If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `CONNECTION_ADMIN` or `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`.
- Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by replication threads, if the server is a replica. In replication setups, it can be useful to enable `read_only` on replica servers to ensure that replicas accept updates only from the replication source server and not from clients.
- Writes to the system table `mysql.gtid_executed`, which stores GTIDs for executed transactions that are not present in the current binary log file.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replicas can be performed with `mysqlcheck --all-databases --analyze`.
- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see [Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#).

- Updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica server independent of the setting on the source.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

Command-Line Format	<code>--read-rnd-buffer-size=#</code>
System Variable	<code>read_rnd_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	1
Maximum Value	2147483647

This variable is used for reads from `MyISAM` tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a `MyISAM` table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 8.2.1.16, “ORDER BY Optimization”](#). Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see [Section 8.12.3.1, “How MySQL Uses Memory”](#). For information about Multi-Range Read optimization, see [Section 8.2.1.11, “Multi-Range Read Optimization”](#).

- `regexp_stack_limit`

Command-Line Format	<code>--regexp-stack-limit=#</code>
System Variable	<code>regexp_stack_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	8000000
Minimum Value	0
Maximum Value	2147483647

The maximum available memory in bytes for the internal stack used for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 12.8.2, “Regular Expressions”](#)).

- `regexp_time_limit`

Command-Line Format	<code>--regexp-time-limit=#</code>
System Variable	<code>regexp_time_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	2147483647

The time limit for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 12.8.2, “Regular Expressions”](#)). This limit is expressed as the maximum permitted number of steps performed by the match engine, and thus affects execution time only indirectly. Typically, it is on the order of milliseconds.

- `require_row_format`

Introduced	8.0.19
System Variable	<code>require_row_format</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable is for internal server use by replication and `mysqlbinlog`. It restricts DML events executed in the session to events encoded in row-based binary logging format only, and temporary tables cannot be created. Queries that do not respect the restrictions fail.

Setting the session value of this system variable to `ON` requires no privileges. Setting the session value of this system variable to `OFF` is a restricted operation, and the session user must have privileges sufficient to set restricted session variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

- `require_secure_transport`

Command-Line Format	<code>--require-secure-transport[={OFF ON}]</code>
System Variable	<code>require_secure_transport</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections encrypted using TLS/SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an [ER_SECURE_TRANSPORT_REQUIRED](#) error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with [REQUIRE SSL](#), enabling [require_secure_transport](#) does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the [shared_memory](#) system variable disabled. Under these conditions, attempts to enable [require_secure_transport](#) at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an [ER_NO_SECURE_TRANSPORTS_CONFIGURED](#) error.

See also [Configuring Encrypted Connections as Mandatory](#).

- [resultset_metadata](#)

System Variable	resultset_metadata
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	FULL
Valid Values	FULL NONE

For connections for which metadata transfer is optional, the client sets the [resultset_metadata](#) system variable to control whether the server returns result set metadata. Permitted values are [FULL](#) (return all metadata; this is the default) and [NONE](#) (return no metadata).

For connections that are not metadata-optional, setting [resultset_metadata](#) to [NONE](#) produces an error.

For details about managing result set metadata transfer, see [C API Optional Result Set Metadata](#).

- [secondary_engine_cost_threshold](#)

Introduced	8.0.16
System Variable	secondary_engine_cost_threshold
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Numeric
Default Value	100000.000000
Minimum Value	0

Maximum Value	DBL_MAX (maximum double value)
---------------	--------------------------------

For future use.

- `schema_definition_cache`

Command-Line Format	<code>--schema-definition-cache=#</code>
System Variable	<code>schema_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of schema definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused schema definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `schema_definition_cache`.

A setting of 0 means that schema definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- `secure_file_priv`

Command-Line Format	<code>--secure-file-priv=dir_name</code>
System Variable	<code>secure_file_priv</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	platform specific
Valid Values	empty string dirname NULL

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server will not create it.

- If set to `NULL`, the server disables import and export operations.

The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR` CMake option.

<code>INSTALL_LAYOUT</code> Value	Default <code>secure_file_priv</code> Value
<code>STANDALONE</code>	empty
<code>DEB</code> , <code>RPM</code> , <code>SVR4</code>	<code>/var/lib/mysql-files</code>
Otherwise	<code>mysql-files</code> under the <code>CMAKE_INSTALL_PREFIX</code> value

The server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `select_into_buffer_size`

Command-Line Format	<code>--select-into-buffer-size=#</code>
Introduced	8.0.22
System Variable	<code>select_into_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	131072
Minimum Value	8192
Maximum Value	2147479552
Unit	bytes

When using `SELECT INTO OUTFILE` or `SELECT INTO DUMPFILE` to dump data into one or more files for backup creation, data migration, or other purposes, writes can often be buffered and then trigger a large burst of write I/O activity to the disk or other storage device and stall other queries that are more sensitive to latency. You can use this variable to control the size of the buffer used to write data to the storage device to determine when buffer synchronization should occur, and thus to prevent write stalls of the kind just described from occurring.

`select_into_buffer_size` overrides any value set for `read_buffer_size`. (`select_into_buffer_size` and `read_buffer_size` have the same default, maximum, and minimum values.) You can also use `select_into_disk_sync_delay` to set a timeout to be observed afterwards, each time synchronization takes place.

- `select_into_disk_sync`

Command-Line Format	<code>--select-into-disk-sync={ON OFF}</code>
Introduced	8.0.22
System Variable	<code>select_into_disk_sync</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes

Type	Boolean
Default Value	OFF
Valid Values	OFF ON

When set on **ON**, enables buffer synchronization of writes to an output file by a long-running **SELECT INTO OUTFILE** or **SELECT INTO DUMPFILE** statement using **select_into_buffer_size**.

- **select_into_disk_sync_delay**

Command-Line Format	<code>--select-into-disk-sync-delay=#</code>
Introduced	8.0.22
System Variable	<code>select_into_disk_sync_delay</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000
Unit	milliseconds

When buffer synchronization of writes to an output file by a long-running **SELECT INTO OUTFILE** or **SELECT INTO DUMPFILE** statement is enabled by **select_into_disk_sync**, this variable sets an optional delay (in milliseconds) following synchronization. 0 (the default) means no delay.

- **session_track_gtids**

Command-Line Format	<code>--session-track-gtids=value</code>
System Variable	<code>session_track_gtids</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF OWN_GTID ALL_GTIDS

Controls whether the server tracks GTIDs within the current session and returns them to the client. Depending on the variable value, at the end of executing each transaction, the server GTIDs are captured by the tracker and returned to the client. These **session_track_gtids** values are permitted:

- **OFF**: The tracker collects no GTIDs. This is the default.
- **OWN_GTID**: The tracker collects GTIDs generated by successfully committed read/write transactions.

- `ALL_GTIDS`: The tracker collects all GTIDs in the `gtid_executed` system variable at the time the current transaction commits, regardless of whether the transaction is read/write or read only.

`session_track_gtids` cannot be set within transactional context.

For more information about session state tracking, see [Section 5.1.17, “Server Tracking of Client Session State Changes”](#).

- `session_track_schema`

Command-Line Format	<code>--session-track-schema[={OFF ON}]</code>
System Variable	<code>session_track_schema</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

For more information about session state tracking, see [Section 5.1.17, “Server Tracking of Client Session State Changes”](#).

- `session_track_state_change`

Command-Line Format	<code>--session-track-state-change[={OFF ON}]</code>
System Variable	<code>session_track_state_change</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:

- The default schema (database).
- Session-specific values for system variables.
- User-defined variables.
- Temporary tables.

- Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

Note

Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name listed in the value of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see [Section 5.1.17, “Server Tracking of Client Session State Changes”](#).

- `session_track_system_variables`

Command-Line Format	<code>--session-track-system-variables=#</code>
System Variable	<code>session_track_system_variables</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names.

To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see [Section 5.1.17, “Server Tracking of Client Session State Changes”](#).

- `session_track_transaction_info`

Command-Line Format	<code>--session-track-transaction-info=value</code>
System Variable	<code>session_track_transaction_info</code>

Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF STATE CHARACTERISTICS

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These [session_track_transaction_info](#) values are permitted:

- [OFF](#): Disable transaction state tracking. This is the default.
- [STATE](#): Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.
- [CHARACTERISTICS](#): Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

```
ISOLATION LEVEL
READ ONLY
READ WRITE
WITH CONSISTENT SNAPSHOT
```

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the [transaction_isolation](#) and [transaction_read_only](#) system variables to correctly determine the session defaults. (To track these variables, list them in the value of the [session_track_system_variables](#) system variable.)

For more information about session state tracking, see [Section 5.1.17, “Server Tracking of Client Session State Changes”](#).

- [sha256_password_auto_generate_rsa_keys](#)

Command-Line Format	<code>--sha256-password-auto-generate-rsa-keys [= {OFF ON}]</code>
System Variable	sha256_password_auto_generate_rsa_keys
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

The server uses this variable to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The [sha256_password_auto_generate_rsa_keys](#) or [caching_sha2_password_auto_generate_rsa_keys](#) system variable is enabled; no RSA

options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

For more information about RSA file autogeneration, including file names and characteristics, see [Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- `sha256_password_private_key_path`

Command-Line Format	<code>--sha256-password-private-key-path=file_name</code>
System Variable	<code>sha256_password_private_key_path</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>private_key.pem</code>

The value of this variable is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

Important

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#).

- `sha256_password_proxy_users`

Command-Line Format	<code>--sha256-password-proxy-users[={OFF ON}]</code>
System Variable	<code>sha256_password_proxy_users</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see [Section 6.2.18, “Proxy Users”](#).

- `sha256_password_public_key_path`

Command-Line Format	<code>--sha256-password-public-key-path=file_name</code>
System Variable	<code>sha256_password_public_key_path</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	File name
Default Value	public_key.pem

The value of this variable is the path name of the RSA public key file for the [sha256_password](#) authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about [sha256_password](#), including information about how clients specify the RSA public key, see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#).

- [shared_memory](#)

Command-Line Format	--shared-memory[={OFF ON}]
System Variable	shared_memory
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	OFF

(Windows only.) Whether the server permits shared-memory connections.

- [shared_memory_base_name](#)

Command-Line Format	--shared-memory-base-name=name
System Variable	shared_memory_base_name
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	MYSQL

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is [MYSQL](#). The name is case-sensitive.

This variable applies only if the server is started with the [shared_memory](#) system variable enabled to support shared-memory connections.

- [show_create_table_skip_secondary_engine](#)

Command-Line Format	--show-create-table-skip-secondary-engine[={OFF ON}]
Introduced	8.0.18
System Variable	show_create_table_skip_secondary_engine
Scope	Session

Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	OFF

Enabling `show_create_table_skip_secondary_engine` causes the `SECONDARY ENGINE` clause to be excluded from `SHOW CREATE TABLE` output, and from `CREATE TABLE` statements dumped by the `mysqldump` utility.

`mysqldump` provides the `--show-create-skip-secondary-engine` option. When specified, it enables the `show_create_table_skip_secondary_engine` system variable for the duration of the dump operation.

Attempting a `mysqldump` operation with the `--show-create-skip-secondary-engine` option on a release prior to MySQL 8.0.18 that does not support the `show_create_table_skip_secondary_engine` variable causes an error.

- `show_create_table_verbosity`

Command-Line Format	<code>--show-create-table-verbosity[={OFF ON}]</code>
System Variable	<code>show_create_table_verbosity</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

`SHOW CREATE TABLE` normally does not show the `ROW_FORMAT` table option if the row format is the default format. Enabling this variable causes `SHOW CREATE TABLE` to display `ROW_FORMAT` regardless of whether it is the default format.

- `show_old_temporals`

Command-Line Format	<code>--show-old-temporals[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>show_old_temporals</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Whether `SHOW CREATE TABLE` output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, `SHOW CREATE TABLE` output looks like this:

```
CREATE TABLE `mytbl` (
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
  `t` time /* 5.5 binary format */ DEFAULT NULL
```

```
) DEFAULT CHARSET=utf8mb4
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable is deprecated and will be removed in a future MySQL release.

- `skip_external_locking`

Command-Line Format	<code>--skip-external-locking[={OFF ON}]</code>
System Variable	<code>skip_external_locking</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.11.5, “External Locking”](#).

- `skip_name_resolve`

Command-Line Format	<code>--skip-name-resolve[={OFF ON}]</code>
System Variable	<code>skip_name_resolve</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to resolve host names when checking client connections. If this variable is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers; in this case, all `Host` column values in the grant tables must be IP addresses. See [Section 5.1.12.3, “DNS Lookups and the Host Cache”](#).

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=127.0.0.1` or `--host>:::1`.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled. If you plan to do that, make sure an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host>:::1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':::1' IDENTIFIED BY 'root-password';
```

- `skip_networking`

Command-Line Format	<code>--skip-networking[={OFF ON}]</code>
---------------------	---

System Variable	<code>skip_networking</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether the server permits TCP/IP connections. By default, it is disabled (permit TCP connections). If enabled, the server permits only local (non-TCP/IP) connections and all interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 5.1.12.3, “DNS Lookups and the Host Cache”](#).

Because starting the server with `--skip-grant-tables` disables authentication checks, the server also disables remote connections in that case by enabling `skip_networking`.

- `skip_show_database`

Command-Line Format	<code>--skip-show-database</code>
System Variable	<code>skip_show_database</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- `slow_launch_time`

Command-Line Format	<code>--slow-launch-time=#</code>
System Variable	<code>slow_launch_time</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>2</code>

If creating a thread takes longer than this many seconds, the server increments the `slow_launch_threads` status variable.

- `slow_query_log`

Command-Line Format	<code>--slow-query-log[={OFF ON}]</code>
System Variable	<code>slow_query_log</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 5.4.5, “The Slow Query Log”](#).

- `slow_query_log_file`

Command-Line Format	<code>--slow-query-log-file=file_name</code>
System Variable	<code>slow_query_log_file</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>host_name-slow.log</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
System Variable	<code>socket</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value (Other)	<code>/tmp/mysql.sock</code>
Default Value (Windows)	<code>MySQL</code>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- `sort_buffer_size`

Command-Line Format	<code>--sort-buffer-size=#</code>
---------------------	-----------------------------------

System Variable	<code>sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	32768
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295
Maximum Value (Windows)	4294967295

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see [Section 8.2.1.16, “ORDER BY Optimization”](#)

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

- `sql_auto_is_null`

System Variable	<code>sql_auto_is_null</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	OFF

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see

[Section 12.16, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

Prior to MySQL 8.0.16, the transformation of `WHERE auto_col IS NULL` to `WHERE auto_col = LAST_INSERT_ID()` was performed only when the statement was executed, so that the value of `sql_auto_is_null` during execution determined whether the query was transformed. In MySQL 8.0.16 and later, the transformation is performed during statement preparation.

The default value of `sql_auto_is_null` is `OFF`.

- `sql_big_selects`

System Variable	<code>sql_big_selects</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

If set to `OFF`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `ON`, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to `OFF`.

- `sql_buffer_result`

System Variable	<code>sql_buffer_result</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is `OFF`.

- `sql_log_off`

System Variable	<code>sql_log_off</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> (enable logging)

	<code>ON</code> (disable logging)
--	-----------------------------------

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is `OFF` (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

- `sql_mode`

Command-Line Format	<code>--sql-mode=name</code>
System Variable	<code>sql_mode</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Set
Default Value	<code>ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION</code>
Valid Values	<code>ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES</code>

	TIME_TRUNCATE_FRACTIONAL
--	--------------------------

The current server SQL mode, which can be set dynamically. For details, see [Section 5.1.11, “Server SQL Modes”](#).

**Note**

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

System Variable	<code>sql_notes</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If enabled (the default), diagnostics of `Note` level increment `warning_count` and the server records them. If disabled, `Note` diagnostics do not increment `warning_count` and the server does not record them. `mysqldump` includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

System Variable	<code>sql_quote_show_create</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.7.7.10, “SHOW CREATE TABLE Statement”](#), and [Section 13.7.7.6, “SHOW CREATE DATABASE Statement”](#).

- `sql_require_primary_key`

Command-Line Format	<code>--sql-require-primary-key[={OFF ON}]</code>
Introduced	8.0.13
System Variable	<code>sql_require_primary_key</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean

Default Value	OFF
---------------	-----

Whether statements that create new tables or alter the structure of existing tables enforce the requirement that tables have a primary key.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

Enabling this variable helps avoid performance problems in row-based replication that can occur when tables have no primary key. Suppose that a table has no primary key and an update or delete modifies multiple rows. On the replication source server, this operation can be performed using a single table scan but, when replicated using row-based replication, results in a table scan for each row to be modified on the replica. With a primary key, these table scans do not occur.

`sql_require_primary_key` applies to both base tables and `TEMPORARY` tables, and changes to its value are replicated to replica servers. As of MySQL 8.0.18, it applies only to storage engines that can participate in replication.

When enabled, `sql_require_primary_key` has these effects:

- Attempts to create a new table with no primary key fail with an error. This includes `CREATE TABLE ... LIKE`. It also includes `CREATE TABLE ... SELECT`, unless the `CREATE TABLE` part includes a primary key definition.
- Attempts to drop the primary key from an existing table fail with an error, with the exception that dropping the primary key and adding a primary key in the same `ALTER TABLE` statement is permitted.

Dropping the primary key fails even if the table also contains a `UNIQUE NOT NULL` index.

- Attempts to import a table with no primary key fail with an error.

The `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE MASTER TO` statement enables a replica to select its own policy for primary key checks. When the option is set to `ON` for a replication channel, the replica always uses the value `ON` for the `sql_require_primary_key` system variable in replication operations, requiring a primary key. When the option is set to `OFF`, the replica always uses the value `OFF` for the `sql_require_primary_key` system variable in replication operations, so that a primary key is never required, even if the source required one. When the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option is set to `STREAM`, which is the default, the replica uses whatever value is replicated from the source for each transaction. With the `STREAM` setting for the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option, if privilege checks are in use for the replication channel, the `PRIVILEGE_CHECKS_USER` account needs privileges sufficient to set restricted session variables, so that it can set the session value for the `sql_require_primary_key` system variable. With the `ON` or `OFF` settings, the account does not need these privileges. For more information, see [Section 17.3.3, “Replication Privilege Checks”](#).

- `sql_safe_updates`

System Variable	<code>sql_safe_updates</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean

Default Value	OFF
---------------	-----

If this variable is enabled, [UPDATE](#) and [DELETE](#) statements that do not use a key in the [WHERE](#) clause or a [LIMIT](#) clause produce an error. This makes it possible to catch [UPDATE](#) and [DELETE](#) statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is [OFF](#).

For the [mysql](#) client, [sql_safe_updates](#) can be enabled by using the [--safe-updates](#) option. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

- [sql_select_limit](#)

System Variable	sql_select_limit
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer

The maximum number of rows to return from [SELECT](#) statements. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $(2^{32})-1$ or $(2^{64})-1$. If you have changed the limit, the default value can be restored by assigning a value of [DEFAULT](#).

If a [SELECT](#) has a [LIMIT](#) clause, the [LIMIT](#) takes precedence over the value of [sql_select_limit](#).

- [sql_warnings](#)

System Variable	sql_warnings
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls whether single-row [INSERT](#) statements produce an information string if warnings occur. The default is [OFF](#). Set the value to [ON](#) to produce an information string.

- [ssl_ca](#)

Command-Line Format	--ssl-ca=file_name
System Variable	ssl_ca
Scope	Global
Dynamic ($\geq 8.0.16$)	Yes
Dynamic ($\leq 8.0.15$)	No
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_capath`

Command-Line Format	<code>--ssl-capath=dir_name</code>
System Variable	<code>ssl_capath</code>
Scope	Global
Dynamic ($\geq 8.0.16$)	Yes
Dynamic ($\leq 8.0.15$)	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

The path name of the directory that contains trusted SSL Certificate Authority (CA) certificate files in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_cert`

Command-Line Format	<code>--ssl-cert=file_name</code>
System Variable	<code>ssl_cert</code>
Scope	Global
Dynamic ($\geq 8.0.16$)	Yes
Dynamic ($\leq 8.0.15$)	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The path name of the server SSL public key certificate file in PEM format.

If the server is started with `ssl_cert` set to a certificate that uses any restricted cipher or cipher category, the server starts with support for encrypted connections disabled. For information about cipher restrictions, see [Connection Cipher Configuration](#).

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_cipher`

Command-Line Format	<code>--ssl-cipher=name</code>
System Variable	<code>ssl_cipher</code>
Scope	Global
Dynamic ($\geq 8.0.16$)	Yes
Dynamic ($\leq 8.0.15$)	No
<code>SET_VAR</code> Hint Applies	No

Type	String
Default Value	NULL

The list of permissible encryption ciphers for connections that use TLS protocols up through TLSv1.2. If no cipher in the list is supported, encrypted connections that use these TLS protocols will not work.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. Examples:

```
[mysqld]
ssl_cipher="AES128-SHA"
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports the syntax for specifying ciphers described in the OpenSSL documentation at <https://www.openssl.org/docs/manmaster/man1/ciphers.html>.

For information about which encryption ciphers MySQL supports, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_crl`

Command-Line Format	<code>--ssl-crl=file_name</code>
System Variable	<code>ssl_crl</code>
Scope	Global
Dynamic (\geq 8.0.16)	Yes
Dynamic (\leq 8.0.15)	No
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The path name of the file containing certificate revocation lists in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_crlpath`

Command-Line Format	<code>--ssl-crlpath=dir_name</code>
System Variable	<code>ssl_crlpath</code>
Scope	Global
Dynamic (\geq 8.0.16)	Yes
Dynamic (\leq 8.0.15)	No
SET_VAR Hint Applies	No
Type	Directory name

Default Value	NULL
---------------	------

The path of the directory that contains certificate revocation-list files in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `ssl_fips_mode`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
System Variable	<code>ssl_fips_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF (or 0) ON (or 1) STRICT (or 2)

Controls whether to enable FIPS mode on the server side. The `ssl_fips_mode` system variable differs from other `ssl_XXX` system variables in that it is not used to control whether the server permits encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 6.8, “FIPS Support”](#).

These `ssl_fips_mode` values are permitted:

- `OFF` (or 0): Disable FIPS mode.
- `ON` (or 1): Enable FIPS mode.
- `STRICT` (or 2): Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` is `OFF`. In this case, setting `ssl_fips_mode` to `ON` or `STRICT` at startup causes the server to produce an error message and exit.

- `ssl_key`

Command-Line Format	<code>--ssl-key=file_name</code>
System Variable	<code>ssl_key</code>
Scope	Global
Dynamic (≥ 8.0.16)	Yes
Dynamic (≤ 8.0.15)	No
SET_VAR Hint Applies	No
Type	File name

Default Value	NULL
---------------	------

The path name of the server SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

If the key file is protected by a passphrase, the server prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- [stored_program_cache](#)

Command-Line Format	<code>--stored-program-cache=#</code>
System Variable	stored_program_cache
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	16
Maximum Value	524288

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

The stored procedure and stored function caches exist in parallel with the stored program definition cache partition of the [dictionary object cache](#). The stored procedure and stored function caches are per connection, while the stored program definition cache is shared. The existence of objects in the stored procedure and stored function caches have no dependence on the existence of objects in the stored program definition cache, and vice versa. For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- [stored_program_definition_cache](#)

Command-Line Format	<code>--stored-program-definition-cache=#</code>
System Variable	stored_program_definition_cache
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256

Maximum Value	524288
---------------	--------

Defines a limit for the number of stored program definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused stored program definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `stored_program_definition_cache`.

A setting of 0 means that stored program definition objects are only kept in the dictionary object cache while they are in use.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

For related information, see [Section 14.4, “Dictionary Object Cache”](#).

- `super_read_only`

Command-Line Format	<code>--super-read-only[={OFF ON}]</code>
System Variable	<code>super_read_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `CONNECTION_ADMIN` or `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Client updates prevented when `super_read_only` is enabled include operations that do not necessarily appear to be updates, such as `CREATE FUNCTION` (to install a UDF), `INSTALL PLUGIN`, and `INSTALL COMPONENT`. These operations are prohibited because they involve changes to tables in the `mysql` system schema.

Changes to `super_read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica independent of the setting on the source.

- `syseventlog.facility`

Command-Line Format	<code>--syseventlog.facility=value</code>
Introduced	8.0.13
System Variable	<code>syseventlog.facility</code>
Scope	Global
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>daemon</code>

The facility for error log output written to `syslog` (what type of program is sending the message). This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.8, “Error Logging to the System Log”](#).

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- `syseventlog.include_pid`

Command-Line Format	<code>--syseventlog.include-pid[={OFF ON}]</code>
Introduced	8.0.13
System Variable	<code>syseventlog.include_pid</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether to include the server process ID in each line of error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.8, “Error Logging to the System Log”](#).

This variable does not exist on Windows.

- `syseventlog.tag`

Command-Line Format	<code>--syseventlog.tag=tag</code>
Introduced	8.0.13
System Variable	<code>syseventlog.tag</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The tag to be added to the server identifier in error log output written to `syslog` or the Windows Event Log. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 5.4.2.8, “Error Logging to the System Log”](#).

By default, no tag is set, so the server identifier is simply `MySQL` on Windows, and `mysqld` on other platforms. If a tag value of `tag` is specified, it is appended to the server identifier with a leading hyphen, resulting in a `syslog` identifier of `mysqld-tag` (or `MySQL-tag` on Windows).

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- `system_time_zone`

System Variable	<code>system_time_zone</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 5.1.14, “MySQL Server Time Zone Support”](#).

- `table_definition_cache`

Command-Line Format	<code>--table-definition-cache=#</code>
System Variable	<code>table_definition_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>-1</code> (signifies autosizing; do not assign this literal value)
Minimum Value	<code>400</code>
Maximum Value	<code>524288</code>

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
MIN(400 + table_open_cache / 2, 2000)
```

For `InnoDB`, `table_definition_cache` acts as a soft limit for the number of open table instances in the `InnoDB` data dictionary cache. If the number of open table instances exceeds the `table_definition_cache` setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by `table_definition_cache`, because parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, `table_definition_cache` defines a soft limit for the number of `InnoDB` file-per-table tablespaces that can be open at one time, which is also controlled by `innodb_open_files`. If both `table_definition_cache` and `innodb_open_files` are set, the highest setting is used. If neither variable is set, `table_definition_cache`, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by `table_definition_cache` or `innodb_open_files`, the LRU mechanism searches the tablespace file LRU list for files that

are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

The table definition cache exists in parallel with the table definition cache partition of the [dictionary object cache](#). Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence objects in the other. For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- [table_encryption_privilege_check](#)

Command-Line Format	<code>--table-encryption-privilege-check[={OFF ON}]</code>
Introduced	8.0.16
System Variable	table_encryption_privilege_check
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Controls the [TABLE_ENCRYPTION_ADMIN](#) privilege check that occurs when creating or altering a schema or general tablespace with encryption that differs from the [default_table_encryption](#) setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. The check is disabled by default.

Setting [table_encryption_privilege_check](#) at runtime requires the [SUPER](#) privilege.

[table_encryption_privilege_check](#) supports [SET PERSIST](#) and [SET PERSIST_ONLY](#) syntax. See [Section 5.1.9.3, “Persisted System Variables”](#).

For more information, see [Defining an Encryption Default for Schemas and General Tablespaces](#).

- [table_open_cache](#)

Command-Line Format	<code>--table-open-cache=#</code>
System Variable	table_open_cache
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	4000
Minimum Value	1
Maximum Value	524288

The number of open tables for all threads. Increasing this value increases the number of file descriptors that [mysqld](#) requires. You can check whether you need to increase the table cache by checking the [Opened_tables](#) status variable. See [Section 5.1.10, “Server Status Variables”](#). If the value of [Opened_tables](#) is large and you do not use [FLUSH TABLES](#) often (which just forces all tables to be closed and reopened), then you should increase the value of the [table_open_cache](#) variable. For more information about the table cache, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

- `table_open_cache_instances`

Command-Line Format	<code>--table-open-cache-instances=#</code>
System Variable	<code>table_open_cache_instances</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	64

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache / table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- `tablespace_definition_cache`

Command-Line Format	<code>--tablespace-definition-cache=#</code>
System Variable	<code>tablespace_definition_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of tablespace definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused tablespace definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `tablespace_definition_cache`.

A setting of 0 means that tablespace definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 14.4, “Dictionary Object Cache”](#).

- `temptable_max_ram`

Command-Line Format	<code>--temptable-max-ram=#</code>
System Variable	<code>temptable_max_ram</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	2097152
Maximum Value	2 ⁶⁴ -1

Defines the maximum amount of memory that can be occupied by the [TempTable](#) storage engine before it starts storing data on disk. The default value is 1073741824 bytes (1GiB). For more information, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- [temptable_use_mmap](#)

Command-Line Format	<code>--temptable-use-mmap[={OFF ON}]</code>
Introduced	8.0.16
System Variable	temptable_use_mmap
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Defines whether the TempTable storage engine allocates space for internal in-memory temporary tables as memory-mapped temporary files when the amount of memory occupied by the TempTable storage engine exceeds the limit defined by the [temptable_max_ram](#) variable. When [temptable_use_mmap](#) is disabled, the TempTable storage engine uses InnoDB on-disk internal temporary tables instead. For more information, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- [thread_cache_size](#)

Command-Line Format	<code>--thread-cache-size=#</code>
System Variable	thread_cache_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	0
Maximum Value	16384

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than [thread_cache_size](#) threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set [thread_cache_size](#) high enough so that most new connections use cached threads. By examining the difference between the [Connections](#) and

`Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.10, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

- `thread_handling`

Command-Line Format	<code>--thread-handling=name</code>
System Variable	<code>thread_handling</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>one-thread-per-connection</code>
Valid Values	<code>no-threads</code> <code>one-thread-per-connection</code> <code>loaded-dynamically</code>

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection), `one-thread-per-connection` (the server uses one thread to handle each client connection), and `loaded-dynamically` (set by the thread pool plugin when it initializes). `no-threads` is useful for debugging under Linux; see [Section 5.9, “Debugging MySQL”](#).

- `thread_pool_algorithm`

Command-Line Format	<code>--thread-pool-algorithm=#</code>
System Variable	<code>thread_pool_algorithm</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_high_priority_connection`

Command-Line Format	<code>--thread-pool-high-priority-connection=#</code>
System Variable	<code>thread_pool_high_priority_connection</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_max_active_query_threads`

Command-Line Format	<code>--thread-pool-max-active-query-threads</code>
Introduced	8.0.19
System Variable	<code>thread_pool_max_active_query_threads</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	512

The maximum permissible number of active (running) query threads per group. If the value is 0, the thread pool plugin uses up to as many threads as are available.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_max_unused_threads`

Command-Line Format	<code>--thread-pool-max-unused-threads=#</code>
System Variable	<code>thread_pool_max_unused_threads</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value	4096
---------------	------

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*–1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_prio_kickup_timer`

Command-Line Format	<code>--thread-pool-prio-kickup-timer=#</code>
System Variable	<code>thread_pool_prio_kickup_timer</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967294

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second).

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_size`

Command-Line Format	<code>--thread-pool-size=#</code>
System Variable	<code>thread_pool_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value (≥ 8.0.19)	512

Maximum Value (\leq 8.0.18)	64
--------------------------------	----

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. If a value outside the range of permissible values is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_stall_limit`

Command-Line Format	<code>--thread-pool-stall-limit=#</code>
System Variable	<code>thread_pool_stall_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	4
Maximum Value	600

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so the default of 6 means 60ms. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#)

- `thread_stack`

Command-Line Format	<code>--thread-stack=#</code>
System Variable	<code>thread_stack</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	286720
Default Value (32-bit platforms)	221184
Minimum Value	131072
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Block Size	1024
------------	------

The stack size for each thread. The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_zone`

System Variable	<code>time_zone</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies (\geq 8.0.17)	Yes
<code>SET_VAR</code> Hint Applies (\leq 8.0.16)	No
Type	String
Default Value	<code>SYSTEM</code>
Minimum Value (\geq 8.0.19)	<code>-14:00</code>
Minimum Value (\leq 8.0.18)	<code>-12:59</code>
Maximum Value (\geq 8.0.19)	<code>+14:00</code>
Maximum Value (\leq 8.0.18)	<code>+13:00</code>

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is '`SYSTEM`' (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 5.1.14, “MySQL Server Time Zone Support”](#).

Note

If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- `timestamp`

System Variable	<code>timestamp</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Numeric
Default Value	<code>UNIX_TIMESTAMP()</code>
Minimum Value	1

Maximum Value	2147483647
---------------	------------

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`, not a value in '`YYYY-MM-DD hh:mm:ss`' format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

`timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part. The maximum value corresponds to '`2038-01-19 03:14:07`' UTC, the same as for the `TIMESTAMP` data type.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be a synonym for `NOW()`, in which case `SET timestamp` affects both functions.

- `tls_ciphersuites`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Introduced	8.0.16
System Variable	<code>tls_ciphersuites</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

Which ciphersuites the server permits for encrypted connections that use TLSv1.3. The value is a list of zero or more colon-separated ciphersuite names.

The ciphersuites that can be named for this variable depend on the SSL library used to compile MySQL. If this variable is not set, its default value is `NULL`, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established. For more information, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `tls_version`

Command-Line Format	<code>--tls-version=protocol_list</code>
System Variable	<code>tls_version</code>
Scope	Global
Dynamic ($\geq 8.0.16$)	Yes
Dynamic ($\leq 8.0.15$)	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value ($\geq 8.0.16$)	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 and higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

Default Value (≤ 8.0.15)	<code>TLSv1,TLSv1.1,TLSv1.2</code>
--------------------------	------------------------------------

Which protocols the server permits for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. Permitted protocols should be chosen such as not to leave “holes” in the list. For details, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#). Prior to MySQL 8.0.16, this variable can be set only at server startup.

- `tmp_table_size`

Command-Line Format	<code>--tmp-table-size=#</code>
System Variable	<code>tmp_table_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	<code>16777216</code>
Minimum Value	<code>1024</code>
Maximum Value	<code>18446744073709551615</code>

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is the smaller of `tmp_table_size` and `max_heap_table_size`. When an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `tmpdir`

Command-Line Format	<code>--tmpdir=dir_name</code>
System Variable	<code>tmpdir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This variable can be set

to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).

- `transaction_alloc_block_size`

Command-Line Format	<code>--transaction-alloc-block-size=#</code>
System Variable	<code>transaction_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	1024
Maximum Value	131072
Block Size	1024

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_isolation`

Command-Line Format	<code>--transaction-isolation=name</code>
System Variable	<code>transaction_isolation</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>REPEATABLE-READ</code>
Valid Values	<code>READ-UNCOMMITTED</code> <code>READ-COMMITTED</code> <code>REPEATABLE-READ</code>

<code>SERIALIZABLE</code>

The transaction isolation level. The default is `REPEATABLE-READ`.

The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the `--transaction-isolation` server option.

At runtime, the isolation level can be set directly using the `SET` statement to assign a value to the `transaction_isolation` system variable, or indirectly using the `SET TRANSACTION` statement. If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_isolation = 'READ-COMMITTED';
```

Setting the global `transaction_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_isolation` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_isolation`:

- To set the session isolation level, use any of these syntaxes:

```
SET @@SESSION.transaction_isolation = value;
SET SESSION transaction_isolation = value;
```

```
SET transaction_isolation = value;
```

For each of those syntaxes, these semantics apply:

- Sets the isolation level for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction isolation level.
- Corresponds to `SET SESSION TRANSACTION ISOLATION LEVEL` (with the `SESSION` keyword).
- To set the next-transaction isolation level, use this syntax:

```
SET @@transaction_isolation = value;
```

For that syntax, these semantics apply:

- Sets the isolation level only for the next single transaction performed within the session.
- Subsequent transactions revert to the session isolation level.
- Not permitted within transactions.
- Corresponds to `SET TRANSACTION ISOLATION LEVEL` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_isolation` system variable, see [Section 13.3.7, “SET TRANSACTION Statement”](#).

- `transaction_prealloc_size`

Command-Line Format	<code>--transaction-prealloc-size=#</code>
System Variable	<code>transaction_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4096
Minimum Value	1024
Maximum Value	131072
Block Size	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `transaction_read_only`

Command-Line Format	<code>--transaction-read-only[={OFF ON}]</code>
System Variable	<code>transaction_read_only</code>

Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

The transaction access mode. The value can be `OFF` (read/write; the default) or `ON` (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.

To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `transaction_read_only` system variable, or indirectly using the `SET TRANSACTION` statement. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_read_only = ON;
```

Setting the global `transaction_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_read_only`,

- To set the session access mode, use any of these syntaxes:

```
SET @@SESSION.transaction_read_only = value;
SET SESSION transaction_read_only = value;
```

```
SET transaction_read_only = value;
```

For each of those syntaxes, these semantics apply:

- Sets the access mode for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.
- Corresponds to `SET SESSION TRANSACTION {READ WRITE | READ ONLY}` (with the `SESSION` keyword).
- To set the next-transaction access mode, use this syntax:

```
SET @@transaction_read_only = value;
```

For that syntax, these semantics apply:

- Sets the access mode only for the next single transaction performed within the session.
- Subsequent transactions revert to the session access mode.
- Not permitted within transactions.
- Corresponds to `SET TRANSACTION {READ WRITE | READ ONLY}` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_read_only` system variable, see [Section 13.3.7, “SET TRANSACTION Statement”](#).

