALUES LESS THAN** clause when using **RANGE COLUMNS**. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where **MAXVALUE** is used as the upper limit for all column values, and this partition definition should appear last in the list of **PARTITION ... VALUES LESS THAN** clauses. In addition, you cannot use **MAXVALUE** as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with **RANGE COLUMNS** partitioning to use non-integer columns as partitioning columns. (See [Section 23.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named **employees** (which is not partitioned), created using the following statement:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,

```

```
store_id INT NOT NULL
);
```

Using [RANGE COLUMNS](#) partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following [ALTER TABLE](#) statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by [RANGE COLUMNS](#) a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case-insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Chapter 10, Character Sets, Collations, Unicode](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the [ALTER TABLE](#) statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
  PARTITION p0 VALUES LESS THAN ('1970-01-01'),
  PARTITION p1 VALUES LESS THAN ('1980-01-01'),
  PARTITION p2 VALUES LESS THAN ('1990-01-01'),
  PARTITION p3 VALUES LESS THAN ('2000-01-01'),
  PARTITION p4 VALUES LESS THAN ('2010-01-01'),
  PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See [Section 13.1.20, “CREATE TABLE Statement”](#), for additional information about [PARTITION BY RANGE COLUMNS](#) syntax.

23.2.3.2 LIST COLUMNS partitioning

MySQL 8.0 provides support for [LIST COLUMNS](#) partitioning. This is a variant of [LIST](#) partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than

integer types to be used as partitioning columns; you can use string types, [DATE](#), and [DATETIME](#) columns. (For more information about permitted data types for [COLUMNS](#) partitioning columns, see [Section 23.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

Region	Cities
1	Oskarshamn, Högsby, Mönsterås
2	Vimmerby, Hultsfred, Västervik
3	Nässjö, Eksjö, Vetlanda
4	Uppvidinge, Alvesta, Växjö

With [LIST COLUMNS](#) partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);
```

As with partitioning by [RANGE COLUMNS](#), you do not need to use expressions in the [COLUMNS\(\)](#) clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with [COLUMNS\(\)](#).)

It is also possible to use [DATE](#) and [DATETIME](#) columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs [LIST COLUMNS](#) partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```
CREATE TABLE customers_2 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
    '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
  PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
    '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
  PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
    '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
  PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
    '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```
CREATE TABLE customers_3 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
  PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
  PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
  PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);
```

See [Section 23.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the [COLUMNS \(\)](#) clause.

See [Section 13.1.20, “CREATE TABLE Statement”](#), for additional information about [PARTITION BY LIST COLUMNS \(\)](#) syntax.

23.2.4 HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly which partition a given column value or set of column values should be stored in; with hash partitioning, this decision is taken care of for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the [CREATE TABLE](#) statement a [PARTITION BY HASH \(expr\)](#) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with [PARTITIONS num](#), where *num* is a positive integer representing the number of partitions into which the table is to be divided.

Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See [Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

The following statement creates a table that uses hashing on the [store_id](#) column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a [PARTITIONS](#) clause, the number of partitions defaults to 1; using the [PARTITIONS](#) keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

expr must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 23.6, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where *date_col* is a column of type *DATE*, then the expression *TO_DAYS(date_col)* is said to vary directly with the value of *date_col*, because for every change in the value of *date_col*, the value of the expression changes in a consistent manner. The variance of the expression *YEAR(date_col)* with respect to *date_col* is not quite as direct as that of *TO_DAYS(date_col)*, because not every possible change in *date_col* produces an equivalent change in *YEAR(date_col)*. Even so, *YEAR(date_col)* is a good candidate for a hashing function, because it varies directly with a portion of *date_col* and there is no possible change in *date_col* that produces a disproportionate change in *YEAR(date_col)*.

By way of contrast, suppose that you have a column named *int_col* whose type is *INT*. Now consider the expression *POW(5-int_col,3) + 6*. This would be a poor choice for a hashing function because a change in the value of *int_col* is not guaranteed to produce a proportional change in the value of the expression. Changing the value of *int_col* by a given amount can produce widely differing changes in the value of the expression. For example, changing *int_col* from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of *int_col* from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation $y=cx$ where *c* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When *PARTITION BY HASH* is used, the storage engine determines which partition of *num* partitions to use based on the modulus of the result of the expression. In other words, for a given expression *expr*, the partition in which the record is stored is partition number *N*, where $N = \text{MOD}(\text{expr}, \text{num})$. Suppose that table *t1* is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into *t1* whose *col3* value is '2005-09-15', then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
```

```
= MOD(2005,4)
= 1
```

MySQL 8.0 also supports a variant of [HASH](#) partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 23.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

23.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the **LINEAR** keyword in the **PARTITION BY** clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then **LOG(2,13)** is 3.7004397181411. **CEILING(3.7004397181411)** is 4, and *V* = **POWER(2,4)**, which is 16.)

2. Set *N* = **F(column_list)** & (*V* - 1).
3. While *N* >= *num*:
 - Set *V* = *V* / 2
 - Set *N* = *N* & (*V* - 1)

Suppose that the table **t1**, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into **t1** having the **col3** column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8 - 1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & ((8 / 2) - 1)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

23.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 8.0:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tml (
```

```
s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 23.6, “Restrictions and Limitations on Partitioning”](#).

Columns with index prefixes are not supported in partitioning keys. This means that `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for `BLOB` and `TEXT` columns in index definitions, it is not possible to use columns of these two types in partitioning keys. Prior to MySQL 8.0.21, columns using prefixes were permitted when creating, altering, or upgrading a partitioned table, even though they were not included in the table's partitioning key; in MySQL 8.0.21 and later, this permissive behavior is deprecated, and the server displays appropriate warnings or errors when one or more such columns are used. See [Column index prefixes not supported for key partitioning](#), for more information and examples.

Note

Tables using the `NDB` storage engine are implicitly partitioned by `KEY`, using the table's primary key as the partitioning key (as with other MySQL storage engines). In the event that the NDB Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDB` storage engine for each NDB Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an `NDB` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for NDB Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 22, MySQL NDB Cluster 8.0](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

The `LINEAR` keyword has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 23.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

23.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) )
  SUBPARTITIONS 2 (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
  );
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

It is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
```

```

        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2,
        SUBPARTITION s3
    )
);

```

This statement would still fail even if it used `SUBPARTITIONS 2`.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s2,
        SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4,
        SUBPARTITION s5
    )
);

```

23.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of NULL with RANGE partitioning. If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```

mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)

```

```

-> )
-> PARTITION BY RANGE(c1) (
->     PARTITION p0 VALUES LESS THAN (-5),
->     PARTITION p1 VALUES LESS THAN (0),
->     PARTITION p2 VALUES LESS THAN (10),
->     PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
>       FROM INFORMATION_SCHEMA.PARTITIONS
>       WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0             | 0           | 0              | 0            |
| t1          | p1             | 0           | 0              | 0            |
| t1          | p2             | 0           | 0              | 0            |
| t2          | p0             | 0           | 0              | 0            |
| t2          | p1             | 0           | 0              | 0            |
| t2          | p2             | 0           | 0              | 0            |
| t2          | p3             | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)

```

(For more information about this table, see [Section 25.21, “The INFORMATION_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id   | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id   | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
>       FROM INFORMATION_SCHEMA.PARTITIONS
>       WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0             | 1           | 20             | 20           |
| t1          | p1             | 0           | 0              | 0            |
| t1          | p2             | 0           | 0              | 0            |
| t2          | p0             | 1           | 20             | 20           |
| t2          | p1             | 0           | 0              | 0            |
| t2          | p2             | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+

```

t2	p3	0	0	0
----	----	---	---	---

7 rows in set (0.01 sec)

You can also demonstrate that these rows were stored in the lowest-numbered partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.9, “ALTER TABLE Statement”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of `NULL` with `LIST` partitioning. A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
```

```

-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7),
->     PARTITION p2 VALUES IN (2, 5, 8),
->     PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->     c1 INT,
->     c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
->     PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
>       FROM INFORMATION_SCHEMA.PARTITIONS
>       WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';

```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
ts2	p0	0	0	0
ts2	p1	0	0	0
ts2	p2	0	0	0
ts2	p3	1	20	20
ts3	p0	0	0	0
ts3	p1	1	20	20
ts3	p2	0	0	0

```

7 rows in set (0.01 sec)

```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of NULL with HASH and KEY partitioning. `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```

mysql> CREATE TABLE th (
->     c1 INT,
->     c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)

```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
th	p0	0	0	0
th	p1	0	0	0

2 rows in set (0.00 sec)

`TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM th;
```

c1	c2
NULL	mothra
0	gigan

2 rows in set (0.01 sec)

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
th	p0	2	20	20
th	p1	0	0	0

2 rows in set (0.00 sec)

By repeating the last example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify that `NULL` is also treated like 0 for this type of partitioning.

23.3 Partition Management

There are a number of ways using SQL statements to modify partitioned tables; it is possible to add, drop, redefine, merge, or split existing partitions using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 23.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 23.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 23.3.5, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 8.0 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 23.3.4, “Maintenance of Partitions”](#).

**Note**

All partitions of a partitioned table must have the same number of subpartitions; it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` option, which has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table; this option (also) always begins with the keywords `PARTITION BY`. Suppose that the following `CREATE TABLE` statement was used to create a table that is partitioned by range:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
  );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. The statement succeeds only if the target storage engine provides partitioning support. You can use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning; see [Section 13.1.9, “ALTER TABLE Statement”](#).

**Important**

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

You can delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

23.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 23.3.2, “Management of HASH and KEY Partitions”](#).

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
->   PARTITION BY RANGE( YEAR(purchased) ) (
->     PARTITION p0 VALUES LESS THAN (1990),
->     PARTITION p1 VALUES LESS THAN (1995),
->     PARTITION p2 VALUES LESS THAN (2000),
->     PARTITION p3 VALUES LESS THAN (2005),
->     PARTITION p4 VALUES LESS THAN (2010),
->     PARTITION p5 VALUES LESS THAN (2015)
```

```

-> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'alarm clock', '1997-11-05'),
-> (3, 'chair', '2009-03-10'),
-> (4, 'bookcase', '1989-01-10'),
-> (5, 'exercise bike', '2014-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'espresso maker', '2011-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '2006-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.05 sec)
Records: 10 Duplicates: 0 Warnings: 0

```

You can see which items should have been inserted into partition `p2` as shown here:

```

mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 2 | alarm clock | 1997-11-05 |
| 10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

You can also get this information using partition selection, as shown here:

```

mysql> SELECT * FROM tr PARTITION (p2);
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 2 | alarm clock | 1997-11-05 |
| 10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

See [Section 23.5, “Partition Selection”](#), for more information.

To drop the partition named `p2`, execute the following command:

```

mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)

```

Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)

```

Note

`DROP PARTITION` is supported by native partitioning in-place APIs and may be used with `ALGORITHM={COPY|INPLACE}`. `DROP PARTITION` with `ALGORITHM=INPLACE` deletes data stored in the partition and drops the partition. However, `DROP PARTITION` with `ALGORITHM=COPY` or `old_alter_table=ON` rebuilds the partitioned table and attempts to

move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted.

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 13.1.37, “TRUNCATE TABLE Statement”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.9, “ALTER TABLE Statement”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
      Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id   | name           | purchased |
+-----+-----+-----+
| 1    | desk organiser | 2003-10-15 |
| 11   | pencil holder  | 1995-07-12 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 23.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1980),
  PARTITION p1 VALUES LESS THAN (1990),
  PARTITION p2 VALUES LESS THAN (2000)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you will soon be admitting members who were born in 2000 (and later). You can modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
  REORGANIZE PARTITION p0 INTO (
    PARTITION n0 VALUES LESS THAN (1970),
    PARTITION n1 VALUES LESS THAN (1980)
  );
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#).

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
```

```
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, *tbl_name* is the name of the partitioned table, and *partition_list* is a comma-separated list of names of one or more existing partitions to be changed. *partition_definitions* is a comma-separated list of new partition definitions, which follow the same rules as for the *partition_definitions* list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip range partitions.

For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

23.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 23.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using `ALTER TABLE ... COALESCE PARTITION`. Suppose that a `clients` table containing data about clients is divided into 12 partitions, created as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from 12 to 8, execute the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
```

```

->     id INT,
->     fname VARCHAR(30),
->     lname VARCHAR(30),
->     signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0

```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

Attempting to remove more partitions than are in the table results in an error like this one:

```

mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead

```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```

ALTER TABLE clients ADD PARTITION PARTITIONS 6;

```

23.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 8.0, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where *pt* is the partitioned table and *p* is the partition or subpartition of *pt* to be exchanged with unpartitioned table *nt*, provided that the following statements are true:

1. Table *nt* is not itself partitioned.
2. Table *nt* is not a temporary table.
3. The structures of tables *pt* and *nt* are otherwise identical.
4. Table *nt* contains no foreign key references, and no other table has any foreign keys that refer to *nt*.
5. There are no rows in *nt* that lie outside the boundaries of the partition definition for *p*. This condition does not apply if `WITHOUT VALIDATION` is used.
6. For InnoDB tables, both tables use the same row format. To determine the row format of an InnoDB table, query `INFORMATION_SCHEMA.INNODB_TABLES`.
7. *nt* does not have any partitions that use the `DATA DIRECTORY` option. This restriction is lifted for InnoDB tables in MySQL 8.0.14 and later.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax for `ALTER TABLE ... EXCHANGE PARTITION` is shown here, where *pt* is the partitioned table, *p* is the partition (or subpartition) to be exchanged, and *nt* is the nonpartitioned table to be exchanged with *p*:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append `WITH VALIDATION` or `WITHOUT VALIDATION`. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform any row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 8.0.

Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table *e* has been created and populated using the following SQL statements:

```
CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
  PARTITION BY RANGE (id) (
    PARTITION p0 VALUES LESS THAN (50),
    PARTITION p1 VALUES LESS THAN (100),
    PARTITION p2 VALUES LESS THAN (150),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
  (1669, "Jim", "Smith"),
  (337, "Mary", "Jones"),
  (16, "Frank", "White"),
  (2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of *e* named *e2*. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (0.04 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.07 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can see which partitions in table *e* contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_NAME = 'e';
```

PARTITION_NAME	TABLE_ROWS
p0	1
p1	0
p2	0
p3	3

```
+-----+
2 rows in set (0.00 sec)
```

**Note**

For partitioned [InnoDB](#) tables, the row count given in the `TABLE_ROWS` column of the `INFORMATION_SCHEMA.PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use `ALTER TABLE`, as shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.04 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the `INFORMATION_SCHEMA.PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+
| p0              | 0           |
| p1              | 0           |
| p2              | 0           |
| p3              | 3           |
+-----+
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
+-----+
| id | fname | lname |
+-----+
| 16 | Frank | White |
+-----+
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table `e`, making sure that this row is stored in partition `p0` by choosing an `id` column value that is less than 50, and verifying this afterward by querying the `PARTITIONS` table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+
| p0              | 1           |
| p1              | 0           |
| p2              | 0           |
| p3              | 3           |
+-----+
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+-----+-----+-----+
| id   | fname | lname |
+-----+-----+-----+
| 16   | Frank | White |
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |
+-----+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             | 1           |
| p1             | 0           |
| p2             | 0           |
| p3             | 3           |
+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM e2;
+-----+-----+-----+
| id | fname | lname |
+-----+-----+-----+
| 41 | Michael | Green |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)
```

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two

partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```
# Create a partitioned table with 1 million rows in each partition

CREATE TABLE e (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
)
    PARTITION BY RANGE (id) (
        PARTITION p0 VALUES LESS THAN (1000001),
        PARTITION p1 VALUES LESS THAN (2000001),
    );

mysql> SELECT COUNT(*) FROM e;
+-----+
| COUNT(*) |
+-----+
| 2000000 |
+-----+
1 row in set (0.27 sec)

# View the rows in each partition

SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Create a nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e2 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e2;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.24 sec)

# Create another nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e3 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e3;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |          0   |
| p1              |    1000000   |
+-----+-----+
2 rows in set (0.00 sec)
```

Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)
```

Confirm that the partition was exchanged with table e2

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |    1000000   |
| p1              |    1000000   |
+-----+-----+
2 rows in set (0.00 sec)
```

Once again, drop the rows from p0 of table e

```
mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)
```

Confirm that there are no rows in partition p0

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |          0   |
| p1              |    1000000   |
+-----+-----+
2 rows in set (0.00 sec)
```

Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)
```

Confirm that the partition was exchanged with table e3

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |    1000000   |
| p1              |    1000000   |
+-----+-----+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using [REPAIR TABLE](#) or [ALTER TABLE ... REPAIR PARTITION](#).

Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see [Section 23.2.6, “Subpartitioning”](#)) with a nonpartitioned table using an [ALTER TABLE ... EXCHANGE PARTITION](#) statement. In the following example, we first create a table `es` that is partitioned by [RANGE](#) and subpartitioned by [KEY](#), populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
->     id INT NOT NULL,
->     fname VARCHAR(30),
->     lname VARCHAR(30)
-> )
->     PARTITION BY RANGE (id)
->     SUBPARTITION BY KEY (lname)
->     SUBPARTITIONS 2 (
->         PARTITION p0 VALUES LESS THAN (50),
->         PARTITION p1 VALUES LESS THAN (100),
->         PARTITION p2 VALUES LESS THAN (150),
->         PARTITION p3 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
->     (1669, "Jim", "Smith"),
->     (337, "Mary", "Jones"),
->     (16, "Frank", "White"),
->     (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` column of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0              | p0sp0             | 1           |
| p0              | p0sp1             | 0           |
| p1              | p1sp0             | 0           |
| p1              | p1sp1             | 0           |
| p2              | p2sp0             | 0           |
| p2              | p2sp1             | 0           |
| p3              | p3sp0             | 3           |
| p3              | p3sp1             | 0           |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` in table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0              | p0sp0             | 1           |
| p0              | p0sp1             | 0           |
| p1              | p1sp0             | 0           |
| p1              | p1sp1             | 0           |

| p3          | p3sp1          | 0 |
+-----+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM es2;
+-----+-----+-----+
| id   | fname | lname |
+-----+-----+-----+
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```

mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition

```

Table structures are compared in a strict fashion; the number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```

mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE es3\G
***** 1. row *****
      Table: es3
Create Table: CREATE TABLE `es3` (
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL

```

23.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out on partitioned tables using SQL statements intended for such purposes.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`,

or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you whether the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

You can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

23.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.

- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

From MySQL 8.0.16, when insertions, deletions, or updates are made to partitioned tables, the binary log records information about the partition and (if any) the subpartition in which the row event took place. A new row event is created for a modification that takes place in a different partition or subpartition, even if the table involved is the same. So if a transaction involves three partitions or subpartitions, three row events are generated. For an update event, the partition information is recorded for both the “before” image and the “after” image. The partition information is displayed if you specify the `-v` or `--verbose` option when viewing the binary log using `mysqlbinlog`. Partition information is only recorded when row-based logging is in use (`binlog_format=ROW`).

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
/*!50100 PARTITION BY RANGE (YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB) */
0 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See [Section 13.7.7.38, “SHOW TABLE STATUS Statement”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 25.21, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that a table `trb1` is created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
```

```
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
       key_len: NULL
         ref: NULL
        rows: 10
      Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
       key_len: NULL
         ref: NULL
        rows: 10
      Extra: Using where
```

`EXPLAIN` also provides information about keys used and possible keys:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0

mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
       key_len: 4
         ref: NULL
        rows: 7
      Extra: Using where
```

If `EXPLAIN` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also [Section 13.8.2, “EXPLAIN Statement”](#).

23.4 Partition Pruning

The optimization known as *partition pruning* is based on a relatively simple concept which can be described as “Do not scan partitions where there can be no matching values”. Suppose a partitioned table `t1` is created by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Suppose that you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions `p0` or `p3`; that is, we need search only in partitions `p1` and `p2` to find matching rows. By limiting the search, it is possible to expend much less time and effort in finding matching rows than by scanning all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

`SELECT`, `DELETE`, and `UPDATE` statements support partition pruning. An `INSERT` statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by `HASH` or `KEY` although this is not currently shown in the output of `EXPLAIN`.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. Pruning can also be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, partitioned on a `DATE` column, is created using the statement shown here:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following statements using `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21';
```

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.

`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.

2. Find the partition containing the high end of the range.

`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.

3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by MySQL Cluster can be pruned if they are explicitly partitioned.

23.5 Partition Selection

Explicit selection of partitions and subpartitions for rows matching a given `WHERE` condition is supported. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA`.
- `LOAD XML`.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a `PARTITION` option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)

partition_names:
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. *partition_names* is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in *partition_names* may be listed in any order, and may overlap.

When the `PARTITION` option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a `SELECT` statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';

CREATE TABLE employees (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    fname VARCHAR(25) NOT NULL,
    lname VARCHAR(25) NOT NULL,
    store_id INT NOT NULL,
    department_id INT NOT NULL
)
PARTITION BY RANGE(id) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (15),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO employees VALUES
    ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
    ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
    ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
    ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
    ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
    ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
    ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
    ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
    ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can see which rows are stored in partition `p1` like this:

```
mysql> SELECT * FROM employees PARTITION (p1);
```

id	fname	lname	store_id	department_id
5	Mary	Jones	1	1
6	Linda	Black	2	3
7	Ed	Jones	2	1
8	June	Wilson	3	1
9	Andy	Smith	1	3

```
5 rows in set (0.00 sec)
```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```
mysql> SELECT * FROM employees PARTITION (p0, p2)
-> WHERE lname LIKE 'S%';
```

id	fname	lname	store_id	department_id
4	Jim	Smith	2	4
11	Jill	Stone	1	4

```
2 rows in set (0.00 sec)
```

```
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
-> FROM employees PARTITION (p0) ORDER BY lname;
```

id	name
3	Ellen Johnson
4	Jim Smith
1	Bob Taylor
2	Frank Williams

```
4 rows in set (0.06 sec)
```

```
mysql> SELECT store_id, COUNT(department_id) AS c
-> FROM employees PARTITION (p1,p2,p3)
-> GROUP BY store_id HAVING c > 4;
```

c	store_id
5	2
5	3

```
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the supported partitioning types. When a table is created using `[LINEAR] HASH` or `[LINEAR] KEY` partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0`, `p1`, `p2`, ..., `pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `pX` the names `pXsp0`, `pXsp1`, `pXsp2`, ..., `pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```
mysql> CREATE TABLE employees_sub (
-> id INT NOT NULL AUTO_INCREMENT,
```

```

->     fname VARCHAR(25) NOT NULL,
->     lname VARCHAR(25) NOT NULL,
->     store_id INT NOT NULL,
->     department_id INT NOT NULL,
->     PRIMARY KEY pk (id, lname)
-> )
->     PARTITION BY RANGE(id)
->     SUBPARTITION BY KEY (lname)
->     SUBPARTITIONS 2 (
->         PARTITION p0 VALUES LESS THAN (5),
->         PARTITION p1 VALUES LESS THAN (10),
->         PARTITION p2 VALUES LESS THAN (15),
->         PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (1.14 sec)

mysql> INSERT INTO employees_sub # reuse data in employees table
->     SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
Records: 18 Duplicates: 0 Warnings: 0

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
->     FROM employees_sub PARTITION (p2sp1);
+-----+
| id | name      |
+-----+
| 10 | Lou Waters |
| 14 | Fred Goldberg |
+-----+
2 rows in set (0.00 sec)

```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```

mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
->     SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM employees_copy;
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 10 | Lou   | Waters | 2        | 4             |
| 11 | Jill  | Stone  | 1        | 4             |
| 12 | Roger | White  | 3        | 2             |
| 13 | Howard | Andrews | 1        | 2             |
| 14 | Fred  | Goldberg | 3        | 3             |
+-----+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```

CREATE TABLE stores (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    city VARCHAR(30) NOT NULL
)
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
    ('', 'Nambucca'), ('', 'Uranga'),
    ('', 'Bellinghen'), ('', 'Grafton');

CREATE TABLE departments (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30) NOT NULL
)

```

```

PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
  ('', 'Sales'), ('', 'Customer Service'),
  ('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellingham (partition `p0` of the `stores` table):

```

mysql> SELECT
->   e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
->   s.city AS City, d.name AS department
-> FROM employees AS e
->   JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
->   JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
-> ORDER BY e.lname;
```

Employee ID	Name	City	department
14	Fred Goldberg	Bellingham	Delivery
5	Mary Jones	Nambucca	Sales
17	Mark Morgan	Bellingham	Delivery
9	Andy Smith	Nambucca	Delivery
8	June Wilson	Bellingham	Sales

5 rows in set (0.00 sec)

For general information about joins in MySQL, see [Section 13.2.10.2, “JOIN Clause”](#).

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

id	fname	lname	store_id	department_id
4	Jim	Smith	2	4
8	June	Wilson	3	1
11	Jill	Stone	1	4

3 rows in set (0.00 sec)

```

mysql> DELETE FROM employees PARTITION (p0, p1)
->   WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)
```

```

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

id	fname	lname	store_id	department_id
11	Jill	Stone	1	4

1 row in set (0.00 sec)

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```

mysql> UPDATE employees PARTITION (p0)
```

```

->      SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 11 | Jill  | Stone | 1        | 4             |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2)
->      SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 11 | Jill  | Stone | 2        | 4             |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
    
```

In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```

mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
    
```

For statements that write multiple rows to a partitioned table that using the `InnoDB` storage engine: If any row in the list following `VALUES` cannot be written to one of the partitions specified in the `partition_names` list, the entire statement fails and no rows are written. This is shown for `INSERT` statements in the following example, reusing the `employees` table created previously:

```

mysql> ALTER TABLE employees
->      REORGANIZE PARTITION p3 INTO (
->          PARTITION p3 VALUES LESS THAN (20),
->          PARTITION p4 VALUES LESS THAN (25),
->          PARTITION p5 VALUES LESS THAN MAXVALUE
->      );
Query OK, 6 rows affected (2.09 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE employees\G
***** 1. row *****
      Table: employees
Create Table: CREATE TABLE `employees` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `fname` varchar(25) NOT NULL,
  `lname` varchar(25) NOT NULL,
  `store_id` int(11) NOT NULL,
  `department_id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=utf8mb4
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
    
```

```

PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
->      (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
->      (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2  Duplicates: 0  Warnings: 0

```

The preceding is true for both `INSERT` statements and `REPLACE` statements that write multiple rows.

Partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as `NDB`.

23.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 23.6.3, “Partitioning Limitations Relating to Functions”](#).

Arithmetic and logical operators. Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see [Section 23.2, “Partitioning Types”](#), for more information).

The `DIV` operator is also supported; the `/` operator is not permitted.

The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed elsewhere in this Manual (see [Section 5.1.11, “Server SQL Modes”](#)), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

For one such change in the server SQL mode making a partitioned tables unusable, consider the following `CREATE TABLE` statement, which can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
->      PARTITION BY RANGE(c1 - 10) (

```

```

-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)

```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain

```

See also [Section 5.1.11, “Server SQL Modes”](#).

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on source and replica can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the source's and replica's copies of a given table, and may even cause inserts into partitioned tables that succeed on the source to fail on the replica. For best results, you should always use the same server SQL mode on the source and on the replica.

Performance considerations. Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. Partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed. For InnoDB-specific exceptions to this limitation, see [Partitioning Operations](#).

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 23.4, “Partition Pruning”](#), for more information.

Index condition pushdown is supported for partitioned tables. See [Section 8.2.1.6, “Index Condition Pushdown Optimization”](#).

- **Performance with LOAD DATA.** In MySQL 8.0, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

Maximum number of partitions.

The maximum possible number of partitions for a given table not using the `NDB` storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the `NDB` storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See [NDB and user-defined partitioning](#), for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.3.2.17, “File Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

Foreign keys not supported for partitioned InnoDB tables.

Partitioned tables using the `InnoDB` storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an `InnoDB` table employing user-defined partitioning may contain foreign key references; no `InnoDB` table whose definition contains foreign key references may be partitioned.
2. No `InnoDB` table definition may contain a foreign key reference to a user-partitioned table; no `InnoDB` table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the `InnoDB` storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

ALTER TABLE ... ORDER BY. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

Effects on REPLACE statements by modification of primary keys. It can be desirable in some cases (see [Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)) to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See [Section 13.2.9, “REPLACE Statement”](#), for more information and an example.

FULLTEXT indexes.

Partitioned tables do not support `FULLTEXT` indexes or searches.

Spatial columns. Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.

Temporary tables.

Temporary tables cannot be partitioned.

Log tables. It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

Data type of partitioning key.

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`; see [Section 23.2.7, “How MySQL Partitioning Handles NULL”](#).

There are two exceptions to this restriction:

1. When partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because the internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
  ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

2. When partitioning by `RANGE COLUMNS` or `LIST COLUMNS`, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
  PARTITION p0 VALUES LESS THAN('1990-01-01'),
  PARTITION p1 VALUES LESS THAN('1995-01-01'),
  PARTITION p2 VALUES LESS THAN('2000-01-01'),
  PARTITION p3 VALUES LESS THAN('2005-01-01'),
  PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
  PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
  PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
  PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to `BLOB` or `TEXT` column types.

Subqueries.

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

Column index prefixes not supported for key partitioning. When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are not used in the table's partitioning function. Consider the following `CREATE TABLE` statement, which has three `VARCHAR` columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```
CREATE TABLE t1 (
  a VARCHAR(10000),
  b VARCHAR(25),
  c VARCHAR(10),
  PRIMARY KEY (a(10), b, c(2))
) PARTITION BY KEY() PARTITIONS 2;
```

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column `b`) for the partitioning key:

```
CREATE TABLE t1 (
```

```

a VARCHAR(10000),
b VARCHAR(25),
c VARCHAR(10),
PRIMARY KEY (a(10), b, c(2))
) PARTITION BY KEY(b) PARTITIONS 2;

```

Prior to MySQL 8.0.21, no warning was issued or any other indication provided that this occurred, except in the event that all columns specified for the partitioning key used prefixes, in which case the statement failed, but with a misleading error message, as shown here:

```

mysql> CREATE TABLE t2 (
->   a VARCHAR(10000),
->   b VARCHAR(25),
->   c VARCHAR(10),
->   PRIMARY KEY (a(10), b(5) c(2))
-> ) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the
table's partitioning function

```

This also occurred when performing `ALTER TABLE` or when upgrading such tables.

This permissive behavior is deprecated as of MySQL 8.0.21 (and is subject to removal in a future version of MySQL). Beginning with MySQL 8.0.21, using one or more columns having a prefix in the partitioning key results in a warning for each such column, as shown here:

```

mysql> CREATE TABLE t1 (
->   a VARCHAR(10000),
->   b VARCHAR(25),
->   c VARCHAR(10),
->   PRIMARY KEY (a(10), b, c(2))
-> ) PARTITION BY KEY() PARTITIONS 2;
Query OK, 0 rows affected, 2 warnings (1.25 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1681
Message: Column 'test.t1.a' having prefix key part 'a(10)' is ignored by the
partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause
is deprecated and will be removed in a future release.
***** 2. row *****
Level: Warning
Code: 1681
Message: Column 'test.t1.c' having prefix key part 'c(2)' is ignored by the
partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause
is deprecated and will be removed in a future release.
2 rows in set (0.00 sec)

```

This includes cases in which the columns used in the partitioning function are defined implicitly as those in the table's primary key by employing an empty `PARTITION BY KEY()` clause.

In MySQL 8.0.21 and later, if all columns specified for the partitioning key employ prefixes, the `CREATE TABLE` statement used fails with an error message that identifies the issue correctly:

```

mysql> CREATE TABLE t1 (
->   a VARCHAR(10000),
->   b VARCHAR(25),
->   c VARCHAR(10),
->   PRIMARY KEY (a(10), b(5), c(2))
-> ) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's
partitioning function (prefixed columns are not considered).

```

For general information about partitioning tables by key, see [Section 23.2.5, “KEY Partitioning”](#).

Issues with subpartitions.

Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ' '
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

DATA DIRECTORY and INDEX DIRECTORY options. Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091). You can employ these options for individual partitions or subpartitions of `InnoDB` tables. As of MySQL 8.0.21, the directory specified in a `DATA DIRECTORY` clause must be known to `InnoDB`. For more information, see [Using the DATA DIRECTORY Clause](#).

Repairing and rebuilding partitioned tables. The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 13.1.9, “ALTER TABLE Statement”](#), for more information about these two statements.

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations are supported with subpartitions. See [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#).

File name delimiters for partitions and subpartitions. Table partition and subpartition file names include generated delimiters such as `#P#` and `#SP#`. The lettercase of such delimiters can vary and should not be depended upon.

23.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
```

```

        col4 INT NOT NULL,
        UNIQUE KEY (col1, col3)
    )
    PARTITION BY HASH(col1 + col3)
    PARTITIONS 4;

```

This example shows the error produced in such cases:

```

mysql> CREATE TABLE t3 (
->     col1 INT NOT NULL,
->     col2 DATE NOT NULL,
->     col3 INT NOT NULL,
->     col4 INT NOT NULL,
->     UNIQUE KEY (col1, col2),
->     UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```

mysql> CREATE TABLE t3 (
->     col1 INT NOT NULL,
->     col2 DATE NOT NULL,
->     col3 INT NOT NULL,
->     col4 INT NOT NULL,
->     UNIQUE KEY (col1, col2, col3),
->     UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)

```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```

CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),

```

```

        UNIQUE KEY(col2)
    )
    PARTITION BY HASH( YEAR(col2) )
    PARTITIONS 4;

```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```

CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
->     PARTITION BY RANGE(c1) (
->         PARTITION p0 VALUES LESS THAN (10),
->         PARTITION p1 VALUES LESS THAN (20),
->         PARTITION p2 VALUES LESS THAN (30),
->         PARTITION p3 VALUES LESS THAN (40)
->     );
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
->   id INT NOT NULL AUTO_INCREMENT,
->   name VARCHAR(50),
->   added DATE,
->   PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH( TO_DAYS(added) )
->   PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH(id)
->   PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

23.6.2 Partitioning Limitations Relating to Storage Engines

In MySQL 8.0, partitioning support is not actually provided by the MySQL Server, but rather by a table storage engine's own or native partitioning handler. In MySQL 8.0, only the `InnoDB` storage engine provides a native partitioning handler. This means that partitioned tables cannot be created using any other storage engine.

Note

MySQL Cluster's `NDB` storage engine also provides native partitioning support, but is not currently supported in MySQL 8.0.

`ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use `InnoDB`. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#).

User-defined partitioning and the NDB storage engine (NDB Cluster). Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the `NDB` storage engine. It is not possible under normal circumstances in NDB Cluster to create an NDB Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

Exception (not for production): It is possible to override this restriction by setting the `new` system variable on NDB Cluster SQL nodes to `ON`. If you choose to do this, you should be aware that tables using partitioning types other than `[LINEAR] KEY` are not supported in production. *In such cases,*

you can create and use tables with partitioning types other than [KEY](#) or [LINEAR KEY](#), but you do this entirely at your own risk.

The maximum number of partitions that can be defined for an [NDB](#) table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See [NDB and user-defined partitioning](#), for more information.

The maximum amount of fixed-size data that can be stored per partition in an [NDB](#) table is 128 TB. Previously, this was 16 GB.

[CREATE TABLE](#) and [ALTER TABLE](#) statements that would cause a user-partitioned [NDB](#) table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned [NDB](#) table is created using an empty column-list (that is, using [PARTITION BY KEY\(\)](#) or [PARTITION BY LINEAR KEY\(\)](#)), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by [KEY](#) must be dumped and reloaded. Partitioned tables using storage engines other than [InnoDB](#) cannot be upgraded from MySQL 5.7 or earlier to MySQL 8.0 or later; you must either drop the partitioning from such tables with [ALTER TABLE ... REMOVE PARTITIONING](#) or convert them to [InnoDB](#) using [ALTER TABLE ... ENGINE=INNODB](#) prior to the upgrade.

For information about converting [MyISAM](#) tables to [InnoDB](#), see [Section 15.6.1.5, “Converting Tables from MyISAM to InnoDB”](#).

23.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- [ABS\(\)](#)
- [CEILING\(\)](#) (see [CEILING\(\) and FLOOR\(\)](#))
- [DATEDIFF\(\)](#)
- [DAY\(\)](#)
- [DAYOFMONTH\(\)](#)
- [DAYOFWEEK\(\)](#)
- [DAYOFYEAR\(\)](#)
- [EXTRACT\(\)](#) (see [EXTRACT\(\) function with WEEK specifier](#))
- [FLOOR\(\)](#) (see [CEILING\(\) and FLOOR\(\)](#))
- [HOUR\(\)](#)
- [MICROSECOND\(\)](#)
- [MINUTE\(\)](#)
- [MOD\(\)](#)
- [MONTH\(\)](#)

- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `TO_SECONDS()`
- `UNIX_TIMESTAMP()` (with `TIMESTAMP` columns)
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

In MySQL 8.0, partition pruning is supported for the `TO_DAYS()`, `TO_SECONDS()`, `YEAR()`, and `UNIX_TIMESTAMP()` functions. See [Section 23.4, “Partition Pruning”](#), for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->     PARTITION p0 VALUES IN (1,3,5),
->     PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier. The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, `EXTRACT()` is not permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See [Section 12.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 11.1, “Numeric Data Types”](#).

24.8 Restrictions on Stored Programs	4250
24.9 Restrictions on Views	4254

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- **Stored procedure:** An object created with `CREATE PROCEDURE` and invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.
- **Stored function:** An object created with `CREATE FUNCTION` and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.
- **Trigger:** An object created with `CREATE TRIGGER` that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.
- **Event:** An object created with `CREATE EVENT` and invoked by the server according to schedule.
- **View:** An object created with `CREATE VIEW` that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.
- Stored programs include stored routines, triggers, and events.
- Stored objects include stored programs and views.

This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 13.1, “Data Definition Statements”](#).
- The `CALL` statement is used to invoke stored procedures. See [Section 13.2.1, “CALL Statement”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 13.6, “Compound Statement Syntax”](#).
- Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.3, “Caching of Prepared Statements and Stored Programs”](#).

24.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (;) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

24.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 8.0 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section 24.8, “Restrictions on Stored Programs”](#).
- Binary logging for stored routines takes place as described in [Section 24.7, “Stored Program Binary Logging”](#).

24.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#)). A procedure is invoked using a `CALL` statement (see [Section 13.2.1, “CALL Statement”](#)), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 13.6, “Compound Statement Syntax”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 13.1.7, “ALTER PROCEDURE Statement”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.8, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [mysql_real_connect\(\)](#), and [C API Multiple Statement Execution Support](#).

In MySQL 8.0.22 and later, a user variable referenced by a statement in a stored procedure has its type determined the first time the procedure is invoked, and retains this type each time the procedure is invoked thereafter.

24.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine

is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.
- The account named as a routine `DEFINER` can see all routine properties, including its definition. The account thus has full access to the routine output as produced by:
 - The contents of the `INFORMATION_SCHEMA.ROUTINES` table.
 - The `SHOW CREATE FUNCTION` and `SHOW CREATE PROCEDURE` statements.
 - The `SHOW FUNCTION CODE` and `SHOW PROCEDURE CODE` statements.
 - The `SHOW FUNCTION STATUS` and `SHOW PROCEDURE STATUS` statements.
- For an account other than the account named as the routine `DEFINER`, access to routine properties depends on the privileges granted to the account:
 - With the `SHOW_ROUTINE` privilege or the global `SELECT` privilege, the account can see all routine properties, including its definition.
 - With the `CREATE ROUTINE`, `ALTER ROUTINE` or `EXECUTE` privilege granted at a scope that includes the routine, the account can see all routine properties except its definition.

24.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 25.30, “The INFORMATION_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 13.7.7.9, “SHOW CREATE PROCEDURE Statement”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 13.7.7.28, “SHOW PROCEDURE STATUS Statement”](#).
- Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation of the internal implementation of the routine. See [Section 13.7.7.27, “SHOW PROCEDURE CODE Statement”](#).

24.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.16, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

24.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by [INSERT](#) or [LOAD DATA](#) statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the [NDB API](#).

Triggers are not activated by changes in [INFORMATION_SCHEMA](#) or [performance_schema](#) tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 8.0 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section 24.8, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 24.7, “Stored Program Binary Logging”](#).

24.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the [CREATE TRIGGER](#) or [DROP TRIGGER](#) statement, described in [Section 13.1.22, “CREATE TRIGGER Statement”](#), and [Section 13.1.34, “DROP TRIGGER Statement”](#).

Here is a simple example that associates a trigger with a table, to activate for [INSERT](#) operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
      FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The [CREATE TRIGGER](#) statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword [BEFORE](#) indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is [AFTER](#).

- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
|          1852.48      |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
      FOR EACH ROW PRECEDES ins_sum
      SET
        @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
        @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
      FOR EACH ROW
      BEGIN
          IF NEW.amount < 0 THEN
              SET NEW.amount = 0;
          ELSEIF NEW.amount > 100 THEN
              SET NEW.amount = 100;
          END IF;
      END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.)

See also [Section 24.8, “Restrictions on Stored Programs”](#).

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For

nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|

delimiter ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
  (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+-----+
| a1    |
+-----+
| 1     |
| 3     |
| 1     |
| 7     |
| 1     |
| 8     |
| 4     |
| 4     |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2    |
+-----+
| 1     |
| 3     |
| 1     |
| 7     |
| 1     |
| 8     |
| 4     |
| 4     |
+-----+
```

```

8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+-----+
| a4 | b4 |
+-----+-----+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+-----+-----+
10 rows in set (0.00 sec)

```

24.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 25.45, “The INFORMATION_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW CREATE TRIGGER` statement. See [Section 13.7.7.11, “SHOW CREATE TRIGGER Statement”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 13.7.7.40, “SHOW TRIGGERS Statement”](#).