- `unique_checks`

System Variable	<code>unique_checks</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `updatable_views_with_limit`

Command-Line Format	<code>--updatable-views-with-limit[={OFF ON}]</code>
System Variable	<code>updatable_views_with_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean

Default Value	1
---------------	---

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- 1 or [YES](#): Issue a warning only (not an error message). This is the default value.
- 0 or [NO](#): Prohibit the update.
- [use_secondary_engine](#)

Introduced	8.0.13
System Variable	use_secondary_engine
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Enumeration
Default Value	ON
Valid Values	OFF ON FORCED

For future use.

- [validate_password.xxx](#)

The [validate_password](#) component implements a set of system variables having names of the form [validate_password.xxx](#). These variables affect password testing by that component; see [Section 6.4.3.2, “Password Validation Options and Variables”](#).

- [validate_user_plugins](#)

Command-Line Format	--validate-user-plugins[={OFF ON}]
System Variable	validate_user_plugins
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.

- The account requires the `sha256_password` or `caching_sha2_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by the plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

- `version`

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

System Variable	<code>version_comment</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The `CMake` configuration program has a `COMPILATION_COMMENT_SERVER` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. (Prior to MySQL 8.0.14, `version_comment` is set by the `COMPILATION_COMMENT` option.) See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

- `version_compile_machine`

System Variable	<code>version_compile_machine</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The type of the server binary.

- `version_compile_os`

System Variable	<code>version_compile_os</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The type of operating system on which MySQL was built.

- `version_compile_zlib`

System Variable	<code>version_compile_zlib</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	String
------	--------

The version of the compiled-in `zlib` library.

- `wait_timeout`

Command-Line Format	<code>--wait-timeout=#</code>
System Variable	<code>wait_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value (Other)	31536000
Maximum Value (Windows)	2147483

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.7.42, “SHOW WARNINGS Statement”](#).

- `windowing_use_high_precision`

Command-Line Format	<code>--windowing-use-high-precision[={OFF ON}]</code>
System Variable	<code>windowing_use_high_precision</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	ON

Whether to compute window operations without loss of precision. See [Section 8.2.1.21, “Window Function Optimization”](#).

5.1.9 Using System Variables

The MySQL server maintains many system variables that configure its operation. [Section 5.1.8, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables may also be installed by server plugins or components:

- System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the `audit_log` plugin implements a system variable named `audit_log_policy`.
- System variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.2, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. At startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent.

When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 ; that is, units of kilobytes, megabytes, or gigabytes, respectively. As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024^4 , 1024^5 or 1024^6 . Thus, the following command starts the server with an `InnoDB` log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb-log-file-size=16M --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
innodb_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `innodb_log_file_size` from being increased to more than 32MB at runtime, use the option `--maximum-innodb-log-file-size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 5.1.9.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. At runtime, system variable names must be written using underscores, not dashes. The following examples briefly illustrate this syntax:

- Set a global system variable:

```
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value):

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value):

```
SET PERSIST_ONLY back_log = 1000;
SET @@PERSIST_ONLY.back_log = 1000;
```

- Set a session system variable:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting and persisting system variables, see [Section 5.1.9.1, “System Variable Privileges”](#)

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	151
basedir	/home/mysql/
binlog_cache_size	32768
bulk_insert_buffer_size	8388608
character_set_client	utf8
character_set_connection	utf8
character_set_database	utf8mb4
character_set_filesystem	binary
character_set_results	utf8
character_set_server	utf8mb4
character_set_system	utf8
character_sets_dir	/home/mysql/share/mysql/charsets/
collation_connection	utf8_general_ci
collation_database	utf8mb4_0900_ai_ci
collation_server	utf8mb4_0900_ai_ci
...	
innodb_autoextend_increment	8
innodb_buffer_pool_size	8388608
innodb_commit_concurrency	0

innodb_concurrency_tickets	500	
innodb_data_file_path	ibdata1:10M:autoextend	
innodb_data_home_dir		
...		
version	8.0.1-dmr-log	
version_comment	Source distribution	
version_compile_machine	i686	
version_compile_os	suse-linux	
wait_timeout	28800	
+-----+-----+-----+		

With a [LIKE](#) clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `_` to match it literally. In practice, this is rarely necessary.

For [SHOW VARIABLES](#), if you specify neither [GLOBAL](#) nor [SESSION](#), MySQL returns [SESSION](#) values.

The reason for requiring the [GLOBAL](#) keyword when setting [GLOBAL](#)-only variables but not when retrieving them is to prevent problems in the future:

- Were a [SESSION](#) variable to be removed that has the same name as a [GLOBAL](#) variable, a client with privileges sufficient to modify global variables might accidentally change the [GLOBAL](#) variable rather than just the [SESSION](#) variable for its own session.
- Were a [SESSION](#) variable to be added with the same name as a [GLOBAL](#) variable, a client that intends to change the [GLOBAL](#) variable might find only its own [SESSION](#) variable changed.

5.1.9.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both:

- For dynamic system variables, the [SET](#) statement can be used to change their global or session runtime value (or both), to affect operation of the current server instance. (For information about dynamic variables, see [Section 5.1.9.2, “Dynamic System Variables”](#).)
- For certain global system variables, [SET](#) can be used to persist their value to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. (For information about persisting system variables and the `mysqld-auto.cnf` file, see [Section 5.1.9.3, “Persisted System Variables”](#).)
- For persisted global system variables, [RESET PERSIST](#) can be used to remove their value from `mysqld-auto.cnf`, to affect server operation for subsequent startups.

This section describes the privileges required for operations that assign values to system variables at runtime. This includes operations that affect runtime values, and operations that persist values.

To set a global system variable, use a [SET](#) statement with the appropriate keyword. These privileges apply:

- To set a global system variable runtime value, use the [SET GLOBAL](#) statement, which requires the [SYSTEM_VARIABLES_ADMIN](#) privilege (or the deprecated [SUPER](#) privilege).
- To persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value), use the [SET PERSIST](#) statement, which requires the [SYSTEM_VARIABLES_ADMIN](#) or [SUPER](#) privilege.

- To persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value), use the `SET PERSIST_ONLY` statement, which requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges. `SET PERSIST_ONLY` can be used for both dynamic and read-only system variables, but is particularly useful for persisting read-only variables, for which `SET PERSIST` cannot be used.
- Some global system variables are persist-restricted (see [Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#)). To persist these variables, use the `SET PERSIST_ONLY` statement, which requires the privileges described previously. In addition, you must connect to the server using an encrypted connection and supply an SSL certificate with the Subject value specified by the `persist_only_admin_x509_subject` system variable.

To remove a persisted global system variable from the `mysqld-auto.cnf` file, use the `RESET PERSIST` statement. These privileges apply:

- For dynamic system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- For read-only system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.
- For persist-restricted variables, `RESET PERSIST` does not require an encrypted connection to the server made using a particular SSL certificate.

If a global system variable has any exceptions to the preceding privilege requirements, the variable description indicates those exceptions. Examples include `default_table_encryption` and `mandatory_roles`, which require additional privileges. These additional privileges apply to operations that set the global runtime value, but not operations that persist the value.

To set a session system variable runtime value, use the `SET SESSION` statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value may have effects outside the current session and thus is a restricted operation that can be done only by users who have a special privilege:

- As of MySQL 8.0.14, the privilege required is `SESSION_VARIABLES_ADMIN`.

Note

Any user who has `SYSTEM_VARIABLES_ADMIN` or `SUPER` effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

- Prior to MySQL 8.0.14, the privilege required is `SYSTEM_VARIABLES_ADMIN` or `SUPER`.

If a session system variable is restricted, the variable description indicates that restriction. Examples include `binlog_format` and `sql_log_bin`. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

`SESSION_VARIABLES_ADMIN` enables administrators to minimize the privilege footprint of users who may previously have been granted `SYSTEM_VARIABLES_ADMIN` or `SUPER` for the purpose of enabling them to modify restricted session system variables. Suppose that an administrator has created the following role to confer the ability to set restricted session system variables:

```
CREATE ROLE set_session_sysvars;
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
```

Any user granted the `set_session_sysvars` role (and who has that role active) is able to set restricted session system variables. However, that user is also able to set global system variables, which may be undesirable.

By modifying the role to have `SESSION_VARIABLES_ADMIN` instead of `SYSTEM_VARIABLES_ADMIN`, the role privileges can be reduced to the ability to set restricted session system variables and nothing else. To modify the role, use these statements:

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
REVOKE SYSTEM_VARIABLES_ADMIN ON *.* FROM set_session_sysvars;
```

Modifying the role has an immediate effect: Any account granted the `set_session_sysvars` role no longer has `SYSTEM_VARIABLES_ADMIN` and is not able to set global system variables without being granted that ability explicitly. A similar `GRANT/REVOKE` sequence can be applied to any account that was granted `SYSTEM_VARIABLES_ADMIN` directly rather than by means of a role.

5.1.9.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting system variables, see [Section 5.1.9.1, “System Variable Privileges”](#)

The following table lists all dynamic system variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from the `ENUM` data type used for table columns, for which the first enumeration value corresponds to 1.

Table 5.4 Dynamic System Variable Summary

Variable Name	Variable Type	Variable Scope
activate_all_roles_on_login	Boolean	Global
admin_ssl_ca	File name	Global
admin_ssl_capath	Directory name	Global
admin_ssl_cert	File name	Global
admin_ssl_cipher	String	Global
admin_ssl_crl	File name	Global
admin_ssl_crlpath	Directory name	Global
admin_ssl_key	File name	Global

5.1.9.3 Persisted System Variables

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the [SET](#) statement to affect operation of the current server instance. [SET](#) can also be used to persist certain global system variables to the [mysqld-auto.cnf](#) file in the data directory, to affect server operation for subsequent startups. [RESET PERSIST](#) removes persisted settings from [mysqld-auto.cnf](#).

The following discussion describes aspects of persisting system variables:

- [Overview of Persisted System Variables](#)
- [Syntax for Persisting System Variables](#)
- [Obtaining Information About Persisted System Variables](#)
- [Format and Server Handling of the \[mysqld-auto.cnf\]\(#\) File](#)

Overview of Persisted System Variables

The capability of persisting global system variables at runtime enables server configuration that persists across server startups. Although many system variables can be set at startup from a [my.cnf](#) option file, or at runtime using the [SET](#) statement, those methods of configuring the server either require login access to the server host, or do not provide the capability of persistently configuring the server at runtime or remotely:

- Modifying an option file requires direct access to that file, which requires login access to the MySQL server host. This is not always convenient.
- Modifying system variables with [SET GLOBAL](#) is a runtime capability that can be done from clients run locally or from remote hosts, but the changes affect only the currently running server instance. The settings are not persistent and do not carry over to subsequent server startups.

To augment administrative capabilities for server configuration beyond what is achievable by editing option files or using [SET GLOBAL](#), MySQL provides variants of [SET](#) syntax that persist system variable settings to a file named [mysqld-auto.cnf](#) file in the data directory. Examples:

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;

SET PERSIST_ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

MySQL also provides a [RESET PERSIST](#) statement for removing persisted system variables from [mysqld-auto.cnf](#).

Server configuration performed by persisting system variables has these characteristics:

- Persisted settings are made at runtime.
- Persisted settings are permanent. They apply across server restarts.
- Persisted settings can be made from local clients or clients who connect from a remote host. This provides the convenience of remotely configuring multiple MySQL servers from a central client host.

- To persist system variables, you need not have login access to the MySQL server host or file system access to option files. Ability to persist settings is controlled using the MySQL privilege system. See [Section 5.1.9.1, “System Variable Privileges”](#).
- An administrator with sufficient privileges can reconfigure a server by persisting system variables, then cause the server to use the changed settings immediately by executing a [RESTART](#) statement.
- Persisted settings provide immediate feedback about errors. An error in a manually entered setting might not be discovered until much later. [SET](#) statements that persist system variables avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration.

Syntax for Persisting System Variables

These [SET](#) syntax options are available for persisting system variables:

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the [PERSIST](#) keyword or the `@@PERSIST.` qualifier:

```
SET PERSIST max_connections = 1000;  
SET @@PERSIST.max_connections = 1000;
```

Like [SET GLOBAL](#), [SET PERSIST](#) sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the [PERSIST_ONLY](#) keyword or the `@@PERSIST_ONLY.` qualifier:

```
SET PERSIST_ONLY back_log = 1000;  
SET @@PERSIST_ONLY.back_log = 1000;
```

Like [PERSIST](#), [PERSIST_ONLY](#) writes the variable setting to `mysqld-auto.cnf`. However, unlike [PERSIST](#), [PERSIST_ONLY](#) does not modify the global variable runtime value. This makes [PERSIST_ONLY](#) suitable for configuring read-only system variables that can be set only at server startup.

For more information about [SET](#), see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

These [RESET PERSIST](#) syntax options are available for removing persisted system variables:

- To remove all persisted variables from `mysqld-auto.cnf`, use [RESET PERSIST](#) without naming any system variable:

```
RESET PERSIST;
```

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

```
RESET PERSIST system_var_name;
```

This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an [IF EXISTS](#) clause to the previous syntax:

```
RESET PERSIST IF EXISTS system_var_name;
```

For more information about [RESET PERSIST](#), see [Section 13.7.8.7, “RESET PERSIST Statement”](#).

Using [SET](#) to persist a global system variable to a value of [DEFAULT](#) or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use [RESET PERSIST](#).

Some system variables cannot be persisted. See [Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#).

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable will not exist when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

Obtaining Information About Persisted System Variables

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See [Section 26.12.14.1, “Performance Schema `persisted_variables` Table”](#).

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See [Section 26.12.14.2, “Performance Schema `variables_info` Table”](#).

`RESET PERSIST` affects the contents of the `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the `variables_info` table until the server is restarted.

Format and Server Handling of the `mysqld-auto.cnf` File

The `mysqld-auto.cnf` file uses a `JSON` format like this (reformatted slightly for readability):

```
{
  "Version": 1,
  "mysql_server": {
    "max_connections": {
      "Value": "152",
      "Metadata": {
        "Timestamp": 1519921341372531,
        "User": "root",
        "Host": "localhost"
      }
    },
    "transaction_isolation": {
      "Value": "READ-COMMITTED",
      "Metadata": {
        "Timestamp": 1519921553880520,
        "User": "root",
        "Host": "localhost"
      }
    }
  },
  "mysql_server_static_options": {
    "innodb_api_enable_md1": {
      "Value": "0",
      "Metadata": {
        "Timestamp": 1519922873467872,
        "User": "root",
        "Host": "localhost"
      }
    },
    "log_slave_updates": {
      "Value": "1",
      "Metadata": {
        "Timestamp": 1519925628441588,
        "User": "root",
        "Host": "localhost"
      }
    }
  }
}
```

```
}
}
```

At startup, the server processes the `mysqld-auto.cnf` file after all other option files (see [Section 4.2.2.2, “Using Option Files”](#)). The server handles the file contents as follows:

- If the `persisted_globals_load` system variable is disabled, the server ignores the `mysqld-auto.cnf` file.
- Only read-only variables persisted using `SET PERSIST_ONLY` appear in the `"mysql_server_static_options"` section. All variables present inside this section are appended to the command line and processed with other command-line options.
- All remaining persisted variables are set by executing the equivalent of a `SET GLOBAL` statement later, just before the server starts listening for client connections. These settings therefore do not take effect until late in the startup process, which might be unsuitable for certain system variables. It may be preferable to set such variables in `my.cnf` rather than in `mysqld-auto.cnf`.

Management of the `mysqld-auto.cnf` file should be left to the server. Manipulation of the file should be performed only using `SET` and `RESET PERSIST` statements, not manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:

```
RESET PERSIST;
```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persisted_globals_load` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysqld-auto.cnf` file. However, as noted previously, removing this file results in a loss of all persisted settings.

5.1.9.4 Nonpersistible and Persist-Restricted System Variables

`SET PERSIST` and `SET PERSIST_ONLY` enable global system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#)). However, not all system variables can be persisted, or can be persisted only under certain restrictive conditions. Here are some reasons why a system variable might be nonpersistible or persist-restricted:

- Session system variables cannot be persisted. Session variables cannot be set at server startup, so there is no reason to persist them.
- A global system variable might involve sensitive data such that it should be settable only by a user with direct access to the server host.
- A global system variable might be read only (that is, set only by the server). In this case, it cannot be set by users at all, whether at server startup or at runtime.
- A global system variable might be intended only for internal use.

Nonpersistible system variables cannot be persisted under any circumstances. As of MySQL 8.0.14, persist-restricted system variables can be persisted with `SET PERSIST_ONLY`, but only by users for which the following conditions are satisfied:

- The `persist_only_admin_x509_subject` system variable is set to an SSL certificate X.509 Subject value.
- The user connects to the server using an encrypted connection and supplies an SSL certificate with the designated Subject value.
- The user has sufficient privileges to use `SET PERSIST_ONLY` (see [Section 5.1.9.1, “System Variable Privileges”](#)).

For example, `protocol_version` is read only and set only by the server, so it cannot be persisted under any circumstances. On the other hand, `bind_address` is persist-restricted, so it can be set by users who satisfy the preceding conditions.

The following system variables are nonpersistible. This list may change with ongoing development.

```
audit_log_current_session
audit_log_filter_id
character_set_system
core_file
have_statement_timeout
have_symlink
hostname
innodb_version

```

To configure the server to enable persisting persist-restricted system variables, use this procedure:

1. Ensure that MySQL is configured to support encrypted connections. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).
2. Designate an SSL certificate X.509 Subject value that signifies the ability to persist persist-restricted system variables, and generate a certificate that has that Subject. See [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
3. Start the server with `persist_only_admin_x509_subject` set to the designated Subject value. For example, put these lines in your server `my.cnf` file:

```

[mysqld]
persist_only_admin_x509_subject="subject-value"

```

The format of the Subject value is the same as used for `CREATE USER ... REQUIRE SUBJECT`. See [Section 13.7.1.3, “CREATE USER Statement”](#).

You must perform this step directly on the MySQL server host because `persist_only_admin_x509_subject` itself cannot be persisted at runtime.

4. Restart the server.
5. Distribute the SSL certificate that has the designated Subject value to users who are to be permitted to persist persist-restricted system variables.

Suppose that `myclient-cert.pem` is the SSL certificate to be used by clients who can persist persist-restricted system variables. Display the certificate contents using the `openssl` command:

```

shell> openssl x509 -text -in myclient-cert.pem
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 2 (0x2)
        Signature Algorithm: md5WithRSAEncryption
        Issuer: C=US, ST=IL, L=Chicago, O=MyOrg, OU=CA, CN=MyCN
        Validity
            Not Before: Oct 18 17:03:03 2018 GMT
            Not After : Oct 15 17:03:03 2028 GMT
        Subject: C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
    ...

```

The `openssl` output shows that the certificate Subject value is:

```
C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```

To specify the Subject for MySQL, use this format:

```
/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN
```

Configure the server `my.cnf` file with the Subject value:

```

[mysqld]
persist_only_admin_x509_subject="/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN"

```

Restart the server so that the new configuration takes effect.

Distribute the SSL certificate (and any other associated SSL files) to the appropriate users. Such a user then connects to the server with the certificate and any other SSL options required to establish an encrypted connection.

To use X.509, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified. For example:

```
shell> mysql --ssl-key=myclient-key.pem --ssl-cert=myclient-cert.pem --ssl-ca=mycacert.pem
```

Assuming that the user has sufficient privileges to use `SET PERSIST_ONLY`, persist-restricted system variables can be persisted like this:

```

mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
Query OK, 0 rows affected (0.00 sec)

```

If the server is not configured to enable persisting persist-restricted system variables, or the user does not satisfy the required conditions for that capability, an error occurs:

```

mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
ERROR 1238 (HY000): Variable 'socket' is a non persistent read only variable

```

5.1.9.5 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`

- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 8.10.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@GLOBAL.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysql --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysql --key_buffer_size=256K \
--extra_cache.key_buffer_size=128K \
--extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
        --hot_cache.key_buffer_size=2M \
        --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@GLOBAL.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.10 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 13.7.7.37, “SHOW STATUS Statement”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| ... |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_files | 3 |
| Created_tmp_tables | 2 |
| ... |
| Threads_created | 217 |
| Threads_running | 88 |
| Uptime | 1389872 |
+-----+-----+
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see [Section 5.1.6, “Server Status Variable Reference”](#).

The status variables have the following meanings.

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.3.2.10, “Communication Errors and Aborted Connections”](#).

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See [Section B.3.2.10, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

- `Authentication_ldap_sasl_supported_methods`

The `authentication_ldap_sasl` plugin that implements SASL LDAP authentication supports multiple authentication methods, but depending on host system configuration, they might not all be available. The `Authentication_ldap_sasl_supported_methods` variable provides discoverability for the supported methods. Its value is a string consisting of supported method names separated by spaces. Example: `"SCRAM-SHA1 GSSAPI"`

This variable was added in MySQL 8.0.21.

- `Binlog_cache_disk_use`

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Acl_cache_items_count`

The number of cached privilege objects. Each object is the privilege combination of a user and its active roles.

- `Binlog_cache_use`

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Caching_sha2_password_rsa_public_key`

The public key used by the `caching_sha2_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables. The value of `Caching_sha2_password_rsa_public_key` comes from the latter file.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

All `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of

requests issued, not to the number of requests successfully completed. For example, because status variables are initialized for each server startup and do not persist across restarts, the `Com_restart` and `Com_shutdown` variables that track `RESTART` and `SHUTDOWN` statements normally have a value of zero, but can be nonzero if `RESTART` or `SHUTDOWN` statements were executed but failed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server, for example, after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

`Com_explain_other` indicates the number of `EXPLAIN FOR CONNECTION` statements executed. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).

`Com_change_repl_filter` indicates the number of `CHANGE REPLICATION FILTER` statements executed.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

As of MySQL 8.0.18, this status variable is deprecated. It will be removed in a future MySQL version. See [Configuring Legacy Connection Compression](#).

- `Compression_algorithm`

The name of the compression algorithm in use for the current connection to the server. The value can be any algorithm permitted in the value of the `protocol_compression_algorithms` system variable. For example, the value is `uncompressed` if the connection does not use compression, or `zlib` if the connection uses the `zlib` algorithm.

For more information, see [Section 4.2.8, “Connection Compression Control”](#).

This variable was added in MySQL 8.0.18.

- `Compression_level`

The compression level in use for the current connection to the server. The value is 6 for `zlib` connections (the default `zlib` algorithm compression level), 1 to 22 for `zstd` connections, and 0 for `uncompressed` connections.

For more information, see [Section 4.2.8, “Connection Compression Control”](#).

This variable was added in MySQL 8.0.18.

- `Connection_errors_xxx`

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 5.1.12.3, “DNS Lookups and the Host Cache”](#)), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

- `Connection_errors_accept`

The number of errors that occurred during calls to `accept()` on the listening port.

- `Connection_errors_internal`

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- `Connection_errors_max_connections`

The number of connections refused because the server `max_connections` limit was reached.

- `Connection_errors_peer_address`

The number of errors that occurred while searching for connecting client IP addresses.

- `Connection_errors_select`

The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- `Connection_errors_tcpwrap`

The number of connections refused by the `libwrap` library.

- `Connections`

The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

The number of internal on-disk temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

**Note**

Due to a known limitation, `Created_tmp_disk_tables` does not count on-disk temporary tables created in memory-mapped files. By default, the TempTable storage engine overflow mechanism creates internal

temporary tables in memory-mapped files. This behavior is controlled by the `temptable_use_mmap` variable, which is enabled by default.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `Created_tmp_files`

How many temporary files `mysqld` has created.

- `Created_tmp_tables`

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Current_tls_ca`

The active `ssl_ca` value in the SSL context that the server uses for new connections. This context value may differ from the current `ssl_ca` system variable value if the system variable has been changed but `ALTER INSTANCE RELOAD TLS` has not subsequently been executed to reconfigure the SSL context from the context-related system variable values and update the corresponding status variables. (This potential difference in values applies to each corresponding pair of context-related system and status variables. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).)

This variable was added in MySQL 8.0.16.

As of MySQL 8.0.21, the `Current_tls_xxx` status variable values are also available through the Performance Schema `tls_channel_status` table. See [Section 26.12.19.8, “The `tls_channel_status` Table”](#).

- `Current_tls_capath`

The active `ssl_capath` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

- `Current_tls_cert`

The active `ssl_cert` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

- `Current_tls_cipher`

The active `ssl_cipher` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

- [Current_tls_ciphersuites](#)

The active [tls_ciphersuites](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current_tls_ca](#).

This variable was added in MySQL 8.0.16.

- [Current_tls_crl](#)

The active [ssl_crl](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current_tls_ca](#).

This variable was added in MySQL 8.0.16.

- [Current_tls_crlpath](#)

The active [ssl_crlpath](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current_tls_ca](#).

This variable was added in MySQL 8.0.16.

- [Current_tls_key](#)

The active [ssl_key](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current_tls_ca](#).

This variable was added in MySQL 8.0.16.

- [Current_tls_version](#)

The active [tls_version](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current_tls_ca](#).

This variable was added in MySQL 8.0.16.

- [Delayed_errors](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [Delayed_insert_threads](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [Delayed_writes](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [dragnet.Status](#)

The result of the most recent assignment to the [dragnet.log_error_filter_rules](#) system variable, empty if no such assignment has occurred.

This variable was added in MySQL 8.0.12.

- [Error_log_buffered_bytes](#)

The number of bytes currently used in the Performance Schema `error_log` table. It is possible for the value to decrease, for example, if a new event will not fit until discarding an old event, but the new event is smaller than the old one.

This variable was added in MySQL 8.0.22.

- `Error_log_buffered_events`

The number of events currently present in the Performance Schema `error_log` table. As with `Error_log_buffered_bytes`, it is possible for the value to decrease.

This variable was added in MySQL 8.0.22.

- `Error_log_expired_events`

The number of events discarded from the Performance Schema `error_log` table to make room for new events.

This variable was added in MySQL 8.0.22.

- `Error_log_latest_write`

The time of the last write to the Performance Schema `error_log` table.

This variable was added in MySQL 8.0.22.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `group_replication_primary_member`

Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

The `group_replication_primary_member` status variable is deprecated and is scheduled to be removed in a future version.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_external_lock`

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, `SELECT coll FROM foo`, assuming that `coll` is indexed).

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `Innodb_buffer_pool_dump_status`

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of [innodb_buffer_pool_dump_at_shutdown](#) or [innodb_buffer_pool_dump_now](#).

For related information and examples, see [Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [Innodb_buffer_pool_load_status](#)

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of [innodb_buffer_pool_load_at_startup](#) or [innodb_buffer_pool_load_now](#). If the operation introduces too much overhead, you can cancel it by setting [innodb_buffer_pool_load_abort](#).

For related information and examples, see [Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [Innodb_buffer_pool_bytes_data](#)

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with [Innodb_buffer_pool_pages_data](#), when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- [Innodb_buffer_pool_pages_data](#)

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. When using [compressed tables](#), the reported [Innodb_buffer_pool_pages_data](#) value may be larger than [Innodb_buffer_pool_pages_total](#) (Bug #59550).

- [Innodb_buffer_pool_bytes_dirty](#)

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with [Innodb_buffer_pool_pages_dirty](#), when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- [Innodb_buffer_pool_pages_dirty](#)

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_flushed](#)

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_free](#)

The number of free [pages](#) in the [InnoDB buffer pool](#).

- [Innodb_buffer_pool_pages_latched](#)

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the [UNIV_DEBUG](#) system is defined at server build time.

- [Innodb_buffer_pool_pages_misc](#)

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as [Innodb_buffer_pool_pages_total](#) - [Innodb_buffer_pool_pages_free](#) - [Innodb_buffer_pool_pages_data](#). When using [compressed tables](#), [Innodb_buffer_pool_pages_misc](#) may report an out-of-bounds value (Bug #59550).

- `Innodb_buffer_pool_pages_total`

The total size of the `InnoDB` buffer pool, in pages. When using `compressed tables`, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550)

- `Innodb_buffer_pool_read_ahead`

The number of pages read into the `InnoDB` buffer pool by the `read-ahead` background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of pages read into the `InnoDB` buffer pool by the `read-ahead` background thread that were subsequently `evicted` without having been accessed by queries.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of “random” read-aheads initiated by `InnoDB`. This happens when a query scans a large portion of a table but in random order.

- `Innodb_buffer_pool_read_requests`

The number of logical read requests.

- `Innodb_buffer_pool_reads`

The number of logical reads that `InnoDB` could not satisfy from the `buffer pool`, and had to read directly from disk.

- `Innodb_buffer_pool_resize_status`

The status of an operation to resize the `InnoDB` buffer pool dynamically, triggered by setting the `innodb_buffer_pool_size` parameter dynamically. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See [Configuring InnoDB Buffer Pool Size Online](#) for related information.

- `Innodb_buffer_pool_wait_free`

Normally, writes to the `InnoDB` buffer pool happen in the background. When `InnoDB` needs to read or create a page and no clean pages are available, `InnoDB` flushes some `dirty pages` first and waits for that operation to finish. This counter counts instances of these waits. If `innodb_buffer_pool_size` has been set properly, this value should be small.

- `Innodb_buffer_pool_write_requests`

The number of writes done to the `InnoDB` buffer pool.

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_reads`

The current number of pending reads.

- `Innodb_data_pending_writes`

The current number of pending writes.

- `Innodb_data_read`

The amount of data read since the server was started (in bytes).

- `Innodb_data_reads`

The total number of data reads (OS file reads).

- `Innodb_data_writes`

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of [pages](#) that have been written to the [doublewrite buffer](#). See [Section 15.11.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See [Section 15.11.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with [atomic instructions](#).

- `Innodb_log_waits`

The number of times that the [log buffer](#) was too small and a [wait](#) was required for it to be [flushed](#) before continuing.

- `Innodb_log_write_requests`

The number of write requests for the [InnoDB redo log](#).

- `Innodb_log_writes`

The number of physical writes to the [InnoDB redo log](#) file.

- `Innodb_num_open_files`

The number of files [InnoDB](#) currently holds open.

- `Innodb_os_log_fsyncs`

The number of `fsync()` writes done to the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_fsyncs`

The number of pending `fsync()` operations for the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_writes`

The number of pending writes to the [InnoDB redo log](#) files.

- `Innodb_os_log_written`

The number of bytes written to the [InnoDB redo log](#) files.

- `Innodb_page_size`

[InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- [Innodb_pages_created](#)

The number of pages created by operations on [InnoDB](#) tables.

- [Innodb_pages_read](#)

The number of pages read from the [InnoDB](#) buffer pool by operations on [InnoDB](#) tables.

- [Innodb_pages_written](#)

The number of pages written by operations on [InnoDB](#) tables.

- [Innodb_redo_log_enabled](#)

Whether redo logging is enabled or disabled. Introduced in MySQL 8.0.21.

See [Disabling Redo Logging](#).

- [Innodb_row_lock_current_waits](#)

The number of [row locks](#) currently being waited for by operations on [InnoDB](#) tables.

- [Innodb_row_lock_time](#)

The total time spent in acquiring [row locks](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_time_avg](#)

The average time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_time_max](#)

The maximum time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_waits](#)

The number of times operations on [InnoDB](#) tables had to wait for a [row lock](#).

- [Innodb_rows_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- [Innodb_rows_inserted](#)

The number of rows inserted into [InnoDB](#) tables.

- [Innodb_rows_read](#)

The number of rows read from [InnoDB](#) tables.

- [Innodb_rows_updated](#)

The number of rows updated in [InnoDB](#) tables.

- [Innodb_system_rows_deleted](#)

The number of rows deleted from [InnoDB](#) tables belonging to system-created schemas.

- [Innodb_system_rows_inserted](#)

The number of rows inserted into [InnoDB](#) tables belonging to system-created schemas.

- `Innodb_system_rows_read`

The number of rows read from `InnoDB` tables belonging to system-created schemas.

- `Innodb_truncated_status_writes`

The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- `Innodb_undo_tablespaces_active`

The number of active undo tablespaces. Includes both implicit (`InnoDB`-created) and explicit (user-created) undo tablespaces. For information about undo tablespaces, see [Section 15.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_explicit`

The number of user-created undo tablespaces. For information about undo tablespaces, see [Section 15.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_implicit`

The number of undo tablespaces created by `InnoDB`. Two default undo tablespaces are created by `InnoDB` when the MySQL instance is initialized. For information about undo tablespaces, see [Section 15.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_total`

The total number of undo tablespaces. Includes both implicit (`InnoDB`-created) and explicit (user-created) undo tablespaces, active and inactive. For information about undo tablespaces, see [Section 15.6.3.4, “Undo Tablespaces”](#).

- `Key_blocks_not_flushed`

The number of key blocks in the `MyISAM` key cache that have changed but have not yet been flushed to disk.

- `Key_blocks_unused`

The number of unused blocks in the `MyISAM` key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in [Section 5.1.8, “Server System Variables”](#).

- `Key_blocks_used`

The number of used blocks in the `MyISAM` key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests`

The number of requests to read a key block from the `MyISAM` key cache.

- `Key_reads`

The number of physical reads of a key block from disk into the `MyISAM` key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- `Key_write_requests`

The number of requests to write a key block to the `MyISAM` key cache.

- `Key_writes`

The number of physical writes of a key block from the [MyISAM](#) key cache to disk.

- [Last_query_cost](#)

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. [Last_query_cost](#) has session scope.

In MySQL 8.0.16 and later, this variable shows the cost of queries that have multiple query blocks, summing the cost estimates of each query block, estimating how many times non-cacheable subqueries are executed, and multiplying the cost of those query blocks by the number of subquery executions. (Bug #92766, Bug #28786951) Prior to MySQL 8.0.16, [Last_query_cost](#) was computed accurately only for simple, “flat” queries, but not for complex queries such as those containing subqueries or [UNION](#). (For the latter, the value was set to 0.)

- [Last_query_partial_plans](#)

The number of iterations the query optimizer made in execution plan construction for the previous query. [Last_query_cost](#) has session scope.

- [Locked_connects](#)

The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see [Section 6.2.19, “Account Locking”](#).

- [Max_execution_time_exceeded](#)

The number of [SELECT](#) statements for which the execution timeout was exceeded.

- [Max_execution_time_set](#)

The number of [SELECT](#) statements for which a nonzero execution timeout was set. This includes statements that include a nonzero [MAX_EXECUTION_TIME](#) optimizer hint, and statements that include no such hint but execute while the timeout indicated by the [max_execution_time](#) system variable is nonzero.

- [Max_execution_time_set_failed](#)

The number of [SELECT](#) statements for which the attempt to set an execution timeout failed.

- [Max_used_connections](#)

The maximum number of connections that have been in use simultaneously since the server started.

- [Max_used_connections_time](#)

The time at which [Max_used_connections](#) reached its current value.

- [Not_flushed_delayed_rows](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [mecab_charset](#)

The character set currently used by the MeCab full-text parser plugin. For related information, see [Section 12.10.9, “MeCab Full-Text Parser Plugin”](#).

- [Ongoing_anonymous_transaction_count](#)

Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- `Ongoing_anonymous_gtid_violating_transaction_count`

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=ANONYMOUS` and that violate GTID consistency.

- `Ongoing_automatic_gtid_violating_transaction_count`

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=AUTOMATIC` and that violate GTID consistency.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached table definitions.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of table definitions that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 26.16, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Questions`

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Rpl_semi_sync_master_clients`

The number of semisynchronous replicas.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

The average time in microseconds the source waited for a replica reply. This variable is always 0, is deprecated and it will be removed in a future version.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

The total time in microseconds the source waited for replica replies. This variable is always 0, is deprecated and it will be removed in a future version.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

The total number of times the source waited for replica replies.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

The number of times the source turned off semisynchronous replication.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a replica.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the source. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

The number of times the source failed when calling time functions such as `gettimeofday()`.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

The average time in microseconds the source waited for each transaction.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_master_tx_wait_time](#)

The total time in microseconds the source waited for transactions.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_master_tx_waits](#)

The total number of times the source waited for transactions.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_master_wait_pos_backtraverse](#)

The total number of times the source waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_master_wait_sessions](#)

The number of sessions currently waiting for replica replies.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_master_yes_tx](#)

The number of commits that were acknowledged successfully by a replica.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- [Rpl_semi_sync_slave_status](#)

Whether semisynchronous replication currently is operational on the replica. This is [ON](#) if the plugin has been enabled and the replication I/O thread is running, [OFF](#) otherwise.

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- [Rsa_public_key](#)

The value of this variable is the public key used by the [sha256_password](#) authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the [sha256_password_private_key_path](#) and [sha256_password_public_key_path](#) system variables. The value of [Rsa_public_key](#) comes from the latter file.

For information about [sha256_password](#), see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#).

- [Secondary_engine_execution_count](#)

For future use. This variable was added in MySQL 8.0.13.

- [Select_full_join](#)

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_open_temp_tables`

The number of temporary tables that the replication SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the replica; see [Section 17.5.1.30, “Replication and Temporary Tables”](#). This variable reports the total count of open temporary tables for *all* replication channels.

- `Slave_rows_last_search_algorithm_used`

The search algorithm that was most recently used by this replica to locate rows for row-based replication. The result shows whether the replica used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

The method used depends on the setting for the `slave_rows_search_algorithms` system variable, and the keys that are available on the relevant table.

This variable is available only for debug builds of MySQL.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 5.4.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites. See [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled replication source server.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled replication source server.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful replica connections to an SSL-enabled replication source server.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value                                |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May 1 14:16:39 2015 GMT |
+-----+-----+
```

- `Ssl_server_not_before`

The first date for which the SSL certificate is valid.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- `Ssl_session_cache_size`

The SSL session cache size.

- `Ssl_session_cache_timeouts`

The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

How many SSL session cache entries were used.

- `Ssl_verify_depth`

The verification depth for replication SSL connections.

- `Ssl_verify_mode`

The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

```
# define SSL_VERIFY_NONE          0x00
# define SSL_VERIFY_PEER          0x01
# define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
# define SSL_VERIFY_CLIENT_ONCE  0x04
```

`SSL_VERIFY_PEER` indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful.

`SSL_VERIFY_CLIENT_ONCE` indicates that a request for the client certificate will be done only in the initial handshake.

- `Ssl_version`

The SSL protocol version of the connection (for example, TLSv1). If the connection is not encrypted, the value is empty.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Table_open_cache_hits`

The number of hits for open tables cache lookups.

- `Table_open_cache_misses`

The number of misses for open tables cache lookups.

- `Table_open_cache_overflows`

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache` / `table_open_cache_instances`.

- `Tc_log_max_pages_used`

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- `Tc_log_page_size`

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- `Tc_log_page_waits`

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- `Threads_cached`

The number of threads in the thread cache.

- `Threads_connected`

The number of currently open connections.

- `Threads_created`

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

- `Threads_running`

The number of threads that are not sleeping.

- `Uptime`

The number of seconds that the server has been up.

- `Uptime_since_flush_status`

The number of seconds since the most recent `FLUSH STATUS` statement.

5.1.11 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Combination SQL Modes](#)
- [Strict SQL Mode](#)
- [Comparison of the IGNORE Keyword and Strict SQL Mode](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 8.0 FAQ: Server SQL Mode”](#).

When working with `InnoDB` tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for `InnoDB` tables.

Setting the SQL Mode

The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

Important

SQL mode and user-defined partitioning. Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the source and replica can also lead to problems. For best results, you should always use the same server SQL mode on the source and replica.

For more information, see [Section 23.6, “Restrictions and Limitations on Partitioning”](#).

The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- `TRADITIONAL`

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

Note

With `TRADITIONAL` mode enabled, an `INSERT` or `UPDATE` aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

- `ALLOW_INVALID_DATES`

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation.

This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

With `ALLOW_INVALID_DATES` disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

Treat `"` as an identifier quote character (like the ``` quote character) and not as a string quote character. You can still use ``` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

- `ERROR_FOR_DIVISION_BY_ZERO`

The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes `MOD(N, 0)`. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If this mode is enabled, division by zero inserts `NULL` and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

`ERROR_FOR_DIVISION_BY_ZERO` is deprecated. `ERROR_FOR_DIVISION_BY_ZERO` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `ERROR_FOR_DIVISION_BY_ZERO` is enabled without also enabling strict mode or vice versa.

Because `ERROR_FOR_DIVISION_BY_ZERO` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `HIGH_NOT_PRECEDENCE`

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 9.2, "Schema Object Names"](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
```

```
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 9.2.5, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. For this reason, `mysqldump` automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (`\`) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on replica servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

By default, `NO_ENGINE_SUBSTITUTION` is enabled.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_UNSIGNED_SUBTRACTION`

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO UNSIGNED SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21) unsigned | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21)         | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 12.11, “Cast Functions and Operators”](#).

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
- If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.

`NO_ZERO_DATE` is deprecated. `NO_ZERO_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- [NO_ZERO_IN_DATE](#)

The [NO_ZERO_IN_DATE](#) mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the [NO_ZERO_DATE](#) mode.) The effect of [NO_ZERO_IN_DATE](#) also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless [IGNORE](#) is given as well. For [INSERT IGNORE](#) and [UPDATE IGNORE](#), dates with zero parts are inserted as '0000-00-00' and produce a warning.

[NO_ZERO_IN_DATE](#) is deprecated. [NO_ZERO_IN_DATE](#) is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if [NO_ZERO_IN_DATE](#) is enabled without also enabling strict mode or vice versa.

Because [NO_ZERO_IN_DATE](#) is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- [ONLY_FULL_GROUP_BY](#)

Reject queries for which the select list, [HAVING](#) condition, or [ORDER BY](#) list refer to nonaggregated columns that are neither named in the [GROUP BY](#) clause nor are functionally dependent on (uniquely determined by) [GROUP BY](#) columns.

A MySQL extension to standard SQL permits references in the [HAVING](#) clause to aliased expressions in the select list. The [HAVING](#) clause can refer to aliases regardless of whether [ONLY_FULL_GROUP_BY](#) is enabled.

For additional discussion and examples, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

- [PAD_CHAR_TO_FULL_LENGTH](#)

By default, trailing spaces are trimmed from [CHAR](#) column values on retrieval. If [PAD_CHAR_TO_FULL_LENGTH](#) is enabled, trimming does not occur and retrieved [CHAR](#) values are padded to their full length. This mode does not apply to [VARCHAR](#) columns, for which trailing spaces are retained on retrieval.

Note

As of MySQL 8.0.13, [PAD_CHAR_TO_FULL_LENGTH](#) is deprecated. It will be removed in a future version of MySQL.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1    | CHAR_LENGTH(c1) |
+-----+-----+
| xy    | 2               |
+-----+-----+
```

```

1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1      | CHAR_LENGTH(c1) |
+-----+-----+
| xy      | 10              |
+-----+-----+
1 row in set (0.00 sec)

```

- [PIPES_AS_CONCAT](#)

Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- [REAL_AS_FLOAT](#)

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- [STRICT_ALL_TABLES](#)

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see [Strict SQL Mode](#).

- [STRICT_TRANS_TABLES](#)

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see [Strict SQL Mode](#).

- [TIME_TRUNCATE_FRACTIONAL](#)

Control whether rounding or truncation occurs when inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column having the same type but fewer fractional digits. The default behavior is to use rounding. If this mode is enabled, truncation occurs instead. The following sequence of statements illustrates the difference:

```

CREATE TABLE t (id INT, tval TIME(1));
SET sql_mode='';
INSERT INTO t (id, tval) VALUES(1, 1.55);
SET sql_mode='TIME_TRUNCATE_FRACTIONAL';
INSERT INTO t (id, tval) VALUES(2, 1.55);

```

The resulting table contents look like this, where the first value has been subject to rounding and the second to truncation:

```

mysql> SELECT id, tval FROM t ORDER BY id;
+-----+-----+
| id  | tval      |
+-----+-----+
| 1   | 00:00:01.6 |
| 2   | 00:00:01.5 |
+-----+-----+

```

See also [Section 11.2.6, “Fractional Seconds in Time Values”](#).

Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, and `ONLY_FULL_GROUP_BY`.

[ANSI](#) mode also causes the server to return an error for queries where a set function *S* with an outer reference *S(outer_ref)* cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, *MAX(t1.b)* cannot be aggregated in the outer query because it appears in the [WHERE](#) clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats *S(outer_ref)* in such queries the same way that it would interpret *S(const)*.

See [Section 1.7, “MySQL Standards Compliance”](#).

- [TRADITIONAL](#)

[TRADITIONAL](#) is equivalent to [STRICT_TRANS_TABLES](#), [STRICT_ALL_TABLES](#), [NO_ZERO_IN_DATE](#), [NO_ZERO_DATE](#), [ERROR_FOR_DIVISION_BY_ZERO](#), and [NO_ENGINE_SUBSTITUTION](#).

Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as [INSERT](#) or [UPDATE](#). A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-[NULL](#) column that has no explicit [DEFAULT](#) clause in its definition. (For a [NULL](#) column, [NULL](#) is inserted if the value is missing.) Strict mode also affects DDL statements such as [CREATE TABLE](#).

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 13.7.7.42, “SHOW WARNINGS Statement”](#)). In strict mode, you can produce this behavior by using [INSERT IGNORE](#) or [UPDATE IGNORE](#).

For statements such as [SELECT](#) that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. [foreign_key_checks](#) can be used for that. (See [Section 5.1.8, “Server System Variables”](#).)

Strict SQL mode is in effect if either [STRICT_ALL_TABLES](#) or [STRICT_TRANS_TABLES](#) is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either [STRICT_ALL_TABLES](#) or [STRICT_TRANS_TABLES](#) is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
 - For [STRICT_ALL_TABLES](#), MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
 - For [STRICT_TRANS_TABLES](#), MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error

and continues processing the statement. Implicit defaults are described in [Section 11.6, “Data Type Default Values”](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes `MOD(N, 0)`:

For data-change operations (`INSERT`, `UPDATE`):

- If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits `'0000-00-00'` as a valid date:
 - If strict mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
 - If strict mode is enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.
- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as `'2010-00-01'` or `'2010-01-00'`):
 - If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
 - If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes.

Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string `'abc'` into an integer column).

Operational Mode	When Statement Default is Error	When Statement Default is Warning
Without <code>IGNORE</code> or strict SQL mode	Error	Warning
With <code>IGNORE</code>	Warning	Warning (same as without <code>IGNORE</code> or strict SQL mode)
With strict SQL mode	Error (same as without <code>IGNORE</code> or strict SQL mode)	Error

Operational Mode	When Statement Default is Error	When Statement Default is Warning
With <code>IGNORE</code> and strict SQL mode	Warning	Warning

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

- [The Effect of IGNORE on Statement Execution](#)
- [The Effect of Strict SQL Mode on Statement Execution](#)

The Effect of IGNORE on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting. (For nonignorable errors, an error occurs regardless of the `IGNORE` keyword.)

Example: If the table `t` has a primary key column `i`, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 't.PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2 Duplicates: 1 Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1062 | Duplicate entry '1' for key 't.PRIMARY' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

These statements support the `IGNORE` keyword:

- **CREATE TABLE ... SELECT:** `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.
- **DELETE:** `IGNORE` causes MySQL to ignore errors during the process of deleting rows.
- **INSERT:** With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- **LOAD DATA, LOAD XML:** With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- **UPDATE:** With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following ignorable errors:

```
ER_BAD_NULL_ERROR
ER_DUP_ENTRY
ER_DUP_ENTRY_WITH_KEY_NAME
ER_DUP_KEY
ER_NO_PARTITION_FOR_GIVEN_VALUE
ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT
ER_NO_REFERENCED_ROW_2
ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET
ER_ROW_IS_REFERENCED_2
ER_SUBQUERY_NO_1_ROW
ER_VIEW_CHECK_FAILED
```

The Effect of Strict SQL Mode on Statement Execution

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.

For example, in non-strict SQL mode, inserting the string `'abc'` into an integer column results in conversion of the value to 0 and a warning:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see [Section 5.1.11](#), “Server SQL Modes”.

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP()`

- [UPDATE](#) (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, which represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a [NOT NULL](#) column that has no explicit [DEFAULT](#) clause in its definition.

```
ER_BAD_NULL_ERROR
ER_CUT_VALUE_GROUP_CONCAT
ER_DATA_TOO_LONG
ER_DATETIME_FUNCTION_OVERFLOW
ER_DIVISION_BY_ZERO
ER_INVALID_ARGUMENT_FOR_LOGARITHM
ER_NO_DEFAULT_FOR_FIELD
ER_NO_DEFAULT_FOR_VIEW_FIELD
ER_TOO_LONG_KEY
ER_TRUNCATED_WRONG_VALUE
ER_TRUNCATED_WRONG_VALUE_FOR_FIELD
ER_WARN_DATA_OUT_OF_RANGE
ER_WARN_NULL_TO_NOTNULL
ER_WARN_TOO_FEW_RECORDS
ER_WRONG_ARGUMENTS
ER_WRONG_VALUE_FOR_TYPE
WARN_DATA_TRUNCATED
```

Note

Because continued MySQL development defines new errors, there may be errors not in the preceding list to which strict SQL mode applies.

5.1.12 Connection Management

This section describes how MySQL Server manages connections. This includes a description of the available connection interfaces, how the server uses connection handler threads, details about the administrative connection interface, and management of DNS lookups.

5.1.12.1 Connection Interfaces

This section describes aspects of how the MySQL server manages client connections.

- [Network Interfaces and Connection Manager Threads](#)
- [Client Connection Thread Management](#)
- [Connection Volume Management](#)

Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, one manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.
- On all platforms, an additional network interface may be enabled to accept administrative TCP/IP connection requests. This interface can use the manager thread that handles “ordinary” TCP/IP requests, or a separate thread.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Individual server plugins or components may implement their own connection interface:

- X Plugin enables MySQL Server to communicate with clients using X Protocol. See [Section 20.5, “X Plugin”](#).

Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#).

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See [Section 5.1.8, “Server System Variables”](#), and [Section 5.1.10, “Server Status Variables”](#).)

- The `thread_cache_size` system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable *N* inactive connection threads to be cached, set `thread_cache_size` to *N* at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.
- To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.
- When the thread stack is too small, this limits the complexity of the SQL statements the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `thread_stack` set to *N*.

Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously than the server is configured to handle (see [Section B.3.2.6, “Too many connections”](#)). If the server refuses a connection because the `max_connections` limit is reached, it increments the `Connection_errors_max_connections` status variable.

`mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

By granting the privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 13.7.7.29, “SHOW PROCESSLIST Statement”](#).

As of MySQL 8.0.14, the server also permits administrative connections on an administrative network interface, which you can set up using a dedicated IP address and port. See [Section 5.1.12.2, “Administrative Connection Management”](#).

The Group Replication plugin interacts with MySQL Server using internal sessions to perform SQL API operations. In releases to MySQL 8.0.18, these sessions count towards the client connections limit specified by the `max_connections` server system variable. In those releases, if the server has reached the `max_connections` limit when Group Replication is started or attempts to perform an operation, the operation is unsuccessful and Group Replication or the server itself might stop. From MySQL 8.0.19, Group Replication's internal sessions are handled separately from client connections, so they do not count towards the `max_connections` limit and are not refused if the server has reached this limit.

The maximum number of client connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.
- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

Increasing the `open_files_limit` system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also [Section B.3.2.17, “File Not Found and Similar Errors”](#).

5.1.12.2 Administrative Connection Management

As mentioned in [Connection Volume Management](#), to allow for the need to perform administrative operations even when `max_connections` connections are already established on the interfaces used for ordinary connections, the MySQL server permits a single administrative connection to users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

Additionally, as of MySQL 8.0.14, the server permits dedicating a TCP/IP port for administrative connections, as described in the following sections.

- [Administrative Interface Characteristics](#)
- [Administrative Interface Support for Encrypted Connections](#)

Administrative Interface Characteristics

The administrative connection interface has these characteristics:

- The server enables the interface only if the `admin_address` system variable is set at startup to indicate the IP address for it. If `admin_address` is not set, the server maintains no administrative interface.
- The `admin_port` system variable specifies the interface TCP/IP port number (default 33062).
- There is no limit on the number of administrative connections.
- Connections are permitted only for users who have the `SERVICE_CONNECTION_ADMIN` privilege.
- The `create_admin_listener_thread` system variable enables DBAs to choose at startup whether the administrative interface has its own separate thread. The default is `OFF`; that is, the manager thread for ordinary connections on the main interface also handles connections for the administrative interface.

These lines in the server `my.cnf` file enable the administrative interface on the loopback interface and configure it to use port number 33064 (that is, a port different from the default):

```
[mysqld]
admin_address=127.0.0.1
admin_port=33064
```

MySQL client programs connect to either the main or administrative interface by specifying appropriate connection parameters. If the server running on the local host is using the default TCP/IP port numbers of 3306 and 33062 for the main and administrative interfaces, these commands connect to those interfaces:

```
mysql --protocol=TCP --port=3306
mysql --protocol=TCP --port=33062
```

Administrative Interface Support for Encrypted Connections

Prior to MySQL 8.0.21, the administrative interface supports encrypted connections using the connection-encryption configuration that applies to the main interface. As of MySQL 8.0.21, the administrative interface has its own configuration parameters for encrypted connections. These correspond to the main interface parameters but enable independent configuration of encrypted connections for the administrative interface:

- The `--admin-ssl` option is like the `--ssl` option, but it enables or disables encrypted connections for the administrative interface rather than the main interface.
- The `admin_tls_xxx` and `admin_ssl_xxx` system variables are like the `tls_xxx` and `ssl_xxx` system variables, but they configure the TLS context for the administrative interface rather than the main interface.

For general information about configuring connection-encryption support, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#). That discussion is written for the main connection interface, but the parameter names are similar for the administrative connection interface. The following remarks provide information specific to the administrative interface.

TLS configuration for the administrative interface follows these rules:

- If `--admin-ssl` is enabled (the default), the administrative interface supports encrypted connections. For connections on the interface, the applicable TLS context depends on whether any nondefault administrative TLS parameter is configured:
 - If all administrative TLS parameters have their default values, the administrative interface uses the same TLS context as the main interface.

- If any administrative TLS parameter has a nondefault value, the administrative interface uses the TLS context defined by its own parameters. (This is the case if any `admin_tls_XXX` or `admin_ssl_XXX` system variable is set to a value different from its default.) If a valid TLS context cannot be created from those parameters, the administrative interface falls back to the main interface TLS context.
- If `--admin-ssl` is disabled, encrypted connections to the administrative interface are disabled. (This is true even if administrative TLS parameters have nondefault values because disabling `--admin-ssl` takes precedence.)

Examples:

- This configuration in the server `my.cnf` file enables the administrative interface, but does not set any of the TLS parameters specific to that interface:

```
[mysqld]
admin_address=127.0.0.1
```

As a result, the administrative interface supports encrypted connections (because encryption is supported by default when the administrative interface is enabled), but uses the main interface TLS context. When clients connect to the administrative interface, they should use the same certificate and key files as for ordinary connections on the main interface. For example (enter the command on a single line):

```
mysql --protocol=TCP --port=33062
      --ssl-ca=ca.pem
      --ssl-cert=client-cert.pem
      --ssl-key=client-key.pem
```

- This server configuration enables the administrative interface and sets the TLS certificate and key file parameters specific to that interface:

```
[mysqld]
admin_address=127.0.0.1
admin_ssl_ca=admin-ca.pem
admin_ssl_cert=admin-server-cert.pem
admin_ssl_key=admin-server-key.pem
```

As a result, the administrative interface supports encrypted connections using its own TLS context. When clients connect to the administrative interface, they should use certificate and key files specific to that interface. For example (enter the command on a single line):

```
mysql --protocol=TCP --port=33062
      --ssl-ca=admin-ca.pem
      --ssl-cert=admin-client-cert.pem
      --ssl-key=admin-client-key.pem
```

- This server configuration enables the administrative interface but disables encrypted connections for it:

```
[mysqld]
admin-ssl=OFF
admin_address=127.0.0.1
```

In this case, if the configuration were to also set administrative TLS parameters such as `admin_ssl_ca`, those parameter settings would have no effect because `admin-ssl=OFF` takes precedence.

5.1.12.3 DNS Lookups and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information. The Performance Schema `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See [Section 26.12.19.2, “The host_cache Table”](#).

**Note**

The server uses the host cache only for nonlocal TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, `127.0.0.1` or `::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

- [Host Cache Operation](#)
- [Host Cache Configuration](#)

Host Cache Operation

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.
- The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs (see [Section B.3.2.5, “Host 'host_name' is blocked”](#)).

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.
2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)
3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see [Section 26.12.19.2, “The host_cache Table”](#).

The server performs host name resolution using the `gethostbyaddr()` and `gethostbyname()` system calls.

To unblock blocked hosts, flush the host cache by executing a `FLUSH HOSTS` statement, a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table, or a `mysqladmin flush-hosts` command. `FLUSH HOSTS` and `mysqladmin flush-hosts` require the `RELOAD` privilege. `TRUNCATE TABLE` requires the `DROP` privilege for the `host_cache` table.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur

because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the [Connection_errors_xxx](#) status variables (see [Section 5.1.10, “Server Status Variables”](#)).

Host Cache Configuration

The host cache is enabled by default. The [host_cache_size](#) system variable controls its size, as well as the size of the Performance Schema [host_cache](#) table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server [my.cnf](#) file:

```
[mysqld]
host_cache_size=200
```

To change the size to 300 at runtime, do this:

```
SET GLOBAL host_cache_size=300;
```

Setting [host_cache_size](#) to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit [FLUSH HOSTS](#) operation that clears the host cache, truncates the [host_cache](#) table, and unblocks any blocked hosts.

Using the [--skip-host-cache](#) option is similar to setting the [host_cache_size](#) system variable to 0, but [host_cache_size](#) is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with [--skip-host-cache](#) does not prevent changes to the value of [host_cache_size](#), but such changes have no effect and the cache is not re-enabled even if [host_cache_size](#) is set larger than 0 at runtime.

To disable DNS host name lookups, start the server with the [skip_name_resolve](#) system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups + by enabling [skip_name_resolve](#) or by increasing the value of [host_cache_size](#) to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the [skip_networking](#) system variable enabled.

5.1.13 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 5.1.13.1, “Verifying System Support for IPv6”](#).

- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the `bind_address` system variable set to an appropriate value. See [Section 5.1.8, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 6.2.4, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
```
- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 12.24, “Miscellaneous Functions”](#).
- From MySQL 8.0.14, Group Replication group members can use IPv6 addresses for communications within the group. A group can contain a mix of members using IPv6 and members using IPv4. See [Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

5.1.13.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [macOS](#)

5.1.13.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces.

Set the `bind_address` system variable at server startup to specify the TCP/IP connections that a server instance accepts. As of MySQL 8.0.13, you can specify multiple values for this option, including any combination of IPv6 addresses, IPv4 addresses, and host names that resolve to IPv6 or IPv4 addresses. Alternatively, you can specify one of the wildcard address formats that permit listening on multiple network interfaces. A value of `*`, which is the default, or a value of `:::`, permit both IPv4

and IPv6 connections on all server host IPv4 and IPv6 interfaces. For more information, see the [bind_address](#) description in [Section 5.1.8, “Server System Variables”](#).

5.1.13.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate [bind_address](#) setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *
```

Specifying `*` (or `::`) as the value for [bind_address](#) permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for [bind_address](#). This example specifies the local host addresses for both IPv4 and IPv6:

```
[mysqld]
bind_address = 127.0.0.1,::1
```

For more information, see the [bind_address](#) description in [Section 5.1.8, “Server System Variables”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 6.2.4, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:  ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1   | ::             |
+-----+-----+
```

5.1.13.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider

assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 5.1.13.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *
```

Specifying `*` (or `::`) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for `bind_address`. This example specifies an IPv4 address as well as the required server host IPv6 address:

```
[mysqld]
bind_address = 198.51.100.20,2001:db8:0:f101::1
```

For more information, see the `bind_address` description in [Section 5.1.8, “Server System Variables”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteipv6user@2001:db8:0:f101::2 | :: |
+-----+-----+
```

5.1.13.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. You can specify `*` (or `::`) as the `bind_address` value, or bind the server to the specific IPv6 address provided by the broker. For more information, see the `bind_address` description in [Section 5.1.8, “Server System Variables”](#).

Note that if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you might be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser  
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

5.1.14 MySQL Server Time Zone Support

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

Beginning with MySQL 8.0.19, time zone offsets are also supported for inserted datetime values; see [Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#), for more information.

- [Time Zone Variables](#)
- [Populating the Time Zone Tables](#)
- [Staying Current with Time Zone Changes](#)
- [Time Zone Leap Second Support](#)

For information about time zone settings in replication setups, see [Section 17.5.1.14, “Replication and System Functions”](#) and [Section 17.5.1.32, “Replication and Time Zones”](#).

Time Zone Variables

MySQL Server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine automatically and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezone` option provides another way to set the system time zone. The permissible values for `TZ` and `--`

`timezone` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

Note

If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege), you can set the global server time zone value at runtime with this statement:

```
SET GLOBAL time_zone = timezone;
```

- Per-session time zones. Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current global and session time zone values can be retrieved like this:

```
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

`timezone` values can be given in several formats, none of which are case-sensitive:

- As the value `'SYSTEM'`, indicating that the server time zone is the same as the system time zone.
- As a string indicating an offset from UTC of the form `[H]H:MM`, prefixed with a `+` or `-`, such as `'+10:00'`, `'-6:00'`, or `'+05:30'`. A leading zero can optionally be used for hours values less than 10; MySQL prepends a leading zero when storing and retrieving the value in such cases. MySQL converts `'-00:00'` or `'-0:00'` to `'+00:00'`.

Prior to MySQL 8.0.19, this value had to be in the range `'-12:59'` to `'+13:00'`, inclusive; beginning with MySQL 8.0.19, the permitted range is `'-14:00'` to `'+14:00'`, inclusive.

- As a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, `'MET'`, or `'UTC'`.

Note

Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated. Otherwise, use of a named time zone results in an error:

```
mysql> SET time_zone = 'UTC';
ERROR 1298 (HY000): Unknown or incorrect time zone: 'UTC'
```

Populating the Time Zone Tables

Several tables in the `mysql` system schema exist to store time zone information (see [Section 5.3, “The mysql System Schema”](#)). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See [Staying Current with Time Zone Changes](#).

If your system has its own `zoneinfo` database (the set of files describing time zones), use the `mysql_tzinfo_to_sql` program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system has no `zoneinfo` database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```

The `mysql` command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` system schema. Adjust the connection parameters as required.

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone must account for leap seconds, initialize leap second information like this, where `tz_file` is the name of your time zone file:

```
mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
```

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no `zoneinfo` database (for example, Windows), you can use a package containing SQL statements that is available for download at the MySQL Developer Zone:

<https://dev.mysql.com/downloads/timezones.html>

Warning

Do *not* use a downloadable time zone package if your system has a `zoneinfo` database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may

cause a difference in datetime handling between MySQL and other applications on your system.

To use an SQL-statement time zone package that you have downloaded, unpack it, then load the unpacked file contents into the time zone tables:

```
mysql -u root -p mysql < file_name
```

Then restart the server.

Warning

Do *not* use a downloadable time zone package that contains [MyISAM](#) tables. That is intended for older MySQL versions. MySQL now uses [InnoDB](#) for the time zone tables. Trying to replace them with [MyISAM](#) tables will cause problems.

Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to [SYSTEM](#). Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:
 - If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.
 - For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.

For instructions for both methods, see [Populating the Time Zone Tables](#). `mysqld` caches time zone information that it looks up, so after updating the time zone tables, restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
|         0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones will obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
  CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') AS time1,
  CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+-----+-----+
| time1          | time2          |
+-----+-----+
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+-----+-----+
```

After updating the tables, you should see the correct result:

```
+-----+-----+
| time1          | time2          |
+-----+-----+
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+-----+-----+
```

Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal `TIMESTAMP` values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
  a INT,
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  PRIMARY KEY (ts)
);
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+-----+-----+-----+
| a    | ts                | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 1    | 2008-12-31 23:59:59 | 1230767999         |
| 2    | 2008-12-31 23:59:59 | 1230768000         |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+-----+-----+
| a    | ts                |
+-----+-----+
| 1    | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+-----+-----+
| a    | ts                |
+-----+-----+
| 2    | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)
```

5.1.15 Resource Groups

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads.

Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups.

For example, to manage execution of batch jobs that need not execute with high priority, a DBA can create a [Batch](#) resource group, and adjust its priority up or down depending on how busy the server is. (Perhaps batch jobs assigned to the group should run at lower priority during the day and at higher priority during the night.) The DBA can also adjust the set of CPUs available to the group. Groups can be enabled or disabled to control whether threads are assignable to them.

The following sections describe aspects of resource group use in MySQL:

- [Resource Group Elements](#)
- [Resource Group Attributes](#)
- [Resource Group Management](#)
- [Resource Group Replication](#)
- [Resource Group Restrictions](#)

**Important**

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations. In particular, Linux systems might require a manual step for some installation methods. For details, see [Resource Group Restrictions](#).

Resource Group Elements

These capabilities provide the SQL interface for resource group management in MySQL:

- SQL statements enable creating, altering, and dropping resource groups, and enable assigning threads to resource groups. An optimizer hint enables assigning individual statements to resource groups.
- Resource group privileges provide control over which users can perform resource group operations.
- The `INFORMATION_SCHEMA.RESOURCE_GROUPS` table exposes information about resource group definitions and the Performance Schema `threads` table shows the resource group assignment for each thread.
- Status variables provide execution counts for each management SQL statement.

Resource Group Attributes

Resource groups have attributes that define the group. All attributes can be set at group creation time. Some attributes are fixed at creation time; others can be modified any time thereafter.

These attributes are defined at resource group creation time and cannot be modified:

- Each group has a name. Resource group names are identifiers like table and column names, and need not be quoted in SQL statements unless they contain special characters or are reserved words. Group names are not case-sensitive and may be up to 64 characters long.
- Each group has a type, which is either `SYSTEM` or `USER`. The resource group type affects the range of priority values assignable to the group, as described later. This attribute together with the differences in permitted priorities enables system threads to be identified so as to protect them from contention for CPU resources against user threads.

System and user threads correspond to background and foreground threads as listed in the Performance Schema `threads` table.

These attributes are defined at resource group creation time and can be modified any time thereafter:

- The CPU affinity is the set of virtual CPUs the resource group can use. An affinity can be any nonempty subset of the available CPUs. If a group has no affinity, it can use all available CPUs.
- The thread priority is the execution priority for threads assigned to the resource group. Priority values range from -20 (highest priority) to 19 (lowest priority). The default priority is 0, for both system and user groups.

System groups are permitted a higher priority than user groups, ensuring that user threads never have a higher priority than system threads:

- For system resource groups, the permitted priority range is -20 to 0.
- For user resource groups, the permitted priority range is 0 to 19.
- Each group can be enabled or disabled, affording administrators control over thread assignment. Threads can be assigned only to enabled groups.

Resource Group Management

By default, there is one system group and one user group, named `SYS_default` and `USR_default`, respectively. These default groups cannot be dropped and their attributes cannot be modified. Each default group has no CPU affinity and priority 0.

Newly created system and user threads are assigned to the `SYS_default` and `USR_default` groups, respectively.

For user-defined resource groups, all attributes are assigned at group creation time. After a group has been created, its attributes can be modified, with the exception of the name and type attributes.

To create and manage user-defined resource groups, use these SQL statements:

- `CREATE RESOURCE GROUP` creates a new group. See [Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”](#).
- `ALTER RESOURCE GROUP` modifies an existing group. See [Section 13.7.2.1, “ALTER RESOURCE GROUP Statement”](#).
- `DROP RESOURCE GROUP` drops an existing group. See [Section 13.7.2.3, “DROP RESOURCE GROUP Statement”](#).

Those statements require the `RESOURCE_GROUP_ADMIN` privilege.

To manage resource group assignments, use these capabilities:

- `SET RESOURCE GROUP` assigns threads to a group. See [Section 13.7.2.4, “SET RESOURCE GROUP Statement”](#).
- The `RESOURCE_GROUP` optimizer hint assigns individual statements to a group. See [Section 8.9.3, “Optimizer Hints”](#).

Those operations require the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

Resource group definitions are stored in the `resource_groups` data dictionary table so that groups persist across server restarts. Because `resource_groups` is part of the data dictionary, it is not directly accessible by users. Resource group information is available using the `INFORMATION_SCHEMA.RESOURCE_GROUPS` table, which is implemented as a view on the data dictionary table. See [Section 25.26, “The INFORMATION_SCHEMA RESOURCE_GROUPS Table”](#).

Initially, the `RESOURCE_GROUPS` table has these rows describing the default groups:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS\G
***** 1. row *****
  RESOURCE_GROUP_NAME: USR_default
  RESOURCE_GROUP_TYPE: USER
RESOURCE_GROUP_ENABLED: 1
          VCPU_IDS: 0-3
    THREAD_PRIORITY: 0
***** 2. row *****
  RESOURCE_GROUP_NAME: SYS_default
  RESOURCE_GROUP_TYPE: SYSTEM
RESOURCE_GROUP_ENABLED: 1
          VCPU_IDS: 0-3
    THREAD_PRIORITY: 0
```

The `THREAD_PRIORITY` values are 0, indicating the default priority. The `VCPU_IDS` values show a range comprising all available CPUs. For the default groups, the displayed value varies depending on the system on which the MySQL server runs.

Earlier discussion mentioned a scenario involving a resource group named `Batch` to manage execution of batch jobs that need not execute with high priority. To create such a group, use a statement similar to this:

```
CREATE RESOURCE GROUP Batch
  TYPE = USER
  VCPU = 2-3          -- assumes a system with at least 4 CPUs
  THREAD_PRIORITY = 10;
```

To verify that the resource group was created as expected, check the `RESOURCE_GROUPS` table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS
      WHERE RESOURCE_GROUP_NAME = 'Batch'\G
***** 1. row *****
RESOURCE_GROUP_NAME: Batch
RESOURCE_GROUP_TYPE: USER
RESOURCE_GROUP_ENABLED: 1
          VCPU_IDS: 2-3
      THREAD_PRIORITY: 10
```

If the `THREAD_PRIORITY` value is 0 rather than 10, check whether your platform or system configuration limits the resource group capability; see [Resource Group Restrictions](#).

To assign a thread to the `Batch` group, do this:

```
SET RESOURCE GROUP Batch FOR thread_id;
```

Thereafter, statements in the named thread execute with `Batch` group resources.

If a session's own current thread should be in the `Batch` group, execute this statement within the session:

```
SET RESOURCE GROUP Batch;
```

Thereafter, statements in the session execute with `Batch` group resources.

To execute a single statement using the `Batch` group, use the `RESOURCE_GROUP` optimizer hint:

```
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Threads assigned to the `Batch` group execute with its resources, which can be modified as desired:

- For times when the system is highly loaded, decrease the number of CPUs assigned to the group, lower its priority, or (as shown) both:

```
ALTER RESOURCE GROUP Batch
  VCPU = 3
  THREAD_PRIORITY = 19;
```

- For times when the system is lightly loaded, increase the number of CPUs assigned to the group, raise its priority, or (as shown) both:

```
ALTER RESOURCE GROUP Batch
  VCPU = 0-3
  THREAD_PRIORITY = 0;
```

Resource Group Replication

Resource group management is local to the server on which it occurs. Resource group SQL statements and modifications to the `resource_groups` data dictionary table are not written to the binary log and are not replicated.

Resource Group Restrictions

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations:

- Resource groups are unavailable if the thread pool plugin is installed.
- Resource groups are unavailable on macOS, which provides no API for binding CPUs to a thread.
- On FreeBSD and Solaris, resource group thread priorities are ignored. (Effectively, all threads run at priority 0.) Attempts to change priorities result in a warning:

```
mysql> ALTER RESOURCE GROUP abc THREAD_PRIORITY = 10;
Query OK, 0 rows affected, 1 warning (0.18 sec)
```

```
mysql> SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 4560 | Attribute thread_priority is ignored (using default value). |
+-----+-----+-----+
```

- On Linux, resource groups thread priorities are ignored unless the `CAP_SYS_NICE` capability is set. Granting `CAP_SYS_NICE` capability to a process enables a range of privileges; consult <http://man7.org/linux/man-pages/man7/capabilities.7.html> for the full list. Please be careful when enabling this capability.

On Linux platforms using systemd and kernel support for Ambient Capabilities (Linux 4.3 or newer), the recommended way to enable `CAP_SYS_NICE` capability is to modify the MySQL service file and leave the `mysqld` binary unmodified. To adjust the service file for MySQL, use this procedure:

- Run the appropriate command for your platform:

- Oracle Linux, Red Hat, and Fedora systems:

```
shell> sudo systemctl edit mysqld
```

- SUSE, Ubuntu, and Debian systems:

```
shell> sudo systemctl edit mysql
```

- Using an editor, add the following text to the service file:

```
[Service]
AmbientCapabilities=CAP_SYS_NICE
```

- Restart the MySQL service.

If you cannot enable the `CAP_SYS_NICE` capability as just described, it can be set manually using the `setcap` command, specifying the path name to the `mysqld` executable (this requires `sudo` access). You can check the capabilities using `getcap`. For example:

```
shell> sudo setcap cap_sys_nice+ep /path/to/mysqld
shell> getcap /path/to/mysqld
/path/to/mysqld = cap_sys_nice+ep
```

As a safety measure, restrict execution of the `mysqld` binary to the `root` user and users with `mysql` group membership:

```
shell> sudo chown root:mysql /path/to/mysqld
shell> sudo chmod 0750 /path/to/mysqld
```

Important

If manual use of `setcap` is required, it must be performed after each reinstall.

- On Windows, threads run at one of five thread priority levels. The resource group thread priority range of -20 to 19 maps onto those levels as indicated in the following table.