24.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 24.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 24.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 24.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `events` data dictionary table in the `mysql` system database. This table is created during the MySQL 8.0 installation procedure. If you are upgrading to MySQL 8.0 from an earlier version, be sure to perform the upgrade procedure to make sure that your system database is up to date. See [Section 2.11, “Upgrading MySQL”](#).

Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section 24.8, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 24.7, “Stored Program Binary Logging”](#).

24.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix [crontab](#) (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 24.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 13.6, “Compound Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK ()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.3, “ALTER EVENT Statement”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section 24.8, “Restrictions on Stored Programs”](#).

24.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here. The default is `ON`.

- `ON`: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
  Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- `OFF`: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed.

When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- `DISABLED`: This value renders the Event Scheduler nonoperational. When the Event Scheduler is `DISABLED`, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to `DISABLED`, `event_scheduler` can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@GLOBAL.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@GLOBAL.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
```

```
SET @@GLOBAL.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@GLOBAL.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by **SELECT** or **SHOW VARIABLES** is always one of **OFF**, **ON**, or **DISABLED**. *DISABLED has no numeric equivalent*. For this reason, **ON** and **OFF** are usually preferred over **1** and **0** when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime. Also, if the Event Scheduler is set to **DISABLED** at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use **ON** (or **1**) or **OFF** (or **0**) in place of the **DISABLED** value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to **DISABLED**. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to **ON** (or **1**). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to **DISABLED**, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 24.4.3, “Event Syntax”](#).

MySQL provides an **EVENTS** table in the **INFORMATION_SCHEMA** database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 24.4.4, “Event Metadata”](#), and [Section 25.14, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#).

24.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.13, “CREATE EVENT Statement”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.3, “ALTER EVENT Statement”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.25, “DROP EVENT Statement”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.13, “CREATE EVENT Statement”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#).

24.4.4 Event Metadata

To obtain metadata about events:

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 25.14, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.7.7, “SHOW CREATE EVENT Statement”](#).
- Use the `SHOW EVENTS` statement. See [Section 13.7.7.18, “SHOW EVENTS Statement”](#).

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the data dictionary, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

Event times can be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ or STZ values. The following table summarizes representation of event times.

Value	<code>INFORMATION_SCHEMA.EVENTS</code>	<code>SHOW EVENTS</code>
Execute at	ETZ	ETZ
Starts	ETZ	ETZ
Ends	ETZ	ETZ
Last executed	ETZ	n/a
Created	STZ	n/a
Last altered	STZ	n/a

24.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 24.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At   LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA        : init_scheduler:313
LUA        : init_scheduler:318
WOC        : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
LLA           : init_queue:148
LUA           : init_queue:168
WOC           : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Statement”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

24.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:31.262022Z 25 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
2013-09-24T12:41:41.271796Z 26 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:41.272761Z 26 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `INFORMATION_SCHEMA.EVENTS` table (see [Section 25.14, “The INFORMATION_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the data dictionary. To drop an event created by another user account, you must be the MySQL `root` user or another user with the necessary privileges.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section 24.8, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

24.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 8.0 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section 24.9, “Restrictions on Views”](#).

24.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.23, “CREATE VIEW Statement”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.11, “ALTER VIEW Statement”](#)), or `DROP VIEW` (see [Section 13.1.35, “DROP VIEW Statement”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 5 | 60 | 300 |
+-----+-----+-----+
```

24.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

- If no `ALGORITHM` clause is present, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see [Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#).

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables and common table expressions. Examples are `SELECT DISTINCT` or `LIMIT` in the subquery. For details, see [Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#).

24.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. Derived tables and common table expressions can also be specified in multiple-table [UPDATE](#) and [DELETE](#) statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions or window functions ([SUM\(\)](#), [MIN\(\)](#), [MAX\(\)](#), [COUNT\(\)](#), and so forth)
- [DISTINCT](#)
- [GROUP BY](#)
- [HAVING](#)
- [UNION](#) or [UNION ALL](#)
- Subquery in the select list

Nondependent subqueries in the select list fail for [INSERT](#), but are okay for [UPDATE](#), [DELETE](#). For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the [FROM](#) clause
- Subquery in the [WHERE](#) clause that refers to a table in the [FROM](#) clause
- Refers only to literal values (in this case, there is no underlying table to update)
- [ALGORITHM = TEMPTABLE](#) (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for [INSERT](#), okay for [UPDATE](#), [DELETE](#))

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 13.1.20.8, “CREATE TABLE and Generated Columns”](#).

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the [MERGE](#) algorithm. For this to work, the view must use an inner join (not an outer join or a [UNION](#)). Also, only a single table in the view definition can be updated, so the [SET](#) clause must name only columns from one of the tables in the view. Views that use [UNION ALL](#) are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with [INSERT](#) statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
```

```
(subquery)
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.8, “Server System Variables”](#).

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

`INSERT`, `UPDATE`, and `DELETE` statements are permitted as follows:

- **INSERT:** The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- **UPDATE:** The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vup`):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET s=s+1;
```

- **DELETE:** The table or tables to be deleted from in a `DELETE` statement must be merged views. Join views are not allowed (this differs from `INSERT` and `UPDATE`).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

24.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

`WITH CHECK OPTION` testing is standard-compliant:

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
```

```
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`.

Inserts for `v2` are checked against its `LOCAL` check option, then the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` also fails:

```
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

24.5.5 View Metadata

To obtain metadata about views:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 25.48, “The INFORMATION_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.7.13, “SHOW CREATE VIEW Statement”](#).

24.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. The privileges applicable to execution of a stored object are controlled by its `DEFINER` attribute and `SQL SECURITY` characteristic.

- [The DEFINER Attribute](#)
- [The SQL SECURITY Characteristic](#)
- [Examples](#)
- [Orphan Stored Objects](#)
- [Risk-Minimization Guidelines](#)

The DEFINER Attribute

A stored object definition can include a `DEFINER` attribute that names a MySQL account. If a definition omits the `DEFINER` attribute, the default object definer is the user who creates it.

The following rules determine which accounts you can specify as the `DEFINER` attribute for a stored object:

- If you have the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege), you can specify any account as the `DEFINER` attribute. If the account does not exist, a warning is generated. Additionally, to set a stored object `DEFINER` attribute to an account that has the `SYSTEM_USER` privilege, you must have the `SYSTEM_USER` privilege.
- Otherwise, the only permitted account is your own, specified either literally or as `CURRENT_USER` or `CURRENT_USER()`. You cannot set the definer to any other account.

Creating a stored object with a nonexistent `DEFINER` account creates an orphan object, which may have negative consequences; see [Orphan Stored Objects](#).

The SQL SECURITY Characteristic

For stored routines (procedures and functions) and views, the object definition can include an `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the definition omits the `SQL SECURITY` characteristic, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored object that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but during object execution, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If the `DEFINER` account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as an administrative account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute has no effect on object execution.

Examples

Consider the following stored procedure, which is declared with `SQL SECURITY DEFINER` to execute in definer security context:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in definer security context and thus executes with the privileges of `'admin'@'localhost'`, the account named as its `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1` referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Unlike `p1`, `p2` executes in invoker security context and thus with the privileges of the invoking user regardless of the `DEFINER` attribute value. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

Orphan Stored Objects

An orphan stored object is one for which its `DEFINER` attribute names a nonexistent account:

- An orphan stored object can be created by specifying a nonexistent `DEFINER` account at object-creation time.

- An existing stored object can become orphaned through execution of a `DROP USER` statement that drops the object `DEFINER` account, or a `RENAME USER` statement that renames the object `DEFINER` account.

An orphan stored object may be problematic in these ways:

- Because the `DEFINER` account does not exist, the object may not work as expected if it executes in definer security context:
 - For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
 - For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.
 - For an event, an error occurs at event execution time if the account does not exist.
 - For a view, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
- The object may present a security risk if the nonexistent `DEFINER` account is subsequently re-created for a purpose unrelated to the object. In this case, the account “adopts” the object and, with the appropriate privileges, is able to execute it even if that is not intended.

As of MySQL 8.0.22, the server imposes additional account-management security checks designed to prevent operations that (perhaps inadvertently) cause stored objects to become orphaned or that cause adoption of stored objects that are currently orphaned:

- `DROP USER` fails with an error if any account to be dropped is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.)
- `RENAME USER` fails with an error if any account to be renamed is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if renaming an account would cause a stored object to become orphaned.)
- `CREATE USER` fails with an error if any account to be created is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.)

In certain situations, it may be necessary to deliberately execute those account-management statements even when they would otherwise fail. To make this possible, if a user has the `SET_USER_ID` privilege, that privilege overrides the orphan object security checks and the statements succeed with a warning rather than failing with an error.

To obtain information about the accounts used as stored object definers in a MySQL installation, query the `INFORMATION_SCHEMA`.

This query identifies which `INFORMATION_SCHEMA` tables describe objects that have a `DEFINER` attribute:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.COLUMNS
        WHERE COLUMN_NAME = 'DEFINER';
```

TABLE_SCHEMA	TABLE_NAME
information_schema	EVENTS
information_schema	ROUTINES
information_schema	TRIGGERS
information_schema	VIEWS

The result tells you which tables to query to discover which stored object `DEFINER` values exist and which objects have a particular `DEFINER` value:

- To identify which **DEFINER** values exist in each table, use these queries:

```
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.EVENTS;  
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.ROUTINES;  
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.TRIGGERS;  
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.VIEWS;
```

The query results are significant for any account displayed as follows:

- If the account exists, dropping or renaming it will cause stored objects to become orphaned. If you plan to drop or rename the account, consider first dropping its associated stored objects or redefining them to have a different definer.
- If the account does not exist, creating it will cause it to adopt currently orphaned stored objects. If you plan to create the account, consider whether the orphaned objects should be associated with it. If not, redefine them to have a different definer.

To redefine an object with a different definer, you can use **ALTER EVENT** or **ALTER VIEW** to directly modify the **DEFINER** account of events and views. For stored procedures and functions and for triggers, you must drop the object and re-create it to assign a different **DEFINER** account

- To identify which objects have a given **DEFINER** account, use these queries, substituting the account of interest for *user_name@host_name*:

```
SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS  
WHERE DEFINER = 'user_name@host_name';  
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE  
FROM INFORMATION_SCHEMA.ROUTINES  
WHERE DEFINER = 'user_name@host_name';  
SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS  
WHERE DEFINER = 'user_name@host_name';  
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS  
WHERE DEFINER = 'user_name@host_name';
```

For the **ROUTINES** table, the query includes the **ROUTINE_TYPE** column so that output rows distinguish whether the **DEFINER** is for a stored procedure or stored function.

If the account you are searching for does not exist, any objects displayed by those queries are orphan objects.

Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- Do not create orphan stored objects; that is, objects for which the **DEFINER** attribute names a nonexistent account. Do not cause stored objects to become orphaned by dropping or renaming an account named by the **DEFINER** attribute of any existing object.
- For a stored routine or view, use **SQL SECURITY INVOKER** in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored objects while using an account that has the **SET_USER_ID** privilege (or the deprecated **SUPER** privilege), specify an explicit **DEFINER** attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged **DEFINER** account only when absolutely necessary.
- Administrators can prevent users from creating stored objects that specify highly privileged **DEFINER** accounts by not granting them the **SET_USER_ID** privilege (or the deprecated **SUPER** privilege).
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:

- A stored routine cannot be referenced by a user who does not have the [EXECUTE](#) privilege for it.
- A view cannot be referenced by a user who does not have the appropriate privilege for it ([SELECT](#) to select from it, [INSERT](#) to insert into it, and so forth).

However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary, and users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.
- An event is executed by the server on a scheduled basis.

In both cases, if the [DEFINER](#) account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

24.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

- For replication, the binary log is used on source replication servers as a record of the statements to be sent to replica servers. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See [Section 17.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on source and replica.
- Replicated statements executed on a replica are processed by the replica SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on source and replica servers, so a user can write a routine containing a dangerous statement that will execute only on the replica where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on source and replica, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the [CALL](#) statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the replica side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (`binlog_format=MIXED`) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers, and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see [Section 17.2.1, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see [Section 5.4.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege), in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SET_USER_ID` or `SUPER` might be required regardless of whether binary logging is enabled. See [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC` keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the `DETERMINISTIC` keyword.
- Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the `DETERMINISTIC` keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when `binlog_format=STATEMENT` is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable at server startup.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 17.5.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the replica side, the replica uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the source server:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
```

```

IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
END IF;
RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;

```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```

SELECT f1(1);
SELECT f1(2);

```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the replica, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
 - It is possible for a function to follow different execution paths on source and replica servers.
 - Statements executed on a replica are processed by the replica SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the replica where it is processed by a thread that has full privileges. For example, if the source and replica servers have server ID values of 1 and 2, respectively, a user on the source server could create and invoke an unsafe function `unsafe_func()` as follows:

```

mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->     IF @@server_id=2 THEN dangerous_statement; END IF;
->     RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());

```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the replica will execute them. Because the replica SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the source and replica and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```

ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)

```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators`

does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
 - It will make a replica different from the source.
 - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a source server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the source server will be observed on replicas. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a replica with the same effect as the original statement that was executed on the source within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the source and replica servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the source and replica tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the replica with the same value as on the source. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the source:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to nontransactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that replicas will make the same changes and rollbacks as on the source.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

24.8 Restrictions on Stored Programs

These restrictions apply to the features described in [Chapter 24, Stored Objects](#).

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some [restrictions specific to stored functions](#) but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some [restrictions specific to triggers](#).

The restrictions for stored procedures also apply to the `DO` clause of Event Scheduler event definitions. There are also some [restrictions specific to events](#).

SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see [Section 13.5, “Prepared Statements”](#). Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.
- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Statement”](#).
- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.
- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See [Section 13.2.10.1, “SELECT ... INTO Statement”](#), and [Section 13.6.6, “Cursors”](#).
- `FLUSH` statements.
- Stored functions cannot be used recursively.
- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.
- `HANDLER ... READ` statements that invoke stored functions can cause replication errors and are disallowed.

Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.
- When using row-based replication, triggers on the replica are not activated by statements originating on the source. The triggers on the replica are activated when using statement-based replication. For more information, see [Section 17.5.1.35, “Replication and Triggers”](#).
- The `RETURN` statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the `LEAVE` statement.
- Triggers are not permitted on tables in the `mysql` database. Nor are they permitted on `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.
- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
    DECLARE i INT DEFAULT 1;
    SELECT i FROM t;
  END;
END;
```

In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

Replication Considerations

Use of stored routines can cause replication problems. This issue is discussed further in [Section 24.7, “Stored Program Binary Logging”](#).

The `--replicate-wild-do-table=db_name.tbl_name` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Debugging Considerations

There are no stored routine debugging facilities.

Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- [UNDO](#) handlers
- [FOR](#) loops

Stored Routine Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See [Section 24.7](#), “[Stored Program Binary Logging](#)”.

Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names [anEvent](#) and [AnEvent](#).
- An event may not be created, altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.
- DDL statements on events are prohibited while a [LOCK TABLES](#) statement is in effect.
- Event timings using the intervals [YEAR](#), [QUARTER](#), [MONTH](#), and [YEAR_MONTH](#) are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the [INFORMATION_SCHEMA.EVENTS](#) table's [LAST_EXECUTED](#) column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)
- Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements have no effect in a given user session on the server's statement counts such as [Com_select](#) and [Com_insert](#) that are displayed by [SHOW STATUS](#). However, such counts *are* updated in the global scope. (Bug #16422)
- Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)

- References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

Stored routines and triggers in NDB Cluster. Stored procedures, stored functions, and triggers are all supported by tables using the `NDB` storage engine; however, it is important to keep in mind that they do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because stored routine and trigger definitions are stored in tables in the `mysql` system database using `InnoDB` tables, which are not copied between Cluster nodes.

Any stored routine or trigger that interacts with MySQL Cluster tables must be re-created by running the appropriate `CREATE PROCEDURE`, `CREATE FUNCTION`, or `CREATE TRIGGER` statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate `ALTER` or `DROP` statements on each MySQL Server accessing the cluster.

Warning

Do *not* attempt to work around the issue just described by converting any `mysql` database tables to use the `NDB` storage engine. *Altering the system tables in the `mysql` database is not supported* and is very likely to produce undesirable results.

24.9 Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

There is a general principle that you cannot modify a table and select from the same table in a subquery. See [Section 13.2.11.12, “Restrictions on Subqueries”](#).

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);

UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you *can* select from the table in the view subquery and still modify that table in the outer query. In this case the view will be stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. MySQL as quickly as possible. Many theoretically updatable views can

be updated now, but limitations still exist. For details, see [Section 24.5.3, “Updatable and Insertable Views”](#).

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user will be unable to call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer replicas that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view will replicate properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

Chapter 25 INFORMATION_SCHEMA Tables

Table of Contents

25.1 Introduction	4258
25.2 The INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS Table	4261
25.3 The INFORMATION_SCHEMA APPLICABLE_ROLES Table	4262

- [Standards Considerations](#)
- [Conventions in the INFORMATION_SCHEMA Reference Sections](#)
- [Related Information](#)

INFORMATION_SCHEMA Usage Notes

`INFORMATION_SCHEMA` is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The `INFORMATION_SCHEMA` database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select `INFORMATION_SCHEMA` as the default database with a `USE` statement, you can only read the contents of tables, not perform `INSERT`, `UPDATE`, or `DELETE` operations on them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
        FROM information_schema.tables
        WHERE table_schema = 'db5'
        ORDER BY table_name;
```

table_name	table_type	engine
fk	BASE TABLE	InnoDB
fk2	BASE TABLE	InnoDB
goto	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
loop	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
t	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
tables	BASE TABLE	MyISAM
v	VIEW	NULL
v2	VIEW	NULL
v3	VIEW	NULL
v56	VIEW	NULL

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N)` `CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

INFORMATION_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in [Section 25.55, “Extensions to SHOW Statements”](#).

INFORMATION_SCHEMA and Privileges

For most `INFORMATION_SCHEMA` tables, each MySQL user has the right to access them, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. Some tables have different privilege requirements; for these, the requirements are mentioned in the applicable table descriptions. For example, `InnoDB` tables (tables with names that begin with `INNODB_`) require the `PROCESS` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed

`COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5>.

Conventions in the INFORMATION_SCHEMA Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine: [Section 25.51, “INFORMATION_SCHEMA InnoDB Tables”](#)
- information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin: [Section 25.52, “INFORMATION_SCHEMA Thread Pool Tables”](#)
- information about `INFORMATION_SCHEMA` tables specific to the `CONNECTION_CONTROL` plugin: [Section 25.53, “INFORMATION_SCHEMA Connection-Control Tables”](#)
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: [Section A.7, “MySQL 8.0 FAQ: INFORMATION_SCHEMA”](#)
- `INFORMATION_SCHEMA` queries and the optimizer: [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#)
- The effect of collation on `INFORMATION_SCHEMA` comparisons: [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#)

25.2 The INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS Table

The `ADMINISTRABLE_ROLE_AUTHORIZATIONS` table (available as of MySQL 8.0.19) provides information about which roles applicable for the current user or role can be granted to other users or roles.

The `ADMINISTRABLE_ROLE_AUTHORIZATIONS` table has these columns:

- `USER`

The user name part of the current user account.

- `HOST`

The host name part of the current user account.

- [GRANTEE](#)

The user name part of the account to which the role is granted.

- [GRANTEE_HOST](#)

The host name part of the account to which the role is granted.

- [ROLE_NAME](#)

The user name part of the granted role.

- [ROLE_HOST](#)

The host name part of the granted role.

- [IS_GRANTABLE](#)

[YES](#) or [NO](#), depending on whether the role is grantable to other accounts.

- [IS_DEFAULT](#)

[YES](#) or [NO](#), depending on whether the role is a default role.

- [IS_MANDATORY](#)

[YES](#) or [NO](#), depending on whether the role is mandatory.

25.3 The INFORMATION_SCHEMA APPLICABLE_ROLES Table

The [APPLICABLE_ROLES](#) table (available as of MySQL 8.0.19) provides information about the roles that are applicable for the current user.

The [APPLICABLE_ROLES](#) table has these columns:

- [USER](#)

The user name part of the current user account.

- [HOST](#)

The host name part of the current user account.

- [GRANTEE](#)

The user name part of the account to which the role is granted.

- [GRANTEE_HOST](#)

The host name part of the account to which the role is granted.

- [ROLE_NAME](#)

The user name part of the granted role.

- [ROLE_HOST](#)

The host name part of the granted role.

- [IS_GRANTABLE](#)

[YES](#) or [NO](#), depending on whether the role is grantable to other accounts.

- [IS_DEFAULT](#)

[YES](#) or [NO](#), depending on whether the role is a default role.

- [IS_MANDATORY](#)

[YES](#) or [NO](#), depending on whether the role is mandatory.

25.4 The INFORMATION_SCHEMA CHARACTER_SETS Table

The [CHARACTER_SETS](#) table provides information about available character sets.

The [CHARACTER_SETS](#) table has these columns:

- [CHARACTER_SET_NAME](#)

The character set name.

- [DEFAULT_COLLATE_NAME](#)

The default collation for the character set.

- [DESCRIPTION](#)

A description of the character set.

- [MAXLEN](#)

The maximum number of bytes required to store one character.

Notes

Character set information is also available from the [SHOW CHARACTER SET](#) statement. See [Section 13.7.7.3, “SHOW CHARACTER SET Statement”](#). The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

25.5 The INFORMATION_SCHEMA CHECK_CONSTRAINTS Table

The [CHECK_CONSTRAINTS](#) table (available as of MySQL 8.0.16) provides information about [CHECK](#) constraints defined on tables.

The [CHECK_CONSTRAINTS](#) table has these columns:

- [CONSTRAINT_CATALOG](#)

The name of the catalog to which the constraint belongs. This value is always [def](#).

- [CONSTRAINT_SCHEMA](#)

The name of the schema (database) to which the constraint belongs.

- [CONSTRAINT_NAME](#)

The name of the constraint.

- [CHECK_CLAUSE](#)

The expression that specifies the constraint condition.

25.6 The INFORMATION_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

The `COLLATIONS` table has these columns:

- `COLLATION_NAME`

The collation name.

- `CHARACTER_SET_NAME`

The name of the character set with which the collation is associated.

- `ID`

The collation ID.

- `IS_DEFAULT`

Whether the collation is the default for its character set.

- `IS_COMPILED`

Whether the character set is compiled into the server.

- `SORTLEN`

This is related to the amount of memory required to sort strings expressed in the character set.

- `PAD_ATTRIBUTE`

The collation pad attribute, either `NO PAD` or `PAD SPACE`. This attribute affects whether trailing spaces are significant in string comparisons; see [Trailing Space Handling in Comparisons](#).

Notes

Collation information is also available from the `SHOW COLLATION` statement. See [Section 13.7.7.4, “SHOW COLLATION Statement”](#). The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

25.7 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation.

The `COLLATION_CHARACTER_SET_APPLICABILITY` table has these columns:

- `COLLATION_NAME`

The collation name.

- `CHARACTER_SET_NAME`

The name of the character set with which the collation is associated.

Notes

The `COLLATION_CHARACTER_SET_APPLICABILITY` columns are equivalent to the first two columns displayed by the `SHOW COLLATION` statement.

25.8 The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables. The related `ST_GEOMETRY_COLUMNS` table provides information about table columns that store spatial data. See [Section 25.35, “The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table”](#).

The `COLUMNS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table containing the column belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the column belongs.

- `TABLE_NAME`

The name of the table containing the column.

- `COLUMN_NAME`

The name of the column.

- `ORDINAL_POSITION`

The position of the column within the table. `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW COLUMNS`, `SELECT` from the `COLUMNS` table does not have automatic ordering.

- `COLUMN_DEFAULT`

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- `IS_NULLABLE`

The column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.

- `DATA_TYPE`

The column data type.

The `DATA_TYPE` value is the type name only with no other information. The `COLUMN_TYPE` value contains the type name and possibly other information such as the precision or length.

- `CHARACTER_MAXIMUM_LENGTH`

For string columns, the maximum length in characters.

- `CHARACTER_OCTET_LENGTH`

For string columns, the maximum length in bytes.

- `NUMERIC_PRECISION`

For numeric columns, the numeric precision.

- `NUMERIC_SCALE`

For numeric columns, the numeric scale.

- `DATETIME_PRECISION`

For temporal columns, the fractional seconds precision.

- `CHARACTER_SET_NAME`

For character string columns, the character set name.

- `COLLATION_NAME`

For character string columns, the collation name.

- `COLUMN_TYPE`

The column data type.

The `DATA_TYPE` value is the type name only with no other information. The `COLUMN_TYPE` value contains the type name and possibly other information such as the precision or length.

- `COLUMN_KEY`

Whether the column is indexed:

- If `COLUMN_KEY` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If `COLUMN_KEY` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If `COLUMN_KEY` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` column.)
- If `COLUMN_KEY` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `COLUMN_KEY` values applies to a given column of a table, `COLUMN_KEY` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- `EXTRA`

Any additional information that is available about a given column. The value is nonempty in these cases:

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute.
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.
- `STORED GENERATED` or `VIRTUAL GENERATED` for generated columns.
- `DEFAULT_GENERATED` for columns that have an expression default value.
- `PRIVILEGES`

The privileges you have for the column.

- `COLUMN_COMMENT`

Any comment included in the column definition.

- `GENERATION_EXPRESSION`

For generated columns, displays the expression used to compute column values. Empty for nongenerated columns. For information about generated columns, see [Section 13.1.20.8, “CREATE TABLE and Generated Columns”](#).

- `SRS_ID`

This value applies to spatial columns. It contains the column `SRID` value that indicates the spatial reference system for values stored in the column. See [Section 11.4.1, “Spatial Data Types”](#), and [Section 11.4.5, “Spatial Reference System Support”](#). The value is `NULL` for nonspatial columns and spatial columns with no `SRID` attribute.

Notes

- In `SHOW COLUMNS`, the `Type` display includes values from several different `COLUMNS` columns.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `COLLATION_NAME`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `COLLATION_NAME` column a value of `utf8_swedish_ci`, the character set is what is before the first underscore: `utf8`.

Column information is also available from the `SHOW COLUMNS` statement. See [Section 13.7.7.5, “SHOW COLUMNS Statement”](#). The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

25.9 The INFORMATION_SCHEMA COLUMNS_EXTENSIONS Table

The `COLUMNS_EXTENSIONS` table (available as of MySQL 8.0.21) provides information about column attributes defined for primary and secondary storage engines.

Note

The `COLUMNS_EXTENSIONS` table is reserved for future use.

The `COLUMNS_EXTENSIONS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table belongs.

- `TABLE_NAME`

The name of the table.

- `COLUMN_NAME`

The name of the column.

- `ENGINE_ATTRIBUTE`

Column attributes defined for the primary storage engine. Reserved for future use.

- `SECONDARY_ENGINE_ATTRIBUTE`

Column attributes defined for the secondary storage engine. Reserved for future use.

25.10 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. It takes its values from the `mysql.columns_priv` system table.

The `COLUMN_PRIVILEGES` table has these columns:

- `GRANTEE`

The name of the account to which the privilege is granted, in '`user_name`'@'`host_name`' format.

- `TABLE_CATALOG`

The name of the catalog to which the table containing the column belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the column belongs.

- `TABLE_NAME`

The name of the table containing the column.

- `COLUMN_NAME`

The name of the column.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the column level; see [Section 13.7.1.6, "GRANT Statement"](#). Each row lists a single privilege, so there is one row per column privilege held by the grantee.

In the output from `SHOW FULL COLUMNS`, the privileges are all in one column and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

Notes

- `COLUMN_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
```

```
SHOW GRANTS ...
```

25.11 The INFORMATION_SCHEMA COLUMN_STATISTICS Table

The `COLUMN_STATISTICS` table provides access to histogram statistics for column values.

For information about histogram statistics, see [Section 8.9.6, “Optimizer Statistics”](#), and [Section 13.7.3.1, “ANALYZE TABLE Statement”](#).

You can see information only for columns for which you have some privilege.

The `COLUMN_STATISTICS` table has these columns:

- `SCHEMA_NAME`

The names of the schema for which the statistics apply.

- `TABLE_NAME`

The names of the column for which the statistics apply.

- `COLUMN_NAME`

The names of the column for which the statistics apply.

- `HISTOGRAM`

A `JSON` object describing the column statistics, stored as a histogram.

25.12 The INFORMATION_SCHEMA ENABLED_ROLES Table

The `ENABLED_ROLES` table (available as of MySQL 8.0.19) provides information about the roles that are enabled within the current session.

The `ENABLED_ROLES` table has these columns:

- `ROLE_NAME`

The user name part of the granted role.

- `ROLE_HOST`

The host name part of the granted role.

- `IS_DEFAULT`

`YES` or `NO`, depending on whether the role is a default role.

- `IS_MANDATORY`

`YES` or `NO`, depending on whether the role is mandatory.

25.13 The INFORMATION_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The `ENGINES` table has these columns:

- `ENGINE`

The name of the storage engine.

- `SUPPORT`

The server's level of support for the storage engine, as shown in the following table.

Value	Meaning
YES	The engine is supported and is active
DEFAULT	Like YES, plus this is the default engine
NO	The engine is not supported
DISABLED	The engine is supported but has been disabled

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See [Section 5.4.2, “The Error Log”](#).

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the **NDB** storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **COMMENT**

A brief description of the storage engine.

- **TRANSACTIONS**

Whether the storage engine supports transactions.

- **XA**

Whether the storage engine supports XA transactions.

- **SAVEPOINTS**

Whether the storage engine supports savepoints.

Notes

- **ENGINES** is a nonstandard **INFORMATION_SCHEMA** table.

Storage engine information is also available from the `SHOW ENGINES` statement. See [Section 13.7.7.16, “SHOW ENGINES Statement”](#). The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

25.14 The INFORMATION_SCHEMA EVENTS Table

The **EVENTS** table provides information about Event Manager events, which are discussed in [Section 24.4, “Using the Event Scheduler”](#).

The **EVENTS** table has these columns:

- **EVENT_CATALOG**

The name of the catalog to which the event belongs. This value is always `def`.

- **EVENT_SCHEMA**

The name of the schema (database) to which the event belongs.

- [EVENT_NAME](#)

The name of the event.

- [DEFINER](#)

The account named in the [DEFINER](#) clause (often the user who created the event), in `'user_name'@'host_name'` format.

- [TIME_ZONE](#)

The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is [SYSTEM](#).

- [EVENT_BODY](#)

The language used for the statements in the event's [DO](#) clause. The value is always [SQL](#).

- [EVENT_DEFINITION](#)

The text of the SQL statement making up the event's [DO](#) clause; in other words, the statement executed by this event.

- [EVENT_TYPE](#)

The event repetition type, either [ONE TIME](#) (transient) or [RECURRING](#) (repeating).

- [EXECUTE_AT](#)

For a one-time event, this is the [DATETIME](#) value specified in the [AT](#) clause of the [CREATE EVENT](#) statement used to create the event, or of the last [ALTER EVENT](#) statement that modified the event. The value shown in this column reflects the addition or subtraction of any [INTERVAL](#) value included in the event's [AT](#) clause. For example, if an event is created using [ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR](#), and the event was created at 2018-02-09 14:05:30, the value shown in this column would be `'2018-02-10 20:05:30'`. If the event's timing is determined by an [EVERY](#) clause instead of an [AT](#) clause (that is, if the event is recurring), the value of this column is [NULL](#).

- [INTERVAL_VALUE](#)

For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always [NULL](#).

- [INTERVAL_FIELD](#)

The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always [NULL](#).

- [SQL_MODE](#)

The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see [Section 5.1.11, "Server SQL Modes"](#).

- [STARTS](#)

The start date and time for a recurring event. This is displayed as a [DATETIME](#) value, and is [NULL](#) if no start date and time are defined for the event. For a transient event, this column is always [NULL](#). For a recurring event whose definition includes a [STARTS](#) clause, this column contains the corresponding [DATETIME](#) value. As with the [EXECUTE_AT](#) column, this value resolves any expressions used. If there is no [STARTS](#) clause affecting the timing of the event, this column is [NULL](#).

- [ENDS](#)

For a recurring event whose definition includes a [ENDS](#) clause, this column contains the corresponding [DATETIME](#) value. As with the [EXECUTE_AT](#) column, this value resolves any expressions used. If there is no [ENDS](#) clause affecting the timing of the event, this column is [NULL](#).

- [STATUS](#)

The event status. One of [ENABLED](#), [DISABLED](#), or [SLAVESIDE_DISABLED](#). [SLAVESIDE_DISABLED](#) indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see [Section 17.5.1.16, “Replication of Invoked Features”](#). information.

- [ON_COMPLETION](#)

One of the two values [PRESERVE](#) or [NOT PRESERVE](#).

- [CREATED](#)

The date and time when the event was created. This is a [TIMESTAMP](#) value.

- [LAST_ALTERED](#)

The date and time when the event was last modified. This is a [TIMESTAMP](#) value. If the event has not been modified since its creation, this value is the same as the [CREATED](#) value.

- [LAST_EXECUTED](#)

The date and time when the event last executed. This is a [DATETIME](#) value. If the event has never executed, this column is [NULL](#).

[LAST_EXECUTED](#) indicates when the event started. As a result, the [ENDS](#) column is never less than [LAST_EXECUTED](#).

- [EVENT_COMMENT](#)

The text of the comment, if the event has one. If not, this value is empty.

- [ORIGINATOR](#)

The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by [ALTER EVENT](#) to the server ID of the server on which that statement occurs, if executed on a replication source. The default value is 0.

- [CHARACTER_SET_CLIENT](#)

The session value of the [character_set_client](#) system variable when the event was created.

- [COLLATION_CONNECTION](#)

The session value of the [collation_connection](#) system variable when the event was created.

- [DATABASE_COLLATION](#)

The collation of the database with which the event is associated.

Notes

- [EVENTS](#) is a nonstandard [INFORMATION_SCHEMA](#) table.
- Times in the [EVENTS](#) table are displayed using the event time zone, the current session time zone, or UTC, as described in [Section 24.4.4, “Event Metadata”](#).

- For more information about [SLAVESIDE_DISABLED](#) and the [ORIGINATOR](#) column, see [Section 17.5.1.16, “Replication of Invoked Features”](#).

Example

Suppose that the user 'jon'@'ghidora' creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END |

DELIMITER ;

ALTER EVENT e_daily
  ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
WHERE EVENT_NAME = 'e_daily'
AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES,
          NO_ZERO_IN_DATE, NO_ZERO_DATE,
          ERROR_FOR_DIVISION_BY_ZERO,
          NO_ENGINE_SUBSTITUTION
STARTS: 2018-08-08 11:06:34
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2018-08-08 11:06:34
LAST_ALTERED: 2018-08-08 11:06:34
LAST_EXECUTED: 2018-08-08 16:06:34
EVENT_COMMENT: Saves total number of sessions then clears the
               table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_0900_ai_ci
DATABASE_COLLATION: utf8mb4_0900_ai_ci
```

Event information is also available from the `SHOW EVENTS` statement. See [Section 13.7.7.18, “SHOW EVENTS Statement”](#). The following statements are equivalent:

```

SELECT
    EVENT_SCHEMA, EVENT_NAME, DEFINER, TIME_ZONE, EVENT_TYPE, EXECUTE_AT,
    INTERVAL_VALUE, INTERVAL_FIELD, STARTS, ENDS, STATUS, ORIGINATOR,
    CHARACTER_SET_CLIENT, COLLATION_CONNECTION, DATABASE_COLLATION
FROM INFORMATION_SCHEMA.EVENTS
WHERE table_schema = 'db_name'
[AND column_name LIKE 'wild']

SHOW EVENTS
[FROM db_name]
[LIKE 'wild']

```

25.15 The INFORMATION_SCHEMA FILES Table

The **FILES** table provides information about the files in which MySQL tablespace data is stored.

The **FILES** table provides information about **InnoDB** data files. In NDB Cluster, this table also provides information about the files in which NDB Cluster Disk Data tables are stored. For additional information specific to **InnoDB**, see [InnoDB Notes](#), later in this section; for additional information specific to NDB Cluster, see [NDB Notes](#).

The **FILES** table has these columns:

- **FILE_ID**

For **InnoDB**: The tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.

For **NDB**: A file identifier. **FILE_ID** column values are auto-generated.

- **FILE_NAME**

For **InnoDB**: The name of the data file. File-per-table and general tablespaces have an `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. The global temporary tablespace is prefixed by `ibttmp`. The file name includes the file path, which may be relative to the MySQL data directory (the value of the `datadir` system variable).

For **NDB**: The name of an undo log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`. In NDB 8.0, the file name is shown with a relative path; for an undo log file, this path is relative to the directory `DataDir/ndb_NodeId_fs/LG`; for a data file, it is relative to the directory `DataDir/ndb_NodeId_fs/TS`. This means, for example, that the name of a data file created with `ALTER TABLESPACE ts ADD DATAFILE 'data_2.dat' INITIAL SIZE 256M` is shown as `./data_2.dat`.

- **FILE_TYPE**

For **InnoDB**: The tablespace file type. There are three possible file types for **InnoDB** files. **TABLESPACE** is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. **TEMPORARY** is the file type for temporary tablespaces. **UNDO LOG** is the file type for undo tablespaces, which hold undo records.

For **NDB**: One of the values **UNDO LOG** or **DATAFILE**. Prior to NDB 8.0.13, **TABLESPACE** was also a possible value.

- **TABLESPACE_NAME**

For **InnoDB**: The SQL name for the tablespace. A general tablespace name is the `SYS_TABLESPACES.NAME` value. For other tablespace files, names start with `innodb_`, such as `innodb_system`, `innodb_undo`, and `innodb_file_per_table`. The file-per-table tablespace name format is `innodb_file_per_table_##`, where `##` is the tablespace ID.

For **NDB**: The name of the tablespace with which the file is associated.

- `TABLE_CATALOG`

This value is always empty.

- `TABLE_SCHEMA`

This is always `NULL`.

- `TABLE_NAME`

This is always `NULL`.

- `LOGFILE_GROUP_NAME`

For `InnoDB`: This is always `NULL`.

For `NDB`: The name of the log file group to which the log file or data file belongs.

- `LOGFILE_GROUP_NUMBER`

For `InnoDB`: This is always `NULL`.

For `NDB`: For a Disk Data undo log file, the auto-generated ID number of the log file group to which the log file belongs. This is the same as the value shown for the `id` column in the `ndbinfo.dict_obj_info` table and the `log_id` column in the `ndbinfo.logspaces` and `ndbinfo.logspaces` tables for this undo log file.

- `ENGINE`

For `InnoDB`: This value is always `InnoDB`.

For `NDB`: This value is always `ndbcluster`.

- `FULLTEXT_KEYS`

This is always `NULL`.

- `DELETED_ROWS`

This is always `NULL`.

- `UPDATE_COUNT`

This is always `NULL`.

- `FREE_EXTENTS`

For `InnoDB`: The number of fully free extents in the current data file.

For `NDB`: The number of extents which have not yet been used by the file.

- `TOTAL_EXTENTS`

For `InnoDB`: The number of full extents used in the current data file. Any partial extent at the end of the file is not counted.

For `NDB`: The total number of extents allocated to the file.

- `EXTENT_SIZE`

For `InnoDB`: Extent size is 1048576 (1MB) for files with a 4KB, 8KB, or 16KB page size. Extent size is 2097152 bytes (2MB) for files with a 32KB page size, and 4194304 (4MB) for files with a 64KB page size. `FILES` does not report `InnoDB` page size. Page size is defined by the

`innodb_page_size` system variable. Extent size information can also be retrieved from the `INNODB_TABLESPACES` table where `FILES.FILE_ID = INNODB_TABLESPACES.SPACE`.

For **NDB**: The size of an extent for the file in bytes.

- `INITIAL_SIZE`

For **InnoDB**: The initial size of the file in bytes.

For **NDB**: The size of the file in bytes. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

- `MAXIMUM_SIZE`

For **InnoDB**: The maximum number of bytes permitted in the file. The value is `NULL` for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum global temporary tablespace file size is defined by `innodb_temp_data_file_path`. A `NULL` value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.

For **NDB**: This value is always the same as the `INITIAL_SIZE` value.

- `AUTOEXTEND_SIZE`

For **InnoDB**: `AUTOEXTEND_SIZE` is the auto-extend size defined by `innodb_data_file_path` for the system tablespace, or by `innodb_temp_data_file_path` for the global temporary tablespace.

For **NDB**: This is always `NULL`.

- `CREATION_TIME`

This is always `NULL`.

- `LAST_UPDATE_TIME`

This is always `NULL`.

- `LAST_ACCESS_TIME`

This is always `NULL`.

- `RECOVER_TIME`

This is always `NULL`.

- `TRANSACTION_COUNTER`

This is always `NULL`.

- `VERSION`

For **InnoDB**: This is always `NULL`.

For **NDB**: The version number of the file.

- `ROW_FORMAT`

For **InnoDB**: This is always `NULL`.

For **NDB**: One of `FIXED` or `DYNAMIC`.

- `TABLE_ROWS`

This is always `NULL`.

- `AVG_ROW_LENGTH`

This is always `NULL`.

- `DATA_LENGTH`

This is always `NULL`.

- `MAX_DATA_LENGTH`

This is always `NULL`.

- `INDEX_LENGTH`

This is always `NULL`.

- `DATA_FREE`

For `InnoDB`: The total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.

For `NDB`: This is always `NULL`.

- `CREATE_TIME`

This is always `NULL`.

- `UPDATE_TIME`

This is always `NULL`.

- `CHECK_TIME`

This is always `NULL`.

- `CHECKSUM`

This is always `NULL`.

- `STATUS`

For `InnoDB`: This value is `NORMAL` by default. `InnoDB` file-per-table tablespaces may report `IMPORTING`, which indicates that the tablespace is not yet available.

For `NDB`: For `NDB Cluster Disk Data` files, this value is always `NORMAL`.

- `EXTRA`

For `InnoDB`: This is always `NULL`.

For `NDB`: (*NDB 8.0.15 and later*) For undo log files, this column shows the undo log buffer size; for data files, it is always `NULL`. A more detailed explanation is provided in the next few paragraphs.

`NDBCLUSTER` stores a copy of each data file and each undo log file on each data node in the cluster. In `NDB 8.0.13` and later, the `FILES` table contains only one row for each such file. Suppose that you run the following two statements on an `NDB Cluster` with four data nodes:

```
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;
```

```
CREATE TABLESPACE myts
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP mygroup
  INITIAL_SIZE 256M
  ENGINE NDBCLUSTER;
```

After running these two statements successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE ENGINE = 'ndbcluster';
```

LOGFILE_GROUP_NAME	FILE_TYPE	EXTRA
mygroup	UNDO LOG	UNDO_BUFFER_SIZE=8388608
mygroup	DATAFILE	NULL

The undo log buffer size information was inadvertently removed in NDB 8.0.13, but was restored in NDB 8.0.15. (Bug #92796, Bug #28800252)

Prior to NDB 8.0.13, the `FILES` table contained a row for each of these files on each data node the file belonged to, as well as the size of its undo buffer. In these versions, the result of the same query contains one row per data node, as shown here:

LOGFILE_GROUP_NAME	FILE_TYPE	EXTRA
mygroup	UNDO LOG	CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608
mygroup	UNDO LOG	CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608
mygroup	UNDO LOG	CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608
mygroup	UNDO LOG	CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608
mygroup	DATAFILE	CLUSTER_NODE=5
mygroup	DATAFILE	CLUSTER_NODE=6
mygroup	DATAFILE	CLUSTER_NODE=7
mygroup	DATAFILE	CLUSTER_NODE=8

Notes

- `FILES` is a nonstandard `INFORMATION_SCHEMA` table.
- As of MySQL 8.0.21, you must have the `PROCESS` privilege to query this table.