Table 5.5 Resource Group Thread Priority on Windows

Priority Range	Windows Priority Level
-20 to -10	<code>THREAD_PRIORITY_HIGHEST</code>
-9 to -1	<code>THREAD_PRIORITY_ABOVE_NORMAL</code>
0	<code>THREAD_PRIORITY_NORMAL</code>
1 to 10	<code>THREAD_PRIORITY_BELOW_NORMAL</code>
11 to 19	<code>THREAD_PRIORITY_LOWEST</code>

5.1.16 Server-Side Help Support

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference Manual (see [Section 13.8.3, “HELP Statement”](#)). This information is stored in several tables in the `mysql` schema (see [Section 5.3, “The mysql System Schema”](#)). Proper operation of the `HELP` statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is upgraded automatically by the server as of MySQL 8.0.16. Prior to MySQL 8.0.16, the content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
mysql -u root -p mysql < fill_help_tables.sql
```

The command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` schema. Adjust the connection parameters as required.

Prior to MySQL 8.0.16, if you are working with Git and a MySQL development source tree, the source tree contains only a “stub” version of `fill_help_tables.sql`. To obtain a non-stub copy, use one from a source or binary distribution.

Note

Each MySQL series has its own series-specific reference manual, so help-table content is series specific as well. This has implications for replication because help-table content should match the MySQL series. If you load MySQL 8.0 help content into a MySQL 8.0 replication server, it does not make sense to replicate that content to a replica server from a different MySQL series and for which that content is not appropriate. For this reason, as you upgrade individual servers in a replication scenario, you should upgrade each server's help tables, using the instructions given earlier. (Manual help-content upgrade is necessary only for replication servers from versions lower than 8.0.16. As mentioned in the preceding instructions, content upgrades occur automatically as of MySQL 8.0.16.)

5.1.17 Server Tracking of Client Session State Changes

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

One use for the tracker mechanism is to provide a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

Another use for the tracker mechanism is to permit applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a

transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:

- Immediately after `START TRANSACTION`
- After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

```
READ ONLY
READ WRITE
ISOLATION LEVEL
WITH CONSISTENT SNAPSHOT
```

To support the preceding session-switching activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
 - The default schema (database).
 - Session-specific values for system variables.
 - User-defined variables.
 - Temporary tables.
 - Prepared statements.

The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.
- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker.
- Available GTIDs. The `session_track_gtid` system variable controls this tracker.
- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see [Section 5.1.8, “Server System Variables”](#). Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected. To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:

- `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See [mysql_session_track_get_first\(\)](#).
- `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See [mysql_session_track_get_next\(\)](#).

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```

DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
SET @@SESSION.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(1, RAND());
COMMIT;

```

Run the script as follows to see the information provided by the enabled trackers. For a description of the [Tracker](#): information displayed by `mysqltest` for the various trackers, see [mysql_session_track_get_first\(\)](#).

```

shell> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_system_variables
-- *

SET @@SESSION.session_track_state_change=ON;
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_state_change
-- ON

USE information_schema;
-- Tracker : SESSION_TRACK_SCHEMA
-- information_schema

-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1

SET NAMES 'utf8mb4';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- character_set_client
-- utf8mb4
-- character_set_connection
-- utf8mb4
-- character_set_results
-- utf8mb4

-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1

SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_transaction_info
-- CHARACTERISTICS

-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1

-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
--

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
--

SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;

```

```

SET TRANSACTION READ WRITE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; SET TRANSACTION READ WRITE;

START TRANSACTION;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; START TRANSACTION READ WRITE;

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____

SELECT 1;
1
1
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____S_

INSERT INTO test.t1 () VALUES();
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____W_S_

INSERT INTO test.t1 () VALUES(1, RAND());
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____WsS_

COMMIT;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
--

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- _____

ok

```

Preceding the `START TRANSACTION` statement, two `SET TRANSACTION` statements execute that set the isolation level and access mode characteristics for the next transaction. The `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value indicates those next-transaction values that have been set.

Following the `COMMIT` statement that ends the transaction, the `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value is reported as empty. This indicates that the next-transaction characteristics that were set preceding the start of the transaction have been reset, and that the session defaults apply. To track changes to those session defaults, track the session values of the `transaction_isolation` and `transaction_read_only` system variables.

5.1.18 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 13.7.8.4, “KILL Statement”](#), in particular for the instructions about killed [REPAIR TABLE](#) or [OPTIMIZE TABLE](#) operations on [MyISAM](#) tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row [UPDATE](#) or [INSERT](#) may leave the table partially updated because the operation can terminate before completion.

If the server is a replication source server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica server, it stops the replication I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a [KILL QUERY](#) or [KILL CONNECTION](#) statement. See also [Section 13.4.2.9, “STOP SLAVE | REPLICA Statement”](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

Note

To guarantee crash safety on the replica, you must run the replica with `--relay-log-recovery` enabled.

See also [Section 17.2.4, “Relay Log and Replication Metadata Repositories”](#)).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. [InnoDB](#) flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. [MyISAM](#) flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by systemd in response to the code, for platforms on which systemd is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
- The `mysql` directory corresponds to the `mysql` system schema, which contains information required by the MySQL server as it runs. This database contains data dictionary tables and system tables. See [Section 5.3, “The mysql System Schema”](#).
- The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See [Chapter 26, MySQL Performance Schema](#).
- The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See [Chapter 27, MySQL sys Schema](#).
- The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See [Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

Other subdirectories correspond to databases created by users or applications.

Note

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See [Section 5.4, “MySQL Server Logs”](#).
- `InnoDB` tablespace and log files. See [Chapter 15, The InnoDB Storage Engine](#).
- Default/autogenerated SSL and RSA certificate and key files. See [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
- The server process ID file (while the server is running).
- The `mysqld-auto.cnf` file that stores persisted global system variable settings. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

5.3 The mysql System Schema

The `mysql` schema is the system schema. It contains tables that store information required by the MySQL server as it runs. A broad categorization is that the `mysql` schema contains data dictionary tables that store database object metadata, and system tables used for other operational purposes. The following discussion further subdivides the set of system tables into smaller categories.

- [Data Dictionary Tables](#)
- [Grant System Tables](#)
- [Object Information System Tables](#)

- [Log System Tables](#)
- [Server-Side Help System Tables](#)
- [Time Zone System Tables](#)
- [Replication System Tables](#)
- [Optimizer System Tables](#)
- [Miscellaneous System Tables](#)

The remainder of this section enumerates the tables in each category, with cross references for additional information. Data dictionary tables and system tables use the [InnoDB](#) storage engine unless otherwise indicated.

`mysql` system tables and data dictionary tables reside in a single [InnoDB](#) tablespace file named `mysql.ibd` in the MySQL data directory. Previously, these tables were created in individual tablespace files in the `mysql` database directory.

Data-at-rest encryption can be enabled for the `mysql` system schema tablespace. For more information, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

Data Dictionary Tables

These tables comprise the data dictionary, which contains metadata about database objects. For additional information, see [Chapter 14, *MySQL Data Dictionary*](#).

Important

The data dictionary is new in MySQL 8.0. A data dictionary-enabled server entails some general operational differences compared to previous MySQL releases. For details, see [Section 14.7, “Data Dictionary Usage Differences”](#). Also, for upgrades to MySQL 8.0 from MySQL 5.7, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see [Section 2.11, “Upgrading MySQL”](#), particularly [Section 2.11.5, “Preparing Your Installation for Upgrade”](#).

- `catalogs`: Catalog information.
- `character_sets`: Information about available character sets.
- `check_constraints`: Information about [CHECK](#) constraints defined on tables. See [Section 13.1.20.6, “CHECK Constraints”](#).
- `collations`: Information about collations for each character set.
- `column_statistics`: Histogram statistics for column values. See [Section 8.9.6, “Optimizer Statistics”](#).
- `column_type_elements`: Information about types used by columns.
- `columns`: Information about columns in tables.
- `dd_properties`: A table that identifies data dictionary properties, such as its version. The server uses this to determine whether the data dictionary must be upgraded to a newer version.
- `events`: Information about Event Scheduler events. See [Section 24.4, “Using the Event Scheduler”](#). If the server is started with the `--skip-grant-tables` option, the event scheduler is disabled and events registered in the table do not run. See [Section 24.4.2, “Event Scheduler Configuration”](#).

- `foreign_keys`, `foreign_key_column_usage`: Information about foreign keys.
- `index_column_usage`: Information about columns used by indexes.
- `index_partitions`: Information about partitions used by indexes.
- `index_stats`: Used to store dynamic index statistics generated when `ANALYZE TABLE` is executed.
- `indexes`: Information about table indexes.
- `innodb_ddl_log`: Stores DDL logs for crash-safe DDL operations.
- `parameter_type_elements`: Information about stored procedure and function parameters, and about return values for stored functions.
- `parameters`: Information about stored procedures and functions. See [Section 24.2, “Using Stored Routines”](#).
- `resource_groups`: Information about resource groups. See [Section 5.1.15, “Resource Groups”](#)
- `routines`: Information about stored procedures and functions. See [Section 24.2, “Using Stored Routines”](#).
- `schemata`: Information about schemata. In MySQL, a schema is a database, so this table provides information about databases.
- `st_spatial_reference_systems`: Information about available spatial reference systems for spatial data.
- `table_partition_values`: Information about values used by table partitions.
- `table_partitions`: Information about partitions used by tables.
- `table_stats`: Information about dynamic table statistics generated when `ANALYZE TABLE` is executed.
- `tables`: Information about tables in databases.
- `tablespace_files`: Information about files used by tablespaces.
- `tablespaces`: Information about active tablespaces.
- `triggers`: Information about triggers.
- `view_routine_usage`: Information about dependencies between views and stored functions used by them.
- `view_table_usage`: Used to track dependencies between views and their underlying tables.

Data dictionary tables are invisible. They cannot be read with `SELECT`, do not appear in the output of `SHOW TABLES`, are not listed in the `INFORMATION_SCHEMA.TABLES` table, and so forth. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried. Conceptually, the `INFORMATION_SCHEMA` provides a view through which MySQL exposes data dictionary metadata. For example, you cannot select from the `mysql.schemata` table directly:

```
mysql> SELECT * FROM mysql.schemata;
ERROR 3554 (HY000): Access to data dictionary table 'mysql.schemata' is rejected.
```

Instead, select that information from the corresponding `INFORMATION_SCHEMA` table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
***** 1. row *****
      CATALOG_NAME: def
```

```

        SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: utf8mb4
        DEFAULT_COLLATION_NAME: utf8mb4_0900_ai_ci
                SQL_PATH: NULL
        DEFAULT_ENCRYPTION: NO
***** 2. row *****
        CATALOG_NAME: def
        SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
        DEFAULT_COLLATION_NAME: utf8_general_ci
                SQL_PATH: NULL
        DEFAULT_ENCRYPTION: NO
...

```

There is no `INFORMATION_SCHEMA` table that corresponds exactly to `mysql.indexes`, but `INFORMATION_SCHEMA.STATISTICS` contains much of the same information.

As of yet, there are no `INFORMATION_SCHEMA` tables that correspond exactly to `mysql.foreign_keys`, `mysql.foreign_key_column_usage`. The standard SQL way to obtain foreign key information is by using the `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS` and `KEY_COLUMN_USAGE` tables; these tables are now implemented as views on the `foreign_keys`, `foreign_key_column_usage`, and other data dictionary tables.

Some system tables from before MySQL 8.0 have been replaced by data dictionary tables and are no longer present in the `mysql` system schema:

- The `events` data dictionary table supersedes the `event` table from before MySQL 8.0.
- The `parameters` and `routines` data dictionary tables together supersede the `proc` table from before MySQL 8.0.

Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them. For additional information about the structure, contents, and purpose of these tables, see [Section 6.2.3, “Grant Tables”](#).

As of MySQL 8.0, the grant tables are `InnoDB` (transactional) tables. Previously, these were `MyISAM` (nontransactional) tables. The change of grant-table storage engine underlies an accompanying change in MySQL 8.0 to the behavior of account-management statements such as `CREATE USER` and `GRANT`. Previously, an account-management statement that named multiple users could succeed for some users and fail for others. The statements are now transactional and either succeed for all named users or roll back and have no effect if any error occurs.

Note

If MySQL is upgraded from an older version but the grant tables have not been upgraded from `MyISAM` to `InnoDB`, the server considers them read only and account-management statements produce an error. For upgrade instructions, see [Section 2.11, “Upgrading MySQL”](#).

- `user`: User accounts, global privileges, and other nonprivilege columns.
- `global_grants`: Assignments of dynamic global privileges to users; see [Static Versus Dynamic Privileges](#).
- `db`: Database-level privileges.
- `tables_priv`: Table-level privileges.
- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.

- `proxies_priv`: Proxy-user privileges.
- `default_roles`: This table lists default roles to be activated after a user connects and authenticates, or executes `SET ROLE DEFAULT`.
- `role_edges`: This table lists edges for role subgraphs.

A given `user` table row might refer to a user account or a role. The server can distinguish whether a row represents a user account, a role, or both by consulting the `role_edges` table for information about relations between authentication IDs.

- `password_history`: Information about password changes.

Object Information System Tables

These system tables contain information about components, user-defined functions, and server-side plugins:

- `component`: The registry for server components installed using `INSTALL COMPONENT`. Any components listed in this table are installed by a loader service during the server startup sequence. See [Section 5.5.1, “Installing and Uninstalling Components”](#).
- `func`: The registry for user-defined functions (UDFs) installed using `CREATE FUNCTION`. During the normal startup sequence, the server loads UDFs registered in this table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable. See [Section 5.7.1, “Installing and Uninstalling User-Defined Functions”](#).

Note

Like the `mysql.func` system table, the Performance Schema `user_defined_functions` table lists UDFs installed using `CREATE FUNCTION`. Unlike the `mysql.func` table, the `user_defined_functions` table also lists UDFs installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which UDFs are installed. See [Section 26.12.19.9, “The user_defined_functions Table”](#).

- `plugin`: The registry for server-side plugins installed using `INSTALL PLUGIN`. During the normal startup sequence, the server loads plugins registered in this table. If the server is started with the `--skip-grant-tables` option, plugins registered in the table are not loaded and are unavailable. See [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

Log System Tables

The server uses these system tables for logging:

- `general_log`: The general query log table.
- `slow_log`: The slow query log table.

Log tables use the `CSV` storage engine.

For more information, see [Section 5.4, “MySQL Server Logs”](#).

Server-Side Help System Tables

These system tables contain server-side help information:

- `help_category`: Information about help categories.
- `help_keyword`: Keywords associated with help topics.

- `help_relation`: Mappings between help keywords and topics.
- `help_topic`: Help topic contents.

For more information, see [Section 5.1.16, “Server-Side Help Support”](#).

Time Zone System Tables

These system tables contain time zone information:

- `time_zone`: Time zone IDs and whether they use leap seconds.
- `time_zone_leap_second`: When leap seconds occur.
- `time_zone_name`: Mappings between time zone IDs and names.
- `time_zone_transition`, `time_zone_transition_type`: Time zone descriptions.

For more information, see [Section 5.1.14, “MySQL Server Time Zone Support”](#).

Replication System Tables

The server uses these system tables to support replication:

- `gtid_executed`: Table for storing GTID values. See [mysql.gtid_executed Table](#).
- `ndb_binlog_index`: Binary log information for NDB Cluster replication. This table is created only if the server is built with `NDBCLUSTER` support. See [Section 22.6.4, “NDB Cluster Replication Schema and Tables”](#).
- `slave_master_info`, `slave_relay_log_info`, `slave_worker_info`: Used to store replication information on replica servers. See [Section 17.2.4, “Relay Log and Replication Metadata Repositories”](#).

All of the tables just listed use the `InnoDB` storage engine.

Optimizer System Tables

These system tables are for use by the optimizer:

- `innodb_index_stats`, `innodb_table_stats`: Used for `InnoDB` persistent optimizer statistics. See [Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).
- `server_cost`, `engine_cost`: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. `server_cost` contains optimizer cost estimates for general server operations. `engine_cost` contains estimates for operations specific to particular storage engines. See [Section 8.9.5, “The Optimizer Cost Model”](#).

Miscellaneous System Tables

Other system tables do not fit the preceding categories:

- `audit_log_filter`, `audit_log_user`: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See [Audit Log Tables](#).
- `firewall_users`, `firewall_whitelist`: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See [Section 6.4.7, “MySQL Enterprise Firewall”](#).
- `servers`: Used by the `FEDERATED` storage engine. See [Section 16.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).

- `innodb_dynamic_metadata`: Used by the `InnoDB` storage engine to store fast-changing table metadata such as auto-increment counter values and index tree corruption flags. Replaces the data dictionary buffer table that resided in the `InnoDB` system tablespace.

5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

Log Type	Information Written to Log
Error log	Problems encountered starting, running, or stopping <code>mysqld</code>
General query log	Established client connections and statements received from clients
Binary log	Statements that change data (also used for replication)
Relay log	Data changes received from a replication source server
Slow query log	Queries that took more than <code>long_query_time</code> seconds to execute
DDL log (metadata log)	Metadata operations performed by DDL statements

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see [The DDL Log](#).) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See [Section 13.7.8.3, “FLUSH Statement”](#), [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#), [Section 5.4.3, “The General Query Log”](#), and [Section 5.4.5, “The Slow Query Log”](#).

The relay log is used only on replicas, to hold data changes from the replication source server that must also be made on the replica. For discussion of relay log contents and configuration, see [Section 17.2.4.1, “The Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 5.4.6, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 6.1.2.3, “Passwords and Logging”](#).

5.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` system database. File output, table output, or both can be selected.

- [Log Control at Server Startup](#)
- [Log Control at Runtime](#)
- [Log Table Benefits and Characteristics](#)

Log Control at Server Startup

The `log_output` system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If `log_output` is not specified at startup, the default logging destination is `FILE`.
- If `log_output` is specified at startup, its value is a list one or more comma-separated words chosen from `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log_output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log_output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log_output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. In this case, because the default log destination is `FILE`, you could omit the `log_output` setting.

Log Control at Runtime

The system variables associated with log tables and files enable runtime control over logging:

- The `log_output` variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Log Table Benefits and Characteristics

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;  
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with

a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

Log Tables and “Too many open files” Errors. If you select `TABLE` as a log destination and the log tables use the `CSV` storage engine, you may find that disabling and enabling the general query log or slow query log repeatedly at runtime results in a number of open file descriptors for the `.CSV` file, possibly resulting in a “Too many open files” error. To work around this issue, execute `FLUSH TABLES` or ensure that the value of `open_files_limit` is greater than the value of `table_open_cache_instances`.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@GLOBAL.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- `CHECK TABLE` is a valid operation on a log table.
- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to replicas.
- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.

- Partitioning of log tables is not permitted.
- A `mysqldump` dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

5.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set and language, see [Section 10.6, “Error Message Character Set”](#), and [Section 10.12, “Setting the Error Message Language”](#).

The error log contains a record of `mysqld` startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if `mysqld` notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

Depending on error log configuration, error messages may also populate the Performance Schema `error_log` table, to provide an SQL interface to the log and enable its contents to be queried. See [Section 26.12.19.1, “The error_log Table”](#).

On some operating systems, the error log contains a stack trace if `mysqld` exits abnormally. The trace can be used to determine where `mysqld` exited. See [Section 5.9, “Debugging MySQL”](#).

If used to start `mysqld`, `mysqld_safe` may write messages to the error log. For example, when `mysqld_safe` notices abnormal `mysqld` exits, it restarts `mysqld` and writes a `mysqld restarted` message to the error log.

The following sections discuss aspects of configuring error logging.

5.4.2.1 Error Log Configuration

In MySQL 8.0, error logging uses the MySQL component architecture described at [Section 5.5, “MySQL Server Components”](#). The error log subsystem consists of components that perform log event filtering and writing, as well as a system variable that configures which components to enable to achieve the desired logging result.

This section discusses how to select components for error logging. For instructions specific to log filters, see [Section 5.4.2.4, “Types of Error Log Filtering”](#). For instructions specific to the JSON and system log sinks, see [Section 5.4.2.7, “Error Logging in JSON Format”](#), and [Section 5.4.2.8, “Error Logging to the System Log”](#). For additional details about all available log components, see [Section 5.5.3, “Error Log Components”](#).

Component-based error logging offers these features:

- Log events can be filtered by filter components to affect the information available for writing.
- Log events are output by sink (writer) components. Multiple sink components can be enabled, to write error log output to multiple destinations.
- Built-in filter and sink components combine to implement the default error log format.
- A loadable sink enables logging in JSON format.
- A loadable sink enables logging to the system log.
- System variables control which log components to enable and how each component operates.

The `log_error_services` system variable controls which log components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed.

By default, `log_error_services` has this value:

```
mysql> SELECT @@GLOBAL.log_error_services;
+-----+
| @@GLOBAL.log_error_services |
+-----+
| log_filter_internal; log_sink_internal |
+-----+
```

That value indicates that log events first pass through the `log_filter_internal` filter component, then through the `log_sink_internal` sink component, both of which are built in. A filter modifies log events seen by components named later in the `log_error_services` value. A sink is a destination for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log.

Note

The final component in the `log_error_services` value cannot be a filter. This is an error because any changes it has on events would have no effect on output:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal';
ERROR 1231 (42000): Variable 'log_error_services' can't be set to the value of 'log_filter_internal'
```

To correct the problem, include a sink at the end of the value:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
Query OK, 0 rows affected (0.00 sec)
```

The combination of `log_filter_internal` and `log_sink_internal` implements the default error log filtering and output behavior. The action of these components is affected by other server options and system variables:

- The output destination is determined by the `--log-error` option (and, on Windows, `--pid-file` and `--console`). These determine whether to write error messages to the console or a file and, if to a file, the error log file name. See [Section 5.4.2.2, “Default Error Log Destination Configuration”](#).
- The `log_error_verbosity` and `log_error_suppression_list` system variables affect which types of log events `log_filter_internal` permits or suppresses. See [Section 5.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#).

To change the set of log components used for error logging, load components as necessary and modify the `log_error_services` value. Adding or removing log components is subject to these constraints:

- To enable a log component, first load it using `INSTALL COMPONENT` (unless it is built in or already loaded), then list the component in the `log_error_services` value.

For a component to be permitted in the `log_error_services` value, it must be known. A component is known if it is built in, or if it is loadable and has been loaded using `INSTALL COMPONENT`. Attempts to name an unknown component at server startup cause `log_error_services` to be set to its default value. Attempts to name an unknown component at runtime produce an error and the `log_error_services` value remains unchanged.

- To disable a log component, remove it from the `log_error_services` value. Then, if the component is loadable and you also want to unload it, use `UNINSTALL COMPONENT`.

Attempts to use `UNINSTALL COMPONENT` to unload a loadable component that is still named in the `log_error_services` value produce an error.

For example, to use the system log sink (`log_sink_syseventlog`) instead of the default sink (`log_sink_internal`), first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

**Note**

The URN to use for loading a log component with `INSTALL COMPONENT` is the component name prefixed with `file://component_`. For example, for the `log_sink_syseventlog` component, the corresponding URN is `file://component_log_sink_syseventlog`.

It is possible to configure multiple log sinks, which enables sending output to multiple destinations. To enable the system log sink in addition to (rather than instead of) the default sink, set the `log_error_services` value like this:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal; log_sink_syseventlog';
```

To revert to using only the default sink and unload the system log sink, execute these statements:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal;
UNINSTALL COMPONENT 'file://component_log_sink_syseventlog';
```

To configure a log component to be enabled at each server startup, use this procedure:

1. If the component is loadable, load it at runtime using `INSTALL COMPONENT`. Loading the component registers it in the `mysql.component` system table so that the server loads it automatically for subsequent startups.
2. Set the `log_error_services` value at startup to include the component name. Set the value either in the server `my.cnf` file, or use `SET PERSIST`, which sets the value for the running MySQL instance and also saves the value to be used for subsequent server restarts; see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). A value set in `my.cnf` takes effect at the next restart. A value set using `SET PERSIST` takes effect immediately, and for subsequent restarts.

Suppose that you want to configure, for every server startup, use of the JSON log sink (`log_sink_json`) in addition to the built-in log filter and sink (`log_filter_internal`, `log_sink_internal`). First load the JSON sink if it is not loaded:

```
INSTALL COMPONENT 'file://component_log_sink_json';
```

Then set `log_error_services` to take effect at server startup. You can set it in `my.cnf`:

```
[mysqld]
log_error_services='log_filter_internal; log_sink_internal; log_sink_json'
```

Or you can set it using `SET PERSIST`:

```
SET PERSIST log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

The order of components named in `log_error_services` is significant, particularly with respect to the relative order of filters and sinks. Consider this `log_error_services` value:

```
log_filter_internal; log_sink_1; log_sink_2
```

In this case, log events pass to the built-in filter, then to the first sink, then to the second sink. Both sinks receive the filtered log events.

Compare that to this `log_error_services` value:

```
log_sink_1; log_filter_internal; log_sink_2
```

In this case, log events pass to the first sink, then to the built-in filter, then to the second sink. The first sink receives unfiltered events. The second sink receives filtered events. You might configure error logging this way if you want one log that contains messages for all log events, and another log that contains messages only for a subset of log events.

**Note**

If the enabled log components include a sink that provides Performance Schema support, events written to the error log are also written to the Performance Schema `error_log` table. This enables examining error log contents using SQL queries. Currently, the traditional-format `log_sink_internal` and JSON-format `log_sink_json` sinks support this capability. See [Section 26.12.19.1, “The error_log Table”](#).

5.4.2.2 Default Error Log Destination Configuration

This section describes which server options configure the default error log destination, which can be the console or a named file. It also indicates which log sink components base their own output destination on the default destination.

In this discussion, “console” means `stderr`, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine the default error log destination somewhat differently for Windows and Unix systems. Be sure to configure the destination using the information appropriate to your platform. After the server interprets the default error log destination options, it sets the `log_error` system variable to indicate the default destination, which affects where several log sink components write error messages. The following sections address these topics.

- [Default Error Log Destination on Windows](#)
- [Default Error Log Destination on Unix and Unix-Like Systems](#)
- [How the Default Error Log Destination Affects Log Sinks](#)

Default Error Log Destination on Windows

On Windows, `mysqld` uses the `--log-error`, `--pid-file`, and `--console` options to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If `--console` is given, the default destination is the console. (`--console` takes precedence over `--log-error` if both are given, and the following items regarding `--log-error` do not apply.)
- If `--log-error` is not given, or is given without naming a file, the default destination is a file named `host_name.err` in the data directory, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.
- If `--log-error` is given to name a file, the default destination is that file (with an `.err` suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

If the default error log destination is the console, the server sets the `log_error` system variable to `stderr`. Otherwise, the default destination is a file and the server sets `log_error` to the file name.

Default Error Log Destination on Unix and Unix-Like Systems

On Unix and Unix-like systems, `mysqld` uses the `--log-error` option to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If `--log-error` is not given, the default destination is the console.
- If `--log-error` is given without naming a file, the default destination is a file named `host_name.err` in the data directory.
- If `--log-error` is given to name a file, the default destination is that file (with an `.err` suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

- If `--log-error` is given in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, on systems that use `mysqld_safe` to start the server, `mysqld_safe` finds and uses the option, and passes it to `mysqld`.

**Note**

It is common for Yum or APT package installations to configure an error log file location under `/var/log` with an option like `log-error=/var/log/mysqld.log` in a server configuration file. Removing the path name from the option causes the `host_name.err` file in the data directory to be used.

If the default error log destination is the console, the server sets the `log_error` system variable to `stderr`. Otherwise, the default destination is a file and the server sets `log_error` to the file name.

How the Default Error Log Destination Affects Log Sinks

After the server interprets the error log destination configuration options, it sets the `log_error` system variable to indicate the default error log destination. Log sink components may base their own output destination on the `log_error` value, or determine their destination independently of `log_error`.

If `log_error` is `stderr`, the default error log destination is the console, and log sinks that base their output destination on the default destination also write to the console:

- `log_sink_internal`, `log_sink_json`, `log_sink_test`: These sinks write to the console. This is true even for sinks such as `log_sink_json` that can be enabled multiple times; all instances write to the console.
- `log_sink_syseventlog`: This sink writes to the system log, regardless of the `log_error` value.

If `log_error` is not `stderr`, the default error log destination is a file and `log_error` indicates the file name. Log sinks that base their output destination on the default destination base output file naming on that file name. (A sink might use exactly that name, or it might use some variant thereof.) Suppose that the `log_error` value `file_name`. Then log sinks use the name like this:

- `log_sink_internal`, `log_sink_test`: These sinks write to `file_name`.
- `log_sink_json`: Successive instances of this sink named in the `log_error_services` value write to files named `file_name` plus a numbered `.NN.json` suffix: `file_name.00.json`, `file_name.01.json`, and so forth.
- `log_sink_syseventlog`: This sink writes to the system log, regardless of the `log_error` value.

5.4.2.3 Error Event Fields

Error events intended for the error log contain a set of fields, each of which consists of a key/value pair. An event field may be classified as core, optional, or user-defined:

- A core field is set up automatically for error events. However, its presence in the event during event processing is not guaranteed because a core field, like any type of field, may be unset by a log filter. If so, the field will be found missing by subsequent processing within that filter and by components that execute after the filter (such as log sinks).
- An optional field is normally absent but may be present for certain event types. When present, an optional field provides additional event information as appropriate and available.
- A user-defined field is any field with a name that is not already defined as a core or optional field. A user-defined field does not exist until created by a log filter.

As implied by the preceding description, any given field may be absent during event processing, either because it was not present in the first place, or was discarded by a filter. For log sinks, the effect of field absence is sink specific. For example, a sink might omit the field from the log message, indicate

that the field is missing, or substitute a default. When in doubt, test: use a filter that unsets the field, then check what the log sink does with it.

The following sections describe the core and optional error event fields. For individual log filter components, there may be additional filter-specific considerations for these fields, or filters may add user-defined fields not listed here. For details, see the documentation for specific filters.

- [Core Error Event Fields](#)
- [Optional Error Event Fields](#)

Core Error Event Fields

These error event fields are core fields:

- `time`

The event timestamp, with microsecond precision.

- `msg`

The event message string.

- `prio`

The event priority, to indicate a system, error, warning, or note/information event. This field corresponds to severity in `syslog`. The following table shows the possible priority levels.

Event Type	Numeric Priority
System event	0
Error event	1
Warning event	2
Note/information event	3

The `prio` value is numeric. Related to it, an error event may also include an optional `label` field representing the priority as a string. For example, an event with a `prio` value of 2 may have a `label` value of `'Warning'`.

Filter components may include or drop error events based on priority, except that system events are mandatory and cannot be dropped.

In general, message priorities are determined as follows:

Is the situation or event actionable?

- Yes: Is the situation or event ignorable?
 - Yes: Priority is warning.
 - No: Priority is error.
- No: Is the situation or event mandatory?
 - Yes: Priority is system.
 - No: Priority is note/information.

- `err_code`

The event error code, as a number (for example, `1022`).

- `err_symbol`

The event error symbol, as a string (for example, `'ER_DUP_KEY'`).

- `SQL_state`

The event SQLSTATE value, as a string (for example, `'23000'`).

- `subsystem`

The subsystem in which the event occurred. Possible values are `InnoDB` (the `InnoDB` storage engine), `RepI` (the replication subsystem), `Server` (otherwise).

Optional Error Event Fields

Optional error event fields fall into the following categories:

- Additional information about the error, such as the error signaled by the operating system or the error label:

- `OS_errno`

The operating system error number.

- `OS_errmsg`

The operating system error message.

- `label`

The label corresponding to the `prio` value, as a string.

- Identification of the client for which the event occurred:

- `user`

The client user.

- `host`

The client host.

- `thread`

The ID of the thread within `mysqld` responsible for producing the error event. This ID indicates which part of the server produced the event, and is consistent with general query log and slow query log messages, which include the connection thread ID.

- `query_id`

The query ID.

- Debugging information:

- `source_file`

The source file in which the event occurred, without any leading path.

- `source_line`

The line within the source file at which the event occurred.

- `function`

The function in which the event occurred.

- `component`

The component or plugin in which the event occurred.

5.4.2.4 Types of Error Log Filtering

Error log configuration normally includes one log filter component and one or more log sink components. For error log filtering, MySQL offers a choice of components:

- `log_filter_internal`: This filter component provides error log filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. `log_filter_internal` is built in and enabled by default. See [Section 5.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#).
- `log_filter_dragnet`: This filter component provides error log filtering based on user-supplied rules, in combination with the `dragnet.log_error_filter_rules` system variable. See [Section 5.4.2.6, “Rule-Based Error Log Filtering \(log_filter_dragnet\)”](#).

5.4.2.5 Priority-Based Error Log Filtering (log_filter_internal)

The `log_filter_internal` log filter component implements a simple form of log filtering based on error event priority and error code. To affect how `log_filter_internal` permits or suppresses error, warning, and information events intended for the error log, set the `log_error_verbosity` and `log_error_suppression_list` system variables.

`log_filter_internal` is built in and enabled by default. If this filter is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect, so filtering must be performed using another filter service instead where desired (for example, with individual filter rules when using `log_filter_dragnet`). For information about filter configuration, see [Section 5.4.2.1, “Error Log Configuration”](#).

- [Verbosity Filtering](#)
- [Suppression-List Filtering](#)
- [Verbosity and Suppression-List Interaction](#)

Verbosity Filtering

Events intended for the error log have a priority of `ERROR`, `WARNING`, or `INFORMATION`. The `log_error_verbosity` system variable controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

<code>log_error_verbosity</code> Value	Permitted Message Priorities
1	<code>ERROR</code>
2	<code>ERROR</code> , <code>WARNING</code>
3	<code>ERROR</code> , <code>WARNING</code> , <code>INFORMATION</code>

If `log_error_verbosity` is 2 or greater, the server logs messages about statements that are unsafe for statement-based logging. If the value is 3, the server logs aborted connections and access-denied errors for new connection attempts. See [Section B.3.2.10, “Communication Errors and Aborted Connections”](#).

If you use replication, a `log_error_verbosity` value of 2 or greater is recommended, to obtain more information about what is happening, such as messages about network failures and reconnections.

If `log_error_verbosity` is 2 or greater on a replica, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

There is also a message priority of `SYSTEM` that is not subject to verbosity filtering. System messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

In the MySQL error log, system messages are labeled as “System”. Other log sinks might or might not follow the same convention, and in the resulting logs, system messages might be assigned the label used for the information priority level, such as “Note” or “Information”. If you apply any additional filtering or redirection for logging based on the labeling of messages, system messages do not override your filter, but are handled by it in the same way as other messages.

Suppression-List Filtering

The `log_error_suppression_list` system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of `WARNING` or `INFORMATION`. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. `log_error_suppression_list` does not suppress messages with a priority of `ERROR` or `SYSTEM`.

The `log_error_suppression_list` value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

```
ER_SERVER_SHUTDOWN_COMPLETE
MY-000031
000031
MY-31
31
```

For readability and portability, symbolic values are preferable to numeric values.

Although codes to be suppressed can be expressed in symbolic or numeric form, the numeric value of each code must be in a permitted range:

- 1 to 999: Global error codes that are used by the server as well as by clients.
- 10000 and higher: Server error codes intended to be written to the error log (not sent to clients).

In addition, each error code specified must actually be used by MySQL. Attempts to specify a code not within a permitted range or within a permitted range but not used by MySQL produce an error and the `log_error_suppression_list` value remains unchanged.

For information about error code ranges and the error symbols and numbers defined within each range, see [Section B.1, “Error Message Sources and Elements”](#), and [MySQL 8.0 Error Message Reference](#).

The server can generate messages for a given error code at differing priorities, so suppression of a message associated with an error code listed in `log_error_suppression_list` depends on its priority. Suppose that the variable has a value of `'ER_PARSER_TRACE,MY-010001,10002'`. Then `log_error_suppression_list` has these effects on messages for those codes:

- Messages generated with a priority of `WARNING` or `INFORMATION` are suppressed.
- Messages generated with a priority of `ERROR` or `SYSTEM` are not suppressed.

Verbosity and Suppression-List Interaction

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. Consider a server started with these settings:

```
[mysqld]
```

```
log_error_verbosity=2      # error and warning messages only
log_error_suppression_list='ER_PARSER_TRACE,MY-010001,10002'
```

In this case, `log_error_verbosity` permits messages with `ERROR` or `WARNING` priority and discards messages with `INFORMATION` priority. Of the nondiscarded messages, `log_error_suppression_list` discards messages with `WARNING` priority and any of the named error codes.

Note

The `log_error_verbosity` value of 2 shown in the example is also its default value, so the effect of this variable on `INFORMATION` messages is as just described by default, without an explicit setting. You must set `log_error_verbosity` to 3 if you want `log_error_suppression_list` to affect messages with `INFORMATION` priority.

Consider a server started with this setting:

```
[mysqld]
log_error_verbosity=1      # error messages only
```

In this case, `log_error_verbosity` permits messages with `ERROR` priority and discards messages with `WARNING` or `INFORMATION` priority. Setting `log_error_suppression_list` has no effect because all error codes it might suppress are already discarded due to the `log_error_verbosity` setting.

5.4.2.6 Rule-Based Error Log Filtering (`log_filter_dragnet`)

The `log_filter_dragnet` log filter component enables log filtering based on user-defined rules.

To enable the `log_filter_dragnet` filter, first load the filter component, then modify the `log_error_services` value. The following example enables `log_filter_dragnet` in combination with the built-in log sink:

```
INSTALL COMPONENT 'file://component_log_filter_dragnet';
SET GLOBAL log_error_services = 'log_filter_dragnet; log_sink_internal';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 5.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

With `log_filter_dragnet` enabled, define its filter rules by setting the `dragnet.log_error_filter_rules` system variable. A rule set consists of zero or more rules, where each rule is an `IF` statement terminated by a period (.) character. If the variable value is empty (zero rules), no filtering occurs.

Example 1. This rule set drops information events, and, for other events, removes the `source_line` field:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.';
```

The effect is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

For readability, you might find it preferable to list the rules on separate lines. For example:

```
SET GLOBAL dragnet.log_error_filter_rules = '
  IF prio>=INFORMATION THEN drop.
  IF EXISTS source_line THEN unset source_line.
  ';
```

Example 2: This rule limits information events to no more than one per 60 seconds:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN throttle 1/60.';
```

Once you have the filtering configuration set up as you desire, consider assigning `dragnet.log_error_filter_rules` using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts. Alternatively, add the setting to the server option file.

To stop using the filtering language, first remove it from the set of error logging components. Usually this means using a different filter component rather than no filter component. For example:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
```

Again, consider using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts.

Then uninstall the filter `log_filter_dragnet` component:

```
UNINSTALL COMPONENT 'file://component_log_filter_dragnet';
```

The following sections describe aspects of `log_filter_dragnet` operation in more detail:

- [Grammar for log_filter_dragnet Rule Language](#)
- [Actions for log_filter_dragnet Rules](#)
- [Field References in log_filter_dragnet Rules](#)

Grammar for log_filter_dragnet Rule Language

The following grammar defines the language for `log_filter_dragnet` filter rules. Each rule is an `IF` statement terminated by a period (.) character. The language is not case-sensitive.

```
rule:
  IF condition THEN action
  [ELSEIF condition THEN action] ...
  [ELSE action]
  .

condition: {
  field comparator value
  | [NOT] EXISTS field
  | condition {AND | OR} condition
}

action: {
  drop
  | throttle {count | count / window_size}
  | set field [:= | =] value
  | unset [field]
}

field: {
  core_field
  | optional_field
  | user_defined_field
}

core_field: {
  time
  | msg
  | prio
  | err_code
  | err_symbol
  | SQL_state
  | subsystem
}

optional_field: {
  OS_errno
  | OS_errmsg
  | label
  | user
  | host
```

```

| thread
| query_id
| source_file
| source_line
| function
| component
}

user_defined_field:
    sequence of characters in [a-zA-Z0-9_] class

comparator: {== | != | <> | >= | => | <= | =< | < | >}

value: {
    string_literal
| integer_literal
| float_literal
| error_symbol
| priority
}

count: integer_literal
window_size: integer_literal

string_literal:
    sequence of characters quoted as '...' or "..."

integer_literal:
    sequence of characters in [0-9] class

float_literal:
    integer_literal[.integer_literal]

error_symbol:
    valid MySQL error symbol such as ER_ACCESS_DENIED_ERROR or ER_STARTUP

priority: {
    ERROR
| WARNING
| INFORMATION
}

```

Simple conditions compare a field to a value or test field existence. To construct more complex conditions, use the [AND](#) and [OR](#) operators. Both operators have the same precedence and evaluate left to right.

To escape a character within a string, precede it by a backslash (`\`). A backslash is required to include backslash itself or the string-quoting character, optional for other characters.

For convenience, [log_filter_dragnet](#) supports symbolic names for comparisons to certain fields. For readability and portability, symbolic values are preferable (where applicable) to numeric values.

- Event priority values 1, 2, and 3 can be specified as [ERROR](#), [WARNING](#), and [INFORMATION](#). Priority symbols are recognized only in comparisons with the [prio](#) field. These comparisons are equivalent:

```

IF prio == INFORMATION THEN ...
IF prio == 3 THEN ...

```

- Error codes can be specified in numeric form or as the corresponding error symbol. For example, [ER_STARTUP](#) is the symbolic name for error [1408](#), so these comparisons are equivalent:

```

IF err_code == ER_STARTUP THEN ...
IF err_code == 1408 THEN ...

```

Error symbols are recognized only in comparisons with the [err_code](#) field and user-defined fields.

To find the error symbol corresponding to a given error code number, use one of these methods:

- Check the list of server errors at [Server Error Message Reference](#).

- Use the `pererror` command. Given an error number argument, `pererror` displays information about the error, including its symbol.

Suppose that a rule set with error numbers looks like this:

```
IF err_code == 10927 OR err_code == 10914 THEN drop.
IF err_code == 1131 THEN drop.
```

Using `pererror`, determine the error symbols:

```
shell> pererror 10927 10914 1131
MySQL error code MY-010927 (ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED):
Access denied for user '%-.48s'@'%-.64s'. Account is locked.
MySQL error code MY-010914 (ER_ABORTING_USER_CONNECTION):
Aborted connection %u to db: '%-.192s' user: '%-.48s' host:
'%-.64s' (%-.64s).
MySQL error code MY-001131 (ER_PASSWORD_ANONYMOUS_USER):
You are using MySQL as an anonymous user and anonymous users
are not allowed to change passwords
```

Substituting error symbols for numbers, the rule set becomes:

```
IF err_code == ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED
OR err_code == ER_ABORTING_USER_CONNECTION THEN drop.
IF err_code == ER_PASSWORD_ANONYMOUS_USER THEN drop.
```

Symbolic names can be specified as quoted strings for comparison with string fields, but in such cases the names are strings that have no special meaning and `log_filter_dragnet` does not resolve them to the corresponding numeric value. Also, typos may go undetected, whereas an error occurs immediately on `SET` for attempts to use an unquoted symbol unknown to the server.

Actions for `log_filter_dragnet` Rules

`log_filter_dragnet` supports these actions in filter rules:

- `drop`: Drop the current log event (do not log it).
- `throttle`: Apply rate limiting to reduce log verbosity for events matching particular conditions. The argument indicates a rate, in the form `count` or `count/window_size`. The `count` value indicates the permitted number of event occurrences to log per time window. The `window_size` value is the time window in seconds; if omitted, the default window is 60 seconds. Both values must be integer literals.

This rule throttles plugin-shutdown messages to 5 occurrences per 60 seconds:

```
IF err_code == ER_PLUGIN_SHUTTING_DOWN_PLUGIN THEN throttle 5.
```

This rule throttles errors and warnings to 1000 occurrences per hour and information messages to 100 occurrences per hour:

```
IF prio <= INFORMATION THEN throttle 1000/3600 ELSE throttle 100/3600.
```

- `set`: Assign a value to a field (and cause the field to exist if it did not already). In subsequent rules, `EXISTS` tests against the field name are true, and the new value can be tested by comparison conditions.
- `unset`: Discard a field. In subsequent rules, `EXISTS` tests against the field name are false, and comparisons of the field against any value are false.

In the special case that the condition refers to exactly one field name, the field name following `unset` is optional and `unset` discards the named field. These rules are equivalent:

```
IF myfield == 2 THEN unset myfield.
IF myfield == 2 THEN unset.
```

Field References in `log_filter_dragnet` Rules

`log_filter_dragnet` rules support references to core, optional, and user-defined fields in error events.

- [Core Field References](#)
- [Optional Field References](#)
- [User-Defined Field References](#)

Core Field References

The `log_filter_dragnet` grammar at [Grammar for `log_filter_dragnet` Rule Language](#) names the core fields that filter rules recognize. For general descriptions of these fields, see [Section 5.4.2.3, “Error Event Fields”](#), with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to core field references as used within `log_filter_dragnet` rules.

- `prio`

The event priority, to indicate an error, warning, or note/information event. In comparisons, each priority can be specified as a symbolic priority name or an integer literal. Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

```
IF prio == INFORMATION THEN ...
IF prio == 3 THEN ...
```

The following table shows the permitted priority levels.

Event Type	Priority Symbol	Numeric Priority
Error event	<code>ERROR</code>	1
Warning event	<code>WARNING</code>	2
Note/information event	<code>INFORMATION</code>	3

There is also a message priority of `SYSTEM`, but system messages cannot be filtered and are always written to the error log.

Priority values follow the principle that higher priorities have lower values, and vice versa. Priority values begin at 1 for the most severe events (errors) and increase for events with decreasing priority. For example, to discard events with priority lower than warnings, test for priority values higher than `WARNING`:

```
IF prio > WARNING THEN drop.
```

The following examples show the `log_filter_dragnet` rules to achieve an effect similar to each `log_error_verbosity` value permitted by the `log_filter_internal` filter:

- Errors only (`log_error_verbosity=1`):

```
IF prio > ERROR THEN drop.
```

- Errors and warnings (`log_error_verbosity=2`):

```
IF prio > WARNING THEN drop.
```

- Errors, warnings, and notes (`log_error_verbosity=3`):

```
IF prio > INFORMATION THEN drop.
```

This rule can actually be omitted because there are no `prio` values greater than `INFORMATION`, so effectively it drops nothing.

- `err_code`

The numeric event error code. In comparisons, the value to test can be specified as a symbolic error name or an integer literal. Error symbols are recognized only in comparisons with the `err_code` field and user-defined fields. These comparisons are equivalent:

```
IF err_code == ER_ACCESS_DENIED_ERROR THEN ...
IF err_code == 1045 THEN ...
```

- `err_symbol`

The event error symbol, as a string (for example, `'ER_DUP_KEY'`). `err_symbol` values are intended more for identifying particular lines in log output than for use in filter rule comparisons because `log_filter_dagnet` does not resolve comparison values specified as strings to the equivalent numeric error code. (For that to occur, an error must be specified using its unquoted symbol.)

Optional Field References

The `log_filter_dagnet` grammar at [Grammar for log_filter_dagnet Rule Language](#) names the optional fields that filter rules recognize. For general descriptions of these fields, see [Section 5.4.2.3, “Error Event Fields”](#), with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to optional field references as used within `log_filter_dagnet` rules.

- `label`

The label corresponding to the `prio` value, as a string. Filter rules can change the label for log sinks that support custom labels. `label` values are intended more for identifying particular lines in log output than for use in filter rule comparisons because `log_filter_dagnet` does not resolve comparison values specified as strings to the equivalent numeric priority.

- `source_file`

The source file in which the event occurred, without any leading path. For example, to test for the `sql/gis/distance.cc` file, write the comparison like this:

```
IF source_file == "distance.cc" THEN ...
```

User-Defined Field References

Any field name in a `log_filter_dagnet` filter rule not recognized as a core or optional field name is taken to refer to a user-defined field.

5.4.2.7 Error Logging in JSON Format

This section describes how to configure error logging using the built-in filter, `log_filter_internal`, and the JSON sink, `log_sink_json`, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see [Section 5.4.2.1, “Error Log Configuration”](#).

To enable the JSON sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_json';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_json';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 5.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

It is permitted to name `log_sink_json` multiple times in the `log_error_services` value. For example, to write unfiltered events with one instance and filtered events with another instance, you could set `log_error_services` like this:

```
SET GLOBAL log_error_services = 'log_sink_json; log_filter_internal; log_sink_json';
```

The JSON log sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable. If `log_error` names a file, the JSON sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.

If `log_error` is `stderr`, the JSON sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.

5.4.2.8 Error Logging to the System Log

It is possible to have `mysqld` write the error log to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

This section describes how to configure error logging using the built-in filter, `log_filter_internal`, and the system log sink, `log_sink_syseventlog`, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see [Section 5.4.2.1, “Error Log Configuration”](#).

To enable the system log sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 5.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

Note

For MySQL 8.0 configuration, you must enable error logging to the system log explicitly. This differs from MySQL 5.7 and earlier, for which error logging to the system log is enabled by default on Windows, and on all platforms requires no component loading.

Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

On Windows, error messages written to the Event Log within the Application log have these characteristics:

- Entries marked as `Error`, `Warning`, and `Note` are written to the Event Log, but not messages such as information statements from individual storage engines.
- Event Log entries have a source of `MySQL` (or `MySQL-tag` if `syseventlog.tag` is defined as `tag`).

On Unix and Unix-like systems, logging to the system log uses `syslog`. The following system variables affect `syslog` messages:

- `syseventlog.facility`: The default facility for `syslog` messages is `daemon`. Set this variable to specify a different facility.
- `syseventlog.include_pid`: Whether to include the server process ID in each line of `syslog` output.
- `syseventlog.tag`: This variable defines a tag to add to the server identifier (`mysqld`) in `syslog` messages. If defined, the tag is appended to the identifier with a leading hyphen.

Note

Prior to MySQL 8.0.13, use the `log_syslog_facility`, `log_syslog_include_pid`, and `log_syslog_tag` system variables rather than the `syseventlog.xxx` variables.

MySQL uses the custom label “System” for important system messages about non-error situations, such as startup, shutdown, and some significant changes to settings. In logs that do not support custom labels, including the Event Log on Windows, and `syslog` on Unix and Unix-like systems, system messages are assigned the label used for the information priority level. However, these messages are printed to the log even if the MySQL `log_error_verbosity` setting normally excludes messages at the information level.

When a log sink must fall back to a label of “Information” instead of “System” in this way, and the log event is further processed outside of the MySQL server (for example, filtered or forwarded by a `syslog` configuration), these events may by default be processed by the secondary application as being of “Information” priority rather than “System” priority.

5.4.2.9 Error Log Output Format

Each error log sink (writer) component has a characteristic output format it uses to write messages to its destination, but other factors may influence the content of the messages:

- The information available to the log sink. If a log filter component executed prior to execution of the sink component removes a log event field, that field is not available for writing. For information about log filtering, see [Section 5.4.2.4, “Types of Error Log Filtering”](#).
- The information relevant to the log sink. Not every sink writes all fields available in error events.
- System variables may affect log sinks. See [System Variables That Affect Error Log Format](#).

For names and descriptions of the fields in error events, see [Section 5.4.2.3, “Error Event Fields”](#). For all log sinks, the thread ID included in error log messages is that of the thread within `mysqld` responsible for writing the message. This ID indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID.

- [log_sink_internal Output Format](#)
- [log_sink_json Output Format](#)
- [log_sink_syseventlog Output Format](#)
- [Early-Startup Logging Output Format](#)
- [System Variables That Affect Error Log Format](#)

log_sink_internal Output Format

The internal log sink produces traditional error log output. For example:

```
2020-08-06T14:25:02.835618Z 0 [Note] [MY-012487] [InnoDB] DDL log recovery : begin
2020-08-06T14:25:02.936146Z 0 [Warning] [MY-010068] [Server] CA certificate /var/mysql/sslinfo/cacert.p
2020-08-06T14:25:02.963127Z 0 [Note] [MY-010253] [Server] IPv6 is available.
2020-08-06T14:25:03.109022Z 5 [Note] [MY-010051] [Server] Event Scheduler: scheduler thread started wit
```

Traditional-format messages have these fields:

```
time thread [label] [err_code] [subsystem] msg
```

The `[` and `]` square bracket characters are literal characters in the message format. They do not indicate that fields are optional.

The `label` value corresponds to the string form of the `prio` error event priority field.

The `[err_code]` and `[subsystem]` fields were added in MySQL 8.0. They are missing from logs generated by older servers. Log parsers can treat these fields as parts of the message text that is present only for logs written by servers recent enough to include them. Parsers must treat the `err_code` part of `[err_code]` indicators as a string value, not a number, because values such as `MY-012487` and `MY-010051` contain nonnumeric characters.

log_sink_json Output Format

The JSON-format log sink produces messages as JSON objects that contain key-value pairs. For example:

```
{
  "prio": 3,
  "err_code": 10051,
  "source_line": 561,
  "source_file": "event_scheduler.cc",
  "function": "run",
  "msg": "Event Scheduler: scheduler thread started with id 5",
  "time": "2020-08-06T14:25:03.109022Z",
  "ts": 1596724012005,
  "thread": 5,
  "err_symbol": "ER_SCHEDULER_STARTED",
  "SQL_state": "HY000",
  "subsystem": "Server",
  "buffered": 1596723903109022,
  "label": "Note"
}
```

The `ts` (timestamp) key was added in MySQL 8.0.20 and is unique to the JSON-format log sink. The value is an integer indicating milliseconds since the epoch ('1970-01-01 00:00:00' UTC).

The `ts` and `buffered` values are Unix timestamp values and can be converted using `FROM_UNIXTIME()` and an appropriate divisor:

```
mysql> SET time_zone = '+00:00';
mysql> SELECT FROM_UNIXTIME(1596724012005/1000.0);
+-----+
| FROM_UNIXTIME(1596724012005/1000.0) |
+-----+
| 2020-08-06 14:26:52.0050           |
+-----+
mysql> SELECT FROM_UNIXTIME(1596723903109022/1000000.0);
+-----+
| FROM_UNIXTIME(1596723903109022/1000000.0) |
+-----+
| 2020-08-06 14:25:03.1090           |
+-----+
```

log_sink_syseventlog Output Format

The system log sink produces output that conforms to the system log format used on the local platform.

Early-Startup Logging Output Format

The server generates some error log messages before startup options have been processed, and thus before it knows error log settings such as the `log_error_verbosity` and `log_timestamps` system variable values, and before it knows which log components are to be used. The server handles error log messages that are generated early in the startup process as follows:

- Prior to MySQL 8.0.14, the server generates messages with the default timestamp, format, and verbosity level, and buffers them. After the startup options are processed and the error log configuration is known, the server flushes the buffered messages. Because these early messages use the default log configuration, they may differ from what is specified by the startup options. Also, the early messages are not flushed to log sinks other than the default. For example, logging to the JSON sink does not include these early messages because they are not in JSON format.
- As of MySQL 8.0.14, the server buffers log events rather than formatted log messages. This enables it to retroactively apply configuration settings to those events after the settings are known, with the result that flushed messages use the configured settings, not the defaults. Also, messages are flushed to all configured sinks, not just the default sink.

If a fatal error occurs before log configuration is known and the server must exit, the server formats buffered messages using the logging defaults so they are not lost. If no fatal error occurs but startup is excessively slow prior to processing startup options, the server periodically formats and flushes buffered messages using the logging defaults so as not to appear unresponsive. Although this behavior is similar to pre-8.0.14 behavior in that the defaults are used, it is preferable to losing messages when exceptional conditions occur.

System Variables That Affect Error Log Format

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the error log (as well as to general query log and slow query log files). The server applies `log_timestamps` to error events before they reach any log sink; it thus affects error message output from all sinks.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (the local system time zone). Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset that indicates the local system time zone adjustment relative to UTC). For example:

2020-08-07T15:02:00.832521Z	(UTC)
2020-08-07T10:02:00.832521-05:00	(SYSTEM)

5.4.2.10 Error Log File Flushing and Renaming

If you flush the error log using a `FLUSH ERROR LOGS` or `FLUSH LOGS` statement, or a `mysqladmin flush-logs` command, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of `host_name.err`, use the following commands to rename the file and create a new one:

```
mv host_name.err host_name.err-old
mysqladmin flush-logs
mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the location of the error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the `/var/log/mysqld.log` file, where the `/var/log` directory is owned by `root` and is not writable by `mysqld`. For information about handling this case, see [Section 5.4.6, “Server Log Maintenance”](#).

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

5.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Each line that shows when a client connects also includes `using connection_type` to indicate the protocol used to establish the connection. `connection_type` is one of `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection established with SSL), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), or `Shared Memory` (Windows shared memory connection).

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query

log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication source server, statements received by its replicas are written to the query log of each replica. Statements are written to the query log of the source if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in [Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#)).

Note

If you specify the `TABLE` log destination, see [Log Tables and “Too many open files” Errors](#).

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also [Section 6.1.2.3, “Passwords and Logging”](#).

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

5.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a replication source server provides a record of the data changes to be sent to replicas. The source sends the information contained in its binary log to its replicas, which reproduce those transactions to make the same data changes that were made on the source. See [Section 17.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 5.4.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is resilient to unexpected halts. Only complete events or transactions are logged or read back.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also [Section 6.1.2.3, “Passwords and Logging”](#).

From MySQL 8.0.14, binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see [Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 17.1.6.4, “Binary Logging Options and Variables”](#).

Binary logging is enabled by default (the `log_bin` system variable is set to ON). The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default, but can be enabled by specifying the `--log-bin` option.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

The `--log-slave-updates` and `--slave-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--log-slave-updates=OFF` and `--skip-slave-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-slave-updates` or `--slave-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

The `--log-bin[=base_name]` option is used to specify the base name for binary log files. If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine. It is recommended that you specify a base name, so that if the host name changes, you can easily continue to use the same binary log file names (see [Section B.3.7, “Known Issues in MySQL”](#)). If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time any of the following events occurs:

- The server is started or restarted
- The server flushes the logs.
- The size of the current log file reaches `max_binlog_size`.

A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

The default location for binary log files and the binary log index file is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

In MySQL 5.7, a server ID had to be specified when binary logging was enabled, or the server would not start. In MySQL 8.0, the `server_id` system variable is set to 1 by default. The server can be started with this default ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `server_id` system variable. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

A client that has privileges sufficient to set restricted session system variables (see [Section 5.1.9.1, “System Variable Privileges”](#)) can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the source uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The replication I/O thread on the replica also verifies events received from the source. You can cause the replication SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported: row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see [Section 5.4.4.1, “Binary Logging Formats”](#). For detailed information about the format of the binary log, see [MySQL Internals: The Binary Log](#).

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replica is started with the `log_slave_updates` system variable enabled by default, meaning that the replica writes to its own binary log any data modifications that are received from the source. The binary log must be enabled for this setting to work (see [Section 17.1.6.3, “Replica Server Options and Variables”](#)). This setting enables the replica to act as a source to other replicas.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 13.7.8.6, “RESET Statement”](#), and [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#).

If you are using replication, you should not delete old binary log files on the source until you are sure that no replica still needs to use them. For example, if your replicas never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the source and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display the contents of the relay log file on a replica, because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends. From MySQL 8.0.17, if binary log encryption is active on the server, the temporary file is encrypted.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 17.5.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 24.7, “Stored Program Binary Logging”](#).

Note that the binary log format differs in MySQL 8.0 from previous versions of MySQL, due to enhancements in replication. See [Section 17.5.2, “Replication Compatibility Between MySQL Versions”](#).

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the replication source server can become inconsistent and replicas can lose synchronization with the source. The `binlog_error_action` system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting, `ABORT_SERVER`, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see [Section 17.4.2, “Handling an Unexpected Halt of a Replica”](#)).
- The setting `IGNORE_ERROR` provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, `log_bin` must be enabled again, which requires a server restart. Only use this option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

By default, the binary log is synchronized to disk at each write (`sync_binlog=1`). If `sync_binlog` was not enabled, and the operating system or machine (not only the MySQL server) crashed, there is a chance that the last statements of the binary log could be lost. To prevent this, enable the `sync_binlog` system variable to synchronize the binary log to disk after every *N* commit groups. See [Section 5.1.8, “Server System Variables”](#). The safest value for `sync_binlog` is 1 (the default), but this is also the slowest.

In earlier MySQL releases, there was a chance of inconsistency between the table content and binary log content if a crash occurred, even with `sync_binlog` set to 1. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes many prepared

transactions to the binary log in sequence, synchronizes the binary log, and then commits the transaction into [InnoDB](#). If the server unexpectedly exited between those two operations, the transaction would be rolled back by [InnoDB](#) at restart but still exist in the binary log. Such an issue was resolved in previous releases by enabling [InnoDB](#) support for two-phase commit in XA transactions. In 8.0.0 and higher, the [InnoDB](#) support for two-phase commit in XA transactions is always enabled.

[InnoDB](#) support for two-phase commit in XA transactions ensures that the binary log and [InnoDB](#) data files are synchronized. However, the MySQL server should also be configured to synchronize the binary log and the [InnoDB](#) logs to disk before committing the transaction. The [InnoDB](#) logs are synchronized by default, and `sync_binlog=1` ensures the binary log is synchronized. The effect of implicit [InnoDB](#) support for two-phase commit in XA transactions and `sync_binlog=1` is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction *xid* values and calculate the last valid position in the binary log file. The MySQL server then tells [InnoDB](#) to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of [InnoDB](#) tables, and therefore the replica remains in synchrony with the source because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed [InnoDB](#) transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the source's data.

The session values of the following system variables are written to the binary log and honored by the replica when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 17.5.1.38](#), “[Replication and Variables](#)”)
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from source to replica. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging* (the default), the source writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a source and replica which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based. This is the default.
- `MIXED` causes logging to use mixed format.

The logging format also can be switched at runtime, although note that there are a number of situations in which you cannot do this, as discussed later in this section. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the source, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If the `NDB` storage engine is enabled.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@SESSION.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (`SET @@PERSIST_ONLY.binlog_format`) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication source server does not cause a replica to change its logging format to match. When using `STATEMENT` mode, the `binlog_format` system variable is not replicated. When using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the replica.

A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log. The replica must therefore use `ROW` or `MIXED` format if the source does. Changing the binary logging format on the source from `STATEMENT` to `ROW` or `MIXED` while replication is ongoing to a replica with `STATEMENT` format can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'` Changing the binary logging format on the replica to `STATEMENT` format when the source is still using `MIXED` or `ROW` format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the source and the replica.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

When row-based binary logging is used, the `binlog_row_event_max_size` system variable and its corresponding startup option `--binlog-row-event-max-size` set a soft limit on the maximum size of row events. The default value is 8192 bytes, and the value can only be changed at server startup. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

Warning

When using *statement-based logging* for replication, it is possible for the data on the source and replica to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.3.7, “Known Issues in MySQL”](#).

5.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see [Section 17.5.1.1, “Replication and AUTO_INCREMENT”](#).

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)
- When a statement refers to one or more system variables. (Bug #31168)

Exception. The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 5.1.9, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 17.5.1.38, “Replication and Variables”](#).

In earlier releases, when mixed binary logging format was in use, if a statement was logged by row and the session that executed the statement had any temporary tables, all subsequent statements were treated as unsafe and logged in row-based format until all temporary tables in use by that session were dropped. As of MySQL 8.0, operations on temporary tables are not logged in mixed binary logging format, and the presence of temporary tables in the session has no impact on the logging mode used for each statement.

Note

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
ARCHIVE	Yes	Yes
BLACKHOLE	Yes	Yes
CSV	Yes	Yes
EXAMPLE	Yes	No
FEDERATED	Yes	Yes
HEAP	Yes	Yes
InnoDB	Yes	Yes when the transaction isolation level is REPEATABLE READ or SERIALIZABLE ; No otherwise.
MyISAM	Yes	Yes
MERGE	Yes	Yes
NDB	Yes	No

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format ([STATEMENT](#), [ROW](#), or [MIXED](#)), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using [ROW](#) format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. **Type**, **binlog_format**, **SLC**, and

RLC columns outline the conditions, and **Error / Warning** and **Logged as** columns represent the corresponding actions. **SLC** stands for “statement-logging capable”, and **RLC** stands for “row-logging capable”.

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
*	*	No	No	Error: Cannot execute statement: Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable.	-
Safe	STATEMENT	Yes	No	-	STATEMENT
Safe	MIXED	Yes	No	-	STATEMENT
Safe	ROW	Yes	No	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = ROW and at least one table uses a storage engine that is not capable of row-based logging.	-
Unsafe	STATEMENT	Yes	No	Warning: Unsafe statement binlogged in statement format, since BINLOG_FORMAT = STATEMENT	STATEMENT
Unsafe	MIXED	Yes	No	Error: Cannot execute statement: Binary logging of an unsafe statement is impossible when the storage engine is limited to statement-based logging, even if BINLOG_FORMAT = MIXED.	-
Unsafe	ROW	Yes	No	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT	-

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				= ROW and at least one table uses a storage engine that is not capable of row-based logging.	
Row Injection	STATEMENT	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	MIXED	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	ROW	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Safe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging.	-
Safe	MIXED	No	Yes	-	ROW
Safe	ROW	No	Yes	-	ROW
Unsafe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is	-

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				impossible since <code>BINLOG_FORMAT = STATEMENT</code> and at least one table uses a storage engine that is not capable of statement-based logging.	
Unsafe	MIXED	No	Yes	-	ROW
Unsafe	ROW	No	Yes	-	ROW
Row Injection	STATEMENT	No	Yes	Error: Cannot execute row injection: Binary logging is not possible since <code>BINLOG_FORMAT = STATEMENT</code> .	-
Row Injection	MIXED	No	Yes	-	ROW
Row Injection	ROW	No	Yes	-	ROW
Safe	STATEMENT	Yes	Yes	-	STATEMENT
Safe	MIXED	Yes	Yes	-	STATEMENT
Safe	ROW	Yes	Yes	-	ROW
Unsafe	STATEMENT	Yes	Yes	Warning: Unsafe statement binlogged in statement format since <code>BINLOG_FORMAT = STATEMENT</code> .	STATEMENT
Unsafe	MIXED	Yes	Yes	-	ROW
Unsafe	ROW	Yes	Yes	-	ROW
Row Injection	STATEMENT	Yes	Yes	Error: Cannot execute row injection: Binary logging is not possible because <code>BINLOG_FORMAT = STATEMENT</code> .	-
Row Injection	MIXED	Yes	Yes	-	ROW
Row Injection	ROW	Yes	Yes	-	ROW

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqlld` error log. Only

one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a replica has `log_error_verbosity` set to display warnings, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

5.4.4.4 Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

5.4.4.5 Binary Log Transaction Compression

From MySQL 8.0.20, you can enable binary log transaction compression on a MySQL server instance. When binary log transaction compression is enabled, transaction payloads are compressed using the `zstd` algorithm, and then written to the server's binary log file as a single event (a `Transaction_payload_event`). Compressed transaction payloads remain in a compressed state while they are sent in the replication stream to replicas, other Group Replication group members, or clients such as `mysqlbinlog`. They are not decompressed by receiver threads, and are written to the relay log still in their compressed state. Binary log transaction compression therefore saves storage space both on the originator of the transaction and on the recipient (and for their backups), and saves network bandwidth when the transactions are sent between server instances.

Compressed transaction payloads are decompressed when the individual events contained in them need to be inspected. For example, the `Transaction_payload_event` is decompressed by an applier thread in order to apply the events it contains on the recipient. Decompression is also carried out during recovery, by `mysqlbinlog` when replaying transactions, and by the `SHOW BINLOG EVENTS` and `SHOW RELAYLOG EVENTS` statements.

You can enable binary log transaction compression on a MySQL server instance using the `binlog_transaction_compression` system variable, which defaults to `OFF`. You can also use the `binlog_transaction_compression_level_zstd` system variable to set the level for the `zstd` algorithm that is used for compression. This value determines the compression effort, from 1 (the lowest effort) to 22 (the highest effort). As the compression level increases, the compression ratio increases, which reduces the storage space and network bandwidth required for the transaction payload. However, the effort required for data compression also increases, taking time and CPU and memory resources on the originating server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

The following types of event are excluded from binary log transaction compression, so are always written uncompressed to the binary log:

- Events relating to the GTID for the transaction (including anonymous GTID events).
- Other types of control event, such as view change events and heartbeat events.

- Incident events and the whole of any transactions that contain them.
- Non-transactional events and the whole of any transactions that contain them. A transaction involving a mix of non-transactional and transactional storage engines does not have its payload compressed.
- Events that are logged using statement-based binary logging. Binary log transaction compression is only applied for the row-based binary logging format.

Binary log encryption can be used on binary log files that contain compressed transactions.

Behaviors When Binary Log Transaction Compression is Enabled

Transactions with payloads that are compressed can be rolled back like any other transaction, and they can also be filtered out on a replica by the usual filtering options. Binary log transaction compression can be applied to XA transactions.

When binary log transaction compression is enabled, the `max_allowed_packet` and `slave_max_allowed_packet` limits for the server still apply, and are measured on the compressed size of the `Transaction_payload_event`, plus the bytes used for the event header. Note that compressed transaction payloads are sent as a single packet, rather than each event of the transaction being sent in an individual packet, as is the case when binary log transaction compression is not in use.

For multithreaded workers, each transaction (including its GTID event and `Transaction_payload_event`) is assigned to a worker thread. The worker thread decompresses the transaction payload and applies the individual events in it one by one. If an error is found applying any event within the `Transaction_payload_event`, the complete transaction is reported to the co-ordinator as having failed. When `slave_parallel_type` is set to `DATABASE`, all the databases affected by the transaction are mapped before the transaction is scheduled. The use of binary log transaction compression with the `DATABASE` policy can reduce parallelism compared to uncompressed transactions, which are mapped and scheduled for each event.

For semisynchronous replication (see [Section 17.4.9, “Semisynchronous Replication”](#)), the replica acknowledges the transaction when the complete `Transaction_payload_event` has been received.

When binary log checksums are enabled (which is the default), the replication source server does not write checksums for individual events in a compressed transaction payload. Instead, a checksum is written for the complete `Transaction_payload_event`, and individual checksums are written for any events that were not compressed, such as events relating to GTIDs.

For the `SHOW BINLOG EVENTS` and `SHOW RELAYLOG EVENTS` statements, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

For operations that reference the end position of an event, such as `START SLAVE` with the `UNTIL` clause, `MASTER_POS_WAIT()`, and `sql_slave_skip_counter`, you must specify the end position of the compressed transaction payload (the `Transaction_payload_event`). When skipping events using `sql_slave_skip_counter`, a compressed transaction payload is counted as a single counter value, so all the events inside it are skipped as a unit.

Combining Compressed and Uncompressed Transaction Payloads

MySQL Server releases that support binary log transaction compression can handle a mix of compressed and uncompressed transaction payloads.

- The system variables relating to binary log transaction compression do not need to be set the same on all Group Replication group members, and are not replicated from sources to replicas in a replication topology. You can decide whether or not binary log transaction compression is appropriate for each MySQL Server instance that has a binary log.

- If transaction compression is enabled then disabled on a server, compression is not applied to future transactions originated on that server, but transaction payloads that have been compressed can still be handled and displayed.
- If transaction compression is specified for individual sessions by setting the session value of `binlog_transaction_compression`, the binary log can contain a mix of compressed and uncompressed transaction payloads.

When a source in a replication topology and its replica both have binary log transaction compression enabled, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then compresses them again after applying for writing to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a source in a replication topology has binary log transaction compression enabled but its replica does not, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then writes them uncompressed to its own binary log, if it has one. Any downstream replicas receive the uncompressed transaction payloads.

When a source in a replication topology does not have binary log transaction compression enabled but its replica does, if the replica has a binary log, it compresses the transaction payloads after applying them, and writes the compressed transaction payloads to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a MySQL server instance has no binary log, if it is at a release from MySQL 8.0.20, it can receive, handle, and display compressed transaction payloads regardless of its value for `binlog_transaction_compression`. Compressed transaction payloads received by such server instances are written in their compressed state to the relay log, so they benefit indirectly from compression that was carried out by other servers in the replication topology.

A replica at a release before MySQL 8.0.20 cannot replicate from a source with binary log transaction compression enabled. A replica at or above MySQL 8.0.20 can replicate from a source at an earlier release that does not support binary log transaction compression, and can carry out its own compression on transactions received from that source when writing them to its own binary log.

Monitoring Binary Log Transaction Compression

You can monitor the effects of binary log transaction compression using the Performance Schema table `binary_log_transaction_compression_stats`. The statistics include the data compression ratio for the monitored period, and you can also view the effect of compression on the last transaction on the server. You can reset the statistics by truncating the table. Statistics for binary logs and relay logs are split out so you can see the impact of compression for each log type. The MySQL server instance must have a binary log to produce these statistics.

The Performance Schema table `events_stages_current` shows when a transaction is in the stage of decompression or compression for its transaction payload, and displays its progress for this stage. Compression is carried out by the worker thread handling the transaction, just before the transaction is committed, provided that there are no events in the finalized capture cache that exclude the transaction from binary log transaction compression (for example, incident events). When decompression is required, it is carried out for one event from the payload at a time.

`mysqlbinlog` with the `--verbose` option includes comments stating the compressed size and the uncompressed size for compressed transaction payloads, and the compression algorithm that was used.

You can enable connection compression at the protocol level for replication connections, using the `MASTER_COMPRESSION_ALGORITHMS` and `MASTER_ZSTD_COMPRESSION_LEVEL` options of the `CHANGE MASTER TO` statement (or the deprecated `slave_compressed_protocol` system variable). If you enable binary log transaction compression in a system where connection compression

is also enabled, the impact of connection compression is reduced, as there might be little opportunity to further compress the compressed transaction payloads. However, connection compression can still operate on uncompressed events and on message headers. Binary log transaction compression can be enabled in combination with connection compression if you need to save storage space as well as network bandwidth. For more information on connection compression for replication connections, see [Section 4.2.8, “Connection Compression Control”](#).

For Group Replication, compression is enabled by default for messages that exceed the threshold set by the `group_replication_compression_threshold` system variable. You can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log, using the `group_replication_recovery_compression_algorithm` and `group_replication_recovery_zstd_compression_level` system variables. If you enable binary log transaction compression in a system where these are configured, Group Replication's message compression can still operate on uncompressed events and on message headers, but its impact is reduced. For more information on message compression for Group Replication, see [Section 18.6.3, “Message Compression”](#).

5.4.5 The Slow Query Log

The slow query log consists of SQL statements that take more than `long_query_time` seconds to execute and require at least `min_examined_row_limit` rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the `mysqldumpslow` command to process a slow query log file and summarize its contents. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

- [Slow Query Log Parameters](#)
- [Slow Query Log Contents](#)

Slow Query Log Parameters

The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in [Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#)).

Note

If you specify the `TABLE` log destination, see [Log Tables and “Too many open files” Errors](#).

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 to

disable the log or to 1 to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the slow query log, enable the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

By default, a replica does not write replicated queries to the slow query log. To change this, enable the `log_slow_slave_statements` system variable. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_slave_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_slave_statements` is enabled.

Slow Query Log Contents

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query

log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

- `Query_time: duration`

The statement execution time in seconds.

- `Lock_time: duration`

The time to acquire locks in seconds.

- `Rows_sent: N`

The number of rows sent to the client.

- `Rows_examined:`

The number of rows examined by the server layer (not counting any processing internal to storage engines).

Enabling the `log_slow_extra` system variable (available as of MySQL 8.0.14) causes the server to write the following extra fields to `FILE` output in addition to those just listed (`TABLE` output is unaffected). Some field descriptions refer to status variable names. Consult the status variable descriptions for more information. However, in the slow query log, the counters are per-statement values, not cumulative per-session values.

- `Thread_id: ID`

The statement thread identifier.

- `Errno: error_number`

The statement error number, or 0 if no error occurred.

- `Killed: N`

If the statement was terminated, the error number indicating why, or 0 if the statement terminated normally.

- `Bytes_received: N`

The `Bytes_received` value for the statement.

- `Bytes_sent: N`

The `Bytes_sent` value for the statement.

- `Read_first: N`

The `Handler_read_first` value for the statement.

- `Read_last: N`

The `Handler_read_last` value for the statement.

- `Read_key: N`

The `Handler_read_key` value for the statement.

- `Read_next: N`

The `Handler_read_next` value for the statement.

- `Read_prev: N`

The `Handler_read_prev` value for the statement.

- `Read_rnd: N`

The `Handler_read_rnd` value for the statement.

- `Read_rnd_next: N`

The `Handler_read_rnd_next` value for the statement.

- `Sort_merge_passes: N`

The `Sort_merge_passes` value for the statement.

- `Sort_range_count: N`

The `Sort_range` value for the statement.

- `Sort_rows: N`

The `Sort_rows` value for the statement.

- `Sort_scan_count: N`

The `Sort_scan` value for the statement.

- `Created_tmp_disk_tables: N`

The `Created_tmp_disk_tables` value for the statement.

- `Created_tmp_tables: N`

The `Created_tmp_tables` value for the statement.

- `Start: timestamp`

The statement execution start time.

- `End: timestamp`

The statement execution end time.

A given slow query log file may contain a mix of lines with and without the extra fields added by enabling `log_slow_extra`. Log file analyzers can determine whether a line contains the additional fields by the field count.

Each statement written to the slow query log file is preceded by a `SET` statement that includes a timestamp. As of MySQL 8.0.14, the timestamp indicates when the slow statement began executing. Prior to 8.0.14, the timestamp indicates when the slow statement was logged (which occurs after the statement finishes executing).

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See [Section 6.1.2.3, “Passwords and Logging”](#).

5.4.6 Server Log Maintenance

As described in [Section 5.4, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 7.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for log maintenance. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all replicas.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. To specify an alternative expiration period, use the `binlog_expire_logs_seconds` system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#)).

To force MySQL to start using new log files, flush the logs. Log flushing occurs when you execute a `FLUSH LOGS` statement or a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 13.7.8.3, “FLUSH Statement”](#), [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the server flushes the binary log automatically when current binary log file size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`). See [Section 13.7.8.3, “FLUSH Statement”](#).

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the `RELOAD` privilege. On Unix and Unix-like systems, another way to flush the logs is to send a signal to the server, which can be done by `root` or the account that owns the server process. (See [Section 4.10, “Unix Signal Handling in MySQL”](#).) Signals enable log flushing to be performed without having to connect to the server:

- A `SIGHUP` signal flushes all the logs. However, `SIGHUP` has additional effects other than log flushing that might be undesirable.
- As of MySQL 8.0.19, `SIGUSR1` causes the server to flush the error log, general query log, and slow query log. If you are interested in flushing only those logs, `SIGUSR1` can be used as a more “lightweight” signal that does not have the `SIGHUP` effects that are unrelated to logs.

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named `mysql.log`, `mysql-slow.log`, and `err.log`, you can use a series of commands like this from the command line:

```
cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old
mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.log.old`, `mysql-slow.log.old`, and `err.log.old`, then remove them from disk.