InnoDB Notes

The following notes apply to `InnoDB` data files.

- Data reported by `FILES` is reported from the `InnoDB` in-memory cache for open files. By comparison, `INNODB_DATAFILES` reports data from the `InnoDB SYS_DATAFILES` internal data dictionary table.
- The data reported by `FILES` includes global temporary tablespace data. This data is not available in the `InnoDB SYS_DATAFILES` internal data dictionary table, and is therefore not reported by `INNODB_DATAFILES`.
- Undo tablespace data is reported by `FILES` when separate undo tablespaces are present, which they are by default in MySQL 8.0
- The following query returns all data pertinent to `InnoDB` tablespaces.

```
SELECT
  FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
  TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE,
```

```
AUTOEXTEND_SIZE, DATA_FREE, STATUS
FROM INFORMATION_SCHEMA.FILES WHERE ENGINE='InnoDB'\G
```

NDB Notes

- The `FILES` table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual `NDB` tables. However, it is possible to see how much space is allocated for each `NDB` table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using `ndb_desc`.
- The `CREATION_TIME`, `LAST_UPDATE_TIME`, and `LAST_ACCESSED` values are as reported by the operating system, and are not supplied by the `NDB` storage engine. Where no value is provided by the operating system, these columns display `NULL`.
- The difference between the `TOTAL_EXTENTS` and `FREE_EXTENTS` columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = './myfile.dat';
```

To approximate the amount of disk space in use by the file, multiply that difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = './myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = './myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. For more information, see [Section 13.1.21, “CREATE TABLESPACE Statement”](#).

- Prior to `NDB 8.0.13`, an additional row was present in the `FILES` table following the creation of a logfile group, having `NULL` in the `FILE_NAME` column. In `NDB 8.0.13` and later, this row — which did not correspond to any file—is no longer shown, and it is necessary to query the `ndbinfo.logspaces` table to obtain undo log file usage information. See the description of this table as well as [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#), for more information.

The remainder of the discussion in this item applies only to `NDB 8.0.12` and earlier. For the row having `NULL` in the `FILE_NAME` column, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `UNDO LOG`, and that of the `STATUS` column is always `NORMAL`. The value of the `ENGINE` column is always `ndbcluster`.

The `FREE_EXTENTS` column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
      ADD UNDOFILE 'undofile.dat'
      INITIAL_SIZE = 16M
      UNDO_BUFFER_SIZE = 1M
      ENGINE = NDB;
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
      FILE_NAME AS File,
      FREE_EXTENTS AS Free,
      TOTAL_EXTENTS AS Total,
      EXTENT_SIZE AS Size,
      INITIAL_SIZE AS Initial
      FROM INFORMATION_SCHEMA.FILES;
```

File	Free	Total	Size	Initial
undofile.dat	NULL	4194304	4	16777216
NULL	4184068	NULL	4	NULL

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
      ADD UNDOFILE 'undofile02.dat'
      INITIAL_SIZE = 4M
      ENGINE = NDB;
```

```
mysql> SELECT DISTINCT
      FILE_NAME AS File,
      FREE_EXTENTS AS Free,
      TOTAL_EXTENTS AS Total,
      EXTENT_SIZE AS Size,
      INITIAL_SIZE AS Initial
      FROM INFORMATION_SCHEMA.FILES;
```

File	Free	Total	Size	Initial
undofile.dat	NULL	4194304	4	16777216
undofile02.dat	NULL	1048576	4	4194304
NULL	5223944	NULL	4	NULL

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
      FREE_EXTENTS AS 'Free Extents',
      FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
      FROM INFORMATION_SCHEMA.FILES
      WHERE LOGFILE_GROUP_NAME = 'lg1'
      AND FILE_NAME IS NULL;
```

Free Extents	Free Bytes
5223944	20895776

```
+-----+-----+
```

If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
      ADD DATAFILE 'data1.dat'
      USE LOGFILE GROUP lg1
      INITIAL_SIZE 512M
      ENGINE = NDB;

mysql> CREATE TABLE dd (
      c1 INT NOT NULL PRIMARY KEY,
      c2 INT,
      c3 DATE
    )
      TABLESPACE ts1 STORAGE DISK
      ENGINE = NDB;

mysql> INSERT INTO dd VALUES
      (NULL, 1234567890, '2007-02-02'),
      (NULL, 1126789005, '2007-02-03'),
      (NULL, 1357924680, '2007-02-04'),
      (NULL, 1642097531, '2007-02-05');

mysql> SELECT
      FREE_EXTENTS AS 'Free Extents',
      FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
      FROM INFORMATION_SCHEMA.FILES
      WHERE LOGFILE_GROUP_NAME = 'lg1'
      AND FILE_NAME IS NULL;
```

Free Extents	Free Bytes
5207565	20830260

- Prior to NDB 8.0.13, an additional row was present in the `FILES` table for each NDB Cluster Disk Data tablespace. Because it did not correspond to an actual file, it was removed in NDB 8.0.13. This row had `NULL` for the value of the `FILE_NAME` column, the value of the `FILE_ID` column was always 0, that of the `FILE_TYPE` column was always `TABLESPACE`, that of the `STATUS` column was always `NORMAL`, and the value of the `ENGINE` column is always `NDBCLUSTER`.

In NDB 8.0.13 and later, you can obtain information about Disk Data tablespaces using the `ndb_desc` utility. For more information, see [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#), as well as the description of `ndb_desc`.

- For additional information, and examples of creating, dropping, and obtaining information about NDB Cluster Disk Data objects, see [Section 22.5.10, “NDB Cluster Disk Data Tables”](#).

25.16 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints. This table provides no information about functional key parts because they are expressions and the table provides information only about columns.

The `KEY_COLUMN_USAGE` table has these columns:

- `CONSTRAINT_CATALOG`

The name of the catalog to which the constraint belongs. This value is always `def`.

- `CONSTRAINT_SCHEMA`

The name of the schema (database) to which the constraint belongs.

- `CONSTRAINT_NAME`

The name of the constraint.

- [TABLE_CATALOG](#)

The name of the catalog to which the table belongs. This value is always `def`.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE_NAME](#)

The name of the table that has the constraint.

- [COLUMN_NAME](#)

The name of the column that has the constraint.

If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- [ORDINAL_POSITION](#)

The column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- [POSITION_IN_UNIQUE_CONSTRAINT](#)

`NULL` for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- [REFERENCED_TABLE_SCHEMA](#)

The name of the schema referenced by the constraint.

- [REFERENCED_TABLE_NAME](#)

The name of the table referenced by the constraint.

- [REFERENCED_COLUMN_NAME](#)

The name of the column referenced by the constraint.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the [KEY_COLUMN_USAGE](#) table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.

For **NDB**: This value is always **NULL**.

- One row with **CONSTRAINT_NAME** = 'CO', **TABLE_NAME** = 't3', **COLUMN_NAME** = 's2', **ORDINAL_POSITION** = 1, **POSITION_IN_UNIQUE_CONSTRAINT** = 1.

25.17 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The **ndb_transid_mysql_connection_map** table provides a mapping between **NDB** transactions, **NDB** transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This information is used when populating the **server_operations** and **server_transactions** tables of the **ndbinfo** NDB Cluster information database.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
mysql_connection_id		MySQL Server connection ID
node_id		Transaction coordinator node ID
ndb_transid		NDB transaction ID

The **mysql_connection_id** is the same as the connection or session ID shown in the output of **SHOW PROCESSLIST**.

There are no **SHOW** statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an **INFORMATION_SCHEMA** plugin; you can verify that it is supported by checking the output of **SHOW PLUGINS**. If **ndb_transid_mysql_connection_map** support is enabled, the output from this statement includes a plugin having this name, of type **INFORMATION_SCHEMA**, and having status **ACTIVE**, as shown here (using emphasized text):

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
mysql_native_password	ACTIVE	AUTHENTICATION	NULL	GPL
CSV	ACTIVE	STORAGE ENGINE	NULL	GPL
MEMORY	ACTIVE	STORAGE ENGINE	NULL	GPL
MRG_MYISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
PERFORMANCE_SCHEMA	ACTIVE	STORAGE ENGINE	NULL	GPL
BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
ARCHIVE	ACTIVE	STORAGE ENGINE	NULL	GPL
ndbcluster	ACTIVE	STORAGE ENGINE	NULL	GPL
ndbinfo	ACTIVE	STORAGE ENGINE	NULL	GPL
ndb_transid_mysql_connection_map	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
InnoDB	ACTIVE	STORAGE ENGINE	NULL	GPL
INNODB_TRX	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_LOCKS	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_LOCK_WAITS	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_CMP	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_CMP_RESET	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_CMPMEM	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
INNODB_CMPMEM_RESET	ACTIVE	INFORMATION_SCHEMA	NULL	GPL
partition	ACTIVE	STORAGE ENGINE	NULL	GPL

22 rows in set (0.00 sec)

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the **--ndb-transid-mysql-connection-map** option. If the plugin is disabled, the status is shown by **SHOW PLUGINS** as **DISABLED**. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the NDB Cluster distribution, or one built from the NDB Cluster sources with [NDB](#) storage engine support enabled. It is not available in the standard MySQL 8.0 Server.

25.18 The INFORMATION_SCHEMA KEYWORDS Table

The [KEYWORDS](#) table lists the words considered keywords by MySQL and, for each one, indicates whether it is reserved. Reserved keywords may require special treatment in some contexts, such as special quoting when used as identifiers (see [Section 9.3, “Keywords and Reserved Words”](#)). This table provides applications a runtime source of MySQL keyword information.

Prior to MySQL 8.0.13, selecting from the [KEYWORDS](#) table with no default database selected produced an error. (Bug #90160, Bug #27729859)

The [KEYWORDS](#) table has these columns:

- [WORD](#)

The keyword.

- [RESERVED](#)

An integer indicating whether the keyword is reserved (1) or nonreserved (0).

These queries lists all keywords, all reserved keywords, and all nonreserved keywords, respectively:

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED = 1;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED = 0;
```

The latter two queries are equivalent to:

```
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE NOT RESERVED;
```

If you build MySQL from source, the build process generates a [keyword_list.h](#) header file containing an array of keywords and their reserved status. This file can be found in the [sql](#) directory under the build directory. This file may be useful for applications that require a static source for the keyword list.

25.19 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The [OPTIMIZER_TRACE](#) table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the [optimizer_trace](#) system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

The [OPTIMIZER_TRACE](#) table has these columns:

- [QUERY](#)

The text of the traced statement.

- [TRACE](#)

The trace, in [JSON](#) format.

- [MISSING_BYTES_BEYOND_MAX_MEM_SIZE](#)

Each remembered trace is a string that is extended as optimization progresses and appends data to it. The [optimizer_trace_max_mem_size](#) variable sets a limit on the total amount of memory

used by all currently remembered traces. If this limit is reached, the current trace is not extended (and thus is incomplete), and the `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` column shows the number of bytes missing from the trace.

- `INSUFFICIENT_PRIVILEGES`

If a traced query uses views or stored routines that have `SQL SECURITY` with a value of `DEFINER`, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and `INSUFFICIENT_PRIVILEGES` has a value of 1. Otherwise, the value is 0.

25.20 The INFORMATION_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The `PARAMETERS` table does not include built-in SQL functions or user-defined functions (UDFs).

The `PARAMETERS` table has these columns:

- `SPECIFIC_CATALOG`

The name of the catalog to which the routine containing the parameter belongs. This value is always `def`.

- `SPECIFIC_SCHEMA`

The name of the schema (database) to which the routine containing the parameter belongs.

- `SPECIFIC_NAME`

The name of the routine containing the parameter.

- `ORDINAL_POSITION`

For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the `RETURNS` clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:

- The `ORDINAL_POSITION` value is 0.
- The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.

- `PARAMETER_MODE`

The mode of the parameter. This value is one of `IN`, `OUT`, or `INOUT`. For a stored function return value, this value is `NULL`.

- `PARAMETER_NAME`

The name of the parameter. For a stored function return value, this value is `NULL`.

- `DATA_TYPE`

The parameter data type.

The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- `CHARACTER_MAXIMUM_LENGTH`

For string parameters, the maximum length in characters.

- [CHARACTER_OCTET_LENGTH](#)

For string parameters, the maximum length in bytes.

- [NUMERIC_PRECISION](#)

For numeric parameters, the numeric precision.

- [NUMERIC_SCALE](#)

For numeric parameters, the numeric scale.

- [DATETIME_PRECISION](#)

For temporal parameters, the fractional seconds precision.

- [CHARACTER_SET_NAME](#)

For character string parameters, the character set name.

- [COLLATION_NAME](#)

For character string parameters, the collation name.

- [DTD_IDENTIFIER](#)

The parameter data type.

The [DATA_TYPE](#) value is the type name only with no other information. The [DTD_IDENTIFIER](#) value contains the type name and possibly other information such as the precision or length.

- [ROUTINE_TYPE](#)

[PROCEDURE](#) for stored procedures, [FUNCTION](#) for stored functions.

25.21 The INFORMATION_SCHEMA PARTITIONS Table

The [PARTITIONS](#) table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see [Chapter 23, Partitioning](#).

The [PARTITIONS](#) table has these columns:

- [TABLE_CATALOG](#)

The name of the catalog to which the table belongs. This value is always `def`.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE_NAME](#)

The name of the table containing the partition.

- [PARTITION_NAME](#)

The name of the partition.

- [SUBPARTITION_NAME](#)

If the [PARTITIONS](#) table row represents a subpartition, the name of subpartition; otherwise `NULL`.

For `NDB`: This value is always `NULL`.

- `PARTITION_ORDINAL_POSITION`

All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.

- `SUBPARTITION_ORDINAL_POSITION`

Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- `PARTITION_METHOD`

One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 23.2, “Partitioning Types”](#).

- `SUBPARTITION_METHOD`

One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 23.2.6, “Subpartitioning”](#).

- `PARTITION_EXPRESSION`

The expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table row for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
```

- `SUBPARTITION_EXPRESSION`

This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, this column is `NULL`.

- `PARTITION_DESCRIPTION`

This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a list of comma-separated integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- `TABLE_ROWS`

The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column is only an estimated value used in SQL optimization, and may not always be exact.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `AVG_ROW_LENGTH`

The average length of the rows stored in this partition or subpartition, in bytes. This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `DATA_LENGTH`

The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `MAX_DATA_LENGTH`

The maximum number of bytes that can be stored in this partition or subpartition.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `INDEX_LENGTH`

The length of the index file for this partition or subpartition, in bytes.

For partitions of `NDB` tables, whether the tables use implicit or explicit partitioning, the `INDEX_LENGTH` column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- `DATA_FREE`

The number of bytes allocated to the partition or subpartition but not used.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `CREATE_TIME`

The time that the partition or subpartition was created.

- `UPDATE_TIME`

The time that the partition or subpartition was last modified.

- `CHECK_TIME`

The last time that the table to which this partition or subpartition belongs was checked.

For partitioned `InnoDB` tables, the value is always `NULL`.

- `CHECKSUM`

The checksum value, if any; otherwise `NULL`.

- `PARTITION_COMMENT`

The text of the comment, if the partition has one. If not, this value is empty.

The maximum length for a partition comment is defined as 1024 characters, and the display width of the `PARTITION_COMMENT` column is also 1024, characters to match this limit.

- `NODEGROUP`

This is the nodegroup to which the partition belongs. This is relevant only to NDB Cluster tables; otherwise, the value is always 0.

- `TABLESPACE_NAME`

The name of the tablespace to which the partition belongs. The value is always `DEFAULT`, unless the table uses the `NDB` storage engine (see the *Notes* at the end of this section).

Notes

- `PARTITIONS` is a nonstandard `INFORMATION_SCHEMA` table.
- A table using any storage engine other than `NDB` and which is not partitioned has one row in the `PARTITIONS` table. However, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. Also, the `PARTITION_COMMENT` column in this case is blank.
- An `NDB` table which is not explicitly partitioned has one row in the `PARTITIONS` table for each data node in the NDB cluster. For each such row:
 - The `SUBPARTITION_NAME`, `SUBPARTITION_ORDINAL_POSITION`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, `CREATE_TIME`, `UPDATE_TIME`, `CHECK_TIME`, `CHECKSUM`, and `TABLESPACE_NAME` columns are all `NULL`.
 - The `PARTITION_METHOD` is always `AUTO`.
 - The `NODEGROUP` column is `default`.
 - The `PARTITION_EXPRESSION` and `PARTITION_COMMENT` columns are empty.

25.22 The INFORMATION_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

The `PLUGINS` table has these columns:

- `PLUGIN_NAME`

The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- `PLUGIN_VERSION`

The version from the plugin's general type descriptor.

- `PLUGIN_STATUS`

The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETING`, or `DELETED`.

- `PLUGIN_TYPE`

The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

- `PLUGIN_TYPE_VERSION`

The version from the plugin's type-specific descriptor.

- `PLUGIN_LIBRARY`

The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- `PLUGIN_LIBRARY_VERSION`

The plugin API interface version.

- `PLUGIN_AUTHOR`

The plugin author.

- `PLUGIN_DESCRIPTION`

A short description of the plugin.

- `PLUGIN_LICENSE`

How the plugin is licensed (for example, `GPL`).

- `LOAD_OPTION`

How the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

Notes

- `PLUGINS` is a nonstandard `INFORMATION_SCHEMA` table.
- For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.
- For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [The MySQL Plugin API](#).

Plugin information is also available from the `SHOW PLUGINS` statement. See [Section 13.7.7.25, “SHOW PLUGINS Statement”](#). These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

25.23 The INFORMATION_SCHEMA PROCESSLIST Table

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The `PROCESSLIST` table is one source of process information. For a comparison of this table with other sources, see [Sources of Process Information](#).

The `PROCESSLIST` table has these columns:

- `ID`

The connection identifier. This is the same value displayed in the `Id` column of the `SHOW PROCESSLIST` statement, displayed in the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- **USER**

The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see [Section 24.4, “Using the Event Scheduler”](#)).

Note

A `USER` value of `system user` is distinct from the `SYSTEM_USER` privilege. The former designates internal threads. The latter distinguishes the system user and regular user account categories (see [Section 6.2.11, “Account Categories”](#)).

- **HOST**

The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- **DB**

The default database for the thread, or `NULL` if none has been selected.

- **COMMAND**

The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.10, “Server Status Variables”](#).

- **TIME**

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See [Section 17.2.3, “Replication Threads”](#).

- **STATE**

An action, event, or state that indicates what the thread is doing. For descriptions of `STATE` values, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **INFO**

The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `INFO` value shows the `SELECT` statement.

Notes

- `PROCESSLIST` is a nonstandard `INFORMATION_SCHEMA` table.

- Like the output from the `SHOW PROCESSLIST` statement, the `PROCESSLIST` table provides information about all threads, even those belonging to other users, if you have the `PROCESS` privilege. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.
- If an SQL statement refers to the `PROCESSLIST` table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST

SHOW FULL PROCESSLIST
```

25.24 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILE` and `SHOW PROFILES` statements (see [Section 13.7.7.30](#), “`SHOW PROFILE` Statement”). The table is empty unless the `profiling` session variable is set to 1.

Note

This table is deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 26.19.1](#), “Query Profiling Using Performance Schema”.

The `PROFILING` table has these columns:

- `QUERY_ID`
A numeric statement identifier.
- `SEQ`
A sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE`
The profiling state to which the row measurements apply.
- `DURATION`
How long statement execution remained in the given state, in seconds.
- `CPU_USER`, `CPU_SYSTEM`
User and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY`, `CONTEXT_INVOLUNTARY`
How many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN`, `BLOCK_OPS_OUT`
The number of block input and output operations.
- `MESSAGES_SENT`, `MESSAGES_RECEIVED`
The number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR`, `PAGE_FAULTS_MINOR`
The number of major and minor page faults.

- [SWAPS](#)

How many swaps occurred.

- [SOURCE_FUNCTION](#), [SOURCE_FILE](#), and [SOURCE_LINE](#)

Information indicating where in the source code the profiled state executes.

Notes

- [PROFILING](#) is a nonstandard [INFORMATION_SCHEMA](#) table.

Profiling information is also available from the [SHOW PROFILE](#) and [SHOW PROFILES](#) statements. See [Section 13.7.7.30, “SHOW PROFILE Statement”](#). For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;  
  
SELECT STATE, FORMAT(DURATION, 6) AS DURATION  
FROM INFORMATION_SCHEMA.PROFILING  
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

25.25 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The [REFERENTIAL_CONSTRAINTS](#) table provides information about foreign keys.

The [REFERENTIAL_CONSTRAINTS](#) table has these columns:

- [CONSTRAINT_CATALOG](#)

The name of the catalog to which the constraint belongs. This value is always [def](#).

- [CONSTRAINT_SCHEMA](#)

The name of the schema (database) to which the constraint belongs.

- [CONSTRAINT_NAME](#)

The name of the constraint.

- [UNIQUE_CONSTRAINT_CATALOG](#)

The name of the catalog containing the unique constraint that the constraint references. This value is always [def](#).

- [UNIQUE_CONSTRAINT_SCHEMA](#)

The name of the schema containing the unique constraint that the constraint references.

- [UNIQUE_CONSTRAINT_NAME](#)

The name of the unique constraint that the constraint references.

- [MATCH_OPTION](#)

The value of the constraint [MATCH](#) attribute. The only valid value at this time is [NONE](#).

- [UPDATE_RULE](#)

The value of the constraint [ON UPDATE](#) attribute. The possible values are [CASCADE](#), [SET NULL](#), [SET DEFAULT](#), [RESTRICT](#), [NO ACTION](#).

- [DELETE_RULE](#)

The value of the constraint `ON DELETE` attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- `TABLE_NAME`

The name of the table. This value is the same as in the `TABLE_CONSTRAINTS` table.

- `REFERENCED_TABLE_NAME`

The name of the table referenced by the constraint.

25.26 The INFORMATION_SCHEMA RESOURCE_GROUPS Table

The `RESOURCE_GROUPS` table provides access to information about resource groups. For general discussion of the resource group capability, see [Section 5.1.15, “Resource Groups”](#).

You can see information only for columns for which you have some privilege.

The `RESOURCE_GROUPS` table has these columns:

- `RESOURCE_GROUP_NAME`

The name of the resource group.

- `RESOURCE_GROUP_TYPE`

The resource group type, either `SYSTEM` or `USER`.

- `RESOURCE_GROUP_ENABLED`

Whether the resource group is enabled (1) or disabled (0);

- `VCPU_IDS`

The CPU affinity; that is, the set of virtual CPUs that the resource group can use. The value is a list of comma-separated CPU numbers or ranges.

- `THREAD_PRIORITY`

The priority for threads assigned to the resource group. The priority ranges from -20 (highest priority) to 19 (lowest priority). System resource groups have a priority that ranges from -20 to 0. User resource groups have a priority that ranges from 0 to 19.

25.27 The INFORMATION_SCHEMA ROLE_COLUMN_GRANTS Table

The `ROLE_COLUMN_GRANTS` table (available as of MySQL 8.0.19) provides information about the column privileges for roles that are available to or granted by the currently enabled roles.

The `ROLE_COLUMN_GRANTS` table has these columns:

- `GRANTOR`

The user name part of the account that granted the role.

- `GRANTOR_HOST`

The host name part of the account that granted the role.

- `GRANTEE`

The user name part of the account to which the role is granted.

- [GRANTEE_HOST](#)

The host name part of the account to which the role is granted.

- [TABLE_CATALOG](#)

The name of the catalog to which the role applies. This value is always [def](#).

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the role applies.

- [TABLE_NAME](#)

The name of the table to which the role applies.

- [COLUMN_NAME](#)

The name of the column to which the role applies.

- [PRIVILEGE_TYPE](#)

The privilege granted. The value can be any privilege that can be granted at the column level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per column privilege held by the grantee.

- [IS_GRANTABLE](#)

[YES](#) or [NO](#), depending on whether the role is grantable to other accounts.

25.28 The INFORMATION_SCHEMA ROLE_ROUTINE_GRANTS Table

The [ROLE_ROUTINE_GRANTS](#) table (available as of MySQL 8.0.19) provides information about the routine privileges for roles that are available to or granted by the currently enabled roles.

The [ROLE_ROUTINE_GRANTS](#) table has these columns:

- [GRANTOR](#)

The user name part of the account that granted the role.

- [GRANTOR_HOST](#)

The host name part of the account that granted the role.

- [GRANTEE](#)

The user name part of the account to which the role is granted.

- [GRANTEE_HOST](#)

The host name part of the account to which the role is granted.

- [SPECIFIC_CATALOG](#)

The name of the catalog to which the routine belongs. This value is always [def](#).

- [SPECIFIC_SCHEMA](#)

The name of the schema (database) to which the routine belongs.

- [SPECIFIC_NAME](#)

The name of the routine.

- [ROUTINE_CATALOG](#)

The name of the catalog to which the routine belongs. This value is always `def`.

- [ROUTINE_SCHEMA](#)

The name of the schema (database) to which the routine belongs.

- [ROUTINE_NAME](#)

The name of the routine.

- [PRIVILEGE_TYPE](#)

The privilege granted. The value can be any privilege that can be granted at the routine level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per column privilege held by the grantee.

- [IS_GRANTABLE](#)

`YES` or `NO`, depending on whether the role is grantable to other accounts.

25.29 The INFORMATION_SCHEMA ROLE_TABLE_GRANTS Table

The [ROLE_TABLE_GRANTS](#) table (available as of MySQL 8.0.19) provides information about the table privileges for roles that are available to or granted by the currently enabled roles.

The [ROLE_TABLE_GRANTS](#) table has these columns:

- [GRANTOR](#)

The user name part of the account that granted the role.

- [GRANTOR_HOST](#)

The host name part of the account that granted the role.

- [GRANTEE](#)

The user name part of the account to which the role is granted.

- [GRANTEE_HOST](#)

The host name part of the account to which the role is granted.

- [TABLE_CATALOG](#)

The name of the catalog to which the role applies. This value is always `def`.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the role applies.

- [TABLE_NAME](#)

The name of the table to which the role applies.

- [PRIVILEGE_TYPE](#)

The privilege granted. The value can be any privilege that can be granted at the table level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per column privilege held by the grantee.

- [IS_GRANTABLE](#)

[YES](#) or [NO](#), depending on whether the role is grantable to other accounts.

25.30 The INFORMATION_SCHEMA ROUTINES Table

The [ROUTINES](#) table provides information about stored routines (stored procedures and stored functions). The [ROUTINES](#) table does not include built-in SQL functions or user-defined functions (UDFs).

The [ROUTINES](#) table has these columns:

- [SPECIFIC_NAME](#)

The name of the routine.

- [ROUTINE_CATALOG](#)

The name of the catalog to which the routine belongs. This value is always [def](#).

- [ROUTINE_SCHEMA](#)

The name of the schema (database) to which the routine belongs.

- [ROUTINE_NAME](#)

The name of the routine.

- [ROUTINE_TYPE](#)

[PROCEDURE](#) for stored procedures, [FUNCTION](#) for stored functions.

- [DATA_TYPE](#)

If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

The [DATA_TYPE](#) value is the type name only with no other information. The [DTD_IDENTIFIER](#) value contains the type name and possibly other information such as the precision or length.

- [CHARACTER_MAXIMUM_LENGTH](#)

For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is [NULL](#).

- [CHARACTER_OCTET_LENGTH](#)

For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is [NULL](#).

- [NUMERIC_PRECISION](#)

For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is [NULL](#).

- [NUMERIC_SCALE](#)

For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is [NULL](#).

- [DATETIME_PRECISION](#)

For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is [NULL](#).

- [CHARACTER_SET_NAME](#)

For stored function character string return values, the character set name. If the routine is a stored procedure, this value is [NULL](#).

- [COLLATION_NAME](#)

For stored function character string return values, the collation name. If the routine is a stored procedure, this value is [NULL](#).

- [DTD_IDENTIFIER](#)

If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

The [DATA_TYPE](#) value is the type name only with no other information. The [DTD_IDENTIFIER](#) value contains the type name and possibly other information such as the precision or length.

- [ROUTINE_BODY](#)

The language used for the routine definition. This value is always [SQL](#).

- [ROUTINE_DEFINITION](#)

The text of the SQL statement executed by the routine.

- [EXTERNAL_NAME](#)

This value is always [NULL](#).

- [EXTERNAL_LANGUAGE](#)

The language of the stored routine. The value is read from the [external_language](#) column of the [mysql.routines](#) data dictionary table.

- [PARAMETER_STYLE](#)

This value is always [SQL](#).

- [IS_DETERMINISTIC](#)

[YES](#) or [NO](#), depending on whether the routine is defined with the [DETERMINISTIC](#) characteristic.

- [SQL_DATA_ACCESS](#)

The data access characteristic for the routine. The value is one of [CONTAINS SQL](#), [NO SQL](#), [READS SQL DATA](#), or [MODIFIES SQL DATA](#).

- [SQL_PATH](#)

This value is always [NULL](#).

- [SECURITY_TYPE](#)

The routine [SQL SECURITY](#) characteristic. The value is one of [DEFINER](#) or [INVOKER](#).

- [CREATED](#)

The date and time when the routine was created. This is a [TIMESTAMP](#) value.

- [LAST_ALTERED](#)

The date and time when the routine was last modified. This is a [TIMESTAMP](#) value. If the routine has not been modified since its creation, this value is the same as the [CREATED](#) value.

- [SQL_MODE](#)

The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see [Section 5.1.11, “Server SQL Modes”](#).

- [ROUTINE_COMMENT](#)

The text of the comment, if the routine has one. If not, this value is empty.

- [DEFINER](#)

The account named in the [DEFINER](#) clause (often the user who created the routine), in `'user_name'@'host_name'` format.

- [CHARACTER_SET_CLIENT](#)

The session value of the `character_set_client` system variable when the routine was created.

- [COLLATION_CONNECTION](#)

The session value of the `collation_connection` system variable when the routine was created.

- [DATABASE_COLLATION](#)

The collation of the database with which the routine is associated.

Notes

- To see information about a routine, you must be the user named as the routine [DEFINER](#), have the [SHOW_ROUTINE](#) privilege, have the [SELECT](#) privilege at the global level, or have the [CREATE ROUTINE](#), [ALTER ROUTINE](#), or [EXECUTE](#) privilege granted at a scope that includes the routine. The [ROUTINE_DEFINITION](#) column is `NULL` if you have only [CREATE ROUTINE](#), [ALTER ROUTINE](#), or [EXECUTE](#).
- Information about stored function return values is also available in the [PARAMETERS](#) table. The return value row for a stored function can be identified as the row that has an [ORDINAL_POSITION](#) value of 0.

25.31 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the [SCHEMATA](#) table provides information about databases.

The [SCHEMATA](#) table has these columns:

- [CATALOG_NAME](#)

The name of the catalog to which the schema belongs. This value is always `def`.

- [SCHEMA_NAME](#)

The name of the schema.

- [DEFAULT_CHARACTER_SET_NAME](#)

The schema default character set.

- [DEFAULT_COLLATION_NAME](#)

The schema default collation.

- [SQL_PATH](#)

This value is always `NULL`.

- [DEFAULT_ENCRYPTION](#)

The schema default encryption. This column was added in MySQL 8.0.16.

Schema names are also available from the [SHOW DATABASES](#) statement. See [Section 13.7.7.14](#), “[SHOW DATABASES Statement](#)”. The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

You see only those databases for which you have some kind of privilege, unless you have the global [SHOW DATABASES](#) privilege.

Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with [SHOW DATABASES](#) or by examining the [SCHEMATA](#) table of [INFORMATION_SCHEMA](#), except databases that have been restricted at the database level by partial revokes.

Notes

- The [SCHEMATA_EXTENSIONS](#) table augments the [SCHEMATA](#) table with information about schema options.

25.32 The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table

The [SCHEMATA_EXTENSIONS](#) table (available as of MySQL 8.0.22) augments the [SCHEMATA](#) table with information about schema options.

The [SCHEMATA_EXTENSIONS](#) table has these columns:

- [CATALOG_NAME](#)

The name of the catalog to which the schema belongs. This value is always `def`.

- [SCHEMA_NAME](#)

The name of the schema.

- [OPTIONS](#)

The options for the schema. If the schema is read only, the value contains `READ ONLY=1`. If the schema is not read only, no `READ ONLY` option appears.

Example

```
mysql> ALTER SCHEMA mydb READ ONLY = 1;
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA_EXTENSIONS
WHERE SCHEMA_NAME = 'mydb';
+-----+-----+-----+
| CATALOG_NAME | SCHEMA_NAME | OPTIONS          |
+-----+-----+-----+
| def          | mydb        | READ ONLY=1     |
+-----+-----+-----+
mysql> ALTER SCHEMA mydb READ ONLY = 0;
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA_EXTENSIONS
      WHERE SCHEMA_NAME = 'mydb';
```

CATALOG_NAME	SCHEMA_NAME	OPTIONS
def	mydb	

Notes

- `SCHEMATA_EXTENSIONS` is a nonstandard `INFORMATION_SCHEMA` table.

25.33 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. It takes its values from the `mysql.db` system table.

The `SCHEMA_PRIVILEGES` table has these columns:

- `GRANTEE`

The name of the account to which the privilege is granted, in '`user_name`'@'`host_name`' format.

- `TABLE_CATALOG`

The name of the catalog to which the schema belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the schema level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

Notes

- `SCHEMA_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES
SHOW GRANTS ...
```

25.34 The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

Columns in `STATISTICS` that represent table statistics hold cached values. The `information_schema_stats_expiry` system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To update cached values at any time for a given table, use `ANALYZE TABLE`. To always retrieve the latest statistics directly from storage engines, set

`information_schema_stats_expiry=0`. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

The `STATISTICS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table containing the index belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the index belongs.

- `TABLE_NAME`

The name of the table containing the index.

- `NON_UNIQUE`

0 if the index cannot contain duplicates, 1 if it can.

- `INDEX_SCHEMA`

The name of the schema (database) to which the index belongs.

- `INDEX_NAME`

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `SEQ_IN_INDEX`

The column sequence number in the index, starting with 1.

- `COLUMN_NAME`

The column name. See also the description for the `EXPRESSION` column.

- `COLLATION`

How the column is sorted in the index. This can have values `A` (ascending), `D` (descending), or `NULL` (not sorted).

- `CARDINALITY`

An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

`CARDINALITY` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `SUB_PART`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

**Note**

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 8.3.5, “Column Indexes”](#), and [Section 13.1.15, “CREATE INDEX Statement”](#).

- `PACKED`

Indicates how the key is packed. `NULL` if it is not.

- `NULLABLE`

Contains `YES` if the column may contain `NULL` values and `''` if not.

- `INDEX_TYPE`

The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `COMMENT`

Information about the index not described in its own column, such as `disabled` if the index is disabled.

- `INDEX_COMMENT`

Any comment provided for the index with a `COMMENT` attribute when the index was created.

- `IS_VISIBLE`

Whether the index is visible to the optimizer. See [Section 8.3.12, “Invisible Indexes”](#).

- `EXPRESSION`

MySQL 8.0.13 and higher supports functional key parts (see [Functional Key Parts](#)), which affects both the `COLUMN_NAME` and `EXPRESSION` columns:

- For a nonfunctional key part, `COLUMN_NAME` indicates the column indexed by the key part and `EXPRESSION` is `NULL`.
- For a functional key part, `COLUMN_NAME` column is `NULL` and `EXPRESSION` indicates the expression for the key part.

Notes

- There is no standard `INFORMATION_SCHEMA` table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for `sp_statistics`, except that `QUALIFIER` and `OWNER` are replaced with `CATALOG` and `SCHEMA`, respectively.

Information about table indexes is also available from the `SHOW INDEX` statement. See [Section 13.7.7.22, “SHOW INDEX Statement”](#). The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
```

```
FROM db_name
```

25.35 The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table

The `ST_GEOMETRY_COLUMNS` table provides information about table columns that store spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard, with extensions as noted. MySQL implements `ST_GEOMETRY_COLUMNS` as a view on the `INFORMATION_SCHEMA COLUMNS` table.

The `ST_GEOMETRY_COLUMNS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table containing the column belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the column belongs.

- `TABLE_NAME`

The name of the table containing the column.

- `COLUMN_NAME`

The name of the column.

- `SRS_NAME`

The spatial reference system (SRS) name.

- `SRS_ID`

The spatial reference system ID (SRID).

- `GEOMETRY_TYPE_NAME`

The column data type. Permitted values are: `geometry`, `point`, `linestring`, `polygon`, `multipoint`, `multilinestring`, `multipolygon`, `geometrycollection`. This column is a MySQL extension to the standard.

25.36 The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table

The `ST_SPATIAL_REFERENCE_SYSTEMS` table provides information about available spatial reference systems (SRSs) for spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard.

Entries in the `ST_SPATIAL_REFERENCE_SYSTEMS` table are based on the [European Petroleum Survey Group](#) (EPSG) data set, except for SRID 0, which corresponds to a special SRS used in MySQL that represents an infinite flat Cartesian plane with no units assigned to its axes. For additional information about SRSs, see [Section 11.4.5, “Spatial Reference System Support”](#).

The `ST_SPATIAL_REFERENCE_SYSTEMS` table has these columns:

- `SRS_NAME`

The spatial reference system name. This value is unique.

- `SRS_ID`

The spatial reference system numeric ID. This value is unique.

`SRS_ID` values represent the same kind of values as the SRID of geometry values or passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

- `ORGANIZATION`

The name of the organization that defined the coordinate system on which the spatial reference system is based.

- `ORGANIZATION_COORDSYS_ID`

The numeric ID given to the spatial reference system by the organization that defined it.

- `DEFINITION`

The spatial reference system definition. `DEFINITION` values are WKT values, represented as specified in the [Open Geospatial Consortium](#) document [OGC 12-063r5](#).

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are stored in the data dictionary cache to enable reuse and avoid incurring parsing overhead for every statement that needs SRS information.

- `DESCRIPTION`

The spatial reference system description.

Notes

- The `SRS_NAME`, `ORGANIZATION`, `ORGANIZATION_COORDSYS_ID`, and `DEFINITION` columns contain information that may be of interest to users, but they are not used by MySQL.

Example

```
mysql> SELECT * FROM ST_SPATIAL_REFERENCE_SYSTEMS
      WHERE SRS_ID = 4326\G
***** 1. row *****
      SRS_NAME: WGS 84
      SRS_ID: 4326
      ORGANIZATION: EPSG
      ORGANIZATION_COORDSYS_ID: 4326
      DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984",
      SPHEROID["WGS 84",6378137,298.257223563,
      AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]],
      PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
      UNIT["degree",0.017453292519943278,
      AUTHORITY["EPSG","9122"]],
      AXIS["Lat",NORTH],AXIS["Long",EAST],
      AUTHORITY["EPSG","4326"]]
      DESCRIPTION:
```

This entry describes the SRS used for GPS systems. It has a name (`SRS_NAME`) of WGS 84 and an ID (`SRS_ID`) of 4326, which is the ID used by the [European Petroleum Survey Group](#) (EPSG).

The `DEFINITION` values for projected and geographic SRSs begin with `PROJCS` and `GEOGCS`, respectively. The definition for SRID 0 is special and has an empty `DEFINITION` value. The following query determines how many entries in the `ST_SPATIAL_REFERENCE_SYSTEMS` table correspond to projected, geographic, and other SRSs, based on `DEFINITION` values:

```
mysql> SELECT
      COUNT(*),
      CASE LEFT(DEFINITION, 6)
      WHEN 'PROJCS' THEN 'Projected'
      WHEN 'GEOGCS' THEN 'Geographic'
```

```

ELSE 'Other'
END AS SRS_TYPE
FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS
GROUP BY SRS_TYPE;

```

COUNT(*)	SRS_TYPE
1	Other
4668	Projected
483	Geographic

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

- **CREATE SPATIAL REFERENCE SYSTEM:** See [Section 13.1.19, “CREATE SPATIAL REFERENCE SYSTEM Statement”](#). The description for this statement includes additional information about SRS components.
- **DROP SPATIAL REFERENCE SYSTEM:** See [Section 13.1.31, “DROP SPATIAL REFERENCE SYSTEM Statement”](#).