To rename the general query log or slow query log at runtime, first connect to the server and disable the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

Note

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, log-flushing operations fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:

```
mv /var/log/mysqld.log /var/log/mysqld.log.old
install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

5.5 MySQL Server Components

MySQL Server includes a component-based infrastructure for extending server capabilities. A component provides services that are available to the server and other components. (With respect to service use, the server is a component, equal to other components.) Components interact with each other only through the services they provide.

MySQL distributions include several components that implement server extensions:

- Components for configuring error logging. See [Section 5.4.2, “The Error Log”](#), and [Section 5.5.3, “Error Log Components”](#).
- A component for checking passwords. See [Section 6.4.3, “The Password Validation Component”](#).
- A component that enables applications to add their own message events to the audit log. See [Section 6.4.6, “The Audit Message Component”](#).

System and status variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

The following sections describe how to install and uninstall components, and how to determine at runtime which components are installed and obtain information about them.

For information about the internal implementation of components, see the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>. For example, if you intend to write your own components, this information is important for understanding how components work.

5.5.1 Installing and Uninstalling Components

Server components must be loaded into the server before they can be used. MySQL supports manual component loading at runtime and automatic loading during server startup.

While a component is loaded, information about it is available as described in [Section 5.5.2, “Obtaining Server Component Information”](#).

The `INSTALL COMPONENT` and `UNINSTALL COMPONENT` SQL statements enable component loading and unloading. For example:

```
INSTALL COMPONENT 'file://component_validate_password';
UNINSTALL COMPONENT 'file://component_validate_password';
```

A loader service handles component loading and unloading, and also registers loaded components in the `mysql.component` system table.

The SQL statements for component manipulation affect server operation and the `mysql.component` system table as follows:

- `INSTALL COMPONENT` loads components into the server. The components become active immediately. The loader service also registers loaded components in the `mysql.component` system table. For subsequent server restarts, the loader service loads any components listed in `mysql.component` during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.
- `UNINSTALL COMPONENT` deactivates components and unloads them from the server. The loader service also unregisters the components from the `mysql.component` system table so that the server no longer loads them during its startup sequence for subsequent restarts.

Compared to the corresponding `INSTALL PLUGIN` statement for server plugins, the `INSTALL COMPONENT` statement for components offers the significant advantage that it is not necessary to know any platform-specific file name suffix for naming the component. This means that a given `INSTALL COMPONENT` statement can be executed uniformly across platforms.

A component when installed may also automatically install related user-defined functions (UDFs). If so, the component when uninstalled also automatically uninstalls those UDFs.

5.5.2 Obtaining Server Component Information

The `mysql.component` system table contains information about currently loaded components and shows which components have been registered using `INSTALL COMPONENT`. To see which components are installed, use this statement:

```
SELECT * FROM mysql.component;
```

5.5.3 Error Log Components

This section describes the characteristics of individual error log components. For general information about configuring error logging, see [Section 5.4.2, “The Error Log”](#).

A log component can be a filter or a sink:

- A filter processes log events, to add, remove, or modify event fields, or to delete events entirely. The resulting events pass to the next log component in the list of enabled components.

- A sink is a destination (writer) for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log. A sink may also write to the Performance Schema `error_log` table; see [Section 26.12.19.1, “The error_log Table”](#). Events pass unmodified to the next log component in the list of enabled components (that is, although a sink formats events to produce output messages, it does not modify events as they pass internally to the next component).

The `log_error_services` system variable value lists the enabled log components. Components not named in the list are disabled.

The following sections describe individual log components, grouped by component type:

- [Filter Error Log Components](#)
- [Sink Error Log Components](#)

Component descriptions include these types of information:

- The component name and intended purpose.
- Whether the component is built in or must be loaded. For a loadable component, the description specifies the URN to use to load and unload the component with the `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements.
- Whether the component can be listed multiple times in the `log_error_services` value.
- For a sink component, the destination to which the component writes output.
- For a sink component, whether it supports an interface to the Performance Schema `error_log` table.

Filter Error Log Components

Error log filter components implement filtering of error log events. If no filter component is enabled, no filtering occurs.

Any enabled filter component affects log events only for components listed later in the `log_error_services` value. In particular, for any log sink component listed in `log_error_services` earlier than any filter component, no log event filtering occurs.

The `log_filter_internal` Component

- Purpose: Implements filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. See [Section 5.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#).
- URN: This component is built in and need not be loaded with `INSTALL COMPONENT` before use.
- Multiple uses permitted: No.

If `log_filter_internal` is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect.

The `log_filter_dragnet` Component

- Purpose: Implements filtering based on the rules defined by the `dragnet.log_error_filter_rules` system variable setting. See [Section 5.4.2.6, “Rule-Based Error Log Filtering \(log_filter_dragnet\)”](#).
- URN: `file://component_log_filter_dragnet`
- Multiple uses permitted: No.

Sink Error Log Components

Error log sink components are writers that implement error log output. If no sink component is enabled, no log output occurs.

Some sink component descriptions refer to the default error log destination. This is the console or a file and is indicated by the value of the `log_error` system variable, determined as described in [Section 5.4.2.2, “Default Error Log Destination Configuration”](#).

The `log_sink_internal` Component

- Purpose: Implements traditional error log message output format.
- URN: This component is built in and need not be loaded with `INSTALL COMPONENT` before use.
- Multiple uses permitted: No.
- Output destination: Writes to the default error log destination.
- Performance Schema support: Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

The `log_sink_json` Component

- Purpose: Implements JSON-format error logging. See [Section 5.4.2.7, “Error Logging in JSON Format”](#).
- URN: `file://component_log_sink_json`
- Multiple uses permitted: Yes.
- Output destination: The JSON log sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable:
 - If `log_error` names a file, the JSON sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.
 - If `log_error` is `stderr`, the JSON sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.
- Performance Schema support: Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

The `log_sink_syseventlog` Component

- Purpose: Implements error logging to the system log. This is the Event Log on Windows, and `syslog` on Unix and Unix-like systems. See [Section 5.4.2.8, “Error Logging to the System Log”](#).
- URN: `file://component_log_sink_syseventlog`
- Multiple uses permitted: No.
- Output destination: Writes to the system log. Does not use the default error log destination.
- Performance Schema support: Does not write to the `error_log` table. Does not provide a parser for reading error log files created by previous server instances.

The `log_sink_test` Component

- Purpose: Intended for internal use in writing test cases, not for production use.
- URN: `file://component_log_sink_test`

Sink properties such as whether multiple uses are permitted and the output destination are not specified for `log_sink_test` because, as mentioned, it is for internal use. As such, its behavior is subject to change at any time.

5.6 MySQL Server Plugins

MySQL supports an plugin API that enables creation of server plugins. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The plugins supported by this interface include, but are not limited to, storage engines, `INFORMATION_SCHEMA` tables, full-text parser plugins, and server extensions.

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See [Section 6.2.17, “Pluggable Authentication”](#).
- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See [Section 6.4.2, “The Connection-Control Plugins”](#).
- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See [Section 6.4.3, “The Password Validation Component”](#).
- Semisynchronous replication plugins implement an interface to replication capabilities that permit the source to proceed as long as at least one replica has responded to each transaction. See [Section 17.4.9, “Semisynchronous Replication”](#).
- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See [Chapter 18, Group Replication](#).
- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 5.6.3, “MySQL Enterprise Thread Pool”](#).
- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See [Section 6.4.5, “MySQL Enterprise Audit”](#).
- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See [Section 6.4.7, “MySQL Enterprise Firewall”](#).
- Query rewrite plugins examine statements received by MySQL Server and possibly rewrite them before the server executes them. See [Section 5.6.4, “The Rewriter Query Rewrite Plugin”](#), and [Section 5.6.5, “The ddl_rewriter Plugin”](#).
- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a `version_tokens` plugin and a set of user-defined functions. See [Section 5.6.6, “Version Tokens”](#).
- Keyring plugins provide secure storage for sensitive information. See [Section 6.4.4, “The MySQL Keyring”](#).
- X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to

expose the ACID compliant storage abilities of MySQL as a document store. See [Section 20.5, “X Plugin”](#).

- Clone permits cloning [InnoDB](#) data from a local or remote MySQL server instance. See [Section 5.6.7, “The Clone Plugin”](#).
- Test framework plugins test server services. For information about these plugins, see the Plugins for Testing Plugin Services section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see [The MySQL Plugin API](#).

5.6.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available as described in [Section 5.6.2, “Obtaining Server Plugin Information”](#).

- [Installing Plugins](#)
- [Controlling Plugin Activation State](#)
- [Uninstalling Plugins](#)
- [Plugins and User-Defined Functions](#)

Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, *plugin_name* stands for a plugin name such as [innodb](#), [csv](#), or [validate_password](#).

- [Built-in Plugins](#)
- [Plugins Registered in the mysql.plugin System Table](#)
- [Plugins Named with Command-Line Options](#)
- [Plugins Installed with the INSTALL PLUGIN Statement](#)

Built-in Plugins

A built-in plugin is known by the server automatically. By default, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

Plugins Registered in the mysql.plugin System Table

The `mysql.plugin` system table serves as a registry of plugins (other than built-in plugins, which need not be registered). During the normal startup sequence, the server loads plugins registered in the table. By default, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

Plugins Named with Command-Line Options

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one takes effect. With multiple instances of `--plugin-load-add`, all of them take effect.
- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to these options:

```
--plugin-load-add=x --plugin-load-add=y
```

and are also equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

Plugins Installed with the `INSTALL PLUGIN` Statement

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load-add` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load-add=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load-add` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically
installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load`.

If a plugin is named both using a `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load-add` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name[=activation_state]` startup option, where *plugin_name* is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case-sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but fails to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable `InnoDB`, other `innodb_xxx` options likely will need to be omitted at startup. In addition, because `InnoDB` is the default storage engine, it will not start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server does not load the plugin during subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove from the `my.cnf` file any options and system variables related to the plugin. If any plugin system variables were persisted to the `mysqld-auto.cnf` file, remove them using `RESET PERSIST var_name` for each one to remove it.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

Plugins and User-Defined Functions

A plugin when installed may also automatically install related user-defined functions (UDFs). If so, the plugin when uninstalled also automatically uninstalls those UDFs.

5.6.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS\G
***** 1. row *****
      PLUGIN_NAME: binlog
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: Oracle Corporation
      PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: FORCE
...
***** 10. row *****
      PLUGIN_NAME: InnoDB
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: ha_innodb_plugin.so
      PLUGIN_LIBRARY_VERSION: 1.0
      PLUGIN_AUTHOR: Oracle Corporation
      PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                        and foreign keys
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
...
```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
***** 1. row *****
      Name: binlog
      Status: ACTIVE
      Type: STORAGE ENGINE
      Library: NULL
      License: GPL
...
***** 10. row *****
      Name: InnoDB
      Status: ACTIVE
```

```
Type: STORAGE ENGINE
Library: ha_innodb_plugin.so
License: GPL
...
```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

5.6.3 MySQL Enterprise Thread Pool

Note

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.
- With too many threads executing in parallel, context switching overhead is high. This also presents a challenge to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.
- Too many transactions executing in parallel increases resource contention. In `InnoDB`, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

Additional Resources

[Section A.15, “MySQL 8.0 FAQ: MySQL Enterprise Thread Pool”](#)

5.6.3.1 Thread Pool Elements

MySQL Enterprise Thread Pool comprises these elements:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation:
 - As of MySQL 8.0.14, the monitoring tables are Performance Schema tables; see [Section 26.12.16, “Performance Schema Thread Pool Tables”](#).
 - Prior to MySQL 8.0.14, the monitoring tables are `INFORMATION_SCHEMA` tables; see [Section 25.52, “INFORMATION_SCHEMA Thread Pool Tables”](#).

The `INFORMATION_SCHEMA` tables now are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_state;
```

Note

If you do not load all the monitoring tables, some or all MySQL Enterprise Monitor thread pool graphs will be empty.

For a detailed description of how the thread pool works, see [Section 5.6.3.3, “Thread Pool Operation”](#).

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

The other related variables are implemented by the thread pool plugin and are not available unless it is enabled:

- `thread_pool_algorithm`: The concurrency algorithm to use for scheduling.
- `thread_pool_high_priority_connection`: How to schedule statement execution for a session.
- `thread_pool_max_active_query_threads`: How many active threads per group to permit.
- `thread_pool_max_unused_threads`: How many sleeping threads to permit.
- `thread_pool_prio_kickup_timer`: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- `thread_pool_size`: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- `thread_pool_stall_limit`: The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see [Section 5.6.3.4, “Thread Pool Tuning”](#).

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```
SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%thread_pool%';
```

For more information, see [Chapter 26, MySQL Performance Schema](#).

5.6.3.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

- [Thread Pool Installation as of MySQL 8.0.14](#)

- [Thread Pool Installation Prior to MySQL 8.0.14](#)

Thread Pool Installation as of MySQL 8.0.14

In MySQL 8.0.14 and higher, the thread pool monitoring tables are Performance Schema tables that are loaded and unloaded along with the thread pool plugin. The [INFORMATION_SCHEMA](#) versions of the tables are deprecated but still available; they are installed per the instructions in [Thread Pool Installation Prior to MySQL 8.0.14](#).

To enable thread pool capability, load the plugin by starting the server with the `--plugin-load-add` option. To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'thread%';
```

PLUGIN_NAME	PLUGIN_STATUS
thread_pool	ACTIVE

To verify that the Performance Schema monitoring tables are available, examine the `INFORMATION_SCHEMA.TABLES` table or use the `SHOW TABLES` statement. For example:

```
mysql> SELECT TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME LIKE 'tp%';
```

TABLE_NAME
tp_thread_group_state
tp_thread_group_stats
tp_thread_state

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If the plugin fails to initialize, check the server error log for diagnostic messages.

Thread Pool Installation Prior to MySQL 8.0.14

Prior to MySQL 8.0.14, the thread pool monitoring tables are plugins separate from the thread pool plugin and can be installed separately.

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load-add` option. For example, if you name only the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

```
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use options like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
```

PLUGIN_NAME	PLUGIN_STATUS
thread_pool	ACTIVE
TP_THREAD_STATE	ACTIVE
TP_THREAD_GROUP_STATE	ACTIVE
TP_THREAD_GROUP_STATS	ACTIVE

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If a plugin fails to initialize, check the server error log for diagnostic messages.

5.6.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

To configure the number of thread groups, use the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see [Section 5.6.3.4, “Thread Pool Tuning”](#).

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that a given thread executes all statements from its connection.

By default, the thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
 - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
 - Queuing occurs if the statement cannot begin executing immediately.

- If immediate execution occurs, the listener thread performs it. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.
- If `thread_pool_max_active_query_threads` is 0, the default algorithm applies as just described for determining the maximum number of active threads per group. The default algorithm takes stalled threads into account and may temporarily permit more active threads. If `thread_pool_max_active_query_threads` is greater than 0, it places a limit on the number of active threads per group.
- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication source server, a thread that is sending binary log events to a replica effectively runs forever.
- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.
- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` is enabled. With `autocommit` enabled, all statements will be low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.

- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms (100 per second) is moved from the low-priority queue to the high-priority queue.
- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.
- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even though the first thread is still executing.
- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.
- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.
- Binary log dump threads that read the binary log and send it to replicas. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.
- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

5.6.3.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is [InnoDB](#), the optimal [thread_pool_size](#) setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

For workloads such as DBT2 and Sysbench, the optimum for [InnoDB](#) seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is [MyISAM](#), the [thread_pool_size](#) setting should be fairly low. Optimal performance is often seen with values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, [thread_pool_stall_limit](#), is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout that can be tuned using the [thread_pool_stall_limit](#) system variable, the value of which is measured in 10ms units. This parameter ensures that the server does not become completely blocked. The value of [thread_pool_stall_limit](#) has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

[thread_pool_stall_limit](#) also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of [thread_pool_stall_limit](#) should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the [thread_pool_stall_limit](#) parameter too high means that long-running statements will block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set [thread_pool_stall_limit](#) to 10 (10 × 10ms = 100ms). The default value of 6 (60ms) is suitable for servers that primarily execute very simple statements.

The [thread_pool_stall_limit](#) parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the [tp_thread_group_stats](#) table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM performance_schema.tp_thread_group_stats;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of [thread_pool_stall_limit](#).

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- [thread_pool_prio_kickup_timer](#) is set to 10000 (10 seconds).
- [thread_pool_stall_limit](#) is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements will be moved to the high-priority queue because it will always already contain statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those will become stalled and it will take 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it will take 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

5.6.4 The Rewriter Query Rewrite Plugin

MySQL supports query rewrite plugins that can examine and possibly modify SQL statements received by the server before the server executes them. See [Query Rewrite Plugins](#).

MySQL distributions include a postparse query rewrite plugin named [Rewriter](#) and scripts for installing the plugin and its associated elements. These elements work together to provide statement-rewriting capability:

- A server-side plugin named [Rewriter](#) examines statements and may rewrite them, based on its in-memory cache of rewrite rules.
- These statements are subject to rewriting:
 - As of MySQL 8.0.12: [SELECT](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and [DELETE](#).
 - Prior to MySQL 8.0.12: [SELECT](#) only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- The [Rewriter](#) plugin uses a database named [query_rewrite](#) containing a table named [rewrite_rules](#). The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the [message](#) column of table rows.
- The [query_rewrite](#) database contains a stored procedure named [flush_rewrite_rules\(\)](#) that loads the contents of the rules table into the plugin.
- A user-defined function named [load_rewrite_rules\(\)](#) is used by the [flush_rewrite_rules\(\)](#) stored procedure.
- The [Rewriter](#) plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information.

The following sections describe how to install and use the [Rewriter](#) plugin, and provide reference information for its associated elements.

5.6.4.1 Installing or Uninstalling the Rewriter Query Rewrite Plugin

Note

If installed, the [Rewriter](#) plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the [Rewriter](#) query rewrite plugin, choose the appropriate script located in the [share](#) directory of your MySQL installation:

- [install_rewriter.sql](#): Choose this script to install the [Rewriter](#) plugin and its associated elements.
- [uninstall_rewriter.sql](#): Choose this script to uninstall the [Rewriter](#) plugin and its associated elements.

Run the chosen script as follows:

```
shell> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)
```

The example here uses the [install_rewriter.sql](#) installation script. Substitute [uninstall_rewriter.sql](#) if you are uninstalling the plugin.

Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| rewriter_enabled | ON    |
+-----+-----+
```

For usage instructions, see [Section 5.6.4.2, “Using the Rewriter Query Rewrite Plugin”](#). For reference information, see [Section 5.6.4.3, “Rewriter Query Rewrite Plugin Reference”](#).

5.6.4.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the [rewriter_enabled](#) system variable. By default, the [Rewriter](#) plugin is enabled when you install it (see [Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```
SET GLOBAL rewriter_enabled = ON;
SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the [Rewriter](#) plugin is enabled, it examines and possibly modifies each rewritable statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the [rewrite_rules](#) table in the [query_rewrite](#) database.

These statements are subject to rewriting:

- As of MySQL 8.0.12: [SELECT](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and [DELETE](#).
- Prior to MySQL 8.0.12: [SELECT](#) only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- [Adding Rewrite Rules](#)
- [How Statement Matching Works](#)
- [Rewriting Prepared Statements](#)

- [Rewriter Plugin Operational Information](#)
- [Rewriter Plugin Use of Character Sets](#)

Adding Rewrite Rules

To add rules for the `Rewriter` plugin, add rows to the `rewrite_rules` table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('SELECT ?', 'SELECT ? + 1');
```

The resulting table contents look like this:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
      id: 1
      pattern: SELECT ?
      pattern_database: NULL
      replacement: SELECT ? + 1
      enabled: YES
      message: NULL
      pattern_digest: NULL
      normalized_pattern: NULL
```

The rule specifies a pattern template indicating which `SELECT` statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the `rewrite_rules` table is not sufficient to cause the `Rewriter` plugin to use the rule. You must invoke `flush_rewrite_rules()` to load the table contents into the plugin in-memory cache:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
```

Tip

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling `flush_rewrite_rules()`.

When the plugin reads each rule from the rules table, it computes a normalized (statement digest) form from the pattern and a digest hash value, and uses them to update the `normalized_pattern` and `pattern_digest` columns:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
      id: 1
      pattern: SELECT ?
      pattern_database: NULL
      replacement: SELECT ? + 1
      enabled: YES
      message: NULL
      pattern_digest: d1b44b0c19af710b5a679907e284acd2ddc285201794bc69a2389d77baedddae
      normalized_pattern: select ?
```

For information about statement digesting, normalized statements, and digest hash values, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

If a rule cannot be loaded due to some error, calling `flush_rewrite_rules()` produces an error:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

When this occurs, the plugin writes an error message to the `message` column of the rule row to communicate the problem. Check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

Patterns use the same syntax as prepared statements (see [Section 13.5.1, “PREPARE Statement”](#)). Within a pattern template, `?` characters act as parameter markers that match data values. Parameter

markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth. The `?` characters should not be enclosed within quotation marks.

Like the pattern, the replacement can contain `?` characters. For a statement that matches a pattern template, the plugin rewrites it, replacing `?` parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:

```
mysql> SELECT PI();
+-----+
| PI()   |
+-----+
| 3.141593 |
+-----+
1 row in set (0.01 sec)

mysql> SELECT 10;
+-----+
| 10 + 1 |
+-----+
|      11 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

No rewriting occurs for the first `SELECT` statement, but does for the second. The second statement illustrates that when the `Rewriter` plugin rewrites a statement, it produces a warning message. To view the message, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1105
Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

A statement need not be rewritten to a statement of the same type. The following example loads a rule that rewrites `DELETE` statements to `UPDATE` statements:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('DELETE FROM db1.t1 WHERE col = ?',
      'UPDATE db1.t1 SET col = NULL WHERE col = ?');
CALL query_rewrite.flush_rewrite_rules();
```

To enable or disable an existing rule, modify its `enabled` column and reload the table into the plugin. To disable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'NO' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'YES' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used only if `appdb` is the default database:

```
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```

Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause. But if there are old applications that cannot be written to change the `SELECT` queries they generate, they will no longer work properly. The `Rewriter` plugin can solve this problem. To match and rewrite statements whether or not they qualify the table name, add the following two rules and reload the rules table:

```
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement) VALUES(
  'SELECT * FROM appdb.users WHERE id = ?',
  'SELECT * FROM appdb.users WHERE user_id = ?'
);
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement, pattern_database) VALUES(
  'SELECT * FROM users WHERE id = ?',
  'SELECT * FROM users WHERE user_id = ?',
  'appdb'
);
CALL query_rewrite.flush_rewrite_rules();
```

`Rewriter` uses the first rule to match statements that use the qualified table name. It uses the second to match statements that used the unqualified name, but only if the default database is `appdb` (the value in `pattern_database`).

How Statement Matching Works

The `Rewriter` plugin uses statement digests and digest hash values to match incoming statements against rewrite rules in stages. The `max_digest_length` system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.
2. If the statement digest hash value matches any pattern digest hash values, match the normalized (statement digest) form of the statement to the normalized form of the matching rule patterns.
3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A `?` character in the pattern matches any literal value in the statement. If the statement prepares a statement, `?` in the pattern also matches `?` in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is nondeterministic which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the `message` column of the rule row to communicate the problem, and sets the `Rewriter_reload_error` status variable to `ON`.

Rewriting Prepared Statements

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.

Prepared statements differ from nonprepared statements in that they may contain `?` characters as parameter markers. To match a `?` in a prepared statement, a [Rewriter](#) pattern must contain `?` in the same location. Suppose that a rewrite rule has this pattern:

```
SELECT ?, 3
```

The following table shows several prepared `SELECT` statements and whether the rule pattern matches them.

Prepared Statement	Whether Pattern Matches Statement
<code>PREPARE s AS 'SELECT 3, 3'</code>	Yes
<code>PREPARE s AS 'SELECT ?, 3'</code>	Yes
<code>PREPARE s AS 'SELECT 3, ?'</code>	No
<code>PREPARE s AS 'SELECT ?, ?'</code>	No

Rewriter Plugin Operational Information

The [Rewriter](#) plugin makes information available about its operation by means of several status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Rewriter_number_loaded_rules | 1 |
| Rewriter_number_reloads | 5 |
| Rewriter_number_rewritten_queries | 1 |
| Rewriter_reload_error | ON |
+-----+-----+
```

For descriptions of these variables, see [Rewriter Query Rewrite Plugin Status Variables](#).

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the `CALL` statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to `ON`:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.

mysql> SHOW GLOBAL STATUS LIKE 'Rewriter_reload_error';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Rewriter_reload_error | ON |
+-----+-----+
```

In this case, check the `rewrite_rules` table for rows with non-`NULL` `message` column values to see what problems exist.

Rewriter Plugin Use of Character Sets

When the `rewrite_rules` table is loaded into the [Rewriter](#) plugin, the plugin interprets statements using the current global value of the `character_set_client` system variable. If the global `character_set_client` value is changed subsequently, the rules table must be reloaded.

A client must have a session `character_set_client` value identical to what the global value was when the rules table was loaded or rule matching will not work for that client.

5.6.4.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these elements associated with the `Rewriter` query rewrite plugin:

- The `Rewriter` rules table in the `query_rewrite` database
- `Rewriter` procedures and functions
- `Rewriter` system and status variables

Rewriter Query Rewrite Plugin Rules Table

The `rewrite_rules` table in the `query_rewrite` database provides persistent storage for the rules that the `Rewriter` plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates information to users by setting the table's `message` column.

Note

The rules table is loaded into the plugin by the `flush_rewrite_rules` stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The `rewrite_rules` table has these columns:

- `id`

The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.

- `pattern`

The template that indicates the pattern for statements that the rule matches. Use `?` to represent parameter markers that match data values.

- `pattern_database`

The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

- `replacement`

The template that indicates how to rewrite statements matching the `pattern` column value. Use `?` to represent parameter markers that match data values. In rewritten statements, the plugin replaces `?` parameter markers in `replacement` using data values matched by the corresponding markers in `pattern`.

- `enabled`

Whether the rule is enabled. Load operations (performed by invoking the `flush_rewrite_rules()` stored procedure) load the rule from the table into the `Rewriter` in-memory cache only if this column is `YES`.

This column makes it possible to deactivate a rule without removing it: Set the column to a value other than `YES` and reload the table into the plugin.

- `message`

The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to `NULL`. A non-`NULL` value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

- Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
- The replacement contains more `?` parameter markers than the pattern.

If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to `ON`.

- `pattern_digest`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- `normalized_pattern`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

Rewriter Query Rewrite Plugin Procedures and Functions

`Rewriter` plugin operation uses a stored procedure that loads the rules table into its in-memory cache, and a helper user-defined function (UDF). Under normal operation, users invoke only the stored procedure. The UDF is intended to be invoked by the stored procedure, not directly by users.

- `flush_rewrite_rules()`

This stored procedure uses the `load_rewrite_rules()` UDF to load the contents of the `rewrite_rules` table into the `Rewriter` in-memory cache.

Calling `flush_rewrite_rules()` implies `COMMIT`.

Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the `message` column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to `ON`.

- `load_rewrite_rules()`

This UDF is a helper routine used by the `flush_rewrite_rules()` stored procedure.

Rewriter Query Rewrite Plugin System Variables

The `Rewriter` query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see [Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)).

- `rewriter_enabled`

System Variable	<code>rewriter_enabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether the `Rewriter` query rewrite plugin is enabled.

- `rewriter_verbose`

System Variable	<code>rewriter_verbose</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer

For internal use.

Rewriter Query Rewrite Plugin Status Variables

The `Rewriter` query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see [Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)).

- `Rewriter_number_loaded_rules`

The number of rewrite plugin rewrite rules successfully loaded from the `rewrite_rules` table into memory for use by the `Rewriter` plugin.

- `Rewriter_number_reloads`

The number of times the `rewrite_rules` table has been loaded into the in-memory cache used by the `Rewriter` plugin.

- `Rewriter_number_rewritten_queries`

The number of queries rewritten by the `Rewriter` query rewrite plugin since it was loaded.

- `Rewriter_reload_error`

Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the `Rewriter` plugin. If the value is `OFF`, no error occurred. If the value is `ON`, an error occurred; check the `message` column of the `rewriter_rules` table for error messages.

5.6.5 The ddl_rewriter Plugin

MySQL 8.0.16 and higher includes a `ddl_rewriter` plugin that modifies `CREATE TABLE` statements received by the server before it parses and executes them. The plugin removes `ENCRYPTION`, `DATA DIRECTORY`, and `INDEX DIRECTORY` clauses, which may be helpful when restoring tables from SQL dump files created from databases that are encrypted or that have their tables stored outside the data directory. For example, the plugin may enable restoring such dump files into an unencrypted instance or in an environment where the paths outside the data directory are not accessible.

Before using the `ddl_rewriter` plugin, install it according to the instructions provided in [Section 5.6.5.1, “Installing or Uninstalling ddl_rewriter”](#).

`ddl_rewriter` examines SQL statements received by the server prior to parsing, rewriting them according to these conditions:

- `ddl_rewriter` considers only `CREATE TABLE` statements, and only if they are standalone statements that occur at the beginning of an input line or at the beginning of prepared statement text. `ddl_rewriter` does not consider `CREATE TABLE` statements within stored program definitions. Statements can extend over multiple lines.
- Within statements considered for rewrite, instances of the following clauses are rewritten and each instance replaced by a single space:

- `ENCRYPTION`
- `DATA DIRECTORY` (at the table and partition levels)
- `INDEX DIRECTORY` (at the table and partition levels)
- Rewriting does not depend on lettercase.

If `ddl_rewriter` rewrites a statement, it generates a warning:

```
mysql> CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data';
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1105
Message: Query 'CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data''
        rewritten to 'CREATE TABLE t (i INT) ' by a query rewrite plugin
1 row in set (0.00 sec)
```

If the general query log or binary log is enabled, the server writes to it statements as they appear after any rewriting by `ddl_rewriter`.

When installed, `ddl_rewriter` exposes the Performance Schema `memory/rewriter/ddl_rewriter` instrument for tracking plugin memory use. See [Section 26.12.18.10, “Memory Summary Tables”](#)

5.6.5.1 Installing or Uninstalling `ddl_rewriter`

This section describes how to install or uninstall the `ddl_rewriter` plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

Note

If installed, the `ddl_rewriter` plugin involves some minimal overhead even when disabled. To avoid this overhead, install `ddl_rewriter` only for the period during which you intend to use it.

The primary use case is modification of statements restored from dump files, so the typical usage pattern is: 1) Install the plugin; 2) restore the dump file or files; 3) uninstall the plugin.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `ddl_rewriter`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `ddl_rewriter` plugin, use the `INSTALL PLUGIN` statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN ddl_rewriter SONAME 'ddl_rewriter.so';
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'ddl%';
+-----+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS | PLUGIN_TYPE |
+-----+-----+-----+
```

```
| ddl_rewriter | ACTIVE | AUDIT |
+-----+-----+-----+
```

As the preceding result shows, `ddl_rewriter` is implemented as an audit plugin.

If the plugin fails to initialize, check the server error log for diagnostic messages.

Once installed as just described, `ddl_rewriter` remains installed until uninstalled. To remove it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN ddl_rewriter;
```

If `ddl_rewriter` is installed, you can use the `--ddl-rewriter` option for subsequent server startups to control `ddl_rewriter` plugin activation. For example, to prevent the plugin from being enabled at runtime, use this option:

```
[mysqld]
ddl-rewriter=OFF
```

5.6.5.2 ddl_rewriter Plugin Options

This section describes the command options that control operation of the `ddl_rewriter` plugin. If values specified at startup time are incorrect, the `ddl_rewriter` plugin may fail to initialize properly and the server does not load it.

To control activation of the `ddl_rewriter` plugin, use this option:

- `--ddl-rewriter[=value]`

Command-Line Format	<code>--ddl-rewriter[=value]</code>
Introduced	8.0.16
Type	Enumeration
Default Value	ON
Valid Values	ON OFF FORCE FORCE_PLUS_PERMANENT

This option controls how the server loads the `ddl_rewriter` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See [Section 5.6.5.1, “Installing or Uninstalling ddl_rewriter”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 5.6.1, “Installing and Uninstalling Plugins”](#). For example, `--ddl-rewriter=OFF` disables the plugin at server startup.

5.6.6 Version Tokens

MySQL includes Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

- Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.
- Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.

- Version token lists are established per server (for example, to specify the server assignment or operational state). In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the elements of Version Tokens, discuss how to install and use it, and provide reference information for its elements.

5.6.6.1 Version Tokens Elements

Version Tokens is based on a plugin library that implements these elements:

- A server-side plugin named `version_tokens` holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The `version_tokens` plugin uses the [audit plugin API](#) to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.
- A set of user-defined functions (UDFs) provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to call any of the Version Token UDFs.
- When the `version_tokens` plugin loads, it defines the `VERSION_TOKEN_ADMIN` dynamic privilege. This privilege can be granted to users of the UDFs.
- A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

5.6.6.2 Installing or Uninstalling Version Tokens

Note

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#), and [Section 5.7.1, “Installing and Uninstalling User-Defined Functions”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `version_tokens`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the Version Tokens plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT
  SONAME 'version_token.so';
```

```
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT  
  SONAME 'version_token.so';  
CREATE FUNCTION version_tokens_unlock RETURNS INT  
  SONAME 'version_token.so';
```

You must install the UDFs to manage the server's version token list, but you must also install the plugin because the UDFs will not work correctly without it.

If the plugin and UDFs are used on a replication source server, install them on all replica servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN version_tokens;  
DROP FUNCTION version_tokens_set;  
DROP FUNCTION version_tokens_show;  
DROP FUNCTION version_tokens_edit;  
DROP FUNCTION version_tokens_delete;  
DROP FUNCTION version_tokens_lock_shared;  
DROP FUNCTION version_tokens_lock_exclusive;  
DROP FUNCTION version_tokens_unlock;
```

5.6.6.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at [Section 5.6.6.2, “Installing or Uninstalling Version Tokens”](#).

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these elements:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.

Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.

If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it will issue (for example, reads versus writes), a client selects an appropriate server and connects to it.
- In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.