25.37 The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table

The `ST_UNITS_OF_MEASURE` table (available as of MySQL 8.0.14) provides information about acceptable units for the `ST_Distance()` function.

The `ST_UNITS_OF_MEASURE` table has these columns:

- **UNIT_NAME**
The name of the unit.
- **UNIT_TYPE**
The unit type (for example, `LINEAR`).
- **CONVERSION_FACTOR**
A conversion factor used for internal calculations.
- **DESCRIPTION**
A description of the unit.

25.38 The INFORMATION_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

Columns in `TABLES` that represent table statistics hold cached values. The `information_schema_stats_expiry` system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To update cached values at any time for a given table, use `ANALYZE TABLE`. To always retrieve the latest statistics directly from storage engines, set `information_schema_stats_expiry` to 0. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use `InnoDB`. For `ANALYZE TABLE` operations that update the key

distribution, failure may occur even if the operation updates the table itself (for example, if it is a [MyISAM](#) table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

The [TABLES](#) table has these columns:

- [TABLE_CATALOG](#)

The name of the catalog to which the table belongs. This value is always `def`.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE_NAME](#)

The name of the table.

- [TABLE_TYPE](#)

`BASE TABLE` for a table, `VIEW` for a view, or `SYSTEM VIEW` for an [INFORMATION_SCHEMA](#) table.

The [TABLES](#) table does not list [TEMPORARY](#) tables.

- [ENGINE](#)

The storage engine for the table. See [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 16, Alternative Storage Engines](#).

For partitioned tables, [ENGINE](#) shows the name of the storage engine used by all partitions.

- [VERSION](#)

This column is unused. With the removal of `.frm` files in MySQL 8.0, this column now reports a hardcoded value of `10`, which is the last `.frm` file version used in MySQL 5.7.

- [ROW_FORMAT](#)

The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For [MyISAM](#) tables, `Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`.

- [TABLE_ROWS](#)

The number of rows. Some storage engines, such as [MyISAM](#), store the exact count. For other storage engines, such as [InnoDB](#), this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

[TABLE_ROWS](#) is `NULL` for [INFORMATION_SCHEMA](#) tables.

For [InnoDB](#) tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the [InnoDB](#) table is partitioned.)

- [AVG_ROW_LENGTH](#)

The average row length.

- [DATA_LENGTH](#)

For [MyISAM](#), [DATA_LENGTH](#) is the length of the data file, in bytes.

For [InnoDB](#), [DATA_LENGTH](#) is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the [InnoDB](#) page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- [MAX_DATA_LENGTH](#)

For [MyISAM](#), [MAX_DATA_LENGTH](#) is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for [InnoDB](#).

Refer to the notes at the end of this section for information regarding other storage engines.

- [INDEX_LENGTH](#)

For [MyISAM](#), [INDEX_LENGTH](#) is the length of the index file, in bytes.

For [InnoDB](#), [INDEX_LENGTH](#) is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the [InnoDB](#) page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- [DATA_FREE](#)

The number of allocated but unused bytes.

[InnoDB](#) tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For NDB Cluster, [DATA_FREE](#) shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the [DATA_LENGTH](#) column.)

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the [INFORMATION_SCHEMA PARTITIONS](#) table, as shown in this example:

```
SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_SCHEMA = 'mydb'
    AND TABLE_NAME   = 'mytable';
```

For more information, see [Section 25.21, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

- [AUTO_INCREMENT](#)

The next [AUTO_INCREMENT](#) value.

- [CREATE_TIME](#)

When the table was created.

- [UPDATE_TIME](#)

When the data file was last updated. For some storage engines, this value is [NULL](#). For example, [InnoDB](#) stores multiple tables in its [system tablespace](#) and the data file timestamp does not apply. Even with [file-per-table](#) mode with each [InnoDB](#) table in a separate [.ibd](#) file, [change buffering](#) can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For [MyISAM](#), the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

`UPDATE_TIME` displays a timestamp value for the last `UPDATE`, `INSERT`, or `DELETE` performed on `InnoDB` tables that are not partitioned. For MVCC, the timestamp value reflects the `COMMIT` time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the `InnoDB` data dictionary cache.

- `CHECK_TIME`

When the table was last checked. Not all storage engines update this time, in which case, the value is always `NULL`.

For partitioned `InnoDB` tables, `CHECK_TIME` is always `NULL`.

- `TABLE_COLLATION`

The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- `CHECKSUM`

The live checksum value, if any.

- `CREATE_OPTIONS`

Extra options used with `CREATE TABLE`.

`CREATE_OPTIONS` shows `partitioned` for a partitioned table.

Prior to MySQL 8.0.16, `CREATE_OPTIONS` shows the `ENCRYPTION` clause specified for tables created in file-per-table tablespaces. As of MySQL 8.0.16, it shows the encryption clause for file-per-table tablespaces if the table is encrypted or if the specified encryption differs from the schema encryption. The encryption clause is not shown for tables created in general tablespaces. To identify encrypted file-per-table and general tablespaces, query the `INNODB_TABLESPACES_ENCRYPTION` column.

When creating a table with `strict mode` disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `ROW_FORMAT` column. `CREATE_OPTIONS` shows the row format that was specified in the `CREATE TABLE` statement.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. The `CREATE_OPTIONS` column may show retained options.

- `TABLE_COMMENT`

The comment used when creating the table (or information as to why MySQL could not access the table information).

Notes

- For `NDB` tables, the output of this statement shows appropriate values for the `AVG_ROW_LENGTH` and `DATA_LENGTH` columns, with the exception that `BLOB` columns are not taken into account.
- For `NDB` tables, `DATA_LENGTH` includes data stored in main memory only; the `MAX_DATA_LENGTH` and `DATA_FREE` columns apply to Disk Data.
- For `NDB Cluster Disk Data` tables, `MAX_DATA_LENGTH` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

- For **MEMORY** tables, the **DATA_LENGTH**, **MAX_DATA_LENGTH**, and **INDEX_LENGTH** values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, most **TABLES** columns are 0 or **NULL** except that **TABLE_NAME** indicates the view name, **CREATE_TIME** indicates the creation time, and **TABLE_COMMENT** says **VIEW**.

Table information is also available from the **SHOW TABLE STATUS** and **SHOW TABLES** statements. See [Section 13.7.7.38, “SHOW TABLE STATUS Statement”](#), and [Section 13.7.7.39, “SHOW TABLES Statement”](#). The following statements are equivalent:

```
SELECT
  TABLE_NAME, ENGINE, VERSION, ROW_FORMAT, TABLE_ROWS, AVG_ROW_LENGTH,
  DATA_LENGTH, MAX_DATA_LENGTH, INDEX_LENGTH, DATA_FREE, AUTO_INCREMENT,
  CREATE_TIME, UPDATE_TIME, CHECK_TIME, TABLE_COLLATION, CHECKSUM,
  CREATE_OPTIONS, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLE STATUS
FROM db_name
[LIKE 'wild']
```

The following statements are equivalent:

```
SELECT
  TABLE_NAME, TABLE_TYPE
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW FULL TABLES
FROM db_name
[LIKE 'wild']
```

25.39 The INFORMATION_SCHEMA TABLES_EXTENSIONS Table

The **TABLES_EXTENSIONS** table (available as of MySQL 8.0.21) provides information about table attributes defined for primary and secondary storage engines.

Note

The **TABLES_EXTENSIONS** table is reserved for future use.

The **TABLES_EXTENSIONS** table has these columns:

- **TABLE_CATALOG**

The name of the catalog to which the table belongs. This value is always **def**.

- **TABLE_SCHEMA**

The name of the schema (database) to which the table belongs.

- **TABLE_NAME**

The name of the table.

- **ENGINE_ATTRIBUTE**

Table attributes defined for the primary storage engine. Reserved for future use.

- **SECONDARY_ENGINE_ATTRIBUTE**

Table attributes defined for the secondary storage engine. Reserved for future use.

25.40 The INFORMATION_SCHEMA TABLESPACES Table

This table is unused. It is deprecated and will be removed in a future MySQL release. Other [INFORMATION_SCHEMA](#) tables may provide related information:

- For [NDB](#), the [INFORMATION_SCHEMA FILES](#) table provides tablespace-related information.
- For [InnoDB](#), the [INFORMATION_SCHEMA INNODB_TABLESPACES](#) and [INNODB_DATAFILES](#) tables provide tablespace metadata.

25.41 The INFORMATION_SCHEMA TABLESPACES_EXTENSIONS Table

The [TABLESPACES_EXTENSIONS](#) table (available as of MySQL 8.0.21) provides information about tablespace attributes defined for primary storage engines.

Note

The [TABLESPACES_EXTENSIONS](#) table is reserved for future use.

The [TABLESPACES_EXTENSIONS](#) table has these columns:

- [TABLESPACE_NAME](#)

The name of the tablespace.

- [ENGINE_ATTRIBUTE](#)

Tablespace attributes defined for the primary storage engine. Reserved for future use.

25.42 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The [TABLE_CONSTRAINTS](#) table describes which tables have constraints.

The [TABLE_CONSTRAINTS](#) table has these columns:

- [CONSTRAINT_CATALOG](#)

The name of the catalog to which the constraint belongs. This value is always [def](#).

- [CONSTRAINT_SCHEMA](#)

The name of the schema (database) to which the constraint belongs.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE_NAME](#)

The name of the table.

- The [CONSTRAINT_TYPE](#)

The type of constraint. The value can be [UNIQUE](#), [PRIMARY KEY](#), [FOREIGN KEY](#), or (as of MySQL 8.0.16) [CHECK](#). This is a [CHAR](#) (not [ENUM](#)) column.

The [UNIQUE](#) and [PRIMARY KEY](#) information is about the same as what you get from the [Key_name](#) column in the output from [SHOW INDEX](#) when the [Non_unique](#) column is 0.

- [ENFORCED](#)

For [CHECK](#) constraints, the value is [YES](#) or [NO](#) to indicate whether the constraint is enforced. For other constraints, the value is always [YES](#).

This column was added in MySQL 8.0.16.

25.43 The INFORMATION_SCHEMA TABLE_CONSTRAINTS_EXTENSIONS Table

The [TABLE_CONSTRAINTS_EXTENSIONS](#) table (available as of MySQL 8.0.21) provides information about table constraint attributes defined for primary and secondary storage engines.

Note

The [TABLE_CONSTRAINTS_EXTENSIONS](#) table is reserved for future use.

The [TABLE_CONSTRAINTS_EXTENSIONS](#) table has these columns:

- [CONSTRAINT_CATALOG](#)

The name of the catalog to which the table belongs.

- [CONSTRAINT_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [CONSTRAINT_NAME](#)

The name of the constraint.

- [TABLE_NAME](#)

The name of the table.

- [ENGINE_ATTRIBUTE](#)

Constraint attributes defined for the primary storage engine. Reserved for future use.

- [SECONDARY_ENGINE_ATTRIBUTE](#)

Constraint attributes defined for the secondary storage engine. Reserved for future use.

25.44 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The [TABLE_PRIVILEGES](#) table provides information about table privileges. It takes its values from the [mysql.tables_priv](#) system table.

The [TABLE_PRIVILEGES](#) table has these columns:

- [GRANTEE](#)

The name of the account to which the privilege is granted, in '[user_name](#)'@'[host_name](#)' format.

- [TABLE_CATALOG](#)

The name of the catalog to which the table belongs. This value is always [def](#).

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE_NAME](#)

The name of the table.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the table level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per table privilege held by the grantee.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE= 'GRANT OPTION'`.

Notes

- `TABLE_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

25.45 The INFORMATION_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. To see information about a table's triggers, you must have the `TRIGGER` privilege for the table.

The `TRIGGERS` table has these columns:

- `TRIGGER_CATALOG`

The name of the catalog to which the trigger belongs. This value is always `def`.

- `TRIGGER_SCHEMA`

The name of the schema (database) to which the trigger belongs.

- `TRIGGER_NAME`

The name of the trigger.

- `EVENT_MANIPULATION`

The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- `EVENT_OBJECT_CATALOG`, `EVENT_OBJECT_SCHEMA`, and `EVENT_OBJECT_TABLE`

As noted in [Section 24.3, “Using Triggers”](#), every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The `EVENT_OBJECT_CATALOG` value is always `def`.

- `ACTION_ORDER`

The ordinal position of the trigger's action within the list of triggers on the same table with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values.

- `ACTION_CONDITION`

This value is always `NULL`.

- `ACTION_STATEMENT`

The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

- `ACTION_ORIENTATION`

This value is always `ROW`.

- `ACTION_TIMING`

Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- `ACTION_REFERENCE_OLD_TABLE`

This value is always `NULL`.

- `ACTION_REFERENCE_NEW_TABLE`

This value is always `NULL`.

- `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW`

The old and new column identifiers, respectively. The `ACTION_REFERENCE_OLD_ROW` value is always `OLD` and the `ACTION_REFERENCE_NEW_ROW` value is always `NEW`.

- `CREATED`

The date and time when the trigger was created. This is a `TIMESTAMP (2)` value (with a fractional part in hundredths of seconds) for triggers.

- `SQL_MODE`

The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 5.1.11, “Server SQL Modes”](#).

- `DEFINER`

The account named in the `DEFINER` clause (often the user who created the trigger), in `'user_name'@'host_name'` format.

- `CHARACTER_SET_CLIENT`

The session value of the `character_set_client` system variable when the trigger was created.

- `COLLATION_CONNECTION`

The session value of the `collation_connection` system variable when the trigger was created.

- `DATABASE_COLLATION`

The collation of the database with which the trigger is associated.

Example

The following example uses the `ins_sum` trigger defined in [Section 24.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
        WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
  EVENT_MANIPULATION: INSERT
    EVENT_OBJECT_CATALOG: def
```

```

EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: account
ACTION_ORDER: 1
ACTION_CONDITION: NULL
ACTION_STATEMENT: SET @sum = @sum + NEW.amount
ACTION_ORIENTATION: ROW
ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
ACTION_REFERENCE_OLD_ROW: OLD
ACTION_REFERENCE_NEW_ROW: NEW
CREATED: 2018-08-08 10:10:12.61
SQL_MODE: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
DEFINER: me@localhost
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_0900_ai_ci
DATABASE_COLLATION: utf8mb4_0900_ai_ci

```

Trigger information is also available from the `SHOW TRIGGERS` statement. See [Section 13.7.7.40](#), “`SHOW TRIGGERS` Statement”.

25.46 The INFORMATION_SCHEMA USER_ATTRIBUTES Table

The `USER_ATTRIBUTES` table (available as of MySQL 8.0.21) provides information about user comments and user attributes. It takes its values from the `mysql.user` system table.

The `USER_ATTRIBUTES` table has these columns:

- `USER`

The user name portion of the account to which the `ATTRIBUTE` column value applies.

- `HOST`

The host name portion of the account to which the `ATTRIBUTE` column value applies.

- `ATTRIBUTE`

The user comment, user attribute, or both belonging to the account specified by the `USER` and `HOST` columns. The value is in JSON object notation. Attributes are shown exactly as set using a `CREATE USER ... ATTRIBUTE ...` or `ALTER USER ... ATTRIBUTE ...` statement. The user comment is shown as a key-value pair having `comment` as the key.

For example, the statement `CREATE USER 'bill'@'localhost' COMMENT 'A comment' ATTRIBUTE '{"foo": "bar", "bazz": "fazz"}'` adds the following row to the `USER_ATTRIBUTES` table:

USER	HOST	ATTRIBUTE
bill	localhost	{"foo": "bar", "bazz": "fazz", "comment": "A comment"}

Notes

- `USER_ATTRIBUTES` is a nonstandard `INFORMATION_SCHEMA` table.
- To obtain only the user comment for a given user as an unquoted string, you can employ a query such as this one:

```

mysql> SELECT ATTRIBUTE->"$.comment" AS Comment
-> FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
-> WHERE USER='bill' AND HOST='localhost';

```

```
+-----+
| Comment |
+-----+
| A comment |
+-----+
```

Similarly, you can obtain the unquoted value for a given user attribute using its key.

- Prior to MySQL 8.0.22, `USER_ATTRIBUTES` contents are accessible by anyone. As of MySQL 8.0.22, `USER_ATTRIBUTES` contents are accessible as follows:
 - All rows are accessible if:
 - The current thread is a replica thread.
 - The access control system has not been initialized (for example, the server was started with the `--skip-grant-tables` option).
 - The currently authenticated account has the `UPDATE` or `SELECT` privilege for the `mysql.user` system table.
 - The currently authenticated account has the `CREATE USER` and `SYSTEM_USER` privileges.
 - Otherwise, the currently authenticated account can see the row for that account. Additionally, if the account has the `CREATE USER` privilege but not the `SYSTEM_USER` privilege, it can see rows for all other accounts that do not have the `SYSTEM_USER` privilege.

For more information about specifying account comments and attributes, see [Section 13.7.1.3, “CREATE USER Statement”](#).

25.47 The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. It takes its values from the `mysql.user` system table.

The `USER_PRIVILEGES` table has these columns:

- `GRANTEE`

The name of the account to which the privilege is granted, in `'user_name'@'host_name'` format.

- `TABLE_CATALOG`

The name of the catalog. This value is always `def`.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the global level; see [Section 13.7.1.6, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

Notes

- `USER_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
```

```
SHOW GRANTS ...
```

25.48 The INFORMATION_SCHEMA VIEWS Table

The [VIEWS](#) table provides information about views in databases. You must have the [SHOW VIEW](#) privilege to access this table.

The [VIEWS](#) table has these columns:

- [TABLE_CATALOG](#)

The name of the catalog to which the view belongs. This value is always [def](#).

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the view belongs.

- [TABLE_NAME](#)

The name of the view.

- [VIEW_DEFINITION](#)

The [SELECT](#) statement that provides the definition of the view. This column has most of what you see in the [Create Table](#) column that [SHOW CREATE VIEW](#) produces. Skip the words before [SELECT](#) and skip the words [WITH CHECK OPTION](#). Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- [CHECK_OPTION](#)

The value of the [CHECK_OPTION](#) attribute. The value is one of [NONE](#), [CASCADE](#), or [LOCAL](#).

- [IS_UPDATABLE](#)

MySQL sets a flag, called the view updatability flag, at [CREATE VIEW](#) time. The flag is set to [YES](#) (true) if [UPDATE](#) and [DELETE](#) (and similar operations) are legal for the view. Otherwise, the flag is set to [NO](#) (false). The [IS_UPDATABLE](#) column in the [VIEWS](#) table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such [UPDATE](#), [DELETE](#), and [INSERT](#) are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 24.5.3, “Updatable and Insertable Views”](#).)

- [DEFINER](#)

The account of the user who created the view, in '[user_name](#)'@'[host_name](#)' format.

- [SECURITY_TYPE](#)

The view [SQL SECURITY](#) characteristic. The value is one of [DEFINER](#) or [INVOKER](#).

- [CHARACTER_SET_CLIENT](#)

The session value of the [character_set_client](#) system variable when the view was created.

- [COLLATION_CONNECTION](#)

The session value of the `collation_connection` system variable when the view was created.

Notes

MySQL permits different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However, an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

25.49 The INFORMATION_SCHEMA VIEW_ROUTINE_USAGE Table

The `VIEW_ROUTINE_USAGE` table (available as of MySQL 8.0.13) provides access to information about stored functions used in view definitions. The table does not list information about built-in SQL functions or user-defined functions (UDFs) used in the definitions.

You can see information only for views for which you have some privilege, and only for functions for which you have some privilege.

The `VIEW_ROUTINE_USAGE` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the view belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the view belongs.

- `TABLE_NAME`

The name of the view.

- `SPECIFIC_CATALOG`

The name of the catalog to which the function used in the view definition belongs. This value is always `def`.

- `SPECIFIC_SCHEMA`

The name of the schema (database) to which the function used in the view definition belongs.

- [SPECIFIC_NAME](#)

The name of the function used in the view definition.

25.50 The INFORMATION_SCHEMA VIEW_TABLE_USAGE Table

The [VIEW_TABLE_USAGE](#) table (available as of MySQL 8.0.13) provides access to information about tables and views used in view definitions.

You can see information only for views for which you have some privilege, and only for tables for which you have some privilege.

The [VIEW_TABLE_USAGE](#) table has these columns:

- [VIEW_CATALOG](#)

The name of the catalog to which the view belongs. This value is always `def`.

- [VIEW_SCHEMA](#)

The name of the schema (database) to which the view belongs.

- [VIEW_NAME](#)

The name of the view.

- [TABLE_CATALOG](#)

The name of the catalog to which the table or view used in the view definition belongs. This value is always `def`.

- [TABLE_SCHEMA](#)

The name of the schema (database) to which the table or view used in the view definition belongs.

- [TABLE_NAME](#)

The name of the table or view used in the view definition.

25.51 INFORMATION_SCHEMA InnoDB Tables

This section provides table definitions for [InnoDB INFORMATION_SCHEMA](#) tables. For related information and examples, see [Section 15.15, “InnoDB INFORMATION_SCHEMA Tables”](#).

[InnoDB INFORMATION_SCHEMA](#) tables can be used to monitor ongoing [InnoDB](#) activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

25.51.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The [INNODB_BUFFER_PAGE](#) table provides information about each [page](#) in the [InnoDB buffer pool](#).

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

Warning

Querying the [INNODB_BUFFER_PAGE](#) table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The `INNODB_BUFFER_PAGE` table has these columns:

- `POOL_ID`

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- `BLOCK_ID`

The buffer pool block ID.

- `SPACE`

The tablespace ID; the same value as `INNODB_TABLES.SPACE`.

- `PAGE_NUMBER`

The page number.

- `PAGE_TYPE`

The page type. The following table shows the permitted values.

Table 25.1 INNODB_BUFFER_PAGE.PAGE_TYPE Values

Page Type	Description
<code>ALLOCATED</code>	Freshly allocated page
<code>BLOB</code>	Uncompressed BLOB page
<code>COMPRESSED_BLOB2</code>	Subsequent comp BLOB page
<code>COMPRESSED_BLOB</code>	First compressed BLOB page
<code>ENCRYPTED_RTREE</code>	Encrypted R-tree
<code>EXTENT_DESCRIPTOR</code>	Extent descriptor page
<code>FILE_SPACE_HEADER</code>	File space header
<code>FIL_PAGE_TYPE_UNUSED</code>	Unused
<code>IBUF_BITMAP</code>	Insert buffer bitmap
<code>IBUF_FREE_LIST</code>	Insert buffer free list
<code>IBUF_INDEX</code>	Insert buffer index
<code>INDEX</code>	B-tree node
<code>INODE</code>	Index node
<code>LOB_DATA</code>	Uncompressed LOB data
<code>LOB_FIRST</code>	First page of uncompressed LOB
<code>LOB_INDEX</code>	Uncompressed LOB index
<code>PAGE_IO_COMPRESSED</code>	Compressed page
<code>PAGE_IO_COMPRESSED_ENCRYPTED</code>	Compressed and encrypted page
<code>PAGE_IO_ENCRYPTED</code>	Encrypted page
<code>RSEG_ARRAY</code>	Rollback segment array
<code>RTREE_INDEX</code>	R-tree index
<code>SDI_BLOB</code>	Uncompressed SDI BLOB
<code>SDI_COMPRESSED_BLOB</code>	Compressed SDI BLOB

Page Type	Description
SDI_INDEX	SDI index
SYSTEM	System page
TRX_SYSTEM	Transaction system data
UNDO_LOG	Undo log page
UNKNOWN	Unknown
ZLOB_DATA	Compressed LOB data
ZLOB_FIRST	First page of compressed LOB
ZLOB_FRAG	Compressed LOB fragment
ZLOB_FRAG_ENTRY	Compressed LOB fragment index
ZLOB_INDEX	Compressed LOB index

- [FLUSH_TYPE](#)

The flush type.

- [FIX_COUNT](#)

The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- [IS_HASHED](#)

Whether a hash index has been built on this page.

- [NEWEST_MODIFICATION](#)

The Log Sequence Number of the youngest modification.

- [OLDEST_MODIFICATION](#)

The Log Sequence Number of the oldest modification.

- [ACCESS_TIME](#)

An abstract number used to judge the first access time of the page.

- [TABLE_NAME](#)

The name of the table the page belongs to. This column is applicable only to pages with a [PAGE_TYPE](#) value of [INDEX](#).

- [INDEX_NAME](#)

The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a [PAGE_TYPE](#) value of [INDEX](#).

- [NUMBER_RECORDS](#)

The number of records within the page.

- [DATA_SIZE](#)

The sum of the sizes of the records. This column is applicable only to pages with a [PAGE_TYPE](#) value of [INDEX](#).

- [COMPRESSED_SIZE](#)

The compressed page size. `NULL` for pages that are not compressed.

- `PAGE_STATE`

The page state. The following table shows the permitted values.

Table 25.2 INNODB_BUFFER_PAGE.PAGE_STATE Values

Page State	Description
<code>FILE_PAGE</code>	A buffered file page
<code>MEMORY</code>	Contains a main memory object
<code>NOT_USED</code>	In the free list
<code>NULL</code>	Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels
<code>READY_FOR_USE</code>	A free page
<code>REMOVE_HASH</code>	Hash index should be removed before placing in the free list

- `IO_FIX`

Whether any I/O is pending for this page: `IO_NONE` = no pending I/O, `IO_READ` = read pending, `IO_WRITE` = write pending.

- `IS_OLD`

Whether the block is in the sublist of old blocks in the LRU list.

- `FREE_PAGE_CLOCK`

The value of the `freed_page_clock` counter when the block was the last placed at the head of the LRU list. The `freed_page_clock` counter tracks the number of blocks removed from the end of the LRU list.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
      BLOCK_ID: 0
      SPACE: 97
      PAGE_NUMBER: 2473
      PAGE_TYPE: INDEX
      FLUSH_TYPE: 1
      FIX_COUNT: 0
      IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
OLDEST_MODIFICATION: 0
      ACCESS_TIME: 3378385672
      TABLE_NAME: `employees`.`salaries`
      INDEX_NAME: PRIMARY
      NUMBER_RECORDS: 468
      DATA_SIZE: 14976
      COMPRESSED_SIZE: 0
      PAGE_STATE: FILE_PAGE
      IO_FIX: IO_NONE
      IS_OLD: YES
      FREE_PAGE_CLOCK: 66
```

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB_BUFFER_PAGE](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.5.1, “Buffer Pool”](#).

25.51.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

The [INNODB_BUFFER_PAGE_LRU](#) table provides information about the pages in the [InnoDB buffer pool](#); in particular, how they are ordered in the LRU list that determines which pages to [evict](#) from the buffer pool when it becomes full.

The [INNODB_BUFFER_PAGE_LRU](#) table has the same columns as the [INNODB_BUFFER_PAGE](#) table, except that the [INNODB_BUFFER_PAGE_LRU](#) table has [LRU_POSITION](#) and [COMPRESSED](#) columns instead of [BLOCK_ID](#) and [PAGE_STATE](#) columns.

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

Warning

Querying the [INNODB_BUFFER_PAGE_LRU](#) table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The [INNODB_BUFFER_PAGE_LRU](#) table has these columns:

- [POOL_ID](#)

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- [LRU_POSITION](#)

The position of the page in the LRU list.

- [SPACE](#)

The tablespace ID; the same value as [INNODB_TABLES.SPACE](#).

- [PAGE_NUMBER](#)

The page number.

- [PAGE_TYPE](#)

The page type. The following table shows the permitted values.

Table 25.3 INNODB_BUFFER_PAGE_LRU.PAGE_TYPE Values

Page Type	Description
ALLOCATED	Freshly allocated page
BLOB	Uncompressed BLOB page
COMPRESSED_BLOB2	Subsequent comp BLOB page

Page Type	Description
COMPRESSED_BLOB	First compressed BLOB page
ENCRYPTED_RTREE	Encrypted R-tree
EXTENT_DESCRIPTOR	Extent descriptor page
FILE_SPACE_HEADER	File space header
FIL_PAGE_TYPE_UNUSED	Unused
IBUF_BITMAP	Insert buffer bitmap
IBUF_FREE_LIST	Insert buffer free list
IBUF_INDEX	Insert buffer index
INDEX	B-tree node
INODE	Index node
LOB_DATA	Uncompressed LOB data
LOB_FIRST	First page of uncompressed LOB
LOB_INDEX	Uncompressed LOB index
PAGE_IO_COMPRESSED	Compressed page
PAGE_IO_COMPRESSED_ENCRYPTED	Compressed and encrypted page
PAGE_IO_ENCRYPTED	Encrypted page
RSEG_ARRAY	Rollback segment array
RTREE_INDEX	R-tree index
SDI_BLOB	Uncompressed SDI BLOB
SDI_COMPRESSED_BLOB	Compressed SDI BLOB
SDI_INDEX	SDI index
SYSTEM	System page
TRX_SYSTEM	Transaction system data
UNDO_LOG	Undo log page
UNKNOWN	Unknown
ZLOB_DATA	Compressed LOB data
ZLOB_FIRST	First page of compressed LOB
ZLOB_FRAG	Compressed LOB fragment
ZLOB_FRAG_ENTRY	Compressed LOB fragment index
ZLOB_INDEX	Compressed LOB index

- **FLUSH_TYPE**

The flush type.

- **FIX_COUNT**

The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- `IS_HASHED`

Whether a hash index has been built on this page.

- `NEWEST_MODIFICATION`

The Log Sequence Number of the youngest modification.

- `OLDEST_MODIFICATION`

The Log Sequence Number of the oldest modification.

- `ACCESS_TIME`

An abstract number used to judge the first access time of the page.

- `TABLE_NAME`

The name of the table the page belongs to. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- `INDEX_NAME`

The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- `NUMBER_RECORDS`

The number of records within the page.

- `DATA_SIZE`

The sum of the sizes of the records. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- `COMPRESSED_SIZE`

The compressed page size. `NULL` for pages that are not compressed.

- `COMPRESSED`

Whether the page is compressed.

- `IO_FIX`

Whether any I/O is pending for this page: `IO_NONE` = no pending I/O, `IO_READ` = read pending, `IO_WRITE` = write pending.

- `IS_OLD`

Whether the block is in the sublist of old blocks in the LRU list.

- `FREE_PAGE_CLOCK`

The value of the `freed_page_clock` counter when the block was the last placed at the head of the LRU list. The `freed_page_clock` counter tracks the number of blocks removed from the end of the LRU list.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
***** 1. row *****
POOL_ID: 0
```

```

LRU_POSITION: 0
SPACE: 97
PAGE_NUMBER: 1984
PAGE_TYPE: INDEX
FLUSH_TYPE: 1
FIX_COUNT: 0
IS_HASHED: YES
NEWEST_MODIFICATION: 719490396
OLDEST_MODIFICATION: 0
ACCESS_TIME: 3378383796
TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
COMPRESSED: NO
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 0

```

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB_BUFFER_PAGE_LRU](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.5.1, “Buffer Pool”](#).

25.51.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

The [INNODB_BUFFER_POOL_STATS](#) table provides much of the same buffer pool information provided in [SHOW ENGINE INNODB STATUS](#) output. Much of the same information may also be obtained using [InnoDB](#) buffer pool [server status variables](#).

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the [sublists](#) at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of [eviction](#).

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

The [INNODB_BUFFER_POOL_STATS](#) table has these columns:

- [POOL_ID](#)

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- [POOL_SIZE](#)

The [InnoDB](#) buffer pool size in pages.

- [FREE_BUFFERS](#)

The number of free pages in the [InnoDB](#) buffer pool.

- [DATABASE_PAGES](#)

The number of pages in the [InnoDB](#) buffer pool containing data. This number includes both dirty and clean pages.

- [OLD_DATABASE_PAGES](#)

The number of pages in the [old](#) buffer pool sublist.

- [MODIFIED_DATABASE_PAGES](#)

The number of modified (dirty) database pages.

- [PENDING_DECOMPRESS](#)

The number of pages pending decompression.

- [PENDING_READS](#)

The number of pending reads.

- [PENDING_FLUSH_LRU](#)

The number of pages pending flush in the LRU.

- [PENDING_FLUSH_LIST](#)

The number of pages pending flush in the flush list.

- [PAGES_MADE_YOUNG](#)

The number of pages made young.

- [PAGES_NOT_MADE_YOUNG](#)

The number of pages not made young.

- [PAGES_MADE_YOUNG_RATE](#)

The number of pages made young per second (pages made young since the last printout / time elapsed).

- [PAGES_MADE_NOT_YOUNG_RATE](#)

The number of pages not made per second (pages not made young since the last printout / time elapsed).

- [NUMBER_PAGES_READ](#)

The number of pages read.

- [NUMBER_PAGES_CREATED](#)

The number of pages created.

- [NUMBER_PAGES_WRITTEN](#)

The number of pages written.

- [PAGES_READ_RATE](#)

The number of pages read per second (pages read since the last printout / time elapsed).

- [PAGES_CREATE_RATE](#)

The number of pages created per second (pages created since the last printout / time elapsed).

- [PAGES_WRITTEN_RATE](#)

The number of pages written per second (pages written since the last printout / time elapsed).

- [NUMBER_PAGES_GET](#)

The number of logical read requests.

- [HIT_RATE](#)

The buffer pool hit rate.

- [YOUNG_MAKE_PER_THOUSAND_GETS](#)

The number of pages made young per thousand gets.

- [NOT_YOUNG_MAKE_PER_THOUSAND_GETS](#)

The number of pages not made young per thousand gets.

- [NUMBER_PAGES_READ_AHEAD](#)

The number of pages read ahead.

- [NUMBER_READ_AHEAD_EVICTED](#)

The number of pages read into the [InnoDB](#) buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- [READ_AHEAD_RATE](#)

The read-ahead rate per second (pages read ahead since the last printout / time elapsed).

- [READ_AHEAD_EVICTED_RATE](#)

The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).

- [LRU_IO_TOTAL](#)

Total LRU I/O.

- [LRU_IO_CURRENT](#)

LRU I/O for the current interval.

- [UNCOMPRESS_TOTAL](#)

The total number of pages decompressed.

- [UNCOMPRESS_CURRENT](#)

The number of pages decompressed in the current interval.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8085
      OLD_DATABASE_PAGES: 2964
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
      PENDING_FLUSH_LIST: 0
      PAGES_MADE_YOUNG: 22821
      PAGES_NOT_MADE_YOUNG: 3544303
      PAGES_MADE_YOUNG_RATE: 357.62602199870594
      PAGES_MADE_NOT_YOUNG_RATE: 0
      NUMBER_PAGES_READ: 2389
      NUMBER_PAGES_CREATED: 12385
      NUMBER_PAGES_WRITTEN: 13111
      PAGES_READ_RATE: 0
      PAGES_CREATE_RATE: 0
      PAGES_WRITTEN_RATE: 0
      NUMBER_PAGES_GET: 33322210
      HIT_RATE: 1000
      YOUNG_MAKE_PER_THOUSAND_GETS: 18
      NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
      NUMBER_PAGES_READ_AHEAD: 2024
      NUMBER_READ_AHEAD_EVICTED: 0
      READ_AHEAD_RATE: 0
      READ_AHEAD_EVICTED_RATE: 0
      LRU_IO_TOTAL: 0
      LRU_IO_CURRENT: 0
      UNCOMPRESS_TOTAL: 0
      UNCOMPRESS_CURRENT: 0
```

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.4 The INFORMATION_SCHEMA INNODB_CACHED_INDEXES Table

The [INNODB_CACHED_INDEXES](#) table reports the number of index pages cached in the [InnoDB](#) buffer pool for each index.

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

The [INNODB_CACHED_INDEXES](#) table has these columns:

- [SPACE_ID](#)

The tablespace ID.

- [INDEX_ID](#)

An identifier for the index. Index identifiers are unique across all the databases in an instance.

- [N_CACHED_PAGES](#)

The number of index pages cached in the [InnoDB](#) buffer pool.

Examples

This query returns the number of index pages cached in the [InnoDB](#) buffer pool for a specific index:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CACHED_INDEXES WHERE INDEX_ID=65\G
***** 1. row *****
      SPACE_ID: 4294967294
      INDEX_ID: 65
N_CACHED_PAGES: 45
```

This query returns the number of index pages cached in the [InnoDB](#) buffer pool for each index, using the [INNODB_INDEXES](#) and [INNODB_TABLES](#) tables to resolve the table name and index name for each [INDEX_ID](#) value.

```
SELECT
  tables.NAME AS table_name,
  indexes.NAME AS index_name,
  cached.N_CACHED_PAGES AS n_cached_pages
FROM
  INFORMATION_SCHEMA.INNODB_CACHED_INDEXES AS cached,
  INFORMATION_SCHEMA.INNODB_INDEXES AS indexes,
  INFORMATION_SCHEMA.INNODB_TABLES AS tables
WHERE
  cached.INDEX_ID = indexes.INDEX_ID
  AND indexes.TABLE_ID = tables.TABLE_ID;
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA_COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.5 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

The [INNODB_CMP](#) and [INNODB_CMP_RESET](#) tables provide status information on operations related to [compressed InnoDB](#) tables.

The [INNODB_CMP](#) and [INNODB_CMP_RESET](#) tables have these columns:

- [PAGE_SIZE](#)

The compressed page size in bytes.

- [COMPRESS_OPS](#)

The number of times a B-tree page of size [PAGE_SIZE](#) has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- [COMPRESS_OPS_OK](#)

The number of times a B-tree page of size [PAGE_SIZE](#) has been successfully compressed. This count should never exceed [COMPRESS_OPS](#).

- [COMPRESS_TIME](#)

The total time in seconds used for attempts to compress B-tree pages of size [PAGE_SIZE](#).

- [UNCOMPRESS_OPS](#)

The number of times a B-tree page of size [PAGE_SIZE](#) has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

- [UNCOMPRESS_TIME](#)

The total time in seconds used for uncompressing B-tree pages of the size [PAGE_SIZE](#).

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP\G
***** 1. row *****
    page_size: 1024
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
    uncompress_ops: 0
    uncompress_time: 0
***** 2. row *****
    page_size: 2048
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
    uncompress_ops: 0
    uncompress_time: 0
***** 3. row *****
    page_size: 4096
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
    uncompress_ops: 0
    uncompress_time: 0
***** 4. row *****
    page_size: 8192
    compress_ops: 86955
compress_ops_ok: 81182
    compress_time: 27
    uncompress_ops: 26828
    uncompress_time: 5
***** 5. row *****
    page_size: 16384
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
    uncompress_ops: 0
    uncompress_time: 0
```

Notes

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) in your database.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 15.9, “InnoDB Table and Page Compression”](#).

25.51.6 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The [INNODB_CMPMEM](#) and [INNODB_CMPMEM_RESET](#) tables provide status information on compressed [pages](#) within the [InnoDB](#) [buffer pool](#).

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have these columns:

- `PAGE_SIZE`

The block size in bytes. Each record of this table describes blocks of this size.

- `BUFFER_POOL_INSTANCE`

A unique identifier for the buffer pool instance.

- `PAGES_USED`

The number of blocks of size `PAGE_SIZE` that are currently in use.

- `PAGES_FREE`

The number of blocks of size `PAGE_SIZE` that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

- `RELOCATION_OPS`

The number of times a block of size `PAGE_SIZE` has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the `INNODB_CMPMEM_RESET` table resets this count.

- `RELOCATION_TIME`

The total time in microseconds used for relocating blocks of size `PAGE_SIZE`. Reading from the table `INNODB_CMPMEM_RESET` resets this count.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
***** 1. row *****
      page_size: 1024
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 2. row *****
      page_size: 2048
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 3. row *****
      page_size: 4096
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 4. row *****
      page_size: 8192
buffer_pool_instance: 0
      pages_used: 7673
      pages_free: 15
      relocation_ops: 4638
      relocation_time: 0
***** 5. row *****
      page_size: 16384
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
```

Notes

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) in your database.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 15.9, “InnoDB Table and Page Compression”](#).

25.51.7 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The [INNODB_CMP_PER_INDEX](#) and [INNODB_CMP_PER_INDEX_RESET](#) tables provide status information on operations related to [compressed InnoDB](#) tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed [InnoDB](#) table, both the table data and all the [secondary indexes](#) are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the [clustered index](#).

The [INNODB_CMP_PER_INDEX](#) and [INNODB_CMP_PER_INDEX_RESET](#) tables have these columns:

- [DATABASE_NAME](#)

The schema (database) containing the applicable table.

- [TABLE_NAME](#)

The table to monitor for compression statistics.

- [INDEX_NAME](#)

The index to monitor for compression statistics.

- [COMPRESS_OPS](#)

The number of compression operations attempted. [Pages](#) are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- [COMPRESS_OPS_OK](#)

The number of successful compression operations. Subtract from the [COMPRESS_OPS](#) value to get the number of [compression failures](#). Divide by the [COMPRESS_OPS](#) value to get the percentage of compression failures.

- [COMPRESS_TIME](#)

The total time in seconds used for compressing data in this index.

- [UNCOMPRESS_OPS](#)

The number of uncompression operations performed. Compressed [InnoDB](#) pages are uncompressed whenever compression [fails](#), or the first time a compressed page is accessed in the [buffer pool](#) and the uncompressed page does not exist.

- [UNCOMPRESS_TIME](#)

The total time in seconds used for uncompressing data in this index.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
***** 1. row *****
  database_name: employees
    table_name: salaries
    index_name: PRIMARY
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
uncompress_ops: 23451
uncompress_time: 4
***** 2. row *****
  database_name: employees
    table_name: salaries
    index_name: emp_no
    compress_ops: 0
compress_ops_ok: 0
    compress_time: 0
uncompress_ops: 1597
uncompress_time: 0
```

Notes

- Use these tables to measure the effectiveness of [InnoDB table compression](#) for specific tables, indexes, or both.
- You must have the [PROCESS](#) privilege to query these tables.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of these tables, including data types and default values.
- Because collecting separate measurements for every index imposes substantial performance overhead, [INNODB_CMP_PER_INDEX](#) and [INNODB_CMP_PER_INDEX_RESET](#) statistics are not gathered by default. You must enable the [innodb_cmp_per_index_enabled](#) system variable before performing the operations on compressed tables that you want to monitor.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 15.9, “InnoDB Table and Page Compression”](#).

25.51.8 The INFORMATION_SCHEMA INNODB_COLUMNS Table

The [INNODB_COLUMNS](#) table provides metadata about [InnoDB table columns](#).

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_COLUMNS](#) table has these columns:

- [TABLE_ID](#)

An identifier representing the table associated with the column; the same value as [INNODB_TABLES.TABLE_ID](#).

- [NAME](#)

The name of the column. These names can be uppercase or lowercase depending on the [lower_case_table_names](#) setting. There are no special system-reserved names for columns.

- [POS](#)

The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The `POS` value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the `POS` column description in [Section 25.51.30](#), “The INFORMATION_SCHEMA INNODB_VIRTUAL Table”.

- `MTYPE`

Stands for “main type”. A numeric identifier for the column type. 1 = `VARCHAR`, 2 = `CHAR`, 3 = `FIXBINARY`, 4 = `BINARY`, 5 = `BLOB`, 6 = `INT`, 7 = `SYS_CHILD`, 8 = `SYS`, 9 = `FLOAT`, 10 = `DOUBLE`, 11 = `DECIMAL`, 12 = `VARMySQL`, 13 = `MySQL`, 14 = `GEOMETRY`.

- `PRTYPE`

The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.

- `LEN`

The column length, for example 4 for `INT` and 8 for `BIGINT`. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as `VARCHAR(N)`; that is, it might be $2*N$, $3*N$, and so on depending on the character encoding.

- `HAS_DEFAULT`

A boolean value indicating whether a column that was added instantly using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT` has a default value. All columns added instantly have a default value, which makes this column an indicator of whether the column was added instantly.

- `DEFAULT_VALUE`

The initial default value of a column that was added instantly using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT`. If the default value is `NULL` or was not specified, this column reports `NULL`. An explicitly specified non-`NULL` default value is shown in an internal binary format. Subsequent modifications of the column default value do not change the value reported by this column.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
    TABLE_ID: 71
      NAME: col1
        POS: 0
        MTYPE: 6
        PRTYPE: 1027
          LEN: 4
    HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL
***** 2. row *****
    TABLE_ID: 71
      NAME: col2
        POS: 1
        MTYPE: 2
        PRTYPE: 524542
          LEN: 10
    HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL
***** 3. row *****
    TABLE_ID: 71
      NAME: col3
        POS: 2
        MTYPE: 1
        PRTYPE: 524303
          LEN: 10
```

```
HAS_DEFAULT: 0
DEFAULT_VALUE: NULL
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.9 The INFORMATION_SCHEMA INNODB_DATAFILES Table

The [INNODB_DATAFILES](#) table provides data file path information for [InnoDB](#) file-per-table and general tablespaces.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

Note

The [INFORMATION_SCHEMA FILES](#) table reports metadata for [InnoDB](#) tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the global temporary tablespace, and undo tablespaces.

The [INNODB_DATAFILES](#) table has these columns:

- [SPACE](#)

The tablespace ID.

- [PATH](#)

The tablespace data file path. If a [file-per-table](#) tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_DATAFILES WHERE SPACE = 57\G
***** 1. row *****
SPACE: 57
PATH:  ./test/t1.ibd
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.10 The INFORMATION_SCHEMA INNODB_FIELDS Table

The [INNODB_FIELDS](#) table provides metadata about the key columns (fields) of [InnoDB](#) indexes.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_FIELDS](#) table has these columns:

- [INDEX_ID](#)

An identifier for the index associated with this key field; the same value as [INNODB_INDEXES.INDEX_ID](#).

- [NAME](#)

The name of the original column from the table; the same value as [INNODB_COLUMNS.NAME](#).

- [POS](#)

The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FIELDS WHERE INDEX_ID = 117\G
***** 1. row *****
INDEX_ID: 117
NAME: coll
POS: 0
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA.COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.11 The INFORMATION_SCHEMA INNODB_FOREIGN Table

The [INNODB_FOREIGN](#) table provides metadata about [InnoDB foreign keys](#).

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_FOREIGN](#) table has these columns:

- [ID](#)

The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, [test/products_fk](#)).

- [FOR_NAME](#)

The name of the [child table](#) in this foreign key relationship.

- [REF_NAME](#)

The name of the [parent table](#) in this foreign key relationship.

- [N_COLS](#)

The number of columns in the foreign key index.

- [TYPE](#)

A collection of bit flags with information about the foreign key column, ORed together. 0 = [ON DELETE/UPDATE RESTRICT](#), 1 = [ON DELETE CASCADE](#), 2 = [ON DELETE SET NULL](#), 4 = [ON UPDATE CASCADE](#), 8 = [ON UPDATE SET NULL](#), 16 = [ON DELETE NO ACTION](#), 32 = [ON UPDATE NO ACTION](#).

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN\G
***** 1. row *****
ID: test/fk1
```

```
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.12 The INFORMATION_SCHEMA INNODB_FOREIGN_COLS Table

The [INNODB_FOREIGN_COLS](#) table provides status information about [InnoDB](#) foreign key columns.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_FOREIGN_COLS](#) table has these columns:

- [ID](#)

The foreign key index associated with this index key field; the same value as [INNODB_FOREIGN.ID](#).

- [FOR_COL_NAME](#)

The name of the associated column in the child table.

- [REF_COL_NAME](#)

The name of the associated column in the parent table.

- [POS](#)

The ordinal position of this key field within the foreign key index, starting from 0.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS WHERE ID = 'test/fk1'\G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.13 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

The [INNODB_FT_BEING_DELETED](#) table provides a snapshot of the [INNODB_FT_DELETED](#) table; it is used only during an [OPTIMIZE TABLE](#) maintenance operation. When [OPTIMIZE TABLE](#) is run, the [INNODB_FT_BEING_DELETED](#) table is emptied, and [DOC_ID](#) values are removed from the [INNODB_FT_DELETED](#) table. Because the contents of [INNODB_FT_BEING_DELETED](#) typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running [OPTIMIZE TABLE](#) on tables with [FULLTEXT](#) indexes, see [Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”](#).

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example, `test/articles`). The output appears similar to the example provided for the `INNODB_FT_DELETED` table.

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_BEING_DELETED` table has these columns:

- `DOC_ID`

The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you perform text searches, to skip rows in the `INNODB_FT_INDEX_TABLE` table before data for deleted rows is physically removed from the `FULLTEXT` index by an `OPTIMIZE TABLE` statement. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

Notes

- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about InnoDB `FULLTEXT` search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.14 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The `INNODB_FT_CONFIG` table provides metadata about the `FULLTEXT` index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example, `test/articles`).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_CONFIG` table has these columns:

- `KEY`

The name designating an item of metadata for an InnoDB table containing a `FULLTEXT` index.

The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

- `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.
- `synced_doc_id`: The next `DOC_ID` to be issued.
- `stopword_table_name`: The *database/table* name for a user-defined stopwords table. The `VALUE` column is empty if there is no user-defined stopwords table.
- `use_stopword`: Indicates whether a stopwords table is used, which is defined when the `FULLTEXT` index is created.
- `VALUE`

The value associated with the corresponding [KEY](#) column, reflecting some limit or current value for an aspect of a [FULLTEXT](#) index for an [InnoDB](#) table.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180 |
| synced_doc_id | 0 |
| stopwords_table_name | test/my_stopwords |
| use_stopword | 1 |
+-----+-----+
```

Notes

- This table is intended only for internal configuration. It is not intended for statistical information purposes.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.15 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The [INNODB_FT_DEFAULT_STOPWORD](#) table holds a list of [stopwords](#) that are used by default when creating a [FULLTEXT](#) index on [InnoDB](#) tables. For information about the default [InnoDB](#) stopwords list and how to define your own stopwords lists, see [Section 12.10.4, “Full-Text Stopwords”](#).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The [INNODB_FT_DEFAULT_STOPWORD](#) table has these columns:

- [value](#)

A word that is used by default as a stopwords for [FULLTEXT](#) indexes on [InnoDB](#) tables. This is not used if you override the default stopwords processing with either the [innodb_ft_server_stopword_table](#) or the [innodb_ft_user_stopword_table](#) system variable.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a |
| about |
| an |
| are |
| as |
| at |
| be |
| by |
| com |
| de |
```

```

```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.16 The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The [INNODB_FT_DELETED](#) table stores rows that are deleted from the [FULLTEXT](#) index for an [InnoDB](#) table. To avoid expensive index reorganization during DML operations for an [InnoDB FULLTEXT](#) index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an [OPTIMIZE TABLE](#) statement for the [InnoDB](#) table. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

This table is empty initially. Before querying it, set the value of the [innodb_ft_aux_table](#) system variable to the name (including the database name) of the table that contains the [FULLTEXT](#) index (for example, [test/articles](#)).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The [INNODB_FT_DELETED](#) table has these columns:

- [DOC_ID](#)

The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by [InnoDB](#) when the table contains no suitable column. This value is used when you perform text searches, to skip rows in the [INNODB_FT_INDEX_TABLE](#) table before data for deleted rows is physically removed from the [FULLTEXT](#) index by an [OPTIMIZE TABLE](#) statement. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      6 |
|      7 |
|      8 |
+-----+
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.17 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

The [INNODB_FT_INDEX_CACHE](#) table provides token information about newly inserted rows in a [FULLTEXT](#) index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when [OPTIMIZE TABLE](#) is run, when the server is shut down, or when the cache size exceeds a limit defined by the [innodb_ft_cache_size](#) or [innodb_ft_total_cache_size](#) system variable.

This table is empty initially. Before querying it, set the value of the [innodb_ft_aux_table](#) system variable to the name (including the database name) of the table that contains the [FULLTEXT](#) index (for example, `test/articles`).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The [INNODB_FT_INDEX_CACHE](#) table has these columns:

- [WORD](#)

A word extracted from the text of a newly inserted row.

- [FIRST_DOC_ID](#)

The first document ID in which this word appears in the [FULLTEXT](#) index.

- [LAST_DOC_ID](#)

The last document ID in which this word appears in the [FULLTEXT](#) index.

- [DOC_COUNT](#)

The number of rows in which this word appears in the [FULLTEXT](#) index. The same word can occur several times within the cache table, once for each combination of [DOC_ID](#) and [POSITION](#) values.

- [DOC_ID](#)

The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by [InnoDB](#) when the table contains no suitable column.

- [POSITION](#)

The position of this particular instance of the word within the relevant document identified by the `DOC_ID` value. The value does not represent an absolute position; it is an offset added to the `POSITION` of the previous instance of that word.

Notes

- This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example `test/articles`). The following example demonstrates how to use the `innodb_ft_aux_table` system variable to show information about a `FULLTEXT` index for a specified table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

WORD	DOC_COUNT	DOC_ID	POSITION
1001	1	4	0
after	1	2	22
comparison	1	5	44
configured	1	6	20
database	2	1	31

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about `InnoDB FULLTEXT` search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.18 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The `INNODB_FT_INDEX_TABLE` table provides information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example, `test/articles`).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_INDEX_TABLE` table has these columns:

- **WORD**

A word extracted from the text of the columns that are part of a **FULLTEXT**.

- **FIRST_DOC_ID**

The first document ID in which this word appears in the **FULLTEXT** index.

- **LAST_DOC_ID**

The last document ID in which this word appears in the **FULLTEXT** index.

- **DOC_COUNT**

The number of rows in which this word appears in the **FULLTEXT** index. The same word can occur several times within the cache table, once for each combination of **DOC_ID** and **POSITION** values.

- **DOC_ID**

The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by **InnoDB** when the table contains no suitable column.

- **POSITION**

The position of this particular instance of the word within the relevant document identified by the **DOC_ID** value.

Notes

- This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the **FULLTEXT** index (for example, `test/articles`). The following example demonstrates how to use the `innodb_ft_aux_table` system variable to show information about a **FULLTEXT** index for a specified table. Before information for newly inserted rows appears in **INNODB_FT_INDEX_TABLE**, the **FULLTEXT** index cache must be flushed to disk. This is accomplished by running an **OPTIMIZE TABLE** operation on the indexed table with the `innodb_optimize_fulltext_only` system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```
mysql> USE test;

mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op      | Msg_type  | Msg_text  |
+-----+-----+-----+-----+
| test.articles | optimize | status    | OK        |
+-----+-----+-----+-----+
```

```
mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
       FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+-----+-----+-----+-----+
| WORD      | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+
| 1001      |          1 |        4 |         0 |
| after     |          1 |        2 |        22 |
| comparison |          1 |        5 |        44 |
| configured |          1 |        6 |        20 |
| database  |          2 |        1 |        31 |
+-----+-----+-----+-----+

mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

25.51.19 The INFORMATION_SCHEMA INNODB_INDEXES Table

The [INNODB_INDEXES](#) table provides metadata about [InnoDB](#) indexes.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_INDEXES](#) table has these columns:

- [INDEX_ID](#)

An identifier for the index. Index identifiers are unique across all the databases in an instance.

- [NAME](#)

The name of the index. Most indexes created implicitly by [InnoDB](#) have consistent names but the index names are not necessarily unique. Examples: [PRIMARY](#) for a primary key index, [GEN_CLUST_INDEX](#) for the index representing a primary key when one is not specified, and [ID_IND](#), [FOR_IND](#), and [REF_IND](#) for foreign key constraints.

- [TABLE_ID](#)

An identifier representing the table associated with the index; the same value as [INNODB_TABLES.TABLE_ID](#).

- [TYPE](#)

A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index ([GEN_CLUST_INDEX](#)); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index; 64 = spatial index; 128 = secondary index on a [virtual generated column](#).

- [N_FIELDS](#)

The number of columns in the index key. For [GEN_CLUST_INDEX](#) indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

- [PAGE_NO](#)

The root page number of the index B-tree. For full-text indexes, the [PAGE_NO](#) column is unused and set to -1 ([FIL_NULL](#)) because the full-text index is laid out in several B-trees (auxiliary tables).

- [SPACE](#)

An identifier for the tablespace where the index resides. 0 means the [InnoDB system tablespace](#). Any other number represents a table created with a separate `.ibd` file in [file-per-table](#) mode. This identifier stays the same after a [TRUNCATE TABLE](#) statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.

- [MERGE_THRESHOLD](#)

The merge threshold value for index pages. If the amount of data in an index page falls below the [MERGE_THRESHOLD](#) value when a row is deleted or when a row is shortened by an update operation, [InnoDB](#) attempts to merge the index page with the neighboring index page. The default threshold value is 50%. For more information, see [Section 15.8.11, “Configuring the Merge Threshold for Index Pages”](#).

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE TABLE_ID = 34\G
***** 1. row *****
      INDEX_ID: 39
      NAME: GEN_CLUST_INDEX
      TABLE_ID: 34
      TYPE: 1
      N_FIELDS: 0
      PAGE_NO: 3
      SPACE: 23
MERGE_THRESHOLD: 50
***** 2. row *****
      INDEX_ID: 40
      NAME: i1
      TABLE_ID: 34
      TYPE: 0
      N_FIELDS: 1
      PAGE_NO: 4
      SPACE: 23
MERGE_THRESHOLD: 50
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.20 The INFORMATION_SCHEMA INNODB_LOCKS Table

The [INNODB_LOCKS](#) table provides information about each lock that an [InnoDB](#) transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

Note

This table is deprecated and is removed as of MySQL 8.0.1. Use the Performance Schema [data_locks](#) table instead. See [Section 26.12.13.1, “The data_locks Table”](#).

Differences between [INNODB_LOCKS](#) and [data_locks](#):

- If a transaction holds a lock, [INNODB_LOCKS](#) displays the lock only if another transaction is waiting for it. [data_locks](#) displays the lock regardless of whether any transaction is waiting for it.
- The [data_locks](#) table has no columns corresponding to [LOCK_SPACE](#), [LOCK_PAGE](#), or [LOCK_REC](#).

- The `INNODB_LOCKS` table requires the global `PROCESS` privilege. The `data_locks` table requires the usual Performance Schema privilege of `SELECT` on the table to be selected from.

The following table shows the mapping from `INNODB_LOCKS` columns to `data_locks` columns. Use this information to migrate applications from one table to the other.

Table 25.4 Mapping from INNODB_LOCKS to data_locks Columns

INNODB_LOCKS Column	data_locks Column
<code>LOCK_ID</code>	<code>ENGINE_LOCK_ID</code>
<code>LOCK_TRX_ID</code>	<code>ENGINE_TRANSACTION_ID</code>
<code>LOCK_MODE</code>	<code>LOCK_MODE</code>
<code>LOCK_TYPE</code>	<code>LOCK_TYPE</code>
<code>LOCK_TABLE</code> (combined schema/table names)	<code>OBJECT_SCHEMA</code> (schema name), <code>OBJECT_NAME</code> (table name)
<code>LOCK_INDEX</code>	<code>INDEX_NAME</code>
<code>LOCK_SPACE</code>	None
<code>LOCK_PAGE</code>	None
<code>LOCK_REC</code>	None
<code>LOCK_DATA</code>	<code>LOCK_DATA</code>

25.51.21 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked `InnoDB` transaction, indicating the lock it has requested and any locks that are blocking that request.

Note

This table is deprecated and is removed as of MySQL 8.0.1. Use the Performance Schema `data_lock_waits` table instead. See [Section 26.12.13.2, “The data_lock_waits Table”](#).

The tables differ in the privileges required: The `INNODB_LOCK_WAITS` table requires the global `PROCESS` privilege. The `data_lock_waits` table requires the usual Performance Schema privilege of `SELECT` on the table to be selected from.

The following table shows the mapping from `INNODB_LOCK_WAITS` columns to `data_lock_waits` columns. Use this information to migrate applications from one table to the other.

Table 25.5 Mapping from INNODB_LOCK_WAITS to data_lock_waits Columns

INNODB_LOCK_WAITS Column	data_lock_waits Column
<code>REQUESTING_TRX_ID</code>	<code>REQUESTING_ENGINE_TRANSACTION_ID</code>
<code>REQUESTED_LOCK_ID</code>	<code>REQUESTING_ENGINE_LOCK_ID</code>
<code>BLOCKING_TRX_ID</code>	<code>BLOCKING_ENGINE_TRANSACTION_ID</code>
<code>BLOCKING_LOCK_ID</code>	<code>BLOCKING_ENGINE_LOCK_ID</code>

25.51.22 The INFORMATION_SCHEMA INNODB_METRICS Table

The `INNODB_METRICS` table provides a wide variety of `InnoDB` performance information, complementing the specific focus areas of the Performance Schema tables for `InnoDB`. With simple

queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the [InnoDB](#) source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables [innodb_monitor_enable](#), [innodb_monitor_disable](#), [innodb_monitor_reset](#), or [innodb_monitor_reset_all](#), using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword [all](#).

For usage information, see [Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

The [INNODB_METRICS](#) table has these columns:

- [NAME](#)

A unique name for the counter.

- [SUBSYSTEM](#)

The aspect of [InnoDB](#) that the metric applies to.

- [COUNT](#)

The value since the counter was enabled.

- [MAX_COUNT](#)

The maximum value since the counter was enabled.

- [MIN_COUNT](#)

The minimum value since the counter was enabled.

- [AVG_COUNT](#)

The average value since the counter was enabled.

- [COUNT_RESET](#)

The counter value since it was last reset. (The [_RESET](#) columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in [COUNT](#), [MAX_COUNT](#), and so on.)

- [MAX_COUNT_RESET](#)

The maximum counter value since it was last reset.

- [MIN_COUNT_RESET](#)

The minimum counter value since it was last reset.

- [AVG_COUNT_RESET](#)

The average counter value since it was last reset.

- [TIME_ENABLED](#)

The timestamp of the last start.

- [TIME_DISABLED](#)

The timestamp of the last stop.

- [TIME_ELAPSED](#)

The elapsed time in seconds since the counter started.

- [TIME_RESET](#)

The timestamp of the last reset.

- [STATUS](#)

Whether the counter is still running ([enabled](#)) or stopped ([disabled](#)).

- [TYPE](#)

Whether the item is a cumulative counter, or measures the current value of some resource.

- [COMMENT](#)

The counter description.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml_inserts'\G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 3
     MAX_COUNT: 3
    MIN_COUNT: NULL
     AVG_COUNT: 0.046153846153846156
   COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
   TIME_ENABLED: 2014-12-04 14:18:28
  TIME_DISABLED: NULL
   TIME_ELAPSED: 65
    TIME_RESET: NULL
        STATUS: enabled
         TYPE: status_counter
      COMMENT: Number of rows inserted
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- Transaction counter [COUNT](#) values may differ from the number of transaction events reported in Performance Schema [EVENTS_TRANSACTIONS_SUMMARY](#) tables. [InnoDB](#) counts only those transactions that it executes, whereas Performance Schema collects events for all non-aborted transactions initiated by the server, including empty transactions.

25.51.23 The INFORMATION_SCHEMA INNODB_SESSION_TEMP_TABLESPACES Table

The [INNODB_SESSION_TEMP_TABLESPACES](#) table provides metadata about session temporary tablespaces used for internal and user-created temporary tables. This table was added in MySQL 8.0.13.

The [INNODB_SESSION_TEMP_TABLESPACES](#) table has these columns:

- **ID**

The process or session ID.

- **SPACE**

The tablespace ID. A range of 400 thousand space IDs is reserved for session temporary tablespaces. Session temporary tablespaces are recreated each time the server is started. Space IDs are not persisted when the server is shut down and may be reused.

- **PATH**

The tablespace data file path. A session temporary tablespace has an `.ibt` file extension.

- **SIZE**

The size of the tablespace, in bytes.

- **STATE**

The state of the tablespace. **ACTIVE** indicates that the tablespace is currently used by a session. **INACTIVE** indicates that the tablespace is in the pool of available session temporary tablespaces.

- **PURPOSE**

The purpose of the tablespace. **INTRINSIC** indicates that the tablespace is used for optimized internal temporary tables use by the optimizer. **SLAVE** indicates that the tablespace is allocated for storing user-created temporary tables on a replication slave. **USER** indicates that the tablespace is used for user-created temporary tables. **NONE** indicates that the tablespace is not in use.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SESSION_TEMP_TABLESPACES;
```

ID	SPACE	PATH	SIZE	STATE	PURPOSE
8	4294566162	./#innodb_temp/temp_10.ibt	81920	ACTIVE	INTRINSIC
8	4294566161	./#innodb_temp/temp_9.ibt	98304	ACTIVE	USER
0	4294566153	./#innodb_temp/temp_1.ibt	81920	INACTIVE	NONE
0	4294566154	./#innodb_temp/temp_2.ibt	81920	INACTIVE	NONE
0	4294566155	./#innodb_temp/temp_3.ibt	81920	INACTIVE	NONE
0	4294566156	./#innodb_temp/temp_4.ibt	81920	INACTIVE	NONE
0	4294566157	./#innodb_temp/temp_5.ibt	81920	INACTIVE	NONE
0	4294566158	./#innodb_temp/temp_6.ibt	81920	INACTIVE	NONE
0	4294566159	./#innodb_temp/temp_7.ibt	81920	INACTIVE	NONE
0	4294566160	./#innodb_temp/temp_8.ibt	81920	INACTIVE	NONE

Notes

- You must have the **PROCESS** privilege to query this table.
- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

25.51.24 The INFORMATION_SCHEMA INNODB_TABLES Table

The **INNODB_TABLES** table provides metadata about **InnoDB** tables.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The **INNODB_TABLES** table has these columns:

- **TABLE_ID**

An identifier for the [InnoDB](#) table. This value is unique across all databases in the instance.

- [NAME](#)

The name of the table, preceded by the schema (database) name where appropriate (for example, [test/t1](#)). Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the [lower_case_table_names](#) setting.

- [FLAG](#)

A numeric value that represents bit-level information about table format and storage characteristics.

- [N_COLS](#)

The number of columns in the table. The number reported includes three hidden columns that are created by [InnoDB](#) ([DB_ROW_ID](#), [DB_TRX_ID](#), and [DB_ROLL_PTR](#)). The number reported also includes [virtual generated columns](#), if present.

- [SPACE](#)

An identifier for the tablespace where the table resides. 0 means the [InnoDB system tablespace](#). Any other number represents either a [file-per-table](#) tablespace or a general tablespace. This identifier stays the same after a [TRUNCATE TABLE](#) statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance.

- [ROW_FORMAT](#)

The table's row format ([Compact](#), [Redundant](#), [Dynamic](#), or [Compressed](#)).

- [ZIP_PAGE_SIZE](#)

The zip page size. Applies only to tables with a row format of [Compressed](#).

- [SPACE_TYPE](#)

The type of tablespace to which the table belongs. Possible values include [System](#) for the system tablespace, [General](#) for general tablespaces, and [Single](#) for file-per-table tablespaces. Tables assigned to the system tablespace using [CREATE TABLE](#) or [ALTER TABLE TABLESPACE=innodb_system](#) have a [SPACE_TYPE](#) of [General](#). For more information, see [CREATE TABLESPACE](#).

- [INSTANT_COLS](#)

The number of columns in the table prior to adding the first instant column using [ALTER TABLE ... ADD COLUMN](#) with [ALGORITHM=INSTANT](#).

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE TABLE_ID = 214\G
***** 1. row *****
TABLE_ID: 214
NAME: test/t1
FLAG: 129
N_COLS: 4
SPACE: 233
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: General
INSTANT_COLS: 0
```

Notes

- You must have the [PROCESS](#) privilege to query this table.

- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.25 The INFORMATION_SCHEMA INNODB_TABLESPACES Table

The [INNODB_TABLESPACES](#) table provides metadata about [InnoDB](#) file-per-table, general, and undo tablespaces.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

Note

The [INFORMATION_SCHEMA FILES](#) table reports metadata for [InnoDB](#) tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the global temporary tablespace, and undo tablespaces.

The [INNODB_TABLESPACES](#) table has these columns:

- [SPACE](#)

The tablespace ID.

- [NAME](#)

The schema (database) and table name.

- [FLAG](#)

A numeric value that represents bit-level information about tablespace format and storage characteristics.

- [ROW_FORMAT](#)

The tablespace row format ([Compact](#) or [Redundant](#), [Dynamic](#) or [Compressed](#), or [Undo](#)). The data in this column is interpreted from the tablespace flag information that resides in the data file.

There is no way to determine from this flag information if the tablespace row format is [Redundant](#) or [Compact](#), which is why one of the possible [ROW_FORMAT](#) values is [Compact](#) or [Redundant](#).

- [PAGE_SIZE](#)

The tablespace page size. The data in this column is interpreted from the tablespace flags information that resides in the [.ibd file](#).

- [ZIP_PAGE_SIZE](#)

The tablespace zip page size. The data in this column is interpreted from the tablespace flags information that resides in the [.ibd file](#).

- [SPACE_TYPE](#)

The type of tablespace. Possible values include [General](#) for general tablespaces, [Single](#) for file-per-table tablespaces, [System](#) for the system tablespace, and [Undo](#) for undo tablespaces.

- [FS_BLOCK_SIZE](#)

The file system block size, which is the unit size used for hole punching. This column pertains to the [InnoDB transparent page compression](#) feature.

- [FILE_SIZE](#)

The apparent size of the file, which represents the maximum size of the file, uncompressed. This column pertains to the [InnoDB transparent page compression](#) feature.

- [ALLOCATED_SIZE](#)

The actual size of the file, which is the amount of space allocated on disk. This column pertains to the [InnoDB transparent page compression](#) feature.

- [SERVER_VERSION](#)

The MySQL version that created the tablespace, or the MySQL version into which the tablespace was imported, or the version of the last major MySQL version upgrade. The value is unchanged by a release series upgrade, such as an upgrade from MySQL 8.0.x to 8.0.y. The value can be considered a “creation” marker or “certified” marker for the tablespace.

- [SPACE_VERSION](#)

The tablespace version, used to track changes to the tablespace format.

- [ENCRYPTION](#)

Whether the tablespace is encrypted. This column was added in MySQL 8.0.13.

- [STATE](#)

The tablespace state. This column was added in MySQL 8.0.14.

For file-per-table and general tablespaces, states include:

- [normal](#): The tablespace is normal and active.
- [discarded](#): The tablespace was discarded by an `ALTER TABLE ... DISCARD TABLESPACE` statement.
- [corrupted](#): The tablespace is identified by [InnoDB](#) as corrupted.

For undo tablespaces, states include:

- [active](#): Rollback segments in the undo tablespace can be allocated to new transactions.
- [inactive](#): Rollback segments in the undo tablespace are no longer used by new transactions. The truncate process is in progress. The undo tablespace was either selected by the purge thread implicitly or was made inactive by an `ALTER UNDO TABLESPACE ... SET INACTIVE` statement.
- [empty](#): The undo tablespace was truncated and is no longer active. It is ready to be dropped or made active again by an `ALTER UNDO TABLESPACE ... SET INACTIVE` statement.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE SPACE = 26\G
***** 1. row *****
    SPACE: 26
    NAME: test/t1
    FLAG: 0
ROW_FORMAT: Compact or Redundant
  PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
  SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
  FILE_SIZE: 98304
ALLOCATED_SIZE: 65536
SERVER_VERSION: 8.0.4
```

```
SPACE_VERSION: 1
ENCRYPTION: N
STATE: normal
```

Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.26 The INFORMATION_SCHEMA INNODB_TABLESPACES_BRIEF Table

The [INNODB_TABLESPACES_BRIEF](#) table provides space ID, name, path, flag, and space type metadata for file-per-table, general, undo, and system tablespaces.

[INNODB_TABLESPACES](#) provides the same metadata but loads more slowly because other metadata provided by the table, such as [FS_BLOCK_SIZE](#), [FILE_SIZE](#), and [ALLOCATED_SIZE](#), must be loaded dynamically.

Space and path metadata is also provided by the [INNODB_DATAFILES](#) table.

The [INNODB_TABLESPACES_BRIEF](#) table has these columns:

- [SPACE](#)

The tablespace ID.

- [NAME](#)

The tablespace name. For file-per-table tablespaces, the name is in the form of *schema/table_name*.

- [PATH](#)

The tablespace data file path. If a [file-per-table](#) tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

- [FLAG](#)

A numeric value that represents bit-level information about tablespace format and storage characteristics.

- [SPACE_TYPE](#)

The type of tablespace. Possible values include [General](#) for InnoDB general tablespaces, [Single](#) for InnoDB file-per-table tablespaces, and [System](#) for the InnoDB system tablespace.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES_BRIEF WHERE SPACE = 7;
+-----+-----+-----+-----+-----+
| SPACE | NAME   | PATH           | FLAG  | SPACE_TYPE |
+-----+-----+-----+-----+-----+
| 7     | test/t1 | ./test/t1.ibd | 16417 | Single     |
+-----+-----+-----+-----+-----+
```

Notes

- You must have the [PROCESS](#) privilege to query this table.

- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.27 The INFORMATION_SCHEMA INNODB_TABLESTATS View

The [INNODB_TABLESTATS](#) table provides a view of low-level status information about [InnoDB](#) tables. This data is used by the MySQL optimizer to calculate which index to use when querying an [InnoDB](#) table. This information is derived from in-memory data structures rather than data stored on disk. There is no corresponding internal [InnoDB](#) system table.

[InnoDB](#) tables are represented in this view if they have been opened since the last server restart and have not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are updated only for [DELETE](#) or [UPDATE](#) operations that modify indexed columns. Statistics are not updated by operations that modify only nonindexed columns.

[ANALYZE TABLE](#) clears table statistics and sets the [STATS_INITIALIZED](#) column to [Uninitialized](#). Statistics are collected again the next time the table is accessed.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”](#).

The [INNODB_TABLESTATS](#) table has these columns:

- [TABLE_ID](#)

An identifier representing the table for which statistics are available; the same value as [INNODB_TABLES.TABLE_ID](#).

- [NAME](#)

The name of the table; the same value as [INNODB_TABLES.NAME](#).

- [STATS_INITIALIZED](#)

The value is [Initialized](#) if the statistics are already collected, [Uninitialized](#) if not.

- [NUM_ROWS](#)

The current estimated number of rows in the table. Updated after each DML operation. The value could be imprecise if uncommitted transactions are inserting into or deleting from the table.

- [CLUST_INDEX_SIZE](#)

The number of pages on disk that store the clustered index, which holds the [InnoDB](#) table data in primary key order. This value might be null if no statistics are collected yet for the table.

- [OTHER_INDEX_SIZE](#)

The number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.

- [MODIFIED_COUNTER](#)

The number of rows modified by DML operations, such as [INSERT](#), [UPDATE](#), [DELETE](#), and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated

- [AUTOINC](#)

The next number to be issued for any auto-increment-based operation. The rate at which the [AUTOINC](#) value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.

- [REF_COUNT](#)

When this counter reaches zero, the table metadata can be evicted from the table cache.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESTATS where TABLE_ID = 71\G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
STATS_INITIALIZED: Initialized
      NUM_ROWS: 1
  CLUST_INDEX_SIZE: 1
  OTHER_INDEX_SIZE: 0
  MODIFIED_COUNTER: 1
      AUTOINC: 0
      REF_COUNT: 1
```

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.28 The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table

The [INNODB_TEMP_TABLE_INFO](#) table provides information about user-created [InnoDB](#) temporary tables that are active in an [InnoDB](#) instance. It does not provide information about internal [InnoDB](#) temporary tables used by the optimizer. The [INNODB_TEMP_TABLE_INFO](#) table is created when first queried, exists only in memory, and is not persisted to disk.

For usage information and examples, see [Section 15.15.7, “InnoDB INFORMATION_SCHEMA Temporary Table Info Table”](#).

The [INNODB_TEMP_TABLE_INFO](#) table has these columns:

- [TABLE_ID](#)

The table ID of the temporary table.

- [NAME](#)

The name of the temporary table.

- [N_COLS](#)

The number of columns in the temporary table. The number includes three hidden columns created by [InnoDB](#) ([DB_ROW_ID](#), [DB_TRX_ID](#), and [DB_ROLL_PTR](#)).

- [SPACE](#)

The ID of the temporary tablespace where the temporary table resides.

Example

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
TABLE_ID: 97
NAME: #sql8c88_43_0
```

N_COLS: 4
SPACE: 76

Notes

- This table is useful primarily for expert-level monitoring.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.29 The INFORMATION_SCHEMA INNODB_TRX Table

The [INNODB_TRX](#) table provides information about every transaction currently executing inside [InnoDB](#), including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

For usage information, see [Section 15.15.2.1, “Using InnoDB Transaction and Locking Information”](#).

The [INNODB_TRX](#) table has these columns:

- [TRX_ID](#)

A unique transaction ID number, internal to [InnoDB](#). These IDs are not created for transactions that are read only and nonlocking. For details, see [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#).

- [TRX_WEIGHT](#)

The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, [InnoDB](#) selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed nontransactional tables are considered heavier than others, regardless of the number of altered and locked rows.

- [TRX_STATE](#)

The transaction execution state. Permitted values are [RUNNING](#), [LOCK WAIT](#), [ROLLING BACK](#), and [COMMITTING](#).

- [TRX_STARTED](#)

The transaction start time.

- [TRX_REQUESTED_LOCK_ID](#)

The ID of the lock the transaction is currently waiting for, if [TRX_STATE](#) is [LOCK WAIT](#); otherwise [NULL](#). To obtain details about the lock, join this column with the [ENGINE_LOCK_ID](#) column of the Performance Schema [data_locks](#) table.

- [TRX_WAIT_STARTED](#)

The time when the transaction started waiting on the lock, if [TRX_STATE](#) is [LOCK WAIT](#); otherwise [NULL](#).

- [TRX_MYSQL_THREAD_ID](#)

The MySQL thread ID. To obtain details about the thread, join this column with the [ID](#) column of the [INFORMATION_SCHEMA PROCESSLIST](#) table, but see [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

- [TRX_QUERY](#)

The SQL statement that is being executed by the transaction.

- [TRX_OPERATION_STATE](#)

The transaction's current operation, if any; otherwise [NULL](#).

- [TRX_TABLES_IN_USE](#)

The number of [InnoDB](#) tables used while processing the current SQL statement of this transaction.

- [TRX_TABLES_LOCKED](#)

The number of [InnoDB](#) tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)

- [TRX_LOCK_STRUCTS](#)

The number of locks reserved by the transaction.

- [TRX_LOCK_MEMORY_BYTES](#)

The total size taken up by the lock structures of this transaction in memory.

- [TRX_ROWS_LOCKED](#)

The approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.

- [TRX_ROWS_MODIFIED](#)

The number of modified and inserted rows in this transaction.

- [TRX_CONCURRENCY_TICKETS](#)

A value indicating how much work the current transaction can do before being swapped out, as specified by the [innodb_concurrency_tickets](#) system variable.

- [TRX_ISOLATION_LEVEL](#)

The isolation level of the current transaction.

- [TRX_UNIQUE_CHECKS](#)

Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

- [TRX_FOREIGN_KEY_CHECKS](#)

Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

- [TRX_LAST_FOREIGN_KEY_ERROR](#)

The detailed error message for the last foreign key error, if any; otherwise [NULL](#).

- [TRX_ADAPTIVE_HASH_LATCHED](#)

Whether the adaptive hash index is locked by the current transaction. When the adaptive hash index search system is partitioned, a single transaction does not lock the entire adaptive hash index. Adaptive hash index partitioning is controlled by [innodb_adaptive_hash_index_parts](#), which is set to 8 by default.

- [TRX_ADAPTIVE_HASH_TIMEOUT](#)

Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. When the adaptive hash index search system is partitioned (controlled by [innodb_adaptive_hash_index_parts](#)), the value remains 0.

- [TRX_IS_READ_ONLY](#)

A value of 1 indicates the transaction is read only.

- [TRX_AUTOCOMMIT_NON_LOCKING](#)

A value of 1 indicates the transaction is a [SELECT](#) statement that does not use the [FOR UPDATE](#) or [LOCK IN SHARED MODE](#) clauses, and is executing with [autocommit](#) enabled so that the transaction contains only this one statement. When this column and [TRX_IS_READ_ONLY](#) are both 1, [InnoDB](#) optimizes the transaction to reduce the overhead associated with transactions that change table data.

- [TRX_SCHEDULE_WEIGHT](#)

The transaction schedule weight assigned by the Contention-Aware Transaction Scheduling (CATS) algorithm to transactions waiting for a lock. The value is relative to the values of other transactions. A higher value has a greater weight. A value is computed only for transactions in a [LOCK WAIT](#) state, as reported by the [TRX_STATE](#) column. A NULL value is reported for transactions that are not waiting for a lock. The [TRX_SCHEDULE_WEIGHT](#) value is different from the [TRX_WEIGHT](#) value, which is computed by a different algorithm for a different purpose.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
***** 1. row *****
      trx_id: 1510
      trx_state: RUNNING
      trx_started: 2014-11-19 13:24:40
      trx_requested_lock_id: NULL
      trx_wait_started: NULL
      trx_weight: 586739
      trx_mysql_thread_id: 2
      trx_query: DELETE FROM employees.salaries WHERE salary > 65000
      trx_operation_state: updating or deleting
      trx_tables_in_use: 1
      trx_tables_locked: 1
      trx_lock_structs: 3003
      trx_lock_memory_bytes: 450768
      trx_rows_locked: 1407513
      trx_rows_modified: 583736
      trx_concurrency_tickets: 0
      trx_isolation_level: REPEATABLE READ
      trx_unique_checks: 1
      trx_foreign_key_checks: 1
      trx_last_foreign_key_error: NULL
      trx_adaptive_hash_latched: 0
      trx_adaptive_hash_timeout: 10000
      trx_is_read_only: 0
      trx_autocommit_non_locking: 0
      trx_schedule_weight: NULL
```

Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.51.30 The INFORMATION_SCHEMA INNODB_VIRTUAL Table

The [INNODB_VIRTUAL](#) table provides metadata about [InnoDB virtual generated columns](#) and columns upon which virtual generated columns are based.

A row appears in the [INNODB_VIRTUAL](#) table for each column upon which a virtual generated column is based.

The [INNODB_VIRTUAL](#) table has these columns:

- [TABLE_ID](#)

An identifier representing the table associated with the virtual column; the same value as [INNODB_TABLES.TABLE_ID](#).

- [POS](#)

The position value of the [virtual generated column](#). The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation:

```
((nth virtual generated column for the InnoDB instance + 1) << 16)
+ the ordinal position of the virtual generated column
```

For example, if the first virtual generated column in the [InnoDB](#) instance is the third column of the table, the formula is $(0 + 1) \ll 16 + 2$. The first virtual generated column in the [InnoDB](#) instance is always number 0. As the third column in the table, the ordinal position of the virtual generated column is 2. Ordinal positions are counted from 0.

- [BASE_POS](#)

The ordinal position of the columns upon which a virtual generated column is based.

Example

```
mysql> CREATE TABLE `t1` (
    `a` int(11) DEFAULT NULL,
    `b` int(11) DEFAULT NULL,
    `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
    `h` varchar(10) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_VIRTUAL
WHERE TABLE_ID IN
    (SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_TABLES
    WHERE NAME LIKE "test/t1");
```

TABLE_ID	POS	BASE_POS
98	65538	0
98	65538	1

Notes

- If a constant value is assigned to a [virtual generated column](#), as in the following table, an entry for the column does not appear in the [INNODB_VIRTUAL](#) table. For an entry to appear, a virtual generated column must have a base column.

```
CREATE TABLE `t1` (
    `a` int(11) DEFAULT NULL,
```

```
`b` int(11) DEFAULT NULL,
`c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

However, metadata for such a column does appear in the [INNODB_COLUMNS](#) table.

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION_SCHEMA_COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

25.52 INFORMATION_SCHEMA Thread Pool Tables

Note

As of MySQL 8.0.14, the thread pool [INFORMATION_SCHEMA](#) tables are also available as Performance Schema tables. (See [Section 26.12.16, “Performance Schema Thread Pool Tables”](#).) The [INFORMATION_SCHEMA](#) tables are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_state;
```

The following sections describe the [INFORMATION_SCHEMA](#) tables associated with the thread pool plugin (see [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)). They provide information about thread pool operation:

- [TP_THREAD_GROUP_STATE](#): Information about thread pool thread group states
- [TP_THREAD_GROUP_STATS](#): Thread group statistics
- [TP_THREAD_STATE](#): Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of [TP_THREAD_STATE](#), all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against [TP_THREAD_STATE](#) from blocking the entire MySQL server.

The [INFORMATION_SCHEMA](#) thread pool tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see [Section 5.6.3.2, “Thread Pool Installation”](#)). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but will be empty.

25.52.1 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table

Note

As of MySQL 8.0.14, the thread pool [INFORMATION_SCHEMA](#) tables are also available as Performance Schema tables. (See [Section 26.12.16, “Performance Schema Thread Pool Tables”](#).) The [INFORMATION_SCHEMA](#) tables are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_GROUP_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_group_state;
```

The `TP_THREAD_GROUP_STATE` table has one row per thread group in the thread pool. Each row provides information about the current state of a group.

For descriptions of the columns in the `INFORMATION_SCHEMA TP_THREAD_GROUP_STATE` table, see [Section 26.12.16.1, “The tp_thread_group_state Table”](#). The Performance Schema `tp_thread_group_state` table has equivalent columns.

25.52.2 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table

Note

As of MySQL 8.0.14, the thread pool `INFORMATION_SCHEMA` tables are also available as Performance Schema tables. (See [Section 26.12.16, “Performance Schema Thread Pool Tables”](#).) The `INFORMATION_SCHEMA` tables are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_GROUP_STATS;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_group_stats;
```

The `TP_THREAD_GROUP_STATS` table reports statistics per thread group. There is one row per group.

For descriptions of the columns in the `INFORMATION_SCHEMA TP_THREAD_GROUP_STATS` table, see [Section 26.12.16.2, “The tp_thread_group_stats Table”](#). The Performance Schema `tp_thread_group_stats` table has equivalent columns.

25.52.3 The INFORMATION_SCHEMA TP_THREAD_STATE Table

Note

As of MySQL 8.0.14, the thread pool `INFORMATION_SCHEMA` tables are also available as Performance Schema tables. (See [Section 26.12.16, “Performance Schema Thread Pool Tables”](#).) The `INFORMATION_SCHEMA` tables are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_state;
```

The `TP_THREAD_STATE` table has one row per thread created by the thread pool to handle connections.

For descriptions of the columns in the `INFORMATION_SCHEMA TP_THREAD_STATE` table, see [Section 26.12.16.3, “The tp_thread_state Table”](#). The Performance Schema `tp_thread_state` table has equivalent columns.

25.53 INFORMATION_SCHEMA Connection-Control Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the `CONNECTION_CONTROL` plugin.

25.53.1 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per account (user/host combination).

`CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` has these columns:

- `USERHOST`

The user/host combination indicating an account that has failed connection attempts, in `'user_name'@'host_name'` format.

- `FAILED_ATTEMPTS`

The current number of consecutive failed connection attempts for the `USERHOST` value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the `FAILED_ATTEMPTS` value and the `connection_control_failed_connections_threshold` system variable value.

Notes

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin must be activated for this table to be available, and the `CONNECTION_CONTROL` plugin must be activated or the table contents will always be empty. See [Section 6.4.2, “The Connection-Control Plugins”](#).
- The table contains rows only for accounts that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When an account connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the account.
- Assigning a value to the `connection_control_failed_connections_threshold` system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

25.54 INFORMATION_SCHEMA MySQL Enterprise Firewall Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with MySQL Enterprise Firewall (see [Section 6.4.7, “MySQL Enterprise Firewall”](#)). They provide views into the firewall in-memory data cache. These tables are available only if the appropriate firewall plugins are enabled.

25.54.1 The INFORMATION_SCHEMA MYSQL_FIREWALL_USERS Table

The `MYSQL_FIREWALL_USERS` table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists registered firewall accounts and their operational modes. It is used in conjunction with the `mysql.firewall_users` system table that provides persistent storage of firewall data; see [MySQL Enterprise Firewall Tables](#).

The `MYSQL_FIREWALL_USERS` table has these columns:

- `USERHOST`

An account registered with the firewall. Each account has the format `user_name@host_name`.

- `MODE`

The current firewall operational mode for the account. The permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, and `RECORDING`. For details about their meanings, see [Firewall Operational Concepts](#).

25.54.2 The INFORMATION_SCHEMA MYSQL_FIREWALL_WHITELIST Table

The `MYSQL_FIREWALL_WHITELIST` table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists registered firewall accounts and their allowlists. It is used in conjunction with the `mysql.firewall_whitelist` system table that provides persistent storage of firewall data; see [MySQL Enterprise Firewall Tables](#).

The `MYSQL_FIREWALL_WHITELIST` table has these columns:

- `USERHOST`

An account registered with the firewall. Each account has the format `user_name@host_name`.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the account. An account allowlist is the union of its rules.

25.55 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS               |
| COLLATIONS                   |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                     |
| COLUMN_PRIVILEGES            |
| ENGINES                      |
| EVENTS                       |
| FILES                        |
| KEY_COLUMN_USAGE             |
| PARTITIONS                   |
| PLUGINS                      |
| PROCESSLIST                  |
| REFERENTIAL_CONSTRAINTS     |
| ROUTINES                     |
| SCHEMATA                     |
| SCHEMA_PRIVILEGES            |
| STATISTICS                   |
| TABLES                      |
| TABLE_CONSTRAINTS          |
| TABLE_PRIVILEGES            |
| TRIGGERS                     |
| USER_PRIVILEGES              |
| VIEWS                        |
+-----+
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES

```

The [WHERE](#) clause, if present, is evaluated against the column names displayed by the [SHOW](#) statement. For example, the [SHOW CHARACTER SET](#) statement produces these output columns:

```

mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...

```

To use a [WHERE](#) clause with [SHOW CHARACTER SET](#), you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```

mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

```

This statement displays the multibyte character sets:

```

mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr   | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk     | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8    | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2    | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

```

26.19.2 Obtaining Parent Event Information	4577
26.20 Restrictions on Performance Schema	4579

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the [PERFORMANCE_SCHEMA](#) storage engine and the [performance_schema](#) database. The Performance Schema focuses primarily on performance data. This differs from [INFORMATION_SCHEMA](#), which serves for inspection of metadata.
- The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.
- Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
- Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.
- Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
- The [PERFORMANCE_SCHEMA](#) storage engine collects event data using “instrumentation points” in server source code.
- Collected events are stored in tables in the [performance_schema](#) database. These tables can be queried using [SELECT](#) statements like other tables.
- Performance Schema configuration can be modified dynamically by updating tables in the [performance_schema](#) database through SQL statements. Configuration changes affect data collection immediately.
- Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.
- Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section 26.20, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by [EXPLAIN](#)) to change.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.

- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- Most Performance Schema tables have indexes, which gives the optimizer access to execution plans other than full table scans. For more information, see [Section 8.2.4, “Optimizing Performance Schema Queries”](#).
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

Note

The MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema. The `sys` schema is installed by default. For usage instructions, see [Chapter 27, MySQL sys Schema](#).

26.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 26.19, “Using the Performance Schema to Diagnose Problems”](#).

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in the server `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees `performance_schema` and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON    |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine, so you will see it listed in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
      WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
```

```

Transactions: NO
          XA: NO
          Savepoints: NO
...

```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
       WHERE TABLE_SCHEMA = 'performance_schema';
```

TABLE_NAME
accounts
cond_instances
...
events_stages_current
events_stages_history
events_stages_history_long
events_stages_summary_by_account_by_event_name
events_stages_summary_by_host_by_event_name

mysql> SHOW TABLES FROM performance_schema;
+-----+
| Tables_in_performance_schema
+-----+
| accounts
| cond_instances
| events_stages_current
| events_stages_history
| events_stages_history_long
| ...

```

The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE performance_schema.setup_consumers\G
***** 1. row *****
      Table: setup_consumers
Create Table: CREATE TABLE `setup_consumers` (
  `NAME` varchar(64) NOT NULL,
  `ENABLED` enum('YES','NO') NOT NULL,
  PRIMARY KEY (`NAME`)
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 26.12, “Performance Schema Table Descriptions”](#).

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```

mysql> UPDATE performance_schema.setup_instruments
      SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)
mysql> UPDATE performance_schema.setup_consumers
      SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)

```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```

mysql> SELECT *
      FROM performance_schema.events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
      END_EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
      SOURCE: thr_lock.c:525
      TIMER_START: 201660494489586
      TIMER_END: 201660494576112
      TIMER_WAIT: 86526
      SPINS: NULL
      OBJECT_SCHEMA: NULL
      OBJECT_NAME: NULL
      INDEX_NAME: NULL
      OBJECT_TYPE: NULL

```

```

OBJECT_INSTANCE_BEGIN: 142270668
  NESTING_EVENT_ID: NULL
  NESTING_EVENT_TYPE: NULL
    OPERATION: lock
  NUMBER_OF_BYTES: NULL
    FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 26.4.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```

mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
FROM performance_schema.events_waits_history
WHERE THREAD_ID = 13
ORDER BY EVENT_ID;

```

EVENT_ID	EVENT_NAME	TIMER_WAIT
86	wait/synch/mutex/mysys/THR_LOCK::mutex	686322
87	wait/synch/mutex/mysys/THR_LOCK_malloc	320535
88	wait/synch/mutex/mysys/THR_LOCK_malloc	339390
89	wait/synch/mutex/mysys/THR_LOCK_malloc	377100
90	wait/synch/mutex/sql/LOCK_plugin	614673
91	wait/synch/mutex/sql/LOCK_open	659925
92	wait/synch/mutex/sql/THD::LOCK_thd_data	494001
93	wait/synch/mutex/mysys/THR_LOCK_malloc	222489
94	wait/synch/mutex/mysys/THR_LOCK_malloc	214947
95	wait/synch/mutex/mysys/LOCK_alarm	312993

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```

mysql> SELECT EVENT_NAME, COUNT_STAR
FROM performance_schema.events_waits_summary_global_by_event_name
ORDER BY COUNT_STAR DESC LIMIT 10;

```

EVENT_NAME	COUNT_STAR
wait/synch/mutex/mysys/THR_LOCK_malloc	6419
wait/io/file/sql/FRM	452
wait/synch/mutex/sql/LOCK_plugin	337
wait/synch/mutex/mysys/THR_LOCK_open	187
wait/synch/mutex/mysys/LOCK_alarm	147
wait/synch/mutex/sql/THD::LOCK_thd_data	115
wait/io/file/myisam/kfile	102

```

| wait/synch/mutex/sql/LOCK_global_system_variables | 89 |
| wait/synch/mutex/mysys/THR_LOCK::mutex          | 89 |
| wait/synch/mutex/sql/LOCK_open                   | 88 |
+-----+-----+
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
       FROM performance_schema.events_waits_summary_global_by_event_name
       ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
+-----+-----+
| EVENT_NAME                                     | SUM_TIMER_WAIT |
+-----+-----+
| wait/io/file/sql/MYSQL_LOG                     | 1599816582     |
| wait/synch/mutex/mysys/THR_LOCK_malloc          | 1530083250     |
| wait/io/file/sql/binlog_index                  | 1385291934     |
| wait/io/file/sql/FRM                           | 1292823243     |
| wait/io/file/myisam/kfile                      | 411193611      |
| wait/io/file/myisam/dfile                      | 322401645      |
| wait/synch/mutex/mysys/LOCK_alarm              | 145126935      |
| wait/io/file/sql/casetest                      | 104324715      |
| wait/synch/mutex/sql/LOCK_plugin               | 86027823       |
| wait/io/file/sql/pid                           | 72591750       |
+-----+-----+

```

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```

mysql> SELECT *
       FROM performance_schema.file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...

```

Setup tables are used to configure and display monitoring characteristics. For example, `setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```

mysql> SELECT NAME, ENABLED, TIMED
       FROM performance_schema.setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| stage/sql/end                           | NO      | NO    |
| stage/sql/executing                     | NO      | NO    |
| stage/sql/init                           | NO      | NO    |
| stage/sql/insert                         | NO      | NO    |
...
| statement/sql/load                       | YES     | YES   |
| statement/sql/grant                      | YES     | YES   |
| statement/sql/check                      | YES     | YES   |

```

statement/sql/flush	YES	YES	
...			
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES	
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES	
wait/synch/mutex/sql/LOCK_lock_db	YES	YES	
wait/synch/mutex/sql/LOCK_manager	YES	YES	
...			
wait/synch/rwlock/sql/LOCK_grant	YES	YES	
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES	
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES	
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES	
...			
wait/io/file/sql/binlog	YES	YES	
wait/io/file/sql/binlog_index	YES	YES	
wait/io/file/sql/casetest	YES	YES	
wait/io/file/sql/dbopt	YES	YES	
...			

To understand how to interpret instrument names, see [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```
mysql> UPDATE performance_schema.setup_instruments
      SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 26.4.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 26.4.1, “Performance Schema Event Timing”](#).

26.2 Performance Schema Build Configuration

The Performance Schema is mandatory and always compiled in. It is possible to exclude certain parts of the Performance Schema instrumentation. For example, to exclude stage and statement instrumentation, do this:

```
shell> cmake . \
        -DDISABLE_PSI_STAGE=1 \
        -DDISABLE_PSI_STATEMENT=1
```

For more information, see the descriptions of the `DISABLE_PSI_XXX` CMake options in [Section 2.9.7, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that has missing or out-of-date tables). One indication of this issue is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'.'events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema'.'events_waits_history_long'
has the wrong structure
...
```

To correct that problem, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#).

Because the Performance Schema is configured into the server at build time, a row for `PERFORMANCE_SCHEMA` appears in the output from `SHOW ENGINES`. This means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

26.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in the server `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Disable the instrument
- `ON`, `TRUE`, or `1`: Enable and time the instrument
- `COUNTED`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 26.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, *consumer_name* is a consumer name such as `events_waits_history`, and *value* is one of these values:

- `OFF`, `FALSE`, or `0`: Do not collect events for the consumer
- `ON`, `TRUE`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

Variable_name	Value
performance_schema	ON
performance_schema_accounts_size	100
performance_schema_digests_size	200
performance_schema_events_stages_history_long_size	10000
performance_schema_events_stages_history_size	10
performance_schema_events_statements_history_long_size	10000
performance_schema_events_statements_history_size	10
performance_schema_events_waits_history_long_size	10000
performance_schema_events_waits_history_size	10
performance_schema_hosts_size	100
performance_schema_max_cond_classes	80
performance_schema_max_cond_instances	1000
...	

The `performance_schema` variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. The Performance Schema autoscales many parameters to use memory only as required; see [Section 26.17, “The Performance Schema Memory-Allocation Model”](#).

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
```

```
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. The Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use `mysqld --verbose --help` and examine the option descriptions, or see [Section 26.15, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup, the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing or autoscaling for a given parameter, set it to a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of `-1`.

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

26.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
       WHERE TABLE_SCHEMA = 'performance_schema'
       AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_threads |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 26.12.2, “Performance Schema Setup Tables”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 26.4.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `init_file` system variable set to name the file. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a

different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `init_file` value when you start the server.

26.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

Performance Schema Timers

Performance Schema timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_schema.performance_timers;
```

TIMER_NAME	TIMER_FREQUENCY	TIMER_RESOLUTION	TIMER_OVERHEAD
CYCLE	2389029850	1	72
NANOSECOND	1000000000	1	112
MICROSECOND	1000000	1	136
MILLISECOND	1036	1	168

If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter.
- `TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds.
- `TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.
- `TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

The Performance Schema assigns timers as follows:

- The wait timer uses `CYCLE`.
- The idle, stage, statement, and transaction timers use `NANOSECOND` on platforms where the `NANOSECOND` timer is available, `MICROSECOND` otherwise.

At server startup, the Performance Schema verifies that assumptions made at build time about timer assignments are correct, and displays a warning if a timer is not available.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the `CYCLE` timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is `NANOSECOND`. The extra “overhead” compared to the `CYCLE` timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the `CYCLE` timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, macOS, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: `TIMER_START` and `TIMER_END` indicate when an event started and finished, and `TIMER_WAIT` indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating aggregate time values in summary tables (sum, minimum, maximum, and average).

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

The timer baseline ("time zero") occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication

is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

While a wait, stage, statement, or transaction event is executing, the respective current-event tables display current-event timing information:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated.
- `TIMER_END` is populated with the current timer value.
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`).

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than *N* picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

26.4.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db          | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager          | YES     | YES   |
...
```

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 26.4.3, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and whether they are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current                   | NO      |
```

events_stages_history	NO	
events_stages_history_long	NO	
events_statements_current	YES	
events_statements_history	YES	
events_statements_history_long	NO	
events_transactions_current	YES	
events_transactions_history	YES	
events_transactions_history_long	NO	
events_waits_current	NO	
events_waits_history	NO	
events_waits_history_long	NO	
global_instrumentation	YES	
thread_instrumentation	YES	
statements_digest	YES	
+-----+-----+		

Filtering can be done at different stages of performance monitoring:

- **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.
- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of [WHERE](#) clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 26.5, “Performance Schema Queries”](#).

26.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
 - [setup_instruments](#) indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables.

An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.

- `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
- `threads` indicates whether monitoring is enabled for each server thread.
- `setup_actors` determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with the exception that modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

26.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments;
```

NAME	ENABLED	TIMED
...		
stage/sql/end	NO	NO
stage/sql/executing	NO	NO
stage/sql/init	NO	NO
stage/sql/insert	NO	NO
...		
statement/sql/load	YES	YES
statement/sql/grant	YES	YES
statement/sql/check	YES	YES
statement/sql/flush	YES	YES
...		
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...		
wait/synch/rwlock/sql/LOCK_grant	YES	YES
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES
...		
wait/io/file/sql/binlog	YES	YES
wait/io/file/sql/binlog_index	YES	YES
wait/io/file/sql/casetest	YES	YES
wait/io/file/sql/dbopt	YES	YES

...

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 26.4.1, “Performance Schema Event Timing”](#).

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 26.4.3, “Event Pre-Filtering”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see [Section 26.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

- Disable all instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO';
```

Now no events will be collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

- Enable all but those instruments in the `mysys` library:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
UPDATE performance_schema.setup_instruments
SET TIMED = 'NO';
```

26.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
```

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
EVENT	mysql	%	NO	NO
EVENT	performance_schema	%	NO	NO
EVENT	information_schema	%	NO	NO
EVENT	%	%	YES	YES
FUNCTION	mysql	%	NO	NO
FUNCTION	performance_schema	%	NO	NO
FUNCTION	information_schema	%	NO	NO
FUNCTION	%	%	YES	YES
PROCEDURE	mysql	%	NO	NO
PROCEDURE	performance_schema	%	NO	NO
PROCEDURE	information_schema	%	NO	NO
PROCEDURE	%	%	YES	YES
TABLE	mysql	%	NO	NO
TABLE	performance_schema	%	NO	NO
TABLE	information_schema	%	NO	NO
TABLE	%	%	YES	YES
TRIGGER	mysql	%	NO	NO
TRIGGER	performance_schema	%	NO	NO
TRIGGER	information_schema	%	NO	NO
TRIGGER	%	%	YES	YES

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or object name, or `'%'` to match any name.

The `ENABLED` column indicates whether matching objects are monitored, and `TIMED` indicates whether to collect timing information. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 26.4.1, “Performance Schema Event Timing”](#).

The effect of the default object configuration is to instrument all objects except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given `OBJECT_TYPE`, the Performance Schema checks rows in this order:

- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='literal'`.
- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='%'`.
- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.

- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

For stored program objects, the Performance Schema takes the `ENABLED` and `TIMED` columns directly from the `setup_objects` row. There is no combining of values with `setup_instruments`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
TABLE	db1	t1	YES	YES
TABLE	db1	t2	NO	NO
TABLE	db2	%	YES	YES
TABLE	db3	%	NO	NO
TABLE	%	%	YES	YES

If an object-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored
- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

26.4.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

```
events_waits_history
events_waits_history_long
events_stages_history
events_stages_history_long
events_statements_history
events_statements_history_long
events_transactions_history
events_transactions_history_long
```

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name.

The `ENABLED` and `HISTORY` columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the `USER` and `HOST` columns (`ROLE` is unused):

- Rows with `USER='literal'` and `HOST='literal'`.
- Rows with `USER='literal'` and `HOST='%'`.
- Rows with `USER='%'` and `HOST='literal'`.
- Rows with `USER='%'` and `HOST='%'`.

The order in which matching occurs matters because different matching `setup_actors` rows can have different `USER` and `HOST` values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination), based on the `ENABLED` and `HISTORY` column values:

- When the best match is a row with `ENABLED=YES`, the `INSTRUMENTED` value for the thread becomes `YES`. When the best match is a row with `HISTORY=YES`, the `HISTORY` value for the thread becomes `YES`.
- When the best match is a row with `ENABLED=NO`, the `INSTRUMENTED` value for the thread becomes `NO`. When the best match is a row with `HISTORY=NO`, the `HISTORY` value for the thread becomes `NO`.
- When no match is found, the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

The `ENABLED` and `HISTORY` columns in `setup_actors` rows can be set to `YES` or `NO` independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To

perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific `HOST/USER` combinations.

Suppose that you modify `setup_actors` as follows:

```
UPDATE performance_schema.setup_actors
SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The `UPDATE` statement changes the default match to disable instrumentation and historical event collection. The `INSERT` statements add rows for more specific matches.

Now the Performance Schema determines how to set the `INSTRUMENTED` and `HISTORY` values for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row. The `INSTRUMENTED` and `HISTORY` values for the thread become `YES`.
- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The `INSTRUMENTED` value for the thread becomes `YES` and the `HISTORY` value becomes `NO`.
- If `joe` connects from any other host, there is no match. The `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.
- If `sam` connects from any host, the connection matches the third inserted row. The `INSTRUMENTED` value for the thread becomes `NO` and the `HISTORY` value becomes `YES`.
- For any other connection, the row with `HOST` and `USER` set to `'%'` matches. This row now has `ENABLED` and `HISTORY` set to `NO`, so the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

26.4.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | YES     |
| events_statements_history_long      | NO      |
| events_transactions_current         | YES     |
| events_transactions_history         | YES     |
| events_transactions_history_long    | NO      |
| events_waits_current                | NO      |
| events_waits_history                | NO      |
| events_waits_history_long           | NO      |
| global_instrumentation              | YES     |
```

thread_instrumentation	YES	
statements_digest	YES	
+-----+-----+		

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Section 26.4.8, “Example Consumer Configurations”](#).

- [Global and Thread Consumers](#)
- [Wait Event Consumers](#)
- [Stage Event Consumers](#)
- [Statement Event Consumers](#)
- [Transaction Event Consumers](#)
- [Statement Digest Consumer](#)

Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.
- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

Transaction Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if `NO`, disables collection of individual transaction events in the `events_transactions_current` table. If `YES`, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.

- `events_transactions_history` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history` table.
- `events_transactions_history_long` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history_long` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history_long` table.

Statement Digest Consumer

The `statements_digest` consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns will be `NULL`).

For more information about statement digesting, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

26.4.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
thread_instrumentation
  events_waits_current
  events_waits_history
  events_waits_history_long
  events_stages_current
  events_stages_history
  events_stages_history_long
  events_statements_current
  events_statements_history
  events_statements_history_long
  events_transactions_current
  events_transactions_history
  events_transactions_history_long
statements_digest
```

Note

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is `NO`, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is `YES`, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see [Section 26.4.7, “Pre-Filtering by Consumer”](#).

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers

are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- [No Instrumentation](#)
- [Global Instrumentation Only](#)
- [Global and Thread Instrumentation Only](#)
- [Global, Thread, and Current-Event Instrumentation](#)
- [Global, Thread, Current-Event, and Event-History instrumentation](#)

No Instrumentation

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | NO      |
| ...                                |         |
+-----+-----+
```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

Global Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | NO      |
| ...                                |         |
+-----+-----+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`

- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`
- `events_transactions_summary_global_by_event_name`

Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                | NO      |
| ...                                |         |
| events_stages_current               | NO      |
| ...                                |         |
| events_statements_current           | NO      |
| ...                                |         |
| events_transactions_current         | NO      |
| ...                                |         |
+-----+-----+
```

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`, `transactions`; and `yyy` is `thread`, `user`, `host`, `account`

Global, Thread, and Current-Event Instrumentation

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	NO
events_waits_history_long	NO
events_stages_current	YES
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	NO
events_transactions_history_long	NO
...	

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Consumers `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	NO
events_stages_current	YES
events_stages_history	YES
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES

events_transactions_history	YES
events_transactions_history_long	NO
...	

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	NO
events_waits_history_long	YES
events_stages_current	YES
events_stages_history	NO
events_stages_history_long	YES
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	NO
events_transactions_history_long	YES
...	

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
events_stages_current	YES
events_stages_history	YES
events_stages_history_long	YES
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	YES
...	

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

26.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/synch/mutex/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `'%/file/%'` will match other instruments that have an element of `'/file/'` anywhere in the name. Even less suitable is the pattern `'%file%'` because it will match instruments with `'file'` anywhere in the name, such as `wait/synch/mutex/innodb/file_open_mutex`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE 'pattern';

SELECT NAME FROM performance_schema.setup_consumers
WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

26.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the `InnoDB` storage engine, use this query:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments
WHERE NAME LIKE 'wait/io/file/innodb/%';
```

NAME	ENABLED	TIMED
wait/io/file/innodb/innodb_tablespace_open_file	YES	YES
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES
wait/io/file/innodb/innodb_arch_file	YES	YES
wait/io/file/innodb/innodb_clone_file	YES	YES

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.

- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

26.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 26.4.3, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
        FROM performance_schema.events_waits_history
        WHERE EVENT_NAME LIKE 'wait/io/file/%'
        AND NUMBER_OF_BYTES IS NOT NULL;
```

THREAD_ID	NUMBER_OF_BYTES
11	66
11	47
11	139
5	24
5	834

Most Performance Schema tables have indexes, which gives the optimizer access to execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables. For more information, see [Section 8.2.4, “Optimizing Performance Schema Queries”](#).

26.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of elements separated by `' / '` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing tables
stage/sql/Sorting result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
errors
```

The instrument name space has a tree-like structure. The elements of an instrument name from left to right provide a progression from more general to more specific. The number of elements a name has depends on the type of instrument.

The interpretation of a given element in a name depends on the elements to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level element of an instrument prefix indicates the type of instrument. This element also determines which event timer in the `performance_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major element (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.
- [Top-Level Instrument Elements](#)
- [Idle Instrument Elements](#)
- [Error Instrument Elements](#)
- [Memory Instrument Elements](#)
- [Stage Instrument Elements](#)
- [Statement Instrument Elements](#)
- [Thread Instrument Elements](#)
- [Wait Instrument Elements](#)

Top-Level Instrument Elements

- `idle`: An instrumented idle event. This instrument has no further elements.
- `error`: An instrumented error event. This instrument has no further elements.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `transaction`: An instrumented transaction event. This instrument has no further elements.
- `wait`: An instrumented wait event.

Idle Instrument Elements

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in [Section 26.12.3.5, “The socket_instances Table”](#).

Error Instrument Elements

The `error` instrument indicates whether to collect information for server errors and warnings. This instrument is enabled by default. The `TIMED` column for the `error` row in the `setup_instruments` table is inapplicable because timing information is not collected.

Memory Instrument Elements

Memory instrumentation is enabled by default. Memory instrumentation can be enabled or disabled at startup, or dynamically at runtime by updating the `ENABLED` column of the relevant

instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see [Section 26.17, “The Performance Schema Memory-Allocation Model”](#).

Stage Instrument Elements

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

Statement Instrument Elements

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see [Section 26.12.6, “Performance Schema Statement Event Tables”](#).
- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`). For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.
- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

Thread Instrument Elements

Instrumented threads are displayed in the `setup_threads` table, which exposes thread class names and attributes.

Thread instruments begin with `thread` (for example, `thread/sql/parser_service` or `thread/performance_schema/setup`).

Wait Instrument Elements

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 26.8, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/lock/metadata/sql/mdl`

An instrumented metadata lock operation.

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/prlock`

A priority `rwlock` lock object.

- `wait/synch/rwlock`

A plain `read/write lock` object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- [wait/synch/sxlock](#)

A shared-exclusive (SX) lock is a type of [rwlock](#) lock object that provides write access to a common resource while permitting inconsistent reads by other threads. [sxlocks](#) optimize concurrency and improve scalability for read-write workloads.

26.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
```

Variable_name	Value
Performance_schema_accounts_lost	0
Performance_schema_cond_classes_lost	0
Performance_schema_cond_instances_lost	0
Performance_schema_digest_lost	0
Performance_schema_file_classes_lost	0
Performance_schema_file_handles_lost	0
Performance_schema_file_instances_lost	0
Performance_schema_hosts_lost	0
Performance_schema_locker_lost	0
Performance_schema_memory_classes_lost	0
Performance_schema_metadata_lock_lost	0
Performance_schema_mutex_classes_lost	0
Performance_schema_mutex_instances_lost	0
Performance_schema_nested_statement_lost	0
Performance_schema_program_lost	0
Performance_schema_rwlock_classes_lost	0
Performance_schema_rwlock_instances_lost	0
Performance_schema_session_connect_attrs_lost	0
Performance_schema_socket_classes_lost	0
Performance_schema_socket_instances_lost	0
Performance_schema_stage_classes_lost	0
Performance_schema_statement_classes_lost	0
Performance_schema_table_handles_lost	0
Performance_schema_table_instances_lost	0
Performance_schema_thread_classes_lost	0
Performance_schema_thread_instances_lost	0
Performance_schema_users_lost	0

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- [Performance_schema_xxx_classes_lost](#) indicates how many instruments of type [xxx](#) could not be loaded.
- [Performance_schema_xxx_instances_lost](#) indicates how many instances of object type [xxx](#) could not be created.
- [Performance_schema_xxx_handles_lost](#) indicates how many instances of object type [xxx](#) could not be opened.
- [Performance_schema_locker_lost](#) indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments [Performance_schema_mutex_classes_lost](#). The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances

that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has $150+40 = 190$ mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for $200-190 = 10$ instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10 |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where *N* is less than the default value. The

default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.

- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
```

```

Type: performance_schema
Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
Type: performance_schema
Name: performance_schema.memory
Status: 26459600
...

```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.7.15, “SHOW ENGINE Statement”](#).

26.8 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

Row#	EVENT_NAME	TIMER_START	TIMER_END
1	wait/io/file/myisam/dfile	10001	10002
2	wait/io/table/sql/handler	10000	NULL

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

26.9 Performance Schema Tables for Current and Historical Events

For wait, stage, statement, and transaction events, the Performance Schema can monitor and store current events. In addition, when events end, the Performance Schema can store them in history tables. For each event type, the Performance Schema uses three tables for storing current and historical events. The tables have names of the following forms, where `xxx` indicates the event type (`waits`, `stages`, `statements`, `transactions`):

- `events_xxx_current`: The “current events” table stores the current monitored event for each thread (one row per thread).
- `events_xxx_history`: The “recent history” table stores the most recent events that have ended per thread (up to a maximum number of rows per thread).
- `events_xxx_history_long`: The “long history” table stores the most recent events that have ended globally (across all threads, up to a maximum number of rows per table).

The `_current` table for each event type contains one row per thread, so there is no system variable for configuring its maximum size. The Performance Schema autosizes the history tables, or the sizes can be configured explicitly at server startup using table-specific system variables, as indicated in the

sections that describe the individual history tables. Typical autosized values are 10 rows per thread for `_history` tables, and 10,000 rows total for `_history_long` tables.

For each event type, the `_current`, `_history`, and `_history_long` tables have the same columns. The `_current` and `_history` tables have the same indexing. The `_history_long` table has no indexing.

The `_current` tables show what is currently happening within the server. When a current event ends, it is removed from its `_current` table.

The `_history` and `_history_long` tables show what has happened in the recent past. When the history tables become full, old events are discarded as new events are added. Rows expire from the `_history` and `_history_long` tables in different ways because the tables serve different purposes:

- `_history` is meant to investigate individual threads, independently of the global server load.
- `_history_long` is meant to investigate the server globally, not each thread.

The difference between the two types of history tables relates to the data retention policy. Both tables contains the same data when an event is first seen. However, data within each table expires differently over time, so that data might be preserved for a longer or shorter time in each table:

- For `_history`, when the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added.
- For `_history_long`, when the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

When a thread ends, all its rows are discarded from the `_history` table but not from the `_history_long` table.

The following example illustrates the differences in how events are added to and discarded from the two types of history tables. The principles apply equally to all event types. The example is based on these assumptions:

- The Performance Schema is configured to retain 10 rows per thread in the `_history` table and 10,000 rows total in the `_history_long` table.
- Thread A generates 1 event per second.

Thread B generates 100 events per second.

- No other threads are running.

After 5 seconds of execution:

- A and B have generated 5 and 500 events, respectively.
- `_history` contains 5 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, no rows have been discarded for A, whereas 490 rows have been discarded for B.
- `_history_long` contains 5 rows for A and 500 rows for B. Because the table has a maximum size of 10,000 rows, no rows have been discarded for either thread.

After 5 minutes (300 seconds) of execution:

- A and B have generated 300 and 30,000 events, respectively.
- `_history` contains 10 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, 290 rows have been discarded for A, whereas 29,990 rows have been discarded for B. Rows for A include data up to 10 seconds old, whereas rows for B include data up to only .1 seconds old.

- `_history_long` contains 10,000 rows. Because A and B together generate 101 events per second, the table contains data up to approximately $10,000/101 = 99$ seconds old, with a mix of rows approximately 100 to 1 from B as opposed to A.

26.10 Performance Schema Statement Digests and Sampling

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form (the statement digest) and computes a SHA-256 hash value (the digest hash value) from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. For each digest, a representative statement that produces the digest is stored as a sample. This section describes how statement digesting and sampling occur and how they can be useful.

Digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as MySQL Enterprise Firewall and query rewrite plugins have access to statement digests.

- [Statement Digest General Concepts](#)
- [Statement Digests in the Performance Schema](#)
- [Statement Digest Memory Use](#)
- [Statement Sampling](#)

Statement Digest General Concepts

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- MySQL Enterprise Firewall is enabled
- A Query Rewrite Plugin is enabled

The parser is also used by the `STATEMENT_DIGEST_TEXT()` and `STATEMENT_DIGEST()` functions, which applications can call to compute a normalized statement digest and a digest hash value, respectively, from an SQL statement.

The `max_digest_length` system variable value determines the maximum number of bytes available per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

After the normalized statement has been computed, a SHA-256 hash value is computed from it. In addition:

- If MySQL Enterprise Firewall is enabled, it is called and the digest as computed is available to it.
- If any Query Rewrite Plugin is enabled, it is called and the statement digest and digest value are available to it.
- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized

statement digest is stored in the appropriate Performance Schema tables, along with the SHA-256 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement digest relative to the original, it does not recompute the SHA-256 hash value.)

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
- Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the parser replaces data values by ? and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the normalized statements differ because the object identifiers differ:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

Statement Digests in the Performance Schema

In the Performance Schema, statement digesting involves these elements:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See [Statement Digest Consumer](#).
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest SHA-256 hash values:

- `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.
- `DIGEST` is the digest SHA-256 hash value computed from the original normalized statement.

See [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements per `SCHEMA_NAME` and `DIGEST` combination. The Performance Schema uses SHA-256 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See [Section 26.12.18.3, “Statement Summary Tables”](#).

Some Performance Tables have a column that stores original SQL statements from which digests are computed:

- The `SQL_TEXT` column of the `events_statements_current`, `events_statements_history`, and `events_statements_history_long` statement event tables.
- The `QUERY_SAMPLE_TEXT` column of the `events_statements_summary_by_digest` summary table.

The maximum space available for statement display is 1024 bytes by default. To change this value, set the `performance_schema_max_sql_text_length` system variable at server startup. Changes affect the storage required for all the columns just named.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available per statement for digest value storage in the Performance Schema. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement elements such as keywords and literal values. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

The `events_statements_summary_by_digest` summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The `events_statements_summary_by_digest` summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the `performance_schema_digests_size` system variable at server startup. If the table becomes full, the Performance Schema groups statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing `performance_schema_digests_size`.

Statement Digest Memory Use

For applications that generate very long statements that differ only at the end, increasing `max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of `max_digest_length` bytes, whereas normalized statement digests stored in the Performance Schema use `performance_schema_max_digest_length` bytes. The following memory-use considerations apply regarding the relative values of `max_digest_length` and `performance_schema_max_digest_length`:

- If `max_digest_length` is less than `performance_schema_max_digest_length`:
 - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
 - The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than `max_digest_length` bytes per digest, which is unnecessary.
- If `max_digest_length` equals `performance_schema_max_digest_length`:
 - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
 - The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as `max_digest_length` bytes per digest.
- If `max_digest_length` is greater than `performance_schema_max_digest_length`:
 - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
 - The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than `max_digest_length` bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting `performance_schema_max_digest_length` smaller than `max_digest_length` enables administrators to balance these factors:

- The need to have long normalized statement digests available for server components outside the Performance Schema
- Many concurrent sessions, each of which allocates digest-computation memory
- The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

The `performance_schema_max_digest_length` setting is not per session, it is per statement, and a session can store multiple statements in the `events_statements_history` table. A typical number of statements in this table is 10 per session, so each session will consume 10 times the memory indicated by the `performance_schema_max_digest_length` value, for this table alone.

Also, there are many statements (and digests) collected globally, most notably in the `events_statements_history_long` table. Here, too, *N* statements stored will consume *N* times the memory indicated by the `performance_schema_max_digest_length` value.

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```
mysql> SELECT NAME
        FROM performance_schema.setup_instruments
        WHERE NAME LIKE '%.sqltext';
+-----+-----+
| NAME                                     |
+-----+-----+
| memory/performance_schema/events_statements_history.sqltext |
| memory/performance_schema/events_statements_current.sqltext |
| memory/performance_schema/events_statements_history_long.sqltext |
```

```

+-----+
mysql> SELECT NAME
      FROM performance_schema.setup_instruments
      WHERE NAME LIKE 'memory/performance_schema/%.tokens';
+-----+
| NAME |
+-----+
| memory/performance_schema/events_statements_history.tokens |
| memory/performance_schema/events_statements_current.tokens |
| memory/performance_schema/events_statements_summary_by_digest.tokens |
| memory/performance_schema/events_statements_history_long.tokens |
+-----+

```

Statement Sampling

The Performance Schema uses statement sampling to collect representative statements that produce each digest value in the `events_statements_summary_by_digest` table. These columns store sample statement information: `QUERY_SAMPLE_TEXT` (the text of the statement), `QUERY_SAMPLE_SEEN` (when the statement was seen), and `QUERY_SAMPLE_TIMER_WAIT` (the statement wait or execution time). The Performance Schema updates all three columns each time it chooses a sample statement.

When a new table row is inserted, the statement that produced the row digest value is stored as the current sample statement associated with the digest. Thereafter, when the server sees other statements with the same digest value, it determines whether to use the new statement to replace the current sample statement (that is, whether to resample). Resampling policy is based on the comparative wait times of the current sample statement and new statement and, optionally, the age of the current sample statement:

- Resampling based on wait times: If the new statement wait time has a wait time greater than that of the current sample statement, it becomes the current sample statement.
- Resampling based on age: If the `performance_schema_max_digest_sample_age` system variable has a value greater than zero and the current sample statement is more than that many seconds old, the current statement is considered “too old” and the new statement replaces it. This occurs even if the new statement wait time is less than that of the current sample statement.

By default, `performance_schema_max_digest_sample_age` is 60 seconds (1 minute). To change how quickly sample statements “expire” due to age, increase or decrease the value. To disable the age-based part of the resampling policy, set `performance_schema_max_digest_sample_age` to 0.

26.11 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the `performance_schema` database are read only and cannot be modified:

```

mysql> TRUNCATE TABLE performance_schema.setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.

```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.
- To change those columns that can be modified, you must have the `UPDATE` privilege.
- To truncate tables that can be truncated, you must have the `DROP` privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use `GRANT ALL` as shorthand for granting privileges at the database or table level fail with an error:

```
mysql> GRANT ALL ON performance_schema.*
      TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
mysql> GRANT ALL ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```
mysql> GRANT SELECT ON performance_schema.*
      TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)

mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

26.12 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

26.12.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

Table 26.1 Performance Schema Tables

Table Name	Description
<code>accounts</code>	Connection statistics per client account
<code>binary_log_transaction_compression_stats</code>	Binary log transaction compression
<code>clone_progress</code>	Clone operation progress
<code>clone_status</code>	Clone operation status
<code>cond_instances</code>	synchronization object instances
<code>data_lock_waits</code>	Data lock wait relationships
<code>data_locks</code>	Data locks held and requested
<code>error_log</code>	Server error log recent entries
<code>events_errors_summary_by_account_by_error</code>	Errors per error code and account
<code>events_errors_summary_by_host_by_error</code>	Errors per error code and host
<code>events_errors_summary_by_thread_by_error</code>	Errors per error code and host
<code>events_errors_summary_by_user_by_error</code>	Errors per error code and host
<code>events_errors_summary_global_by_error</code>	Errors per error code
<code>events_stages_current</code>	Current stage events
<code>events_stages_history</code>	Most recent stage events per thread
<code>events_stages_history_long</code>	Most recent stage events overall
<code>events_stages_summary_by_account_by_event_name</code>	Stage events per account and event name
<code>events_stages_summary_by_host_by_event_name</code>	Stage events per host name and event name
<code>events_stages_summary_by_thread_by_event_name</code>	Stage waits per thread and event name
<code>events_stages_summary_by_user_by_event_name</code>	Stage events per user name and event name
<code>events_stages_summary_global_by_event_name</code>	Stage waits per event name
<code>events_statements_current</code>	Current statement events
<code>events_statements_histogram_by_digest</code>	Statement histograms per schema and digest value
<code>events_statements_histogram_global</code>	Statement histogram summarized globally
<code>events_statements_history</code>	Most recent statement events per thread
<code>events_statements_history_long</code>	Most recent statement events overall
<code>events_statements_summary_by_account_by_event_name</code>	Statement events per account and event name
<code>events_statements_summary_by_digest</code>	Statement events per schema and digest value
<code>events_statements_summary_by_host_by_event_name</code>	Statement events per host name and event name
<code>events_statements_summary_by_program</code>	Statement events per stored program
<code>events_statements_summary_by_thread_by_event_name</code>	Statement events per thread and event name
<code>events_statements_summary_by_user_by_event_name</code>	Statement events per user name and event name
<code>events_statements_summary_global_by_event_name</code>	Statement events per event name
<code>events_transactions_current</code>	Current transaction events
<code>events_transactions_history</code>	Most recent transaction events per thread
<code>events_transactions_history_long</code>	Most recent transaction events overall

Performance Schema Table Index

Table Name	Description
events_transactions_summary_by_account_by_event_name	Transaction events per account and event name
events_transactions_summary_by_host_by_event_name	Transaction events per host name and event name
events_transactions_summary_by_thread_by_event_name	Transaction events per thread and event name
events_transactions_summary_by_user_by_event_name	Transaction events per user name and event name
events_transactions_summary_global_by_event_name	Transaction events per event name
events_waits_current	Current wait events
events_waits_history	Most recent wait events per thread
events_waits_history_long	Most recent wait events overall
events_waits_summary_by_account_by_event_name	Wait events per account and event name
events_waits_summary_by_host_by_event_name	Wait events per host name and event name
events_waits_summary_by_instance	Wait events per instance
events_waits_summary_by_thread_by_event_name	Wait events per thread and event name
events_waits_summary_by_user_by_event_name	Wait events per user name and event name
events_waits_summary_global_by_event_name	Wait events per event name
file_instances	File instances
file_summary_by_event_name	File events per event name
file_summary_by_instance	File events per file instance
global_status	Global status variables
global_variables	Global system variables
host_cache	Information from the internal host cache
hosts	Connection statistics per client host name
keyring_keys	Metadata for keyring keys
log_status	Information about server logs for backup purposes
memory_summary_by_account_by_event_name	Memory operations per account and event name
memory_summary_by_host_by_event_name	Memory operations per host and event name
memory_summary_by_thread_by_event_name	Memory operations per thread and event name
memory_summary_by_user_by_event_name	Memory operations per user and event name
memory_summary_global_by_event_name	Memory operations globally per event name
metadata_locks	Metadata locks and lock requests
mutex_instances	Mutex synchronization object instances
objects_summary_global_by_type	Object summaries
performance_timers	Which event timers are available
persisted_variables	Contents of <code>mysqld-auto.cnf</code> file
prepared_statements_instances	Prepared statement instances and statistics
processlist	Process list information

Table Name	Description
<code>replication_applier_configuration</code>	Configuration parameters for the replication applier on the replica
<code>replication_applier_status</code>	Current status of the replication applier on the replica
<code>replication_applier_status_by_coordinator</code>	SQL or coordinator thread applier status
<code>replication_applier_status_by_worker</code>	Worker thread applier status (empty unless replica is multithreaded)
<code>replication_connection_configuration</code>	Configuration parameters for connecting to the source
<code>replication_connection_status</code>	Current status of the connection to the source
<code>rwlock_instances</code>	Lock synchronization object instances
<code>session_account_connect_attrs</code>	Connection attributes per for the current session
<code>session_connect_attrs</code>	Connection attributes for all sessions
<code>session_status</code>	Status variables for current session
<code>session_variables</code>	System variables for current session
<code>setup_actors</code>	How to initialize monitoring for new foreground threads
<code>setup_consumers</code>	Consumers for which event information can be stored
<code>setup_instruments</code>	Classes of instrumented objects for which events can be collected
<code>setup_objects</code>	Which objects should be monitored
<code>setup_threads</code>	Instrumented thread names and attributes
<code>socket_instances</code>	Active connection instances
<code>socket_summary_by_event_name</code>	Socket waits and I/O per event name
<code>socket_summary_by_instance</code>	Socket waits and I/O per instance
<code>status_by_account</code>	Session status variables per account
<code>status_by_host</code>	Session status variables per host name
<code>status_by_thread</code>	Session status variables per session
<code>status_by_user</code>	Session status variables per user name
<code>table_handles</code>	Table locks and lock requests
<code>table_io_waits_summary_by_index_usage</code>	Table I/O waits per index
<code>table_io_waits_summary_by_table</code>	Table I/O waits per table
<code>table_lock_waits_summary_by_table</code>	Table lock waits per table
<code>threads</code>	Information about server threads
<code>tls_channel_status</code>	TLS status for each connection interface
<code>tp_thread_group_state</code>	Information about thread pool thread group states
<code>tp_thread_group_stats</code>	Thread group statistics
<code>tp_thread_state</code>	Information about thread pool thread states
<code>user_defined_functions</code>	Registered user-defined functions
<code>user_variables_by_thread</code>	User-defined variables per thread

Table Name	Description
<code>users</code>	Connection statistics per client user name
<code>variables_by_thread</code>	Session system variables per session
<code>variables_info</code>	How system variables were most recently set

26.12.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_threads`: Instrumented thread names and attributes

26.12.2.1 The `setup_actors` Table

The `setup_actors` table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_actors_size` system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` and `HISTORY` column values are used to set the `INSTRUMENTED` and `HISTORY` columns, respectively, of the `threads` table row for the thread. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination). If there is no match, the `INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

For information about how to use the `setup_actors` table to affect event monitoring, see [Section 26.4.6, “Pre-Filtering by Thread”](#).

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

The `setup_actors` table has these columns:

- `HOST`

The host name. This should be a literal name, or `'%'` to mean “any host.”

- `USER`

The user name. This should be a literal name, or `'%'` to mean “any user.”

- `ROLE`

Unused.

- `ENABLED`

Whether to enable instrumentation for foreground threads matched by the row. The value is `YES` or `NO`.

- `HISTORY`

Whether to log historical events for foreground threads matched by the row. The value is `YES` or `NO`.

The `setup_actors` table has these indexes:

- Primary key on (`HOST`, `USER`, `ROLE`)

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

26.12.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Section 26.4.7, “Pre-Filtering by Consumer”](#).

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- `NAME`

The consumer name.

- `ENABLED`

Whether the consumer is enabled. The value is [YES](#) or [NO](#). This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

The [setup_consumers](#) table has these indexes:

- Primary key on ([NAME](#))

[TRUNCATE TABLE](#) is not permitted for the [setup_consumers](#) table.

26.12.2.3 The [setup_instruments](#) Table

The [setup_instruments](#) table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM performance_schema.setup_instruments\G
***** 1. row *****
      NAME: wait/synch/mutex/pfs/LOCK_pfs_share_list
      ENABLED: NO
      TIMED: NO
      PROPERTIES: singleton
      VOLATILITY: 1
DOCUMENTATION: Components can provide their own performance_schema tables.
                This lock protects the list of such tables definitions.
...
***** 369. row *****
      NAME: stage/sql/executing
      ENABLED: NO
      TIMED: NO
      PROPERTIES:
      VOLATILITY: 0
DOCUMENTATION: NULL
...
***** 687. row *****
      NAME: statement/abstract/Query
      ENABLED: YES
      TIMED: YES
      PROPERTIES: mutable
      VOLATILITY: 0
DOCUMENTATION: SQL query just received from the network. At this point,
                the real statement type is unknown, the type will be
                refined after SQL parsing.
...
***** 696. row *****
      NAME: memory/performance_schema/metadata_locks
      ENABLED: YES
      TIMED: NULL
      PROPERTIES: global_statistics
      VOLATILITY: 1
DOCUMENTATION: Memory used for table performance_schema.metadata_locks
...
```

Each instrument added to the source code provides a row for the [setup_instruments](#) table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the [xxx_instances](#) tables, such as [file_instances](#) or [rwlock_instances](#).

Modifications to most [setup_instruments](#) rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the [setup_instruments](#) table in event filtering, see [Section 26.4.3, “Event Pre-Filtering”](#).

The [setup_instruments](#) table has these columns:

- [NAME](#)

The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#). Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- `ENABLED`

Whether the instrument is enabled. The value is `YES` or `NO`. A disabled instrument produces no events. This column can be modified, although setting `ENABLED` has no effect for instruments that have already been created.

- `TIMED`

Whether the instrument is timed. The value is `YES`, `NO`, or `NULL`. This column can be modified, although setting `TIMED` has no effect for instruments that have already been created.

A `TIMED` value of `NULL` indicates that the instrument does not support timing. For example, memory operations are not timed, so their `TIMED` column is `NULL`.

Setting `TIMED` to `NULL` for an instrument that supports timing has no effect, as does setting `TIMED` to non-`NULL` for an instrument that does not support timing.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

- `PROPERTIES`

The instrument properties. This column uses the `SET` data type, so multiple flags from the following list can be set per instrument:

- `global_statistics`: The instrument produces only global summaries. Summaries for finer levels are unavailable, such as per thread, account, user, or host. For example, most memory instruments produce only global summaries.
- `mutable`: The instrument can “mutate” into a more specific one. This property applies only to statement instruments.
- `progress`: The instrument is capable of reporting progress data. This property applies only to stage instruments.
- `singleton`: The instrument has a single instance. For example, most global mutex locks in the server are singletons, so the corresponding instruments are as well.
- `user`: The instrument is directly related to user workload (as opposed to system workload). One such instrument is `wait/io/socket/sql/client_connection`.

- `VOLATILITY`

The instrument volatility. Volatility values range from low to high. The values correspond to the `PSI_VOLATILITY_XXX` constants defined in the `mysql/psi/psi_base.h` header file:

```
#define PSI_VOLATILITY_UNKNOWN 0
#define PSI_VOLATILITY_PERMANENT 1
#define PSI_VOLATILITY_PROVISIONING 2
#define PSI_VOLATILITY_DDL 3
#define PSI_VOLATILITY_CACHE 4
#define PSI_VOLATILITY_SESSION 5
#define PSI_VOLATILITY_TRANSACTION 6
#define PSI_VOLATILITY_QUERY 7
#define PSI_VOLATILITY_INTRA_QUERY 8
```

The `VOLATILITY` column is purely informational, to provide users (and the Performance Schema code) some hint about the instrument runtime behavior.

Instruments with a low volatility index (`PERMANENT = 1`) are created once at server startup, and never destroyed or re-created during normal server operation. They are destroyed only during server shutdown.

For example, the `wait/synch/mutex/pfs/LOCK_pfs_share_list` mutex is defined with a volatility of 1, which means it is created once. Possible overhead from the instrumentation itself (namely, mutex initialization) has no effect for this instrument then. Runtime overhead occurs only when locking or unlocking the mutex.

Instruments with a higher volatility index (for example, `SESSION = 5`) are created and destroyed for every user session. For example, the `wait/synch/mutex/sql/THD::LOCK_query_plan` mutex is created each time a session connects, and destroyed when the session disconnects.

This mutex is more sensitive to Performance Schema overhead, because overhead comes not only from the lock and unlock instrumentation, but also from mutex create and destroy instrumentation, which is executed more often.

Another aspect of volatility concerns whether and when an update to the `ENABLED` column actually has some effect:

- An update to `ENABLED` affects instrumented objects created subsequently, but has no effect on instruments already created.
- Instruments that are more “volatile” use new settings from the `setup_instruments` table sooner.

For example, this statement does not affect the `LOCK_query_plan` mutex for existing sessions, but does have an effect on new sessions created subsequent to the update:

```
UPDATE performance_schema.setup_instruments
SET ENABLED=value
WHERE NAME = 'wait/synch/mutex/sql/THD::LOCK_query_plan';
```

This statement actually has no effect at all:

```
UPDATE performance_schema.setup_instruments
SET ENABLED=value
WHERE NAME = 'wait/synch/mutex/pfs/LOCK_pfs_share_list';
```

This mutex is permanent, and was created already before the update is executed. The mutex is never created again, so the `ENABLED` value in `setup_instruments` is never used. To enable or disable this mutex, use the `mutex_instances` table instead.

- [DOCUMENTATION](#)

A string describing the instrument purpose. The value is `NULL` if no description is available.

The `setup_instruments` table has these indexes:

- Primary key on (`NAME`)

`TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

26.12.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
```

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
EVENT	mysql	%	NO	NO
EVENT	performance_schema	%	NO	NO
EVENT	information_schema	%	NO	NO
EVENT	%	%	YES	YES
FUNCTION	mysql	%	NO	NO
FUNCTION	performance_schema	%	NO	NO
FUNCTION	information_schema	%	NO	NO
FUNCTION	%	%	YES	YES
PROCEDURE	mysql	%	NO	NO
PROCEDURE	performance_schema	%	NO	NO
PROCEDURE	information_schema	%	NO	NO
PROCEDURE	%	%	YES	YES
TABLE	mysql	%	NO	NO
TABLE	performance_schema	%	NO	NO
TABLE	information_schema	%	NO	NO
TABLE	%	%	YES	YES
TRIGGER	mysql	%	NO	NO
TRIGGER	performance_schema	%	NO	NO
TRIGGER	information_schema	%	NO	NO
TRIGGER	%	%	YES	YES

Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see [Section 26.4.3, “Event Pre-Filtering”](#).

The `setup_objects` table has these columns:

- OBJECT_TYPE**

The type of object to instrument. The value is one of `'EVENT'` (Event Scheduler event), `'FUNCTION'` (stored function), `'PROCEDURE'` (stored procedure), `'TABLE'` (base table), or `'TRIGGER'` (trigger).

`TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

- OBJECT_SCHEMA**

The schema that contains the object. This should be a literal name, or `'%'` to mean “any schema.”

- OBJECT_NAME**

The name of the instrumented object. This should be a literal name, or '`%`' to mean “any object.”

- `ENABLED`

Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- `TIMED`

Whether events for the object are timed. This column can be modified.

The `setup_objects` table has these indexes:

- Index on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)

`TRUNCATE TABLE` is permitted for the `setup_objects` table. It removes the rows.

26.12.2.5 The `setup_threads` Table

The `setup_threads` table lists instrumented thread classes. It exposes thread class names and attributes:

```
mysql> SELECT * FROM performance_schema.setup_threads\G
***** 1. row *****
      NAME: thread/performance_schema/setup
      ENABLED: YES
      HISTORY: YES
      PROPERTIES: singleton
      VOLATILITY: 0
      DOCUMENTATION: NULL
      ...
***** 4. row *****
      NAME: thread/sql/main
      ENABLED: YES
      HISTORY: YES
      PROPERTIES: singleton
      VOLATILITY: 0
      DOCUMENTATION: NULL
***** 5. row *****
      NAME: thread/sql/one_connection
      ENABLED: YES
      HISTORY: YES
      PROPERTIES: user
      VOLATILITY: 0
      DOCUMENTATION: NULL
      ...
***** 10. row *****
      NAME: thread/sql/event_scheduler
      ENABLED: YES
      HISTORY: YES
      PROPERTIES: singleton
      VOLATILITY: 0
      DOCUMENTATION: NULL
```

The `setup_threads` table has these columns:

- `NAME`

The instrument name. Thread instruments begin with `thread` (for example, `thread/sql/parser_service` or `thread/performance_schema/setup`).

- `ENABLED`

Whether the instrument is enabled. The value is `YES` or `NO`. This column can be modified, although setting `ENABLED` has no effect for threads that are already running.

For background threads, setting the `ENABLED` value controls whether `INSTRUMENTED` is set to `YES` or `NO` for threads that are subsequently created for this instrument and listed in the `threads` table. For foreground threads, this column has no effect; the `setup_actors` table takes precedence.

- `HISTORY`

Whether to log historical events for the instrument. The value is `YES` or `NO`. This column can be modified, although setting `HISTORY` has no effect for threads that are already running.

For background threads, setting the `HISTORY` value controls whether `HISTORY` is set to `YES` or `NO` for threads that are subsequently created for this instrument and listed in the `threads` table. For foreground threads, this column has no effect; the `setup_actors` table takes precedence.

- `PROPERTIES`

The instrument properties. This column uses the `SET` data type, so multiple flags from the following list can be set per instrument:

- `singleton`: The instrument has a single instance. For example, there is only one thread for the `thread/sql/main` instrument.
- `user`: The instrument is directly related to user workload (as opposed to system workload). For example, threads such as `thread/sql/one_connection` executing a user session have the `user` property to differentiate them from system threads.

- `VOLATILITY`

The instrument volatility. This column has the same meaning as in the `setup_instruments` table. See [Section 26.12.2.3, “The setup_instruments Table”](#).

- `DOCUMENTATION`

A string describing the instrument purpose. The value is `NULL` if no description is available.

The `setup_threads` table has these indexes:

- Primary key on (`NAME`)

`TRUNCATE TABLE` is not permitted for the `setup_threads` table.

26.12.2.6 The `setup_timers` Table

This table was removed in MySQL 8.0.4.

26.12.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple

parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 26.19, “Using the Performance Schema to Diagnose Problems”](#)

26.12.3.1 The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented condition.

The `cond_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)

`TRUNCATE TABLE` is not permitted for the `cond_instances` table.

26.12.3.2 The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

The `file_instances` table has these indexes:

- Primary key on (`FILE_NAME`)
- Index on (`EVENT_NAME`)

`TRUNCATE TABLE` is not permitted for the `file_instances` table.

26.12.3.3 The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented mutex.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

The `mutex_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)
- Index on (`LOCKED_BY_THREAD_ID`)

`TRUNCATE TABLE` is not permitted for the `mutex_instances` table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
 - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
 - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables

- `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

26.12.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` (read write lock) instances seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an `sxlock` and optimizes concurrency and improves scalability for read-write workloads.

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`

The instrument name associated with the lock.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented lock.

- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

The `rwlock_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)
- Index on (`WRITE_LOCKED_BY_THREAD_ID`)

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

26.12.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see [Section 26.12.18.9, “Socket Summary Tables”](#)).

```
mysql> SELECT * FROM performance_schema.socket_instances\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
      THREAD_ID: 1
      SOCKET_ID: 16
        IP:
      PORT: 0
      STATE: ACTIVE
***** 2. row *****
      EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
      THREAD_ID: 21
      SOCKET_ID: 39
        IP: 127.0.0.1
      PORT: 55233
      STATE: ACTIVE
***** 3. row *****
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
      THREAD_ID: 1
      SOCKET_ID: 14
        IP: 0.0.0.0
      PORT: 50603
      STATE: ACTIVE
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.
2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

The `socket_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`THREAD_ID`)
- Index on (`SOCKET_ID`)
- Index on (`IP`, `PORT`)

`TRUNCATE TABLE` is not permitted for the `socket_instances` table.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_XXX` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0.
- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

26.12.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store wait events:

- `events_waits_current`: The current wait event for each thread.
- `events_waits_history`: The most recent wait events that have ended per thread.
- `events_waits_history_long`: The most recent wait events that have ended globally (across all threads).

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see [Section 26.12.18.1, “Wait Event Summary Tables”](#).

For more information about the relationship between the three wait event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

Configuring Wait Event Collection

To control whether to collect wait events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `wait`. Use these instruments to enable or disable collection of individual wait event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical wait event table names. Use these consumers to filter collection of wait events.

Some wait instruments are enabled by default; others are disabled. For example:

```
mysql> SELECT NAME, ENABLED, TIMED
      FROM performance_schema.setup_instruments
      WHERE NAME LIKE 'wait/io/file/innodb%';
```

NAME	ENABLED	TIMED
wait/io/file/innodb/innodb_tablespace_open_file	YES	YES
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES
wait/io/file/innodb/innodb_arch_file	YES	YES
wait/io/file/innodb/innodb_clone_file	YES	YES

```
mysql> SELECT NAME, ENABLED, TIMED
      FROM performance_schema.setup_instruments
      WHERE NAME LIKE 'wait/io/socket/%';
```

NAME	ENABLED	TIMED
wait/io/socket/sql/server_tcpip_socket	NO	NO
wait/io/socket/sql/server_unix_socket	NO	NO
wait/io/socket/sql/client_connection	NO	NO

The wait consumers are disabled by default:

```
mysql> SELECT *
      FROM performance_schema.setup_consumers
      WHERE NAME LIKE 'events_waits%';
```

NAME	ENABLED
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO

```
+-----+-----+
```

To control wait event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/%=ON'
performance-schema-consumer-events-waits-current=ON
performance-schema-consumer-events-waits-history=ON
performance-schema-consumer-events-waits-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/%=OFF'
performance-schema-consumer-events-waits-current=OFF
performance-schema-consumer-events-waits-history=OFF
performance-schema-consumer-events-waits-history-long=OFF
```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_waits%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_waits%';
```

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding to the desired tables.

For additional information about configuring event collection, see [Section 26.3, “Performance Schema Startup Configuration”](#), and [Section 26.4, “Performance Schema Runtime Configuration”](#).

26.12.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events. The table stores one row per thread showing the current status of the thread's most recent monitored wait event, so there is no system variable for configuring the table size.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three wait event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 26.12.4, “Performance Schema Wait Event Tables”](#).

The `events_waits_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 26.4.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.

- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.
- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation. For table I/O waits (events for the `wait/io/table/sql/handler` instrument), `NUMBER_OF_BYTES` indicates the number of rows. If the value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of `t1`, `t2`, `t3`:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table `t3` is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from `t1`, 20 rows from `t2` per row from `t1`, and 30 rows from `t3` per row of table `t2`. With single-row reporting, the total number of instrumented operations is:

```
10 + (10 * 20) + (10 * 20 * 30) = 6210
```

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from `t1` and `t2`). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table `t3` rather than for each row, and the number of instrumented row operations reduces to:

```
10 + (10 * 20) + (10 * 20) = 410
```

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
- Query execution does not request a single row from the table (so, for example, `eq_ref` access prevents use of batch reporting)
- Query execution does not evaluate a subquery containing table access for the table

- `FLAGS`

Reserved for future use.

The `events_waits_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_waits_current` table. It removes the rows.

26.12.4.2 The `events_waits_history` Table

The `events_waits_history` table contains the *N* most recent wait events that have ended per thread. Wait events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of *N* during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup.

The `events_waits_history` table has the same columns and indexing as `events_waits_current`. See [Section 26.12.4.1, “The `events_waits_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history` table. It removes the rows.

For more information about the relationship between the three wait event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 26.12.4, “Performance Schema Wait Event Tables”](#).

26.12.4.3 The `events_waits_history_long` Table

The `events_waits_history_long` table contains *N* the most recent wait events that have ended globally, across all threads. Wait events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of *N* during server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup.

The `events_waits_history_long` table has the same columns as `events_waits_current`. See [Section 26.12.4.1, “The events_waits_current Table”](#). Unlike `events_waits_current`, `events_waits_history_long` has no indexing.

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For more information about the relationship between the three wait event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 26.12.4, “Performance Schema Wait Event Tables”](#).

26.12.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- `events_stages_current`: The current stage event for each thread.
- `events_stages_history`: The most recent stage events that have ended per thread.
- `events_stages_history_long`: The most recent stage events that have ended globally (across all threads).

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see [Section 26.12.18.2, “Stage Summary Tables”](#).

For more information about the relationship between the three stage event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Stage Event Collection](#)
- [Stage Event Progress Information](#)

Configuring Stage Event Collection

To control whether to collect stage events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of individual stage event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical stage event table names. Use these consumers to filter collection of stage events.

Other than those instruments that provide statement progress information, the stage instruments are disabled by default. For example:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments
WHERE NAME RLIKE 'stage/sql/[a-c]';
+-----+-----+-----+
| NAME                                | ENABLED | TIMED |
+-----+-----+-----+
```

stage/sql/After create	NO	NO
stage/sql/allocating local table	NO	NO
stage/sql/altering table	NO	NO
stage/sql/committing alter table to storage engine	NO	NO
stage/sql/Changing master	NO	NO
stage/sql/Checking master version	NO	NO
stage/sql/checking permissions	NO	NO
stage/sql/cleaning up	NO	NO
stage/sql/closing tables	NO	NO
stage/sql/Connecting to master	NO	NO
stage/sql/converting HEAP to MyISAM	NO	NO
stage/sql/Copying to group table	NO	NO
stage/sql/Copying to tmp table	NO	NO
stage/sql/copy to tmp table	NO	NO
stage/sql/Creating sort index	NO	NO
stage/sql/creating table	NO	NO
stage/sql/Creating tmp table	NO	NO

Stage event instruments that provide statement progress information are enabled and timed by default:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments
WHERE ENABLED='YES' AND NAME LIKE "stage/%";
```

NAME	ENABLED	TIMED
stage/sql/copy to tmp table	YES	YES
stage/sql/Applying batch of row changes (write)	YES	YES
stage/sql/Applying batch of row changes (update)	YES	YES
stage/sql/Applying batch of row changes (delete)	YES	YES
stage/innodb/alter table (end)	YES	YES
stage/innodb/alter table (flush)	YES	YES
stage/innodb/alter table (insert)	YES	YES
stage/innodb/alter table (log apply index)	YES	YES
stage/innodb/alter table (log apply table)	YES	YES
stage/innodb/alter table (merge sort)	YES	YES
stage/innodb/alter table (read PK and internal sort)	YES	YES
stage/innodb/buffer pool load	YES	YES
stage/innodb/clone (file copy)	YES	YES
stage/innodb/clone (redo copy)	YES	YES
stage/innodb/clone (page copy)	YES	YES

The stage consumers are disabled by default:

```
mysql> SELECT *
FROM performance_schema.setup_consumers
WHERE NAME LIKE 'events_stages%';
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO

To control stage event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

- Disable:

```
[mysqld]
```

```
performance-schema-instrument='stage/%=OFF'
performance-schema-consumer-events-stages-current=OFF
performance-schema-consumer-events-stages-history=OFF
performance-schema-consumer-events-stages-history-long=OFF
```

To control stage event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_stages%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_stages%';
```

To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

For additional information about configuring event collection, see [Section 26.3, “Performance Schema Startup Configuration”](#), and [Section 26.4, “Performance Schema Runtime Configuration”](#).

Stage Event Progress Information

The Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- `WORK_COMPLETED`: The number of work units completed for the stage
- `WORK_ESTIMATED`: The number of work units expected for the stage

Each column is `NULL` if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.
- The `WORK_COMPLETED` value can increase one or many units at a time, depending on the instrumented code.
- The `WORK_ESTIMATED` value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- No progress instrumentation

This is the most typical case, where no progress data is provided. The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both `NULL`.

- Unbounded progress instrumentation

Only the `WORK_COMPLETED` column is meaningful. No data is provided for the `WORK_ESTIMATED` column, which displays 0.

By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- Bounded progress instrumentation

The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both meaningful.

This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the `WORK_COMPLETED` / `WORK_ESTIMATED` ratio.

The `stage/sql/copy to tmp table` instrument illustrates how progress indicators work. During execution of an `ALTER TABLE` statement, the `stage/sql/copy to tmp table` stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the `stage/sql/copy to tmp table` stage is instrumented to provide bounded progress information: The work unit used is number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```
UPDATE performance_schema.setup_instruments
SET ENABLED='YES'
WHERE NAME='stage/sql/copy to tmp table';

UPDATE performance_schema.setup_consumers
SET ENABLED='YES'
WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

26.12.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events. The table stores one row per thread showing the current status of the thread's most recent monitored stage event, so there is no system variable for configuring the table size.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three stage event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

The `events_stages_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 26.4.1, “Performance Schema Event Timing”](#).

- `WORK_COMPLETED`, `WORK_ESTIMATED`

These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see [Stage Event Progress Information](#).

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

The `events_stages_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

26.12.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the `N` most recent stage events that have ended per thread. Stage events are not added to the table until they have ended. When the table contains the

maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of *N* during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup.

The `events_stages_history` table has the same columns and indexing as `events_stages_current`. See [Section 26.12.5.1, “The events_stages_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For more information about the relationship between the three stage event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

26.12.5.3 The events_stages_history_long Table

The `events_stages_history_long` table contains the *N* most recent stage events that have ended globally, across all threads. Stage events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of *N* during server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.

The `events_stages_history_long` table has the same columns as `events_stages_current`. See [Section 26.12.5.1, “The events_stages_current Table”](#). Unlike `events_stages_current`, `events_stages_history_long` has no indexing.

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For more information about the relationship between the three stage event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

26.12.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- `events_statements_current`: The current statement event for each thread.
- `events_statements_history`: The most recent statement events that have ended per thread.
- `events_statements_history_long`: The most recent statement events that have ended globally (across all threads).
- `prepared_statements_instances`: Prepared statement instances and statistics

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see [Section 26.12.18.3, “Statement Summary Tables”](#).

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Statement Event Collection](#)
- [Statement Monitoring](#)

Configuring Statement Event Collection

To control whether to collect statement events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `statement`. Use these instruments to enable or disable collection of individual statement event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the `events_statements_current`, `events_statements_history`, and `statements_digest` statement consumers are enabled by default:

```
mysql> SELECT NAME, ENABLED, TIMED
FROM performance_schema.setup_instruments
WHERE NAME LIKE 'statement/%';
```

NAME	ENABLED	TIMED
statement/sql/select	YES	YES
statement/sql/create_table	YES	YES
statement/sql/create_index	YES	YES
...		
statement/sp/stmt	YES	YES
statement/sp/set	YES	YES
statement/sp/set_trigger_field	YES	YES
statement/scheduler/event	YES	YES
statement/com/Sleep	YES	YES
statement/com/Quit	YES	YES
statement/com/Init DB	YES	YES
...		
statement/abstract/Query	YES	YES
statement/abstract/new_packet	YES	YES
statement/abstract/relay_log	YES	YES

```
mysql> SELECT *
FROM performance_schema.setup_consumers
WHERE NAME LIKE '%statements%';
```

NAME	ENABLED
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
statements_digest	YES

To control statement event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='statement/%=ON'
performance-schema-consumer-events-statements-current=ON
performance-schema-consumer-events-statements-history=ON
performance-schema-consumer-events-statements-history-long=ON
performance-schema-consumer-statements-digest=ON
```

- Disable:

```
[mysqld]
```

```
performance-schema-instrument='statement/%=OFF'
performance-schema-consumer-events-statements-current=OFF
performance-schema-consumer-events-statements-history=OFF
performance-schema-consumer-events-statements-history-long=OFF
performance-schema-consumer-statements-digest=OFF
```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'statement/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE '%statements%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'statement/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%statements%';
```

To collect only specific statement events, enable only the corresponding statement instruments. To collect statement events only for specific statement event tables, enable the statement instruments but only the statement consumers corresponding to the desired tables.

For additional information about configuring event collection, see [Section 26.3, “Performance Schema Startup Configuration”](#), and [Section 26.4, “Performance Schema Runtime Configuration”](#).

Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.

- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replica
- As an event from the Event Scheduler

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.
2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.
3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replica:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.
2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the replica as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/`

`scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds *between* separate instrumented operations. This differs from the sequence of refinement that occurs *within* a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/new_packet` and `statement/abstract/Query`. Similarly, for replicated statements to be instrumented, `statement/abstract/relay_log` must be enabled.

No statistics are aggregated for abstract instruments such as `statement/abstract/Query` because no statement is ever classified with an abstract instrument as the final statement name.

26.12.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events. The table stores one row per thread showing the current status of the thread's most recent monitored statement event, so there is no system variable for configuring the table size.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

The `events_statements_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the `EVENT_NAME` value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 26.4.1, “Performance Schema Event Timing”](#).

- `LOCK_TIME`

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- `SQL_TEXT`

The text of the SQL statement. For a command not associated with an SQL statement, the value is `NULL`.

The maximum space available for statement display is 1024 bytes by default. To change this value, set the `performance_schema_max_sql_text_length` system variable at server startup. (Changing this value affects columns in other Performance Schema tables as well. See [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).)

- `DIGEST`

The statement digest SHA-256 value as a string of 64 hexadecimal characters, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

- `DIGEST_TEXT`

The normalized statement digest text, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available per session for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement elements such as keywords and literal values in digest buffer. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

- `CURRENT_SCHEMA`

The default database for the statement, `NULL` if there is none.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`

For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are `NULL`.

- `OBJECT_INSTANCE_BEGIN`

This column identifies the statement. The value is the address of an object in memory.

- `MYSQL_ERRNO`

The statement error number, from the statement diagnostics area.

- `RETURNED_SQLSTATE`

The statement SQLSTATE value, from the statement diagnostics area.

- `MESSAGE_TEXT`

The statement error message, from the statement diagnostics area.

- `ERRORS`

Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with 00 (completion) or 01 (warning). The value is 1 if the SQLSTATE value is anything else.

- `WARNINGS`

The number of warnings, from the statement diagnostics area.

- `ROWS_AFFECTED`

The number of rows affected by the statement. For a description of the meaning of “affected,” see [mysql_affected_rows\(\)](#).

- `ROWS_SENT`

The number of rows returned by the statement.

- `ROWS_EXAMINED`

The number of rows examined by the server layer (not counting any processing internal to storage engines).

- `CREATED_TMP_DISK_TABLES`

Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- `CREATED_TMP_TABLES`

Like the `Created_tmp_tables` status variable, but specific to the statement.

- `SELECT_FULL_JOIN`

Like the `Select_full_join` status variable, but specific to the statement.

- `SELECT_FULL_RANGE_JOIN`

Like the `Select_full_range_join` status variable, but specific to the statement.

- `SELECT_RANGE`

Like the `Select_range` status variable, but specific to the statement.

- `SELECT_RANGE_CHECK`

Like the `Select_range_check` status variable, but specific to the statement.

- `SELECT_SCAN`

Like the `Select_scan` status variable, but specific to the statement.

- `SORT_MERGE_PASSES`

Like the `Sort_merge_passes` status variable, but specific to the statement.

- `SORT_RANGE`

Like the `Sort_range` status variable, but specific to the statement.

- `SORT_ROWS`

Like the `Sort_rows` status variable, but specific to the statement.

- `SORT_SCAN`

Like the `Sort_scan` status variable, but specific to the statement.

- `NO_INDEX_USED`

1 if the statement performed a table scan without using an index, 0 otherwise.

- `NO_GOOD_INDEX_USED`

1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 8.8.2, “EXPLAIN Output Format”](#).

- `NESTING_EVENT_ID`, `NESTING_EVENT_TYPE`, `NESTING_EVENT_LEVEL`

These three columns are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

For top level statements:

```
OBJECT_TYPE = NULL
OBJECT_SCHEMA = NULL
OBJECT_NAME = NULL
NESTING_EVENT_ID = NULL
NESTING_EVENT_TYPE = NULL
NESTING_LEVEL = 0
```

For nested statements:

```
OBJECT_TYPE = the parent statement object type
OBJECT_SCHEMA = the parent statement object schema
OBJECT_NAME = the parent statement object name
NESTING_EVENT_ID = the parent statement EVENT_ID
NESTING_EVENT_TYPE = 'STATEMENT'
NESTING_LEVEL = the parent statement NESTING_LEVEL plus one
```

- `STATEMENT_ID`

The query ID maintained by the server at the SQL level. The value is unique for the server instance because these IDs are generated using a global counter that is incremented atomically. This column was added in MySQL 8.0.14.

The `events_statements_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

26.12.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the *N* most recent statement events that have ended per thread. Statement events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of *N* during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup.

The `events_statements_history` table has the same columns and indexing as `events_statements_current`. See [Section 26.12.6.1, “The `events_statements_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

26.12.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the *N* most recent statement events that have ended globally, across all threads. Statement events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup.

The `events_statements_history_long` table has the same columns as `events_statements_current`. See [Section 26.12.6.1, “The `events_statements_current` Table”](#). Unlike `events_statements_current`, `events_statements_history_long` has no indexing.

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

26.12.6.4 The `prepared_statements_instances` Table

The Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

C API Function	Corresponding Server Command
<code>mysql_stmt_prepare()</code>	<code>COM_STMT_PREPARE</code>
<code>mysql_stmt_execute()</code>	<code>COM_STMT_EXECUTE</code>
<code>mysql_stmt_close()</code>	<code>COM_STMT_CLOSE</code>

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

SQL Statement	Corresponding Server Command
PREPARE	SQLCOM_PREPARE
EXECUTE	SQLCOM_EXECUTE
DEALLOCATE PREPARE , DROP PREPARE	SQLCOM_DEALLOCATE PREPARE

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the [prepared_statements_instances](#) table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the [performance_schema_max_prepared_statements_instances](#) system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the [setup_instruments](#) table.

Instrument	Server Command
statement/com/Prepare	COM_STMT_PREPARE
statement/com/Execute	COM_STMT_EXECUTE
statement/sql/prepare_sql	SQLCOM_PREPARE
statement/sql/execute_sql	SQLCOM_EXECUTE

The Performance Schema manages the contents of the [prepared_statements_instances](#) table as follows:

- Statement preparation

A [COM_STMT_PREPARE](#) or [SQLCOM_PREPARE](#) command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the [prepared_statements_instances](#) table. If the statement cannot be instrumented, [Performance_schema_prepared_statements_lost](#) status variable is incremented.

- Prepared statement execution

Execution of a [COM_STMT_EXECUTE](#) or [SQLCOM_EXECUTE](#) command for an instrumented prepared statement instance updates the corresponding [prepared_statements_instances](#) table row.

- Prepared statement deallocation

Execution of a [COM_STMT_CLOSE](#) or [SQLCOM_DEALLOCATE_PREPARE](#) command for an instrumented prepared statement instance removes the corresponding [prepared_statements_instances](#) table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The [prepared_statements_instances](#) table has these columns:

- [OBJECT_INSTANCE_BEGIN](#)

The address in memory of the instrumented prepared statement.

- [STATEMENT_ID](#)

The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- [STATEMENT_NAME](#)

For the binary protocol, this column is [NULL](#). For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

```
PREPARE stmt FROM 'SELECT 1';
```

- [SQL_TEXT](#)

The prepared statement text, with `?` placeholder markers.

- [OWNER_THREAD_ID](#), [OWNER_EVENT_ID](#)

These columns indicate the event that created the prepared statement.

- [OWNER_OBJECT_TYPE](#), [OWNER_OBJECT_SCHEMA](#), [OWNER_OBJECT_NAME](#)

For a prepared statement created by a client session, these columns are [NULL](#). For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

```
SELECT
  OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME,
  STATEMENT_NAME, SQL_TEXT
FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;
```

- [TIMER_PREPARE](#)

The time spent executing the statement preparation itself.

- [COUNT_REPREPARE](#)

The number of times the statement was reprepared internally (see [Section 8.10.3, “Caching of Prepared Statements and Stored Programs”](#)). Timing statistics for reparation are not available because it is counted as part of statement execution, not as a separate operation.

- [COUNT_EXECUTE](#), [SUM_TIMER_EXECUTE](#), [MIN_TIMER_EXECUTE](#), [AVG_TIMER_EXECUTE](#), [MAX_TIMER_EXECUTE](#)

Aggregated statistics for executions of the prepared statement.

- [SUM_xxx](#)

The remaining [SUM_xxx](#) columns are the same as for the statement summary tables (see [Section 26.12.18.3, “Statement Summary Tables”](#)).

The [prepared_statements_instances](#) table has these indexes:

- Primary key on ([OBJECT_INSTANCE_BEGIN](#))
- Index on ([STATEMENT_ID](#))
- Index on ([STATEMENT_NAME](#))
- Index on ([OWNER_THREAD_ID](#), [OWNER_EVENT_ID](#))
- Index on ([OWNER_OBJECT_TYPE](#), [OWNER_OBJECT_SCHEMA](#), [OWNER_OBJECT_NAME](#))

`TRUNCATE TABLE` resets the statistics columns of the `prepared_statements_instances` table.

26.12.7 Performance Schema Transaction Tables

The Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- `events_transactions_current`: The current transaction event for each thread.
- `events_transactions_history`: The most recent transaction events that have ended per thread.
- `events_transactions_history_long`: The most recent transaction events that have ended globally (across all threads).

The following sections describe the transaction event tables. There are also summary tables that aggregate information about transaction events; see [Section 26.12.18.5, “Transaction Summary Tables”](#).

For more information about the relationship between the three transaction event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Transaction Event Collection](#)
- [Transaction Boundaries](#)
- [Transaction Instrumentation](#)
- [Transactions and Nested Events](#)
- [Transactions and Stored Programs](#)
- [Transactions and Savepoints](#)
- [Transactions and Errors](#)

Configuring Transaction Event Collection

To control whether to collect transaction events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains an instrument named `transaction`. Use this instrument to enable or disable collection of individual transaction event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical transaction event table names. Use these consumers to filter collection of transaction events.

The `transaction` instrument and the `events_transactions_current` and `events_transactions_history` transaction consumers are enabled by default:

```
mysql> SELECT NAME, ENABLED, TIMED
      FROM performance_schema.setup_instruments
      WHERE NAME = 'transaction';
+-----+-----+-----+
| NAME          | ENABLED | TIMED |
+-----+-----+-----+
| transaction   | YES     | YES   |
+-----+-----+-----+
mysql> SELECT *
      FROM performance_schema.setup_consumers
      WHERE NAME LIKE 'events_transactions%';
+-----+-----+-----+
| NAME          | ENABLED | TIMED |
+-----+-----+-----+
```

NAME	ENABLED
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO

To control transaction event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='transaction=ON'
performance-schema-consumer-events-transactions-current=ON
performance-schema-consumer-events-transactions-history=ON
performance-schema-consumer-events-transactions-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='transaction=OFF'
performance-schema-consumer-events-transactions-current=OFF
performance-schema-consumer-events-transactions-history=OFF
performance-schema-consumer-events-transactions-history-long=OFF
```

To control transaction event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_transactions%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_transactions%';
```

To collect transaction events only for specific transaction event tables, enable the `transaction` instrument but only the transaction consumers corresponding to the desired tables.

For additional information about configuring event collection, see [Section 26.3, “Performance Schema Startup Configuration”](#), and [Section 26.4, “Performance Schema Runtime Configuration”](#).

Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

```
START TRANSACTION | BEGIN | XA START | XA BEGIN
```

Transactions also start implicitly. For example, when the `autocommit` system variable is enabled, the start of each statement starts a new transaction.

When `autocommit` is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT | ROLLBACK | XA COMMIT | XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to `START TRANSACTION` also apply to `BEGIN`, `XA START`, and `XA BEGIN`. Similarly, references to `COMMIT` and `ROLLBACK` apply to `XA COMMIT` and `XA ROLLBACK`, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the `START TRANSACTION` statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of `COMMIT` or `ROLLBACK`.

There are subtle implications to this approach:

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.
- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```
1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION;                -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
                                           -- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3); -- Update nontransactional table
7. UPDATE t2 SET a = a + 1;             -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6); -- Write to transactional table
                                           -- Transaction 2 START (implicit)
9. COMMIT;                             -- Transaction 2 COMMIT
```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

Transaction Instrumentation

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

Transactions and Nested Events

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.

Transactions and Stored Programs

Transactions and stored program events are related as follows:

- **Stored Procedures**

Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- **Stored Functions**

Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- **Triggers**

Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- **Scheduled Events**

The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

26.12.7.1 The `events_transactions_current` Table

The `events_transactions_current` table contains current transaction events. The table stores one row per thread showing the current status of the thread's most recent monitored transaction event, so there is no system variable for configuring the table size. For example:

```
mysql> SELECT *
      FROM performance_schema.events_transactions_current LIMIT 1\G
***** 1. row *****
      THREAD_ID: 26
      EVENT_ID: 7
      END_EVENT_ID: NULL
      EVENT_NAME: transaction
      STATE: ACTIVE
      TRX_ID: NULL
      GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56
      XID: NULL
      XA_STATE: NULL
      SOURCE: transaction.cc:150
      TIMER_START: 420833537900000
      TIMER_END: NULL
      TIMER_WAIT: NULL
      ACCESS_MODE: READ WRITE
      ISOLATION_LEVEL: REPEATABLE READ
      AUTOCOMMIT: NO
      NUMBER_OF_SAVEPOINTS: 0
      NUMBER_OF_ROLLBACK_TO_SAVEPOINT: 0
      NUMBER_OF_RELEASE_SAVEPOINT: 0
      OBJECT_INSTANCE_BEGIN: NULL
      NESTING_EVENT_ID: 6
      NESTING_EVENT_TYPE: STATEMENT
```

Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three transaction event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 26.12.7, “Performance Schema Transaction Tables”](#).

The `events_transactions_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 26.6, “Performance Schema Instrument Naming Conventions”](#).

- `STATE`

The current transaction state. The value is `ACTIVE` (after `START TRANSACTION` or `BEGIN`), `COMMITTED` (after `COMMIT`), or `ROLLED BACK` (after `ROLLBACK`).

- `TRX_ID`

Unused.

- `GTID`

The GTID column contains the value of `gtid_next`, which can be one of `ANONYMOUS`, `AUTOMATIC`, or a GTID using the format `UUID:NUMBER`. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either `ON` or `ON_PERMISSIVE`, the GTID column changes to the transaction's GTID. If `gtid_mode` is either `OFF` or `OFF_PERMISSIVE`, the GTID column changes to `ANONYMOUS`.

- `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL`

The elements of the XA transaction identifier. They have the format described in [Section 13.3.8.1, “XA Transaction SQL Statements”](#).

- `XA_STATE`

The state of the XA transaction. The value is `ACTIVE` (after `XA START`), `IDLE` (after `XA END`), `PREPARED` (after `XA PREPARE`), `ROLLED BACK` (after `XA ROLLBACK`), or `COMMITTED` (after `XA COMMIT`).

On a replica, the same XA transaction can appear in the `events_transactions_current` table with different states on different threads. This is because immediately after the XA transaction is prepared, it is detached from the replica's applier thread, and can be committed or rolled back by any thread on the replica. The `events_transactions_current` table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the `PREPARED` state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the `PREPARED` state and need to be recovered, use the `XA RECOVER` statement rather than the Performance Schema transaction tables.

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 26.4.1, “Performance Schema Event Timing”](#).

- `ACCESS_MODE`

The transaction access mode. The value is `READ WRITE` or `READ ONLY`.

- `ISOLATION_LEVEL`

The transaction isolation level. The value is `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, or `SERIALIZABLE`.

- `AUTOCOMMIT`

Whether autocommit mode was enabled when the transaction started.

- `NUMBER_OF_SAVEPOINTS`, `NUMBER_OF_ROLLBACK_TO_SAVEPOINT`,
`NUMBER_OF_RELEASE_SAVEPOINT`

The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- `OBJECT_INSTANCE_BEGIN`

Unused.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`. (`TRANSACTION` will not appear because transactions cannot be nested.)

The `events_transactions_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_transactions_current` table. It removes the rows.

26.12.7.2 The `events_transactions_history` Table

The `events_transactions_history` table contains the *N* most recent transaction events that have ended per thread. Transaction events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of *N* during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_transactions_history_size` system variable at server startup.

The `events_transactions_history` table has the same columns and indexing as `events_transactions_current`. See [Section 26.12.7.1, “The `events_transactions_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history` table. It removes the rows.

For more information about the relationship between the three transaction event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 26.12.7, “Performance Schema Transaction Tables”](#).

26.12.7.3 The `events_transactions_history_long` Table

The `events_transactions_history_long` table contains the *N* most recent transaction events that have ended globally, across all threads. Transaction events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of `N` is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_long_size` system variable at server startup.

The `events_transactions_history_long` table has the same columns as `events_transactions_current`. See [Section 26.12.7.1, “The `events_transactions_current` Table”](#). Unlike `events_transactions_current`, `events_transactions_history_long` has no indexing.

`TRUNCATE TABLE` is permitted for the `events_transactions_history_long` table. It removes the rows.

For more information about the relationship between the three transaction event tables, see [Section 26.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 26.12.7, “Performance Schema Transaction Tables”](#).

26.12.8 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and host name, using these tables:

- `accounts`: Connection statistics per client account
- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `hosts` table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.
- The `users` table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

`TRUNCATE TABLE` is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `_summary_by_account`, `_summary_by_host`, or `_summary_by_user` in the name. To identify them, use this query:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
ORDER BY TABLE_NAME;
```

TABLE_NAME
events_errors_summary_by_account_by_error
events_errors_summary_by_host_by_error
events_errors_summary_by_user_by_error
events_stages_summary_by_account_by_event_name
events_stages_summary_by_host_by_event_name
events_stages_summary_by_user_by_event_name
events_statements_summary_by_account_by_event_name
events_statements_summary_by_host_by_event_name
events_statements_summary_by_user_by_event_name
events_transactions_summary_by_account_by_event_name
events_transactions_summary_by_host_by_event_name
events_transactions_summary_by_user_by_event_name
events_waits_summary_by_account_by_event_name
events_waits_summary_by_host_by_event_name
events_waits_summary_by_user_by_event_name
memory_summary_by_account_by_event_name
memory_summary_by_host_by_event_name
memory_summary_by_user_by_event_name

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: [Section 26.12.18.1, “Wait Event Summary Tables”](#)
- Stage event summaries: [Section 26.12.18.2, “Stage Summary Tables”](#)
- Statement event summaries: [Section 26.12.18.3, “Statement Summary Tables”](#)
- Transaction event summaries: [Section 26.12.18.5, “Transaction Summary Tables”](#)
- Memory event summaries: [Section 26.12.18.10, “Memory Summary Tables”](#)
- Error event summaries: [Section 26.12.18.11, “Error Summary Tables”](#)

`TRUNCATE TABLE` is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

Table 26.2 Implicit Effects of Connection Table Truncation

Truncated Connection Table	Implicitly Truncated Summary Tables
<code>accounts</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_thread</code>
<code>hosts</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_host</code> , <code>_summary_by_thread</code>
<code>users</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_user</code> , <code>_summary_by_thread</code>

Truncating a `_summary_global` summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

26.12.8.1 The `accounts` Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 26.12.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

The `accounts` table has these indexes:

- Primary key on (`USER`, `HOST`)

26.12.8.2 The `hosts` Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 26.12.8, “Performance Schema Connection Tables”](#).

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the host.

- `TOTAL_CONNECTIONS`

The total number of connections for the host.

The `hosts` table has these indexes:

- Primary key on (`HOST`)

26.12.8.3 The `users` Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 26.12.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the user.

- `TOTAL_CONNECTIONS`

The total number of connections for the user.

The `users` table has these indexes:

- Primary key on (`USER`)

26.12.9 Performance Schema Connection Attribute Tables

Connection attributes are key-value pairs that application programs can pass to the server at connect time. For applications based on the C API implemented by the `libmysqlclient` client library, the `mysql_options()` and `mysql_options4()` functions define the connection attribute set. Other MySQL Connectors may provide their own attribute-definition methods.

These Performance Schema tables expose attribute information:

- `session_account_connect_attrs`: Connection attributes for the current session, and other sessions associated with the session account
- `session_connect_attrs`: Connection attributes for all sessions

In addition, connect events written to the audit log may include connection attributes. See [Section 6.4.5.4, “Audit Log File Formats”](#).

Attribute names that begin with an underscore (`_`) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes, and enables application programs to define their own attributes that do not collide with internal attributes.

- [Available Connection Attributes](#)
- [Connection Attribute Limits](#)

Available Connection Attributes

The set of connection attributes visible within a given connection varies depending on factors such as your platform, MySQL Connector used to establish the connection, or client program.

The `libmysqlclient` client library sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library).
- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_thread`: The client thread ID (Windows only).

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/C++ 8.0.16 and higher defines these attributes for applications that use X DevAPI or X DevAPI for C:

- `_client_license`: The connector license (for example `GPL-2.0`).
- `_client_name`: The connector name (`mysql-connector-cpp`).
- `_client_version`: The connector version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_source_host`: The host name of the machine on which the client is running.
- `_thread`: The client thread ID (Windows only).

MySQL Connector/J defines these attributes:

- `_client_name`: The client name
- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_client_license`: The connector license type
- `_platform`: The machine platform (for example, `x86_64`)
- `_runtime_vendor`: The Java runtime environment (JRE) vendor

- `_runtime_version`: The Java runtime environment (JRE) version

MySQL Connector/NET defines these attributes:

- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_program_name`: The client name.
- `_thread`: The client thread ID (Windows only).

PHP defines attributes that depend on how it was compiled:

- Compiled using `libmysqlclient`: The standard `libmysqlclient` attributes, described previously.
- Compiled using `mysqlnd`: Only the `_client_name` attribute, with a value of `mysqlnd`.

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively. MySQL Shell sets `program_name` to `mysqlsh`.

Some MySQL client programs define additional attributes:

- `mysql` (as of MySQL 8.0.17):
 - `os_user`: The name of the operating system user running the program. Available on Unix and Unix-like systems and Windows.
 - `os_sudouser`: The value of the `SUDO_USER` environment variable. Available on Unix and Unix-like systems.

`mysql` connection attributes for which the value is empty are not sent.

- `mysqlbinlog`:
 - `_client_role`: `binary_log_listener`
- Replica connections:
 - `program_name`: `mysqld`
 - `_client_role`: `binary_log_listener`
 - `_client_replication_channel_name`: The channel name.
- `FEDERATED` storage engine connections:
 - `program_name`: `mysqld`
 - `_client_role`: `federated_storage`

Connection Attribute Limits

There are limits on the amount of connection attribute data transmitted from client to server:

- A fixed limit imposed by the client prior to connect time.
- A fixed limit imposed by the server at connect time.

- A configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the `libmysqlclient` library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to `mysql_options()` that cause this limit to be exceeded produce a `CR_INVALID_PARAMETER_NO` error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

- The server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. Otherwise, the server considers the attribute buffer valid and tracks the size of the longest such buffer in the `Performance_schema_session_connect_attrs_longest_seen` status variable.
- For accepted connections, the Performance Schema checks aggregate attribute size against the value of the `performance_schema_session_connect_attrs_size` system variable. If attribute size exceeds this value, these actions take place:
 - The Performance Schema truncates the attribute data and increments the `Performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.
 - The Performance Schema writes a message to the error log if the `log_error_verbosity` system variable is greater than 1:

```
Connection attributes of length N were truncated
(N bytes lost)
for connection N, user user_name@host_name
(as user_name), auth: {yes|no}
```

The information in the warning message is intended to help DBAs identify clients for which attribute truncation occurred.

- A `_truncated` attribute is added to the session attributes with a value indicating how many bytes were lost, if the attribute buffer has sufficient space. This enables the Performance Schema to expose per-connection truncation information in the connection attribute tables. This information can be examined without having to check the error log.

26.12.9.1 The `session_account_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see [Section 26.12.9, “Performance Schema Connection Attribute Tables”](#).

The `session_account_connect_attrs` table contains connection attributes only for the current session, and other sessions associated with the session account. To see connection attributes for all sessions, use the `session_connect_attrs` table.

The `session_account_connect_attrs` table has these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

The `session_account_connect_attrs` table has these indexes:

- Primary key on (`PROCESSLIST_ID`, `ATTR_NAME`)

`TRUNCATE TABLE` is not permitted for the `session_account_connect_attrs` table.

26.12.9.2 The `session_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see [Section 26.12.9, “Performance Schema Connection Attribute Tables”](#).

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for the current session, and other sessions associated with the session account, use the `session_account_connect_attrs` table.

The `session_connect_attrs` table has these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

The `session_connect_attrs` table has these indexes:

- Primary key on (`PROCESSLIST_ID`, `ATTR_NAME`)

`TRUNCATE TABLE` is not permitted for the `session_connect_attrs` table.

26.12.10 Performance Schema User-Defined Variable Tables

The Performance Schema provides a `user_variables_by_thread` table that exposes user-defined variables. These are variables defined within a specific session and include a `@` character preceding the name; see [Section 9.4, “User-Defined Variables”](#).

The `user_variables_by_thread` table has these columns:

- `THREAD_ID`

The thread identifier of the session in which the variable is defined.

- `VARIABLE_NAME`

The variable name, without the leading `@` character.

- `VARIABLE_VALUE`

The variable value.

The `user_variables_by_thread` table has these indexes:

- Primary key on (`THREAD_ID`, `VARIABLE_NAME`)

`TRUNCATE TABLE` is not permitted for the `user_variables_by_thread` table.

26.12.11 Performance Schema Replication Tables

The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but representation in table form is more accessible and has usability benefits:

- `SHOW SLAVE STATUS` output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about replica status can be searched using general `SELECT` queries, including complex `WHERE` conditions, joins, and so forth.
- Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.
- The replication tables provide better diagnostic information. For multithreaded replica operation, `SHOW SLAVE STATUS` reports all coordinator and worker thread errors using the `Last_SQL_Errno` and `Last_SQL_Error` fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.
- The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from `SHOW SLAVE STATUS`.
- Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

Replication Table Descriptions

The Performance Schema provides the following replication-related tables:

- Tables that contain information about the connection of the replica to the source:
 - `replication_connection_configuration`: Configuration parameters for connecting to the source
 - `replication_connection_status`: Current status of the connection to the source
- Tables that contain general (not thread-specific) information about the transaction applier:
 - `replication_applier_configuration`: Configuration parameters for the transaction applier on the replica.
 - `replication_applier_status`: Current status of the transaction applier on the replica.
- Tables that contain information about specific threads responsible for applying transactions received from the source:
 - `replication_applier_status_by_coordinator`: Status of the coordinator thread (empty unless the replica is multithreaded).
 - `replication_applier_status_by_worker`: Status of the applier thread or worker threads if the replica is multithreaded.
- Tables that contain information about channel based replication filters:

- `replication_applier_filters`: Provides information about the replication filters configured on specific replication channels.
- `replication_applier_global_filters`: Provides information about global replication filters, which apply to all replication channels.
- Tables that contain information about Group Replication members:
 - `replication_group_members`: Provides network and status information for group members.
 - `replication_group_member_stats`: Provides statistical information about group members and transactions in which they participate.

For more information see [Section 18.3, “Monitoring Group Replication”](#).

The following Performance Schema replication tables continue to be populated when the Performance Schema is disabled:

- `replication_connection_configuration`
- `replication_connection_status`
- `replication_applier_configuration`
- `replication_applier_status`
- `replication_applier_status_by_coordinator`
- `replication_applier_status_by_worker`

The exception is local timing information (start and end timestamps for transactions) in the replication tables `replication_connection_status`, `replication_applier_status_by_coordinator`, and `replication_applier_status_by_worker`. This information is not collected when the Performance Schema is disabled.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

- Prior to execution of `CHANGE MASTER TO`, the tables are empty.
- After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active replication threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.
- After `START SLAVE`, non-`NULL` `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the source has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.
- After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.
- The tables are preserved after `STOP SLAVE` or threads stopping due to an error.

- The `replication_applier_status_by_worker` table is nonempty only when the replica is operating in multithreaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

Replica Status Information Not In the Replication Tables

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

```
Master_Log_File
Read_Master_Log_Pos
Relay_Log_File
Relay_Log_Pos
Relay_Master_Log_File
Exec_Master_Log_Pos
Until_Condition
Until_Log_File
Until_Log_Pos
```

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file used for the replica's source metadata repository, which has been superseded by the use of crash-safe tables for the repository.
- The following fields are based on `server_id`, not `server_uuid`, and are not preserved:

```
Master_Server_Id
Replicate_Ignore_Server_Ids
```

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.
- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

```
Last_Errno
Last_Error
```

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_worker` table (and `replication_applier_status_by_coordinator` if the replica is multithreaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

```
Replicate_Do_DB
Replicate_Ignore_DB
Replicate_Do_Table
Replicate_Ignore_Table
Replicate_Wild_Do_Table
Replicate_Wild_Ignore_Table
```

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA.PROCESSLIST` table to select the `STATE` column of the latter table.
- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by

the replica. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.

- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

Replication Channels

The first column of the replication Performance Schema tables is `CHANNEL_NAME`. This enables the tables to be viewed per replication channel. In a non-multisource replication setup there is a single default replication channel. When you are using multiple replication channels on a replica, you can filter the tables per replication channel to monitor a specific replication channel. See [Section 17.2.2, “Replication Channels”](#) and [Section 17.1.5.8, “Monitoring Multi-Source Replication”](#) for more information.

26.12.11.1 The `replication_connection_configuration` Table

This table shows the configuration parameters used by the replica for connecting to the source. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

Compared to the `replication_connection_status` table, `replication_connection_configuration` changes less frequently. It contains values that define how the replica connects to the source and that remain constant during the connection, whereas `replication_connection_status` contains values that change during the connection.

The `replication_connection_configuration` table has the following columns. The column descriptions indicate the corresponding `CHANGE MASTER TO` options from which the column values are taken, and the table given later in this section shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, “Replication Channels”](#) for more information. (`CHANGE MASTER TO` option: `FOR CHANNEL`)

- `HOST`

The host name of the source that the replica is connected to. (`CHANGE MASTER TO` option: `MASTER_HOST`)

- `PORT`

The port used to connect to the source. (`CHANGE MASTER TO` option: `MASTER_PORT`)

- `USER`

The user name of the replication user account used to connect to the source. (`CHANGE MASTER TO` option: `MASTER_USER`)

- `NETWORK_INTERFACE`

The network interface that the replica is bound to, if any. (`CHANGE MASTER TO` option: `MASTER_BIND`)

- `AUTO_POSITION`

1 if GTID auto-positioning is in use; otherwise 0. (`CHANGE MASTER TO` option: `MASTER_AUTO_POSITION`)

- `SSL_ALLOWED`, `SSL_CA_FILE`, `SSL_CA_PATH`, `SSL_CERTIFICATE`, `SSL_CIPHER`, `SSL_KEY`, `SSL_VERIFY_SERVER_CERTIFICATE`, `SSL_CRL_FILE`, `SSL_CRL_PATH`

These columns show the SSL parameters used by the replica to connect to the source, if any.

`SSL_ALLOWED` has these values:

- `Yes` if an SSL connection to the source is permitted
- `No` if an SSL connection to the source is not permitted
- `Ignored` if an SSL connection is permitted but the replica does not have SSL support enabled

`CHANGE MASTER TO` options for the other SSL columns: `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, `MASTER_SSL_VERIFY_SERVER_CERT`.

- `CONNECTION_RETRY_INTERVAL`

The number of seconds between connect retries. (`CHANGE MASTER TO` option: `MASTER_CONNECT_RETRY`)

- `CONNECTION_RETRY_COUNT`

The number of times the replica can attempt to reconnect to the source in the event of a lost connection. (`CHANGE MASTER TO` option: `MASTER_RETRY_COUNT`)

- `HEARTBEAT_INTERVAL`

The replication heartbeat interval on a replica, measured in seconds. (`CHANGE MASTER TO` option: `MASTER_HEARTBEAT_PERIOD`)

- `TLS_VERSION`

The list of TLS protocol versions that are permitted by the replica for the replication connection. For TLS version information, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). (`CHANGE MASTER TO` option: `MASTER_TLS_VERSION`)

- `TLS_CIPHERSUITES`

The list of ciphersuites that are permitted by the replica for the replication connection. For TLS ciphersuite information, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). (`CHANGE MASTER TO` option: `MASTER_TLS_CIPHERSUITES`)

- `PUBLIC_KEY_PATH`

The path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. This column applies to replicas that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. (`CHANGE MASTER TO` option: `MASTER_PUBLIC_KEY_PATH`)

If `PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_PUBLIC_KEY`.

- `GET_PUBLIC_KEY`

Whether to request from the source the public key required for RSA key pair-based password exchange. This column applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the source does not send the public key unless requested. (`CHANGE MASTER TO` option: `MASTER_GET_PUBLIC_KEY`)

If `PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_PUBLIC_KEY`.

- `COMPRESSION_ALGORITHMS`

The permitted compression algorithms for connections to the source. (`CHANGE MASTER TO` option: `MASTER_COMPRESSION_ALGORITHMS`)

For more information, see [Section 4.2.8, “Connection Compression Control”](#).

This column was added in MySQL 8.0.18.

- `ZSTD_COMPRESSION_LEVEL`

The compression level to use for connections to the source that use the `zstd` compression algorithm. (`CHANGE MASTER TO` option: `MASTER_ZSTD_COMPRESSION_LEVEL`)

For more information, see [Section 4.2.8, “Connection Compression Control”](#).

This column was added in MySQL 8.0.18.

The `replication_connection_configuration` table has these indexes:

- Primary key on (`CHANNEL_NAME`)

`TRUNCATE TABLE` is not permitted for the `replication_connection_configuration` table.

The following table shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

<code>replication_connection_configuration</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>CHANNEL_NAME</code>	<code>Channel_name</code>
<code>HOST</code>	<code>Master_Host</code>
<code>PORT</code>	<code>Master_Port</code>
<code>USER</code>	<code>Master_User</code>
<code>NETWORK_INTERFACE</code>	<code>Master_Bind</code>
<code>AUTO_POSITION</code>	<code>Auto_Position</code>
<code>SSL_ALLOWED</code>	<code>Master_SSL_Allowed</code>
<code>SSL_CA_FILE</code>	<code>Master_SSL_CA_File</code>
<code>SSL_CA_PATH</code>	<code>Master_SSL_CA_Path</code>
<code>SSL_CERTIFICATE</code>	<code>Master_SSL_Cert</code>
<code>SSL_CIPHER</code>	<code>Master_SSL_Cipher</code>
<code>SSL_KEY</code>	<code>Master_SSL_Key</code>
<code>SSL_VERIFY_SERVER_CERTIFICATE</code>	<code>Master_SSL_Verify_Server_Cert</code>
<code>SSL_CRL_FILE</code>	<code>Master_SSL_Crl</code>
<code>SSL_CRL_PATH</code>	<code>Master_SSL_Crlpath</code>
<code>CONNECTION_RETRY_INTERVAL</code>	<code>Connect_Retry</code>
<code>CONNECTION_RETRY_COUNT</code>	<code>Master_Retry_Count</code>
<code>HEARTBEAT_INTERVAL</code>	<code>None</code>
<code>TLS_VERSION</code>	<code>Master_TLS_Version</code>
<code>PUBLIC_KEY_PATH</code>	<code>Master_public_key_path</code>
<code>GET_PUBLIC_KEY</code>	<code>Get_master_public_key</code>
<code>COMPRESSION_ALGORITHMS</code>	<code>[None]</code>
<code>ZSTD_COMPRESSION_LEVEL</code>	<code>[None]</code>

26.12.11.2 The `replication_connection_status` Table

This table shows the current status of the I/O thread that handles the replica's connection to the source, information on the last transaction queued in the relay log, and information on the transaction currently being queued in the relay log.

Compared to the [replication_connection_configuration](#) table, [replication_connection_status](#) changes more frequently. It contains values that change during the connection, whereas [replication_connection_configuration](#) contains values which define how the replica connects to the source and that remain constant during the connection.

The [replication_connection_status](#) table has these columns:

- [CHANNEL_NAME](#)

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, “Replication Channels”](#) for more information.

- [GROUP_NAME](#)

If this server is a member of a group, shows the name of the group the server belongs to.

- [SOURCE_UUID](#)

The [server_uuid](#) value from the source.

- [THREAD_ID](#)

The I/O thread ID.

- [SERVICE_STATE](#)

[ON](#) (thread exists and is active or idle), [OFF](#) (thread no longer exists), or [CONNECTING](#) (thread exists and is connecting to the source).

- [RECEIVED_TRANSACTION_SET](#)

The set of global transaction IDs (GTIDs) corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- [LAST_ERROR_NUMBER](#), [LAST_ERROR_MESSAGE](#)

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the [LAST_ERROR_MESSAGE](#) value is not empty, the error values also appear in the replica's error log.

Issuing [RESET MASTER](#) or [RESET SLAVE](#) resets the values shown in these columns.

- [LAST_ERROR_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the most recent I/O error took place.

- [LAST_HEARTBEAT_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the most recent heartbeat signal was received by a replica.

- [COUNT_RECEIVED_HEARTBEATS](#)

The total number of heartbeat signals that a replica received since the last time it was restarted or reset, or a [CHANGE MASTER TO](#) statement was issued.

- `LAST_QUEUED_TRANSACTION`

The global transaction ID (GTID) of the last transaction that was queued to the relay log.

- `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction queued in the relay log was committed on the original source.

- `LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction queued in the relay log was committed on the immediate source.

- `LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction was placed in the relay log queue by this I/O thread.

- `LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction was queued to the relay log files.

- `QUEUEING_TRANSACTION`

The global transaction ID (GTID) of the currently queueing transaction in the relay log.

- `QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the currently queueing transaction was committed on the original source.

- `QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the currently queueing transaction was committed on the immediate source.

- `QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the first event of the currently queueing transaction was written to the relay log by this I/O thread.

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for queued transactions are zero.

The `replication_connection_status` table has these indexes:

- Primary key on (`CHANNEL_NAME`)
- Index on (`THREAD_ID`)

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

<code>replication_connection_status</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>SOURCE_UUID</code>	<code>Master_UUID</code>
<code>THREAD_ID</code>	None
<code>SERVICE_STATE</code>	<code>Slave_IO_Running</code>
<code>RECEIVED_TRANSACTION_SET</code>	<code>Retrieved_Gtid_Set</code>

<code>replication_connection_status</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>LAST_ERROR_NUMBER</code>	<code>Last_IO_Errno</code>
<code>LAST_ERROR_MESSAGE</code>	<code>Last_IO_Error</code>
<code>LAST_ERROR_TIMESTAMP</code>	<code>Last_IO_Error_Timestamp</code>

26.12.11.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the replica. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

The `replication_applier_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, “Replication Channels”](#) for more information.

- `DESIRED_DELAY`

The number of seconds that the replica must lag the source. (`CHANGE MASTER TO` option: `MASTER_DELAY`) See [Section 17.4.10, “Delayed Replication”](#) for more information.

- `PRIVILEGE_CHECKS_USER`

The user account that provides the security context for the channel (`CHANGE MASTER TO` option: `PRIVILEGE_CHECKS_USER`). This is escaped so that it can be copied into a SQL statement to execute individual transactions. See [Section 17.3.3, “Replication Privilege Checks”](#) for more information.

- `REQUIRE_ROW_FORMAT`

Whether the channel accepts only row-based events (`CHANGE MASTER TO` option: `REQUIRE_ROW_FORMAT`). See [Section 17.3.3, “Replication Privilege Checks”](#) for more information.

- `REQUIRE_TABLE_PRIMARY_KEY_CHECK`

Whether the channel requires primary keys always, never, or according to the source's setting (`CHANGE MASTER TO` option: `REQUIRE_TABLE_PRIMARY_KEY_CHECK`). See [Section 17.3.3, “Replication Privilege Checks”](#) for more information.

The `replication_applier_configuration` table has these indexes:

- Primary key on (`CHANNEL_NAME`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_configuration` table.

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_configuration</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>DESIRED_DELAY</code>	<code>SQL_Delay</code>

26.12.11.4 The `replication_applier_status` Table

This table shows the current general transaction execution status on the replica. The table provides information about general aspects of transaction applier status.

that are not specific to any thread involved. Thread-specific status information is available in the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the replica is multithreaded).

The `replication_applier_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, “Replication Channels”](#) for more information.

- `SERVICE_STATE`

Shows `ON` when the replication channel's applier threads are active or idle, `OFF` means that the applier threads are not active.

- `REMAINING_DELAY`

If the replica is waiting for `DESIRED_DELAY` seconds to pass since the source applied a transaction, this field contains the number of delay seconds remaining. At other times, this field is `NULL`. (The `DESIRED_DELAY` value is stored in the `replication_applier_configuration` table.) See [Section 17.4.10, “Delayed Replication”](#) for more information.

- `COUNT_TRANSACTIONS_RETRIES`

Shows the number of retries that were made because the replication SQL thread failed to apply a transaction. The maximum number of retries for a given transaction is set by the `slave_transaction_retries` system variable. The `replication_applier_status_by_worker` table shows detailed information on transaction retries for a single-threaded or multithreaded replica.

The `replication_applier_status` table has these indexes:

- Primary key on (`CHANNEL_NAME`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_status` table.

The following table shows the correspondence between `replication_applier_status` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_status</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>SERVICE_STATE</code>	None
<code>REMAINING_DELAY</code>	<code>SQL_Remaining_Delay</code>

26.12.11.5 The `replication_applier_status_by_coordinator` Table

For a multithreaded replica, the replica uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. For a single-threaded replica, this table is empty. For a multithreaded replica, the `replication_applier_status_by_worker` table shows the status of the worker threads. This table provides information about the last transaction which was buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering. The start timestamp refers to when this thread read the first event of the transaction from the relay log to buffer it to a worker's queue, while the end timestamp refers to when the last event finished buffering to the worker's queue.

The `replication_applier_status_by_coordinator` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, “Replication Channels”](#) for more information.

- [THREAD_ID](#)

The SQL/coordinator thread ID.

- [SERVICE_STATE](#)

[ON](#) (thread exists and is active or idle) or [OFF](#) (thread no longer exists).

- [LAST_ERROR_NUMBER](#), [LAST_ERROR_MESSAGE](#)

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message which is an empty string means “no error”. If the [LAST_ERROR_MESSAGE](#) value is not empty, the error values also appear in the replica's error log.

Issuing [RESET MASTER](#) or [RESET SLAVE](#) resets the values shown in these columns.

All error codes and messages displayed in the [LAST_ERROR_NUMBER](#) and [LAST_ERROR_MESSAGE](#) columns correspond to error values listed in [Server Error Message Reference](#).

- [LAST_ERROR_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the most recent SQL/coordinator error occurred.

- [LAST_PROCESSED_TRANSACTION](#)

The global transaction ID (GTID) of the last transaction processed by this coordinator.

- [LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the last transaction processed by this coordinator was committed on the original source.

- [LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the last transaction processed by this coordinator was committed on the immediate source.

- [LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when this coordinator thread started writing the last transaction to the buffer of a worker thread.

- [LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the last transaction was written to the buffer of a worker thread by this coordinator thread.

- [PROCESSING_TRANSACTION](#)

The global transaction ID (GTID) of the transaction that this coordinator thread is currently processing.

- [PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the currently processing transaction was committed on the original source.

- [PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when the currently processing transaction was committed on the immediate source.

- [PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP](#)

A timestamp in '[YYYY-MM-DD hh:mm:ss\[.fraction\]](#)' format that shows when this coordinator thread started writing the currently processing transaction to the buffer of a worker thread.

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for buffered transactions are zero.

The [replication_applier_status_by_coordinator](#) table has these indexes:

- Primary key on ([CHANNEL_NAME](#))
- Index on ([THREAD_ID](#))

The following table shows the correspondence between [replication_applier_status_by_coordinator](#) columns and [SHOW SLAVE STATUS](#) columns.

replication_applier_status_by_coordinator Column	SHOW SLAVE STATUS Column
THREAD_ID	None
SERVICE_STATE	Slave_SQL_Running
LAST_ERROR_NUMBER	Last_SQL_Errno
LAST_ERROR_MESSAGE	Last_SQL_Error
LAST_ERROR_TIMESTAMP	Last_SQL_Error_Timestamp

26.12.11.6 The [replication_applier_status_by_worker](#) Table

This table provides details of the transactions handled by applier threads on a replica or Group Replication group member. For a single-threaded replica, data is shown for the replica's single applier thread. For a multithreaded replica, data is shown individually for each applier thread. The applier threads on a multithreaded replica are sometimes called workers. The number of applier threads on a replica or Group Replication group member is set by the [slave_parallel_workers](#) system variable, which is set to zero for a single-threaded replica. A multithreaded replica also has a coordinator thread to manage the applier threads, and the status of this thread is shown in the [replication_applier_status_by_coordinator](#) table.

All error codes and messages displayed in the columns relating to errors correspond to error values listed in [Server Error Message Reference](#).

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for applied transactions are zero. The start timestamps in this table refer to when the worker started applying the first event, and the end timestamps refer to when the last event of the transaction was applied.

When a replica is restarted by a [START SLAVE](#) statement, the columns beginning [APPLYING_TRANSACTION](#) are reset. Before MySQL 8.0.13, these columns were not reset on a replica that was operating in single-threaded mode, only on a multithreaded replica.

The [replication_applier_status_by_worker](#) table has these columns:

- [CHANNEL_NAME](#)

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.2, "Replication Channels"](#) for more information.

- `WORKER_ID`

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

- `THREAD_ID`

The worker thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `LAST_ERROR_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the most recent worker error occurred.

- `LAST_APPLIED_TRANSACTION`

The global transaction ID (GTID) of the last transaction applied by this worker.

- `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction applied by this worker was committed on the original source.

- `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the last transaction applied by this worker was committed on the immediate source.

- `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when this worker started applying the last applied transaction.

- `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when this worker finished applying the last applied transaction.

- `APPLYING_TRANSACTION`

The global transaction ID (GTID) of the transaction this worker is currently applying.

- `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the transaction this worker is currently applying was committed on the original source.

- `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when the transaction this worker is currently applying was committed on the immediate source.

- `APPLYING_TRANSACTION_START_APPLY_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format that shows when this worker started its first attempt to apply the transaction that is currently being applied. Before MySQL 8.0.13, this timestamp was refreshed when a transaction was retried due to a transient error, so it showed the timestamp for the most recent attempt to apply the transaction.

- `LAST_APPLIED_TRANSACTION_RETRIES_COUNT`

The number of times the last applied transaction was retried by the worker after the first attempt. If the transaction was applied at the first attempt, this number is zero.

- `LAST_APPLIED_TRANSACTION_LAST_TRANSIENT_ERROR_NUMBER`

The error number of the last transient error that caused the transaction to be retried.

- `LAST_APPLIED_TRANSACTION_LAST_TRANSIENT_ERROR_MESSAGE`

The message text for the last transient error that caused the transaction to be retried.

- `LAST_APPLIED_TRANSACTION_LAST_TRANSIENT_ERROR_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format for the last transient error that caused the transaction to be retried.

- `APPLYING_TRANSACTION_RETRIES_COUNT`

The number of times the transaction that is currently being applied was retried until this moment. If the transaction was applied at the first attempt, this number is zero.

- `APPLYING_TRANSACTION_LAST_TRANSIENT_ERROR_NUMBER`

The error number of the last transient error that caused the current transaction to be retried.

- `APPLYING_TRANSACTION_LAST_TRANSIENT_ERROR_MESSAGE`

The message text for the last transient error that caused the current transaction to be retried.

- `APPLYING_TRANSACTION_LAST_TRANSIENT_ERROR_TIMESTAMP`

A timestamp in '`YYYY-MM-DD hh:mm:ss[.fraction]`' format for the last transient error that caused the current transaction to be retried.

The `replication_applier_status_by_worker` table has these indexes:

- Primary key on (`CHANNEL_NAME`, `WORKER_ID`)
- Index on (`THREAD_ID`)

The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_status_by_worker</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>WORKER_ID</code>	None
<code>THREAD_ID</code>	None
<code>SERVICE_STATE</code>	None
<code>LAST_ERROR_NUMBER</code>	<code>Last_SQL_Errno</code>
<code>LAST_ERROR_MESSAGE</code>	<code>Last_SQL_Error</code>
<code>LAST_ERROR_TIMESTAMP</code>	<code>Last_SQL_Error_Timestamp</code>

26.12.11.7 The replication_applier_global_filters Table

This table shows the global replication filters configured on this replica. The `replication_applier_global_filters` table has these columns:

- `FILTER_NAME`

The type of replication filter that has been configured.

- `FILTER_RULE`

The rules configured for the replication filter type using either `--replicate-*` command options or `CHANGE REPLICATION FILTER`.

- `CONFIGURED_BY`

The method used to configure the replication filter, can be one of:

- `CHANGE_REPLICATION_FILTER` configured by a global replication filter using a `CHANGE REPLICATION FILTER` statement.
- `STARTUP_OPTIONS` configured by a global replication filter using a `--replicate-*` option.
- `ACTIVE_SINCE`

Timestamp of when the replication filter was configured.

26.12.11.8 The replication_applier_filters Table

This table shows the replication channel specific filters configured on this replica. Each row provides information on a replication channel's configured type of filter. The `replication_applier_filters` table has these columns:

- `CHANNEL_NAME`

The name of replication channel with a replication filter configured.

- `FILTER_NAME`

The type of replication filter that has been configured for this replication channel.

- `FILTER_RULE`

The rules configured for the replication filter type using either `--replicate-*` command options or `CHANGE REPLICATION FILTER`.

- `CONFIGURED_BY`

The method used to configure the replication filter, can be one of:

- `CHANGE_REPLICATION_FILTER` configured by a global replication filter using a `CHANGE REPLICATION FILTER` statement.
- `STARTUP_OPTIONS` configured by a global replication filter using a `--replicate-*` option.
- `CHANGE_REPLICATION_FILTER_FOR_CHANNEL` configured by a channel specific replication filter using a `CHANGE REPLICATION FILTER FOR CHANNEL` statement.
- `STARTUP_OPTIONS_FOR_CHANNEL` configured by a channel specific replication filter using a `--replicate-*` option.
- `ACTIVE_SINCE`

Timestamp of when the replication filter was configured.

- `COUNTER`

The number of times the replication filter has been used since it was configured.

26.12.11.9 The `replication_group_members` Table

This table shows network and status information for replication group members. The network addresses shown are the addresses used to connect clients to the group, and should not be confused with the member's internal group communication address specified by `group_replication_local_address`.

The `replication_group_members` table has these columns:

- `CHANNEL_NAME`

Name of the Group Replication channel.

- `MEMBER_ID`

The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.

- `MEMBER_HOST`

Network address of this member (host name or IP address). Retrieved from the member's `hostname` variable. This is the address which clients connect to, unlike the `group_replication_local_address` which is used for internal group communication.

- `MEMBER_PORT`

Port on which the server is listening. Retrieved from the member's `port` variable.

- `MEMBER_STATE`

Current state of this member; can be any one of the following:

- `ONLINE`: The member is in a fully functioning state.
- `RECOVERING`: The server has joined a group from which it is retrieving data.
- `OFFLINE`: The group replication plugin is installed but has not been started.
- `ERROR`: The member has encountered an error, either during applying transactions or during the recovery phase, and is not participating in the group's transactions.
- `UNREACHABLE`: The failure detection process suspects that this member cannot be contacted, because the group messages have timed out.

See [Section 18.3.1, “Group Replication Server States”](#).

- `MEMBER_ROLE`

Role of the member in the group, either `PRIMARY` or `SECONDARY`.

- `MEMBER_VERSION`

MySQL version of the member.

The `replication_group_members` table has these indexes:

- None

`TRUNCATE TABLE` is not permitted for the `replication_group_members` table.

26.12.11.10 The `replication_group_member_stats` Table

This table shows statistical information for replication group members. It is populated only when Group Replication is running.

The `replication_group_member_stats` table has these columns:

- `CHANNEL_NAME`

Name of the Group Replication channel

- `VIEW_ID`

Current view identifier for this group.

- `MEMBER_ID`

The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.

- `COUNT_TRANSACTIONS_IN_QUEUE`

The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.

- `COUNT_TRANSACTIONS_CHECKED`

The number of transactions that have been checked for conflicts.

- `COUNT_CONFLICTS_DETECTED`

The number of transactions that have not passed the conflict detection check.

- `COUNT_TRANSACTIONS_ROWS_VALIDATING`