On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.
- The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server's version token list is empty. Token list maintenance is performed by calling user-defined functions (UDFs). The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to call any of the Version Token UDFs, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named `emp` and `prod`, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are `read` or `write` depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client sets its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the `version_tokens_set()` UDF. (There are also UDFs for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

Server 1:

```
mysql> SELECT version_tokens_set('emp=read;prod=read');
+-----+
| version_tokens_set('emp=read;prod=read') |
+-----+
| 2 version tokens set.                    |
+-----+
```

Server 2:

```
mysql> SELECT version_tokens_set('emp=write;prod=read');
+-----+
| version_tokens_set('emp=write;prod=read') |
+-----+
| 2 version tokens set.                    |
+-----+
```

Server 3:

```
mysql> SELECT version_tokens_set('emp=read;prod=write');
+-----+
| version_tokens_set('emp=read;prod=write') |
+-----+
| 2 version tokens set.                      |
+-----+
```

The token list in each case is specified as a semicolon-separated list of *name=value* pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the `emp` database.
- Only server 3 accepts updates for the `prod` database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the `emp` database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its `version_tokens_session` system variable:

```
mysql> SET @@SESSION.version_tokens_session = 'emp=write';
```

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----+-----+
| last_name | first_name |
+-----+-----+
| Smith     | Abe        |
+-----+-----+
1 row in set (0.01 sec)
```

Discrepancies between the server and client version token lists can occur two ways:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):

Server 1:

```
mysql> SELECT version_tokens_edit('emp=write');
+-----+
| version_tokens_edit('emp=write') |
+-----+
| 1 version tokens updated.          |
+-----+
```

Server 2:

```
mysql> SELECT version_tokens_edit('emp=read');
+-----+
| version_tokens_edit('emp=read') |
+-----+
| 1 version tokens updated.        |
+-----+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

Note

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of `'emp=read'`, there is nothing in Version Tokens to prevent the client from sending updates for the `emp` database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
- Perform the comparison between the server and client token lists
- Execute the statement or produce an error depending on the comparison result
- Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the user-defined included in the Version Tokens plugin library, but there are others. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked.

These UDFs permit the server's list of version tokens to be created, changed, removed, and inspected:

- `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.
- `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-----+
| version_tokens_set('tok1=a;tok2=b') |
+-----+
| 2 version tokens set.                |
+-----+
mysql> SELECT version_tokens_edit('tok3=c');
+-----+
| version_tokens_edit('tok3=c') |
+-----+
| 1 version tokens updated.      |
+-----+
mysql> SELECT version_tokens_delete('tok2;tok1');
+-----+
| version_tokens_delete('tok2;tok1') |
+-----+
| 2 version tokens deleted.          |
+-----+
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c;               |
+-----+
```

Warnings occur if a token list is malformed:

```
mysql> SELECT version_tokens_set('tok1=a; =c');
+-----+
| version_tokens_set('tok1=a; =c') |
+-----+
| 1 version tokens set.            |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 42000
Message: Invalid version token pair encountered. The list provided
        is only partially updated.
1 row in set (0.00 sec)
```

As mentioned previously, version tokens are defined using a semicolon-separated list of *name=value* pairs. Consider this invocation of `version_tokens_set()`:

```
mysql> SELECT version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3\'4')
+-----+
| version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3\'4') |
+-----+
| 3 version tokens set.                                          |
+-----+
```

Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For `version_tokens_delete()`, which takes a list of names without values, whitespace around names is ignored.)
- There is no quoting mechanism.
- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding `version_tokens_set()` call results in a token list with two tokens: `tok1` has the value `1\'2 3\'4`, and `tok2` has the value `a = b`. To verify this, call `version_tokens_show()`:

```
mysql> SELECT version_tokens_show();
```

```
+-----+
| version_tokens_show() |
+-----+
| tok2=a = b;tok1=1'2 3"4; |
+-----+
```

If the token list contains two tokens, why did `version_tokens_set()` return the value 3 `version_tokens set`? That occurred because the original token list contained two definitions for `tok1`, and the second definition replaced the first.

The Version Tokens token-manipulation UDFs place these constraints on token names and values:

- Token names cannot contain `=` or `;` characters and have a maximum length of 64 characters.
- Token values cannot contain `;` characters. Length of values is constrained by the value of the `max_allowed_packet` system variable.
- Version Tokens treats token names and values as binary strings, so comparisons are case-sensitive.

Version Tokens also includes a set of UDFs enabling tokens to be locked and unlocked:

- `version_tokens_lock_exclusive()` acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_lock_shared()` acquires shared version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_unlock()` releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 0);
+-----+
| version_tokens_lock_shared('lock1', 'lock2', 0) |
+-----+
| 1 |
+-----+

mysql> SELECT version_tokens_lock_shared(NULL, 0);
ERROR 3131 (42000): Incorrect locking service lock name '(null)'.
```

Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexistent token names. This does not create the tokens.

Note

Version Tokens locking functions are based on the locking service described at [Section 5.6.8.1, “The Locking Service”](#), and thus have the same semantics for shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service UDF interface, so those UDFs need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see [Locking Service Monitoring](#).

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and `=` and `;` characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

5.6.6.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens elements:

- [Version Tokens Functions](#)
- [Version Tokens System Variables](#)

Version Tokens Functions

The Version Tokens plugin library includes several user-defined functions. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to invoke any Version Tokens UDF.

The following UDFs permit the server's list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in [Section 5.6.6.3, "Using Version Tokens"](#), which provides details about the syntax for specifying tokens, as well as additional examples.

- `version_tokens_delete(name_list)`

Deletes tokens from the server's list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.

```
mysql> SELECT version_tokens_delete('tok1;tok3');
+-----+
| version_tokens_delete('tok1;tok3') |
+-----+
| 2 version tokens deleted.          |
+-----+
```

An argument of `NULL` is treated as an empty string, which has no effect on the token list.

`version_tokens_delete()` deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexistent tokens.) To clear the token list entirely without knowing which tokens are in the list, pass `NULL` or a string containing no tokens to `version_tokens_set()`:

```
mysql> SELECT version_tokens_set(NULL);
+-----+
| version_tokens_set(NULL) |
+-----+
| Version tokens list cleared. |
+-----+
mysql> SELECT version_tokens_set('');
+-----+
| version_tokens_set('') |
+-----+
| Version tokens list cleared. |
+-----+
```

- `version_tokens_edit(token_list)`

Modifies the server's list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is `NULL` or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set.                        |
+-----+
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
+-----+
| version_tokens_edit('tok2=new_value2;tok3=new_value3') |
+-----+
```

```
| 2 version tokens updated. |
+-----+

```

- `version_tokens_set(token_list)`

Replaces the server's list of version tokens with the tokens defined in the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is `NULL` or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set. |
+-----+

```

- `version_tokens_show()`

Returns the server's list of version tokens as a binary string containing a semicolon-separated list of `name=value` pairs.

```
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok2=value2;tok1=value1; |
+-----+

```

The following UDFs permit version tokens to be locked and unlocked:

- `version_tokens_lock_exclusive(token_name[, token_name] ..., timeout)`

Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_exclusive('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+

```

- `version_tokens_lock_shared(token_name[, token_name] ..., timeout)`

Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_shared('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+

```

- `version_tokens_unlock()`

Releases all locks that were acquired within the current session using `version_tokens_lock_exclusive()` and `version_tokens_lock_shared()`.

```
mysql> SELECT version_tokens_unlock();
+-----+
| version_tokens_unlock() |
+-----+
| 1 |
+-----+

```

The locking functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Token names are strings.
- In contrast to argument handling for the UDFs that manipulate the server token list, whitespace surrounding token name arguments is not ignored and `=` and `;` characters are permitted.
- It is possible to lock nonexistent token names. This does not create the tokens.
- Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.
- Version Tokens locking functions are based on the locking service described at [Section 5.6.8.1, “The Locking Service”](#).

Version Tokens System Variables

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see [Section 5.6.6.2, “Installing or Uninstalling Version Tokens”](#)).

System variables:

- `version_tokens_session`

Command-Line Format	<code>--version-tokens-session=value</code>
System Variable	<code>version_tokens_session</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the `version_tokens_session` variable is `NULL` (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the `version_tokens_session` variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

It is not a mismatch for the server version token list to include a token not named in the `version_tokens_session` value.

Suppose that a management application has set the server token list as follows:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+-----+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
+-----+
```

```
| 3 version tokens set. |
+-----+
```

A client registers the tokens it requires the server to match by setting its `version_tokens_session` value. Then, for each subsequent statement sent by the client, the server checks its token list against the client `version_tokens_session` value and produces an error if there is a mismatch:

```
mysql> SET @@SESSION.version_tokens_session = 'tok1=a;tok2=b';
mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+

mysql> SET @@SESSION.version_tokens_session = 'tok1=b';
mysql> SELECT 1;
ERROR 3136 (42000): Version token mismatch for tok1. Correct value a
```

The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```
mysql> SELECT version_tokens_edit('tok1=b');
+-----+
| version_tokens_edit('tok1=b') |
+-----+
| 1 version tokens updated.      |
+-----+

mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c;tok1=b;tok2=b; |
+-----+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```
mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
```

- `version_tokens_session_number`

Command-Line Format	<code>--version-tokens-session-number=#</code>
System Variable	<code>version_tokens_session_number</code>
Scope	Global, Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0

This variable is for internal use.

5.6.7 The Clone Plugin

The clone plugin permits cloning data locally or from a remote MySQL server instance. Cloned data is a physical snapshot of data stored in [InnoDB](#) that includes schemas, tables, tablespaces, and data dictionary metadata. The cloned data comprises a fully functional data directory, which permits using the clone plugin for MySQL server provisioning.

Figure 5.1 Local Cloning Operation

A local cloning operation clones data from the MySQL server instance where the cloning operation is initiated to a directory on the same server or node where MySQL server instance runs.

Figure 5.2 Remote Cloning Operation

A remote cloning operation involves a local MySQL server instance (the “recipient”) where the cloning operation is initiated, and a remote MySQL server instance (the “donor”) where the source data is located. When a remote cloning operation is initiated on the recipient, cloned data is transferred over the network from the donor to the recipient. By default, a remote cloning operation removes the data in the recipient data directory and replaces it with the cloned data. Optionally, you can clone data to a different directory on the recipient to avoid removing existing data.

There is no difference with respect to data that is cloned by a local cloning operation as compared to a remote cloning operation. Both operations clone the same data.

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts and transfers replication coordinates from the donor and applies them on the recipient, which enables

using the clone plugin for provisioning Group Replication members and replicas. Using the clone plugin for provisioning is considerably faster and more efficient than replicating a large number of transactions (see [Section 5.6.7.6, “Cloning for Replication”](#)). Group Replication members can also be configured to use the clone plugin as an alternative method of recovery, so that members automatically choose the most efficient way to retrieve group data from seed members. For more information, see [Section 18.4.3.2, “Cloning for Distributed Recovery”](#).

The clone plugin supports cloning of encrypted and page-compressed data. See [Section 5.6.7.4, “Cloning Encrypted Data”](#), and [Section 5.6.7.5, “Cloning Compressed Data”](#).

The clone plugin must be installed before you can use it. For installation instructions, see [Section 5.6.7.1, “Installing the Clone Plugin”](#). For cloning instructions, see [Section 5.6.7.2, “Cloning Data Locally”](#), and [Section 5.6.7.3, “Cloning Remote Data”](#).

Performance Schema tables and instrumentation are provided for monitoring cloning operations. See [Section 5.6.7.9, “Monitoring Cloning Operations”](#).

5.6.7.1 Installing the Clone Plugin

This section describes how to install and configure the clone plugin. For remote cloning operations, the clone plugin must be installed on the donor and recipient MySQL server instances.

For general information about installing or uninstalling plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `mysql_clone.so`. The file name suffix differs by platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=mysql_clone.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Note

The `--plugin-load-add` option cannot be used to load the clone plugin when restarting the server during an upgrade from a previous MySQL version. For example, after upgrading binaries or packages from MySQL 5.7 to MySQL 8.0, attempting to restart the server with `plugin-load-add=mysql_clone.so` causes this error: `[ERROR] [MY-013238] [Server] Error installing plugin 'clone': Cannot install during upgrade`. The workaround is to upgrade the server before attempting to start the server with `plugin-load-add=mysql_clone.so`.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` system table to cause the plugin to be loaded for each subsequent normal server startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME = 'clone';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| clone       | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for clone or plugin-related diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`, you can use the `--clone` option at server startup to control the plugin activation state. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=mysql_clone.so
clone=FORCE_PLUS_PERMANENT
```

If you want to prevent the server from running without the clone plugin, use `--clone` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For more information about plugin activation states, see [Controlling Plugin Activation State](#).

5.6.7.2 Cloning Data Locally

The clone plugin supports the following syntax for cloning data locally; that is, cloning data from the local MySQL data directory to another directory on the same server or node where the MySQL server instance runs:

```
CLONE LOCAL DATA DIRECTORY [=] 'clone_dir';
```

To use `CLONE` syntax, the clone plugin must be installed. For installation instructions, see [Section 5.6.7.1, “Installing the Clone Plugin”](#).

The `BACKUP_ADMIN` privilege is required to execute `CLONE LOCAL DATA DIRECTORY` statements.

```
mysql> GRANT BACKUP_ADMIN ON *.* TO 'clone_user';
```

where `clone_user` is the MySQL user that will perform the cloning operation. The user you select to perform the cloning operation can be any MySQL user with the `BACKUP_ADMIN` privilege on `*.*`.

The following example demonstrates cloning data locally:

```
mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/clone_dir';
```

where `/path/to/clone_dir` is the full path of the local directory that data is cloned to. An absolute path is required, and the specified directory (“`clone_dir`”) must not exist, but the specified path must be an existent path. The MySQL server must have the necessary write access to create the directory.

Note

A local cloning operation does not support cloning of user-created tables or tablespaces that reside outside of the data directory. Attempting to clone such tables or tablespaces causes the following error: `ERROR 1086 (HY000): File '/path/to/tablespace_name.ibd' already exists`. Cloning a tablespace with the same path as the source tablespace would cause a conflict and is therefore prohibited.

All other user-created InnoDB tables and tablespaces, the InnoDB system tablespace, redo logs, and undo tablespaces are cloned to the specified directory.

If desired, you can start the MySQL server on the cloned directory after the cloning operation is complete.

```
shell> mysqld_safe --datadir=clone_dir
```

where *clone_dir* is the directory that data was cloned to.

For information about monitoring cloning operation status and progress, see [Section 5.6.7.9, “Monitoring Cloning Operations”](#).

5.6.7.3 Cloning Remote Data

The clone plugin supports the following syntax for cloning remote data; that is, cloning data from a remote MySQL server instance (the donor) and transferring it to the MySQL instance where the cloning operation was initiated (the recipient).

```
CLONE INSTANCE FROM 'user'@'host':port
IDENTIFIED BY 'password'
[DATA DIRECTORY [=] 'clone_dir']
[REQUIRE [NO] SSL];
```

where:

- *user* is the clone user on the donor MySQL server instance.
- *password* is the *user* password.
- *host* is the *hostname* address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- *port* is the *port* number of the donor MySQL server instance. (The X Protocol port specified by *mysqlx_port* is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- `DATA DIRECTORY [=] 'clone_dir'` is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional `DATA DIRECTORY [=] 'clone_dir'` clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

- `[REQUIRE [NO] SSL]` explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see [Configuring an Encrypted Connection for Cloning](#).

Note

By default, user-created InnoDB tables and tablespaces that reside in the data directory on the donor MySQL server instance are cloned to the data directory on the recipient MySQL server instance. If the `DATA DIRECTORY [=] 'clone_dir'` clause is specified, they are cloned to the specified directory.

User-created [InnoDB](#) tables and tablespaces that reside outside of the data directory on the donor MySQL server instance are cloned to the same path on the recipient MySQL server instance. An error is reported if a table or tablespace already exists.

By default, the [InnoDB](#) system tablespace, redo logs, and undo tablespaces are cloned to the same locations that are configured on the donor (as defined by [innodb_data_home_dir](#) and [innodb_data_file_path](#), [innodb_log_group_home_dir](#), and [innodb_undo_directory](#), respectively). If the `DATA DIRECTORY [=] 'clone_dir'` clause is specified, those tablespaces and logs are cloned to the specified directory.

Remote Cloning Prerequisites

To perform a cloning operation, the clone plugin must be active on both the donor and recipient MySQL server instances. For installation instructions, see [Section 5.6.7.1, “Installing the Clone Plugin”](#).

A MySQL user on the donor and recipient is required for executing the cloning operation (the “clone user”).

- On the donor, the clone user requires the [BACKUP_ADMIN](#) privilege for accessing and transferring data from the donor, and for blocking DDL during the cloning operation.
- On the recipient, the clone user requires the [CLONE_ADMIN](#) privilege for replacing recipient data, blocking DDL during the cloning operation, and automatically restarting the server. The [CLONE_ADMIN](#) privilege includes [BACKUP_ADMIN](#) and [SHUTDOWN](#) privileges implicitly.

Instructions for creating the clone user and granting the required privileges are included in the remote cloning example that follows this prerequisite information.

The following prerequisites are checked when the `CLONE INSTANCE` statement is executed:

- The donor and recipient must have the same MySQL server version. The clone plugin is supported in MySQL 8.0.17 and higher.

```
mysql> SHOW VARIABLES LIKE 'version';
+-----+
| Variable_name | Value |
+-----+
| version       | 8.0.17 |
+-----+
```

- The donor and recipient MySQL server instances must run on the same operating system and platform. For example, if the donor instance runs on a Linux 64-bit platform, the recipient instance must also run on that platform. Refer to your operating system documentation for information about how to determine your operating system platform.
- The recipient must have enough disk space for the cloned data. By default, recipient data is removed prior to cloning the donor data, so you only require enough space for the donor data. If you clone to a named directory using the `DATA DIRECTORY` clause, you must have enough disk space for the existing recipient data and the cloned data. You can estimate the size of your data by checking the data directory size on your file system and the size of any tablespaces that reside outside of the data directory. When estimating data size on the donor, remember that only [InnoDB](#) data is cloned. If you store data in other storage engines, adjust your data size estimate accordingly.
- [InnoDB](#) permits creating some tablespace types outside of the data directory. If the donor MySQL server instance has tablespaces that reside outside of the data directory, the cloning operation must be able access those tablespaces. You can query the `INFORMATION_SCHEMA.FILES` table to identify tablespaces that reside outside of the data directory. Files that reside outside of the data directory have a fully qualified path to a directory other than the data directory.

```
mysql> SELECT FILE_NAME FROM INFORMATION_SCHEMA.FILES;
```

- Plugins that are active on the donor, including any keyring plugin, must also be active on the recipient. You can identify active plugins by issuing a `SHOW PLUGINS` statement or by querying the `INFORMATION_SCHEMA.PLUGINS` table.
- The donor and recipient must have the same MySQL server character set and collation. For information about MySQL server character set and collation configuration, see [Section 10.15, “Character Set Configuration”](#).
- The same `innodb_page_size` and `innodb_data_file_path` settings are required on the donor and recipient. The `innodb_data_file_path` setting on the donor and recipient must specify the same number of data files of an equivalent size. You can check variable settings using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'innodb_page_size';
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
```

- If cloning encrypted or page-compressed data, the donor and recipient must have the same file system block size. For page-compressed data, the recipient file system must support sparse files and hole punching for hole punching to occur on the recipient. For information about these features and how to identify tables and tablespaces that use them, see [Section 5.6.7.4, “Cloning Encrypted Data”](#), and [Section 5.6.7.5, “Cloning Compressed Data”](#). To determine your file system block size, refer to your operating system documentation.
- A secure connection is required if you are cloning encrypted data. See [Configuring an Encrypted Connection for Cloning](#).
- The `clone_valid_donor_list` setting on the recipient must include the host address of the donor MySQL server instance. You can only clone data from a host on the valid donor list. A MySQL user with the `SYSTEM_VARIABLES_ADMIN` privilege is required to configure this variable. Instructions for setting the `clone_valid_donor_list` variable are provided in the remote cloning example that follows this section. You can check the `clone_valid_donor_list` setting using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'clone_valid_donor_list';
```

- There must be no other cloning operation running. Only a single cloning operation is permitted at a time. To determine if a clone operation is running, query the `clone_status` table. See [Monitoring Cloning Operations using Performance Schema Clone Tables](#).
- The clone plugin transfers data in 1MB packets plus metadata. The minimum required `max_allowed_packet` value is therefore 2MB on the donor and the recipient MySQL server instances. A `max_allowed_packet` value less than 2MB results in an error. Use the following query to check your `max_allowed_packet` setting:

```
mysql> SHOW VARIABLES LIKE 'max_allowed_packet';
```

The following prerequisites also apply:

- Undo tablespace file names on the donor must be unique. When data is cloned to the recipient, undo tablespaces, regardless of their location on the donor, are cloned to the `innodb_undo_directory` location on the recipient or to the directory specified by the `DATA DIRECTORY [=] 'clone_dir'` clause, if used. Duplicate undo tablespace file names on the donor are not permitted for this reason. As of MySQL 8.0.18, an error is reported if duplicate undo tablespace file names are encountered during a cloning operation. Prior to MySQL 8.0.18, cloning undo tablespaces with the same file name could result in undo tablespace files being overwritten on the recipient.

To view undo tablespace file names on the donor to ensure that they are unique, query `INFORMATION_SCHEMA.FILES`:

```
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES
```

```
WHERE FILE_TYPE LIKE 'UNDO LOG';
```

For information about dropping and adding undo tablespace files, see [Section 15.6.3.4, “Undo Tablespaces”](#).

- By default, the recipient MySQL server instance is restarted (stopped and started) automatically after the data is cloned. For an automatic restart to occur, a monitoring process must be available on the recipient to detect server shutdowns. Otherwise, the cloning operation halts with the following error after the data is cloned, and the recipient MySQL server instance is shut down:

```
ERROR 3707 (HY000): Restart server failed (mysqld is not managed by supervisor process).
```

This error does not indicate a cloning failure. It means that the recipient MySQL server instance must be started again manually after the data is cloned. After starting the server manually, you can connect to the recipient MySQL server instance and check the Performance Schema clone tables to verify that the cloning operation completed successfully (see [Monitoring Cloning Operations using Performance Schema Clone Tables](#).) The `RESTART` statement has the same monitoring process requirement. For more information, see [Section 13.7.8.8, “RESTART Statement”](#). This requirement is not applicable if cloning to a named directory using the `DATA DIRECTORY` clause, as an automatic restart is not performed in this case.

- Several variables control various aspects of a remote cloning operation. Before performing a remote cloning operation, review the variables and adjust settings as necessary to suit your computing environment. Clone variables are set on recipient MySQL server instance where the cloning operation is executed. See [Section 5.6.7.12, “Clone System Variables”](#).

Cloning Remote Data

The following example demonstrates cloning remote data. By default, a remote cloning operation removes the data in the recipient data directory, replaces it with the cloned data, and restarts the MySQL server afterward.

The example assumes that remote cloning prerequisites are met. See [Remote Cloning Prerequisites](#).

- Login to the donor MySQL server instance with an administrative user account.

- Create a clone user with the `BACKUP_ADMIN` privilege.

```
mysql> CREATE USER 'donor_clone_user'@'example.donor.host.com' IDENTIFIED BY 'password';
mysql> GRANT BACKUP_ADMIN on *.* to 'donor_clone_user'@'example.donor.host.com';
```

- Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

- Login to the recipient MySQL server instance with an administrative user account.

- Create a clone user with the `CLONE_ADMIN` privilege.

```
mysql> CREATE USER 'recipient_clone_user'@'example.recipient.host.com' IDENTIFIED BY 'password';
mysql> GRANT CLONE_ADMIN on *.* to 'recipient_clone_user'@'example.recipient.host.com';
```

- Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

- Add the host address of the donor MySQL server instance to the `clone_valid_donor_list` variable setting.

```
mysql> SET GLOBAL clone_valid_donor_list = 'example.donor.host.com:3306';
```

- Log on to the recipient MySQL server instance as the clone user you created previously (`recipient_clone_user'@'example.recipient.host.com`) and execute the `CLONE INSTANCE` statement.

```
mysql> CLONE INSTANCE FROM 'donor_clone_user'@'example.donor.host.com':3306
IDENTIFIED BY 'password';
```

After the data is cloned, the MySQL server instance on the recipient is restarted automatically.

For information about monitoring cloning operation status and progress, see [Section 5.6.7.9, “Monitoring Cloning Operations”](#).

Cloning to a Named Directory

By default, a remote cloning operation removes the data in the recipient data directory and replaces it with the cloned data. By cloning to a named directory, you can avoid removing existing data from the recipient data directory.

The procedure for cloning to a named directory is the same procedure described in [Cloning Remote Data](#) with one exception: The `CLONE INSTANCE` statement must include the `DATA DIRECTORY` clause. For example:

```
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306
IDENTIFIED BY 'password'
DATA DIRECTORY = '/path/to/clone_dir';
```

An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When cloning to a named directory, the recipient MySQL server instance is not restarted automatically after the data is cloned. If you want to restart the MySQL server on the named directory, you must do so manually:

```
shell> mysqld_safe --datadir=/path/to/clone_dir
```

where `/path/to/clone_dir` is the path to the named directory on the recipient.

Configuring an Encrypted Connection for Cloning

You can configure an encrypted connection for remote cloning operations to protect data as it is cloned over the network. An encrypted connection is required by default when cloning encrypted data. (see [Section 5.6.7.4, “Cloning Encrypted Data”](#).)

The instructions that follow describe how to configure the recipient MySQL server instance to use an encrypted connection. It is assumed that the donor MySQL server instance is already configured to use encrypted connections. If not, refer to [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#) for server-side configuration instructions.

To configure the recipient MySQL server instance to use an encrypted connection:

1. Make the client certificate and key files of the donor MySQL server instance available to the recipient host. Either distribute the files to the recipient host using a secure channel or place them on a mounted partition that is accessible to the recipient host. The client certificate and key files to make available include:

- `ca.pem`

The self-signed certificate authority (CA) file.

- `client-cert.pem`

The client public key certificate file.

- `client-key.pem`

The client private key file.

2. Configure the following SSL options on the recipient MySQL server instance.

- `clone_ssl_ca`

Specifies the path to the self-signed certificate authority (CA) file.

- `clone_ssl_cert`

Specifies the path to the client public key certificate file.

- `clone_ssl_key`

Specifies the path to the client private key file.

For example:

```
clone_ssl_ca=/path/to/ca.pem
clone_ssl_cert=/path/to/client-cert.pem
clone_ssl_key=/path/to/client-key.pem
```

3. To require that an encrypted connection is used, include the `REQUIRE SSL` clause when issuing the `CLONE` statement on the recipient.

```
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306
      IDENTIFIED BY 'password'
      DATA DIRECTORY = '/path/to/clone_dir'
      REQUIRE SSL;
```

If an SSL clause is not specified, the clone plugin attempts to establish an encrypted connection by default, falling back to an unencrypted connection if the encrypted connection attempt fails.

Note

If you are cloning encrypted data, an encrypted connection is required by default regardless of whether the `REQUIRE SSL` clause is specified. Using `REQUIRE NO SSL` causes an error if you attempt to clone encrypted data.

5.6.7.4 Cloning Encrypted Data

Cloning of encrypted data is supported. The following requirements apply:

- A secure connection is required when cloning remote data to ensure safe transfer of unencrypted tablespace keys over the network. Tablespace keys are decrypted at the donor before transport and re-encrypted at the recipient using the recipient master key. An error is reported if an encrypted connection is not available or the `REQUIRE NO SSL` clause is used in the `CLONE INSTANCE` statement. For information about configuring an encrypted connection for cloning, see [Configuring an Encrypted Connection for Cloning](#).
- When cloning data to a local data directory that uses a locally managed keyring, the same keyring must be used when starting the MySQL server on the clone directory.
- When cloning data to a remote data directory (the recipient directory) that uses a locally managed keyring, the recipient keyring must be used when starting the MySQL server on the cloned directory.

Note

The `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt` variable settings cannot be modified while a cloning operation is in progress.

For information about the data encryption feature, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

5.6.7.5 Cloning Compressed Data

Cloning of page-compressed data is supported. The following requirements apply when cloning remote data:

- The recipient file system must support sparse files and hole punching for hole punching to occur on the recipient.
- The donor and recipient file systems must have the same block size. If file system block sizes differ, an error similar to the following is reported: `ERROR 3868 (HY000): Clone Configuration FS Block Size: Donor value: 114688 is different from Recipient value: 4096`.

For information about the page compression feature, see [Section 15.9.2, “InnoDB Page Compression”](#).

5.6.7.6 Cloning for Replication

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts replication coordinates from the donor and transfers them to the recipient, which enables using the clone plugin for provisioning Group Replication members and replicas. Using the clone plugin for provisioning is considerably faster and more efficient than replicating a large number of transactions.

Group Replication members can also be configured to use the clone plugin as an option for distributed recovery, in which case joining members automatically choose the most efficient way to retrieve group data from existing group members. For more information, see [Section 18.4.3.2, “Cloning for Distributed Recovery”](#).

During the cloning operation, both the binary log position (filename, offset) and the `gtid_executed` GTID set are extracted and transferred from the donor MySQL server instance to the recipient. This data permits initiating replication at a consistent position in the replication stream. The binary logs and relay logs, which are held in files, are not copied from the donor to the recipient. To initiate replication, the binary logs required for the recipient to catch up to the donor must not be purged between the time that the data is cloned and the time that replication is started. If the required binary logs are not available, a replication handshake error is reported. A cloned instance should therefore be added to a replication group without excessive delay to avoid required binary logs being purged or the new member lagging behind significantly, requiring more recovery time.

- Issue this query on a cloned MySQL server instance to check the binary log position that was transferred to the recipient:

```
mysql> SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
```

- Issue this query on a cloned MySQL server instance to check the `gtid_executed` GTID set that was transferred to the recipient:

```
mysql> SELECT @@GLOBAL.GTID_EXECUTED;
```

When `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` are set on the recipient (which is the default in MySQL 8.0), the replication metadata repositories are held in tables that are copied from the donor to the recipient during the cloning operation. The replication metadata repositories hold replication-related configuration settings that can be used to resume replication correctly after the cloning operation.

- In MySQL 8.0.17 and 8.0.18, only the table `mysql.slave_master_info` (the connection metadata repository) is copied.
- From MySQL 8.0.19, the tables `mysql.slave_relay_log_info` (the applier metadata repository) and `mysql.slave_worker_info` (the applier worker metadata repository) are also copied.

For a list of what is included in each table, see [Section 17.2.4.2, “Replication Metadata Repositories”](#). Note that if `master_info_repository=FILE` and `relay_log_info_repository=FILE` are set on the server (which is not the default in MySQL 8.0 and is deprecated), the replication metadata repositories are not cloned; they are only cloned if `TABLE` is set.

To clone for replication, perform the following steps:

1. For a new group member for Group Replication, first configure the MySQL Server instance for Group Replication, following the instructions in [Section 18.2.1.6, “Adding Instances to the Group”](#). Also set up the prerequisites for cloning described in [Section 18.4.3.2, “Cloning for Distributed Recovery”](#). When you issue `START GROUP REPLICATION` on the joining member, the cloning operation is managed automatically by Group Replication, so you do not need to carry out the operation manually, and you do not need to perform any further setup steps on the joining member.
2. For a replica in a source/replica MySQL replication topology, first clone the data from the donor MySQL server instance to the recipient manually. The donor must be a source or replica in the replication topology. For cloning instructions, see [Section 5.6.7.3, “Cloning Remote Data”](#).
3. After the cloning operation completes successfully, if you want to use the same replication channels on the recipient MySQL server instance that were present on the donor, verify which of them can resume replication automatically in the source/replica MySQL replication topology, and which need to be set up manually.
 - For GTID-based replication, if the recipient is configured with `gtid_mode=ON` and has cloned from a donor with `gtid_mode=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE`, the `gtid_executed` GTID set from the donor is applied on the recipient. If the recipient is cloned from a replica already in the topology, replication channels on the recipient that use GTID auto-positioning (as specified by the `MASTER_AUTO_POSITION` option on the `CHANGE MASTER TO` statement) can resume replication automatically after the cloning operation when the channel is started. You do not need to perform any manual setup if you just want to use these same channels.
 - For binary log file position based replication, if the recipient is at MySQL 8.0.17 or 8.0.18, the binary log position from the donor is not applied on the recipient, only recorded in the Performance Schema `clone_status` table. Replication channels on the recipient that use binary log file position based replication must therefore be set up manually to resume replication after the cloning operation. Ensure that these channels are not configured to start replication automatically at server startup, as they will not have the binary log position and will attempt to start replication from the beginning.
 - For binary log file position based replication, if the recipient is at MySQL 8.0.19 or above, the binary log position from the donor is applied on the recipient. Replication channels on the recipient that use binary log file position based replication automatically attempt to carry out the relay log recovery process, using the cloned relay log information, before restarting replication. For a single-threaded replica (`slave_parallel_workers` is set to 0), relay log recovery should succeed in the absence of any other issues, enabling the channel to resume replication with no further setup. For a multithreaded replica (`slave_parallel_workers` is greater than 0), relay log recovery is likely to fail because it cannot usually be completed automatically. In this case, an error message is issued, and you must set the channel up manually.
4. If you need to set up cloned replication channels manually, or want to use different replication channels on the recipient, the following instructions provide a summary and abbreviated examples for adding a recipient MySQL server instance to a replication topology. Also refer to the detailed instructions that apply to your replication setup.
 - To add a recipient MySQL server instance to a MySQL replication topology that uses GTID-based transactions as the replication data source, configure the instance as required, following the instructions in [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#). Add replication channels for the instance as shown in the following abbreviated example. The `CHANGE MASTER TO` statement must define the host address and port number of the source, and the `MASTER_AUTO_POSITION` option should be enabled, as shown:

```
mysql> CHANGE MASTER TO MASTER_HOST = 'source_host_name', MASTER_PORT = source_port_num,
...
MASTER_AUTO_POSITION = 1,
FOR CHANNEL 'setup_channel';
```

```
mysql> START SLAVE USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

- To add a recipient MySQL server instance to a MySQL replication topology that uses binary log file position based replication, configure the instance as required, following the instructions in [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#). Add replication channels for the instance as shown in the following abbreviated example, using the binary log position that was transferred to the recipient during the cloning operation:

```
mysql> SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
mysql> CHANGE MASTER TO MASTER_HOST = 'source_host_name', MASTER_PORT = source_port_num,
...
MASTER_LOG_FILE = 'source_log_name',
MASTER_LOG_POS = source_log_pos,
FOR CHANNEL 'setup_channel';
mysql> START SLAVE USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

5.6.7.7 Directories and Files Created During a Cloning Operation

When data is cloned, the following directories and files are created for internal use. They should not be modified.

- `#clone`: Contains internal clone files used by the cloning operation. Created in the directory that data is cloned to.
- `#ib_archive`: Contains internally archived log files, archived on the donor during the cloning operation.
- `*.#clone` files: Temporary data files created on the recipient while the existing data directory is replaced by a remote cloning operation.

5.6.7.8 Remote Cloning Operation Failure Handling

This section describes failure handling at different stages of a cloning operation.

1. Prerequisites are checked (see [Remote Cloning Prerequisites](#)).
 - If a failure occurs during the prerequisite check, the `CLONE INSTANCE` operation reports an error.
2. A backup lock is taken to block DDL operations.
 - If the cloning operation is unable to obtain a DDL lock within the time limit specified by the `clone_ddl_timeout` variable, an error is reported.
3. User-created data (schemas, tables, tablespaces) and binary logs on the recipient are removed before data is cloned to the recipient data directory.
 - When user created data is removed from the recipient during a remote cloning operation, existing data in the recipient data directory is not saved and may be lost if a failure occurs. If the data to be replaced on the recipient is of importance, a backup should be taken before initiating a remote cloning operation.

For informational purposes, warnings are printed to the server error log to specify when data removal starts and finishes:

```
[Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning:
Started...

[Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning:
Finished
```

If a failure occurs while removing data, the recipient may be left with a partial set of schemas, tables, and tablespaces that existed before the cloning operation. Any time during the execution of a cloning operation or after a failure, the server is always in a consistent state.

4. Data is cloned from the donor. User-created data, dictionary metadata, and other system data are cloned.

- If a failure occurs while cloning data, the cloning operation is rolled back and all cloned data removed. At this stage, the previously existing data on the recipient has also been removed, which leaves the recipient with no user data.

Should this scenario occur, you can either rectify the cause of the failure and re-execute the cloning operation, or forgo the cloning operation and restore the recipient data from a backup taken before the cloning operation.

5. The server is restarted automatically (applies to remote cloning operations that do not clone to a named directory). During startup, typical server startup tasks are performed.

- If the automatic server restart fails, you can restart the server manually to complete the cloning operation.

If a network error occurs during a cloning operation, the operation resumes if the error is resolved within five minutes. Otherwise, the operation aborts and returns an error.

5.6.7.9 Monitoring Cloning Operations

This section describes options for monitoring cloning operations.

- [Monitoring Cloning Operations using Performance Schema Clone Tables](#)
- [Monitoring Cloning Operations Using Performance Schema Stage Events](#)
- [Monitoring Cloning Operations Using Performance Schema Clone Instrumentation](#)
- [The Com_clone Status Variable](#)

Monitoring Cloning Operations using Performance Schema Clone Tables

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. You can monitor the status and progress of a cloning operation on the recipient MySQL server instance using the `clone_status` and `clone_progress` Performance Schema tables.

Note

The `clone_status` and `clone_progress` Performance Schema tables can be used to monitor a cloning operation on the recipient MySQL server instance only. To monitor a cloning operation on the donor MySQL server instance, use the clone stage events, as described in [Monitoring Cloning Operations Using Performance Schema Stage Events](#).

- The `clone_status` table provides the state of the current or last executed cloning operation. A clone operation has four possible states: `Not Started`, `In Progress`, `Completed`, and `Failed`.
- The `clone_progress` table provides progress information for the current or last executed clone operation, by stage. The stages of a cloning operation include `DROP DATA`, `FILE COPY`, `PAGE COPY`, `REDO COPY`, `FILE SYNC`, `RESTART`, and `RECOVERY`.

The `SELECT` and `EXECUTE` privileges on the Performance Schema is required to access the Performance Schema clone tables.

To check the state of a cloning operation:

1. Connect to the recipient MySQL server instance.
2. Query the `clone_status` table:

```
mysql> SELECT STATE FROM performance_schema.clone_status;
```

STATE
Completed

Should a failure occur during a cloning operation, you can query the `clone_status` table for error information:

```
mysql> SELECT STATE, ERROR_NO, ERROR_MESSAGE FROM performance_schema.clone_status;
```

STATE	ERROR_NO	ERROR_MESSAGE
Failed	xxx	"xxxxxxxxxxxxx"

To review the details of each stage of a cloning operation:

1. Connect to the recipient MySQL server instance.
2. Query the `clone_progress` table. For example, the following query provides state and end time data for each stage of the cloning operation:

```
mysql> SELECT STAGE, STATE, END_TIME FROM performance_schema.clone_progress;
```

stage	state	end_time
DROP DATA	Completed	2019-01-27 22:45:43.141261
FILE COPY	Completed	2019-01-27 22:45:44.457572
PAGE COPY	Completed	2019-01-27 22:45:44.577330
REDO COPY	Completed	2019-01-27 22:45:44.679570
FILE SYNC	Completed	2019-01-27 22:45:44.918547
RESTART	Completed	2019-01-27 22:45:48.583565
RECOVERY	Completed	2019-01-27 22:45:49.626595

For other clone status and progress data points that you can monitor, refer to [Section 26.12.17, “Performance Schema Clone Tables”](#).

Monitoring Cloning Operations Using Performance Schema Stage Events

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. There are three stage events for monitoring the progress of a cloning operation. Each stage event reports `WORK_COMPLETED` and `WORK_ESTIMATED` values. Reported values are revised as the operation progresses.

This method of monitoring a cloning operation can be used on the donor or recipient MySQL server instance.

In order of occurrence, cloning operation stage events include:

- `stage/innodb/clone (file copy)`: Indicates progress of the file copy phase of the cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are file chunks. The number of files to be transferred is known at the start of the file copy phase, and the number of chunks is estimated based on the number of files. `WORK_ESTIMATED` is set to the number of estimated file chunks. `WORK_COMPLETED` is updated after each chunk is sent.
- `stage/innodb/clone (page copy)`: Indicates progress of the page copy phase of cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are pages. Once the file copy phase is completed, the number of pages to be transferred is known, and `WORK_ESTIMATED` is set to this value. `WORK_COMPLETED` is updated after each page is sent.
- `stage/innodb/clone (redo copy)`: Indicates progress of the redo copy phase of cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are redo chunks. Once the page copy phase is completed, the number of redo chunks to be transferred is known, and `WORK_ESTIMATED` is set to this value. `WORK_COMPLETED` is updated after each chunk is sent.

The following example demonstrates how to enable `stage/innodb/clone%` event instruments and related consumer tables to monitor a cloning operation. For information about Performance Schema stage event instruments and related consumers, see [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/clone%` instruments:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
      WHERE NAME LIKE 'stage/innodb/clone%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%stages%';
```

3. Run a cloning operation. In this example, a local data directory is cloned to a directory named `cloned_dir`.

```
mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/cloned_dir';
```

4. Check the progress of the cloning operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on the cloning phase that is in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column shows the work required in total.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
      WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/clone (redo copy)	1	1

The `events_stages_current` table returns an empty set if the cloning operation has finished. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history
      WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/clone (file copy)	301	301
stage/innodb/clone (page copy)	0	0
stage/innodb/clone (redo copy)	1	1

Monitoring Cloning Operations Using Performance Schema Clone Instrumentation

[Performance Schema](#) provides instrumentation for advanced performance monitoring of clone operations. To view the available clone instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
      WHERE NAME LIKE WHERE NAME LIKE '%clone%';
```

NAME	ENABLED
wait/synch/mutex/innodb/clone_snapshot_mutex	NO
wait/synch/mutex/innodb/clone_sys_mutex	NO
wait/synch/mutex/innodb/clone_task_mutex	NO
wait/io/file/innodb/innodb_clone_file	YES
stage/innodb/clone (file copy)	YES
stage/innodb/clone (redo copy)	YES
stage/innodb/clone (page copy)	YES
statement/abstract/clone	YES
statement/clone/local	YES
statement/clone/client	YES

statement/clone/server	YES
memory/innodb/clone	YES
memory/clone/data	YES
+-----+	

Wait Instruments

Performance schema wait instruments track events that take time. Clone wait event instruments include:

- `wait/synch/mutex/innodb/clone_snapshot_mutex`: Tracks wait events for the clone snapshot mutex, which synchronizes access to the dynamic snapshot object (on the donor and recipient) between multiple clone threads.
- `wait/synch/mutex/innodb/clone_sys_mutex`: Tracks wait events for the clone sys mutex. There is one clone system object in a MySQL server instance. This mutex synchronizes access to the clone system object on the donor and recipient. It is acquired by clone threads and other foreground and background threads.
- `wait/synch/mutex/innodb/clone_task_mutex`: Tracks wait events for the clone task mutex, used for clone task management. The `clone_task_mutex` is acquired by clone threads.
- `wait/io/file/innodb/innodb_clone_file`: Tracks all I/O wait operations for files that clone operates on.

For information about monitoring InnoDB mutex waits, see [Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#). For information about monitoring wait events in general, see [Section 26.12.4, “Performance Schema Wait Event Tables”](#).

Stage Instruments

Performance Schema stage events track steps that occur during the statement-execution process. Clone stage event instruments include:

- `stage/innodb/clone (file copy)`: Indicates progress of the file copy phase of the cloning operation.
- `stage/innodb/clone (redo copy)`: Indicates progress of the redo copy phase of cloning operation.
- `stage/innodb/clone (page copy)`: Indicates progress of the page copy phase of cloning operation.

For information about monitoring cloning operations using stage events, see [Monitoring Cloning Operations Using Performance Schema Stage Events](#). For general information about monitoring stage events, see [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

Statement Instruments

Performance Schema statement events track statement execution. When a clone operation is initiated, the different statement types tracked by clone statement instruments may be executed in parallel. You can observe these statement events in the Performance Schema statement event tables. The number of statements that execute depends on the `clone_max_concurrency` and `clone_autotune_concurrency` settings.

Clone statement event instruments include:

- `statement/abstract/clone`: Tracks statement events for any clone operation before it is classified as a local, client, or server operation type.
- `statement/clone/local`: Tracks clone statement events for local clone operations; generated when executing a `CLONE LOCAL` statement.
- `statement/clone/client`: Tracks remote cloning statement events that occur on the recipient MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.

- `statement/clone/server`: Tracks remote cloning statement events that occur on the donor MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.

For information about monitoring Performance Schema statement events, see [Section 26.12.6, “Performance Schema Statement Event Tables”](#).

Memory Instruments

Performance Schema memory instruments track memory usage. Clone memory usage instruments include:

- `memory/innodb/clone`: Tracks memory allocated by InnoDB for the dynamic snapshot.
- `memory/clone/data`: Tracks memory allocated by the clone plugin during a clone operation.

For information about monitoring memory usage using Performance Schema, see [Section 26.12.18.10, “Memory Summary Tables”](#).

The Com_clone Status Variable

The `Com_clone` status variable provides a count of `CLONE` statement executions.

For more information, refer to the discussion about `Com_xxx` statement counter variables in [Section 5.1.10, “Server Status Variables”](#).

5.6.7.10 Stopping a Cloning Operation

If necessary, you can stop a cloning operation with a `KILL QUERY processlist_id` statement.

On the recipient MySQL server instance, you can retrieve the processlist identifier (PID) for a cloning operation from the `PID` column of the `clone_status` table.

```
mysql> SELECT * FROM performance_schema.clone_status\G
***** 1. row *****
      ID: 1
      PID: 8
      STATE: In Progress
  BEGIN_TIME: 2019-07-15 11:58:36.767
    END_TIME: NULL
      SOURCE: LOCAL INSTANCE
  DESTINATION: /path/to/clone_dir/
      ERROR_NO: 0
  ERROR_MESSAGE:
    BINLOG_FILE:
  BINLOG_POSITION: 0
      GTID_EXECUTED:
```

You can also retrieve the processlist identifier from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, or the `PROCESSLIST_ID` column of the Performance Schema `threads` table. These methods of obtaining the PID information can be used on the donor or recipient MySQL server instance.

5.6.7.11 Clone System Variable Reference

Table 5.6 Clone System Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
<code>clone_autotune_concurrency</code>	Yes	Yes	Yes		Global	Yes
<code>clone_buffer_size</code>	Yes	Yes	Yes		Global	Yes

5.6.7.12 Clone System Variables

This section describes the system variables that control operation of the clone plugin. If values specified at startup are incorrect, the clone plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other clone settings because it will not recognize them.

Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. They can be changed dynamically at runtime using the [SET](#) statement, which enables you to modify operation of the server without having to stop and restart it.

Setting a global system variable runtime value normally requires the [SYSTEM_VARIABLES_ADMIN](#) privilege (or the deprecated [SUPER](#) privilege). For more information, see [Section 5.1.9.1, “System Variable Privileges”](#).

Clone variables are configured on the recipient MySQL server instance where the cloning operation is executed.

- [clone_autotune_concurrency](#)

Command-Line Format	<code>--clone-autotune-concurrency</code>
Introduced	8.0.17
System Variable	clone_autotune_concurrency
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

When [clone_autotune_concurrency](#) is enabled (the default), additional threads for remote cloning operations are spawned dynamically to optimize data transfer speed. The setting is applicable to recipient MySQL server instance only.

During a cloning operation, the number of threads increases incrementally toward a target of double the current thread count. The effect on the data transfer speed is evaluated at each increment. The process either continues or stops according to the following rules:

- If the data transfer speed degrades more than 5% with an incremental increase, the process stops.
- If there is at least a 5% improvement after reaching 25% of the target, the process continues. Otherwise, the process stops.
- If there is at least a 10% improvement after reaching 50% of the target, the process continues. Otherwise, the process stops.
- If there is at least a 25% improvement after reaching the target, the process continues toward a new target of double the current thread count. Otherwise, the process stops.

The autotuning process does not support decreasing the number of threads.

The `clone_max_concurrency` variable defines the maximum number of threads that can be spawned.

If `clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

- `clone_buffer_size`

Command-Line Format	<code>--clone-buffer-size</code>
Introduced	8.0.17
System Variable	<code>clone_buffer_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4194304
Minimum Value	1048576
Maximum Value	268435456

Defines the size of the intermediate buffer used when transferring data during a local cloning operation. This setting is not applicable to remote cloning operations. The default value is 4 mebibytes (MiB). A larger buffer size may permit I/O device drivers to fetch data in parallel, which can improve cloning performance.

- `clone_ddl_timeout`

Command-Line Format	<code>--clone-ddl-timeout</code>
Introduced	8.0.17
System Variable	<code>clone_ddl_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	0
Maximum Value	2592000

The time in seconds to wait for a backup lock when executing a cloning operation. This setting is applied on both the donor and recipient MySQL server instances. A cloning operation cannot run concurrently with DDL operations. A backup lock is required on the donor and recipient MySQL server instances. The cloning operation waits for current DDL operations to finish. Once backup locks are acquired, DDL operations must wait for the cloning operation to finish. A value of 0 means that no backup lock is to be taken for the cloning operation. In this case, the cloning operation fails with an error if a DDL operation is attempted concurrently.

- `clone_enable_compression`

Command-Line Format	<code>--clone-enable-compression</code>
Introduced	8.0.17

System Variable	<code>clone_enable_compression</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enables compression of data at the network layer during a remote cloning operation. Compression saves network bandwidth at the cost of CPU. Enabling compression may improve the data transfer rate. This setting is only applied on the recipient MySQL server instance.

- `clone_max_concurrency`

Command-Line Format	<code>--clone-max-concurrency</code>
Introduced	8.0.17
System Variable	<code>clone_max_concurrency</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	128

Defines the maximum number of concurrent threads for a remote cloning operation. The default value is 16. A greater number of threads can improve cloning performance but also reduces the number of permitted simultaneous client connections, which can affect the performance of existing client connections. This setting is only applied on the recipient MySQL server instance.

If `clone_autotune_concurrency` is enabled (the default), `clone_max_concurrency` is the maximum number of threads that can be dynamically spawned for a remote cloning operation. If `clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

A minimum data transfer rate of 1 mebibyte (MiB) per thread is recommended for remote cloning operations. The data transfer rate for a remote cloning operation is controlled by the `clone_max_data_bandwidth` variable.

- `clone_max_data_bandwidth`

Command-Line Format	<code>--clone-max-data-bandwidth</code>
Introduced	8.0.17
System Variable	<code>clone_max_data_bandwidth</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1048576

Defines the maximum data transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable helps manage the performance impact of a cloning operation. A limit should be set only when donor disk I/O bandwidth is saturated, affecting performance. A value of 0 means “unlimited”, which permits cloning operations to run at the highest possible data transfer rate. This setting is only applicable to the recipient MySQL server instance.

The minimum data transfer rate is 1 MiB per second, per thread. For example, if there are 8 threads, the minimum transfer rate is 8 MiB per second. The `clone_max_concurrency` variable controls the maximum number threads spawned for a remote cloning operation.

The requested data transfer rate specified by `clone_max_data_bandwidth` may differ from the actual data transfer rate reported by the `DATA_SPEED` column in the `performance_schema.clone_progress` table. If your cloning operation is not achieving the desired data transfer rate and you have available bandwidth, check I/O usage on the recipient and donor. If there is underutilized bandwidth, I/O is the next mostly likely bottleneck.

- `clone_max_network_bandwidth`

Command-Line Format	<code>--clone-max-network-bandwidth</code>
Introduced	8.0.17
System Variable	<code>clone_max_network_bandwidth</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1048576

Specifies the maximum approximate network transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable can be used to manage the performance impact of a cloning operation on network bandwidth. It should be set only when network bandwidth is saturated, affecting performance on the donor instance. A value of 0 means “unlimited”, which permits cloning at the highest possible data transfer rate over the network, providing the best performance. This setting is only applicable to the recipient MySQL server instance.

- `clone_ssl_ca`

Command-Line Format	<code>--clone-ssl-ca=file_name</code>
Introduced	8.0.14
System Variable	<code>clone_ssl_ca</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	empty string

Specifies the path to the certificate authority (CA) file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_ssl_cert`

Command-Line Format	<code>--clone-ssl-cert=file_name</code>
Introduced	8.0.14
System Variable	<code>clone_ssl_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

Specifies the path to the public key certificate. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_ssl_key`

Command-Line Format	<code>--clone-ssl-key=file_name</code>
Introduced	8.0.14
System Variable	<code>clone_ssl_key</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

Specifies the path to the private key file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_valid_donor_list`

Command-Line Format	<code>--clone-valid-donor-list=value</code>
Introduced	8.0.17
System Variable	<code>clone_valid_donor_list</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

Defines valid donor host addresses for remote cloning operations. This setting is applied on the recipient MySQL server instance. A comma-separated list of values is permitted in the following format: `"HOST1:PORT1,HOST2:PORT2,HOST3:PORT3"`. Spaces are not permitted.

The `clone_valid_donor_list` variable adds a layer of security by providing control over the sources of cloned data. The privilege required to configure `clone_valid_donor_list` is different from the privilege required to execute remote cloning operations, which permits assigning those responsibilities to different roles. Configuring `clone_valid_donor_list` requires the

[SYSTEM_VARIABLES_ADMIN](#) privilege, whereas executing a remote cloning operation requires the [CLONE_ADMIN](#) privilege.

Internet Protocol version 6 (IPv6) address format is not supported. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.

5.6.7.13 Clone Plugin Limitations

The clone plugin is subject to these limitations:

- DDL, including [TRUNCATE TABLE](#), is not permitted during a cloning operation. This limitation should be considered when selecting data sources. A workaround is to use dedicated donor instances, which can accommodate DDL operations being blocked while data is cloned. Concurrent DML is permitted.
- An instance cannot be cloned from a different MySQL server version or release. The donor and recipient must have exactly the same MySQL server version and release. For example, you cannot clone between MySQL 5.7 and MySQL 8.0, or between MySQL 8.0.19 and MySQL 8.0.20. The clone plugin is only supported in MySQL 8.0.17 and higher.
- Only a single MySQL instance can be cloned at a time. Cloning multiple MySQL instances in a single cloning operation is not supported.
- The X Protocol port specified by [mysqlx_port](#) is not supported for remote cloning operations (when specifying the port number of the donor MySQL server instance in a [CLONE INSTANCE](#) statement).
- The clone plugin does not support cloning of MySQL server configurations. The recipient MySQL server instance retains its configuration, including persisted system variable settings (see [Section 5.1.9.3, “Persisted System Variables”](#)).
- The clone plugin does not support cloning of binary logs.
- The clone plugin only clones data stored in [InnoDB](#). Other storage engine data is not cloned. [MyISAM](#) and [CSV](#) tables stored in any schema including the [sys](#) schema are cloned as empty tables.
- Connecting to the donor MySQL server instance through MySQL Router is not supported.
- Local cloning operations do not support cloning of general tablespaces that were created with an absolute path. A cloned tablespace file with the same path as the source tablespace file would cause a conflict.

5.6.8 MySQL Plugin Services

MySQL server plugins have access to server “plugin services.” The plugin services interface complements the plugin API by exposing server functionality that plugins can call. For developer information about writing plugin services, see [MySQL Services for Plugins](#). The following sections describe plugin services available at the SQL and C-language levels.

5.6.8.1 The Locking Service

MySQL distributions provide a locking interface that is accessible at two levels:

- At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or user-defined functions.

For general information about plugin services, see [Section 5.6.8, “MySQL Plugin Services”](#). For general information about user-defined functions, see [Adding a User-Defined Function](#).

The locking interface has these characteristics:

- Locks have three attributes: Lock namespace, lock name, and lock mode:
 - Locks are identified by the combination of namespace and lock name. The namespace enables different applications to use the same lock names without colliding by creating locks in separate namespaces. For example, if applications A and B use namespaces of `ns1` and `ns2`, respectively, each application can use lock names `lock1` and `lock2` without interfering with the other application.
 - A lock mode is either read or write. Read locks are shared: If a session has a read lock on a given lock identifier, other sessions can acquire a read lock on the same identifier. Write locks are exclusive: If a session has a write lock on a given lock identifier, other sessions cannot acquire a read or write lock on the same identifier.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters. A namespace or lock name specified as `NULL`, the empty string, or a string longer than 64 characters results in an `ER_LOCKING_SERVICE_WRONG_NAME` error.
- The locking interface treats namespace and lock names as binary strings, so comparisons are case-sensitive.
- The locking interface provides functions to acquire locks and release locks. No special privilege is required to call these functions. Privilege checking is the responsibility of the calling application.
- Locks can be waited for if not immediately available. Lock acquisition calls take an integer timeout value that indicates how many seconds to wait to acquire locks before giving up. If the timeout is reached without successful lock acquisition, an `ER_LOCKING_SERVICE_TIMEOUT` error occurs. If the timeout is 0, there is no waiting and the call produces an error if locks cannot be acquired immediately.
- The locking interface detects deadlock between lock-acquisition calls in different sessions. In this case, the locking service chooses a caller and terminates its lock-acquisition request with an `ER_LOCKING_SERVICE_DEADLOCK` error. This error does not cause transactions to roll back. To choose a session in case of deadlock, the locking service prefers sessions that hold read locks over sessions that hold write locks.
- A session can acquire multiple locks with a single lock-acquisition call. For a given call, lock acquisition is atomic: The call succeeds if all locks are acquired. If acquisition of any lock fails, the call acquires no locks and fails, typically with an `ER_LOCKING_SERVICE_TIMEOUT` or `ER_LOCKING_SERVICE_DEADLOCK` error.
- A session can acquire multiple locks for the same lock identifier (namespace and lock name combination). These lock instances can be read locks, write locks, or a mix of both.
- Locks acquired within a session are released explicitly by calling a release-locks function, or implicitly when the session terminates (either normally or abnormally). Locks are not released when transactions commit or roll back.
- Within a session, all locks for a given namespace when released are released together.

The interface provided by the locking service is distinct from that provided by `GET_LOCK()` and related SQL functions (see [Section 12.15, “Locking Functions”](#)). For example, `GET_LOCK()` does not implement namespaces and provides only exclusive locks, not distinct read and write locks.

The Locking Service C Interface

This section describes how to use the locking service C language interface. To use the UDF interface instead, see [The Locking Service UDF Interface](#). For general characteristics of the locking service interface, see [Section 5.6.8.1, “The Locking Service”](#). For general information about plugin services, see [Section 5.6.8, “MySQL Plugin Services”](#).

Source files that use the locking service should include this header file:

```
#include <mysql/service_locking.h>
```

To acquire one or more locks, call this function:

```
int mysql_acquire_locking_service_locks(MYSQL_THD opaque_thd,
                                       const char* lock_namespace,
                                       const char**lock_names,
                                       size_t lock_num,
                                       enum enum_locking_service_lock_type lock_type,
                                       unsigned long lock_timeout);
```

The arguments have these meanings:

- `opaque_thd`: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- `lock_namespace`: A null-terminated string that indicates the lock namespace.
- `lock_names`: An array of null-terminated strings that provides the names of the locks to acquire.
- `lock_num`: The number of names in the `lock_names` array.
- `lock_type`: The lock mode, either `LOCKING_SERVICE_READ` or `LOCKING_SERVICE_WRITE` to acquire read locks or write locks, respectively.
- `lock_timeout`: An integer number of seconds to wait to acquire the locks before giving up.

To release locks acquired for a given namespace, call this function:

```
int mysql_release_locking_service_locks(MYSQL_THD opaque_thd,
                                       const char* lock_namespace);
```

The arguments have these meanings:

- `opaque_thd`: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- `lock_namespace`: A null-terminated string that indicates the lock namespace.

Locks acquired or waited for by the locking service can be monitored at the SQL level using the Performance Schema. For details, see [Locking Service Monitoring](#).

The Locking Service UDF Interface

This section describes how to use the locking service user-defined function (UDF) interface. To use the C language interface instead, see [The Locking Service C Interface](#). For general characteristics of the locking service interface, see [Section 5.6.8.1, “The Locking Service”](#). For general information about user-defined functions, see [Adding a User-Defined Function](#).

- [Installing or Uninstalling the UDF Locking Interface](#)
- [Using the UDF Locking Interface](#)
- [Locking Service Monitoring](#)
- [Locking Service UDF Interface Reference](#)

Installing or Uninstalling the UDF Locking Interface

The locking service routines described in [The Locking Service C Interface](#) need not be installed because they are built into the server. The same is not true of the user-defined functions (UDFs) that map onto calls to the service routines: The UDFs must be installed before use. This section describes how to do that. For general information about UDF installation, see [Section 5.7.1, “Installing and Uninstalling User-Defined Functions”](#).

The locking service UDFs are implemented in a plugin library file located in the directory named by the `plugin_dir` system variable. The file base name is `locking_service`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the locking service UDFs, use the `CREATE FUNCTION` statement, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION service_get_read_locks RETURNS INT
  SONAME 'locking_service.so';
CREATE FUNCTION service_get_write_locks RETURNS INT
  SONAME 'locking_service.so';
CREATE FUNCTION service_release_locks RETURNS INT
  SONAME 'locking_service.so';
```

If the UDFs are used on a source replication server, install them on all replica servers as well to avoid replication problems.

Once installed, the UDFs remain installed until uninstalled. To remove them, use the `DROP FUNCTION` statement:

```
DROP FUNCTION service_get_read_locks;
DROP FUNCTION service_get_write_locks;
DROP FUNCTION service_release_locks;
```

Using the UDF Locking Interface

Before using the locking service UDFs, install them according to the instructions provided at [Installing or Uninstalling the UDF Locking Interface](#).

To acquire one or more read locks, call this function:

```
mysql> SELECT service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10);
+-----+
| service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10) |
+-----+
|                                                                1 |
+-----+
```

The first argument is the lock namespace. The final argument is an integer timeout indicating how many seconds to wait to acquire the locks before giving up. The arguments in between are the lock names.

For the example just shown, the function acquires locks with lock identifiers (`myspace, rlock1`) and (`myspace, rlock2`).

To acquire write locks rather than read locks, call this function:

```
mysql> SELECT service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10);
+-----+
| service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10) |
+-----+
|                                                                1 |
+-----+
```

In this case, the lock identifiers are (`myspace, wlock1`) and (`myspace, wlock2`).

To release all locks for a namespace, use this function:

```
mysql> SELECT service_release_locks('mynamespace');
+-----+
| service_release_locks('mynamespace') |
+-----+
|                                     1 |
+-----+
```

Each locking function returns nonzero for success. If the function fails, an error occurs. For example, the following error occurs because lock names cannot be empty:

```
mysql> SELECT service_get_read_locks('myspace', '', 10);
ERROR 3131 (42000): Incorrect locking service lock name ''.
```

A session can acquire multiple locks for the same lock identifier. As long as a different session does not have a write lock for an identifier, the session can acquire any number of read or write locks. Each lock request for the identifier acquires a new lock. The following statements acquire three write locks with the same identifier, then three read locks for the same identifier:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock1', 'lock1', 0);
SELECT service_get_read_locks('ns', 'lock1', 'lock1', 'lock1', 0);
```

If you examine the Performance Schema `metadata_locks` table at this point, you will find that the session holds six distinct locks with the same (`ns`, `lock1`) identifier. (For details, see [Locking Service Monitoring](#).)

Because the session holds at least one write lock on (`ns`, `lock1`), no other session can acquire a lock for it, either read or write. If the session held only read locks for the identifier, other sessions could acquire read locks for it, but not write locks.

Locks for a single lock-acquisition call are acquired atomically, but atomicity does not hold across calls. Thus, for a statement such as the following, where `service_get_write_locks()` is called once per row of the result set, atomicity holds for each individual call, but not for the statement as a whole:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock2', 0) FROM t1 WHERE ... ;
```

Caution

Because the locking service returns a separate lock for each successful request for a given lock identifier, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT service_get_write_locks('ns', t1.col_name, 0) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

Locking Service Monitoring

The locking service is implemented using the MySQL Server metadata locks framework, so you monitor locking service locks acquired or waited for by examining the Performance Schema `metadata_locks` table.

First, enable the metadata lock instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

Then acquire some locks and check the contents of the `metadata_locks` table:

```
mysql> SELECT service_get_write_locks('myspace', 'lock1', 0);
+-----+
| service_get_write_locks('myspace', 'lock1', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT service_get_read_locks('myspace', 'lock2', 0);
+-----+
```

```
| service_get_read_locks('mynamespace', 'lock2', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT OBJECT_TYPE, OBJECT_SCHEMA, OBJECT_NAME, LOCK_TYPE, LOCK_STATUS
-> FROM performance_schema.metadata_locks
-> WHERE OBJECT_TYPE = 'LOCKING SERVICE'\G
***** 1. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: mynamespace
OBJECT_NAME: lock1
LOCK_TYPE: EXCLUSIVE
LOCK_STATUS: GRANTED
***** 2. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: mynamespace
OBJECT_NAME: lock2
LOCK_TYPE: SHARED
LOCK_STATUS: GRANTED
```

Locking service locks have an `OBJECT_TYPE` value of `LOCKING SERVICE`. This is distinct from, for example, locks acquired with the `GET_LOCK()` function, which have an `OBJECT_TYPE` of `USER LEVEL LOCK`.

The lock namespace, name, and mode appear in the `OBJECT_SCHEMA`, `OBJECT_NAME`, and `LOCK_TYPE` columns. Read and write locks have `LOCK_TYPE` values of `SHARED` and `EXCLUSIVE`, respectively.

The `LOCK_STATUS` value is `GRANTED` for an acquired lock, `PENDING` for a lock that is being waited for. You will see `PENDING` if one session holds a write lock and another session is attempting to acquire a lock having the same identifier.

Locking Service UDF Interface Reference

The SQL interface to the locking service implements the user-defined functions described in this section. For usage examples, see [Using the UDF Locking Interface](#).

The functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters.
- Timeout values must be integers indicating how many seconds to wait to acquire locks before giving up with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

These locking service UDFs are available:

- `service_get_read_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more read (shared) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_get_write_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more write (exclusive) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_release_locks(namespace)`

For the given namespace, releases all locks that were acquired within the current session using `service_get_read_locks()` and `service_get_write_locks()`.

It is not an error for there to be no locks in the namespace.

5.6.8.2 The Keyring Service

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. MySQL distributions provide a keyring interface that is accessible at two levels:

- At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or user-defined functions.

This section describes how to use the keyring service functions to store, retrieve, and remove keys in the MySQL keyring keystore. For information about the SQL interface that uses UDFs, [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#). For general keyring information, see [Section 6.4.4, “The MySQL Keyring”](#).

The keyring service uses whatever underlying keyring plugin is enabled, if any. If no keyring plugin is enabled, keyring service calls fail.

A “record” in the keystore consists of data (the key itself) and a unique identifier through which the key is accessed. The identifier has two parts:

- **key_id**: The key ID or name. **key_id** values that begin with `mysql_` are reserved by MySQL Server.
- **user_id**: The session effective user ID. If there is no user context, this value can be `NULL`. The value need not actually be a “user”; the meaning depends on the application.

Functions that implement the keyring UDF interface pass the value of `CURRENT_USER()` as the **user_id** value to keyring service functions.

The keyring service functions have these characteristics in common:

- Each function returns 0 for success, 1 for failure.
- The **key_id** and **user_id** arguments form a unique combination indicating which key in the keyring to use.
- The **key_type** argument provides additional information about the key, such as its encryption method or intended use.
- Keyring service functions treat key IDs, user names, types, and values as binary strings, so comparisons are case sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

These keyring service functions are available:

- `my_key_fetch()`

Deobfuscates and retrieves a key from the keyring, along with its type. The function allocates the memory for the buffers used to store the returned key and key type. The caller should zero or obfuscate the memory when it is no longer needed, then free it.

Syntax:

```
bool my_key_fetch(const char *key_id, const char **key_type,
                  const char* user_id, void **key, size_t *key_len)
```

Arguments:

- **key_id**, **user_id**: Null-terminated strings that as a pair form a unique identifier indicating which key to fetch.

- `key_type`: The address of a buffer pointer. The function stores into it a pointer to a null-terminated string that provides additional information about the key (stored when the key was added).
- `key`: The address of a buffer pointer. The function stores into it a pointer to the buffer containing the fetched key data.
- `key_len`: The address of a variable into which the function stores the size in bytes of the `*key` buffer.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_generate()`

Generates a new random key of a given type and length and stores it in the keyring. The key has a length of `key_len` and is associated with the identifier formed from `key_id` and `user_id`. The type and length values must be consistent with the values supported by the underlying keyring plugin. See [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

Syntax:

```
bool my_key_generate(const char *key_id, const char *key_type,
                    const char *user_id, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be generated.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key_len`: The size in bytes of the key to be generated.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_remove()`

Removes a key from the keyring.

Syntax:

```
bool my_key_remove(const char *key_id, const char* user_id)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be removed.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_store()`

Obfuscates and stores a key in the keyring.

Syntax:

```
bool my_key_store(const char *key_id, const char *key_type,
```

```
const char* user_id, void *key, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be stored.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key`: The buffer containing the key data to be stored.
- `key_len`: The size in bytes of the `key` buffer.

Return value:

Returns 0 for success, 1 for failure.

5.7 MySQL Server User-Defined Functions

MySQL Server enables user-defined functions (UDFs) to be created and loaded into the server to extend server capabilities. Server capabilities can be implemented in whole or in part using UDFs. In addition, you can write your own UDFs.

The following sections describe how to install and uninstall UDFs, and how to determine at runtime which UDFs are installed and obtain information about them. For a table listing user-defined functions, see [Section 12.2, “User-Defined Function Reference”](#). For information about writing UDFs, see [Adding Functions to MySQL](#).

5.7.1 Installing and Uninstalling User-Defined Functions

User-defined functions (UDFs) must be loaded into the server before they can be used. MySQL supports manual UDF loading at runtime and automatic loading during server startup.

While a UDF is loaded, information about it is available as described in [Section 5.7.2, “Obtaining User-Defined Function Information”](#).

- [Installing User-Defined Functions](#)
- [Uninstalling User-Defined Functions](#)
- [Reinstalling or Upgrading User-Defined Functions](#)

Installing User-Defined Functions

To load a UDF manually, use the `CREATE FUNCTION` statement. For example:

```
CREATE FUNCTION metaphon
  RETURNS STRING
  SONAME 'udf_example.so';
```

The UDF file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

`CREATE FUNCTION` has these effects:

- It loads the UDF into the server to make it available immediately.
- It registers the UDF in the `mysql.func` system table to make it persistent across server restarts. For this reason, `CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database.
- It adds the UDF to the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs. See [Section 5.7.2, “Obtaining User-Defined Function Information”](#).

Automatic UDF loading occurs during the normal server startup sequence:

- UDFs registered in the `mysql.func` table are installed.
- Server components or plugins that are installed at startup may automatically install related UDFs.
- Automatic UDF installation adds the UDFs to the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs.

If the server is started with the `--skip-grant-tables` option, UDFs registered in the `mysql.func` table are not loaded and are unavailable. This does not apply to UDFs installed automatically by a component or plugin.

Uninstalling User-Defined Functions

To remove a UDF, use the `DROP FUNCTION` statement. For example:

```
DROP FUNCTION metaphon;
```

`DROP FUNCTION` has these effects:

- It unloads the UDF to make it unavailable.
- It removes the UDF from the `mysql.func` system table. For this reason, `DROP FUNCTION` requires the `DELETE` privilege for the `mysql` system database. With the UDF no longer registered in the `mysql.func` table, the server does not load the UDF during subsequent restarts.
- It removes the UDF from the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs.

`DROP FUNCTION` cannot be used to drop a UDF that is installed automatically by server components or plugins rather than by using `CREATE FUNCTION`. Such a UDF is also dropped automatically, when the component or plugin that installed it is uninstalled.

Reinstalling or Upgrading User-Defined Functions

To reinstall or upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

5.7.2 Obtaining User-Defined Function Information

The Performance Schema `user_defined_functions` table contains information about the currently installed user-defined functions (UDFs):

```
SELECT * FROM performance_schema.user_defined_functions;
```

The `mysql.func` system table also lists installed UDFs, but only those installed using `CREATE FUNCTION`. The `user_defined_functions` table lists UDFs installed using `CREATE FUNCTION` as well as UDFs installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which UDFs are installed. See [Section 26.12.19.9, “The user_defined_functions Table”](#).

5.8 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.7 and one from MySQL 8.0, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 4.2.2, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 5.8.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause each server to listen to a different address.

- `--socket={file_name|pipe_name}`

`--socket` controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[=file_name]`
- `--slow_query_log_file=file_name`
- `--log-error[=file_name]`

For further discussion of log file options, see [Section 5.4, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

5.8.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See [Section 2.10, “Postinstallation Setup and Testing”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.

- Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

5.8.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 5.8, “Running Multiple MySQL Instances on One Machine”](#).

5.8.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.4.6, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
```

```
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

5.8.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-8.0.23`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 8.0.23.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 8.0.23 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 8.0.23. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
```

```
[mysqld1]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-8.0.23
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-8.0.23\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:

```
C:\> SC START mysqld1
C:\> SC START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` or `SC STOP` with the appropriate service names:

```
C:\> SC STOP mysqld1
C:\> SC STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 8.0.23 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-8.0.23
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
      --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-8.0.23\bin\mysqld --install mysqld2
      --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `SC DELETE mysqld_service_name` for each one. Alternatively, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it when using `mysqld --remove`.

5.8.3 Running Multiple MySQL Instances on Unix

Note

The discussion here uses `mysqld_safe` to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by `systemd` on several Linux platforms. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For information about using `systemd` to handle multiple MySQL instances, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.7 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 8.0.23 server to have different operating parameters, use a `CMake` command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
             -DMYSQL_UNIX_ADDR=file_name \
             -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-8.0.23
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file rather than TCP/IP. To explicitly specify the transport protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
```

```
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> bin/mysqld --initialize --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 4.9, “Environment Variables”](#), includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See [Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”](#).

5.8.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 4.9, “Environment Variables”](#).
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 4.2.2.2, “Using Option Files”](#).
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [C API Function Descriptions](#).
- If you are using the Perl `DBD:mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test:mysql_read_default_group=client;"
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See [Section 28.9, “MySQL Perl API”](#).

Other programming interfaces may provide similar capabilities for reading option files.

5.9 Debugging MySQL

This section describes debugging techniques that assist efforts to track down problems in MySQL.

5.9.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 5, MySQL Server Administration](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.1, “General Installation Guidance”](#).

5.9.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

5.9.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become **very large**! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see [Section 1.6, “How to Report Bugs or Problems”](#).

The trace file is made with the **DEBUG** package by Fred Fish. See [Section 5.9.4, “The DEBUG Package”](#).

5.9.1.3 Using WER with PDB to create a Windows crashdump

Program Database files (with suffix `.pdb`) are included in the **ZIP Archive Debug Binaries & Test Suite** distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem. This is a separate download from the standard MSI or Zip file.

Note

The PDB files are available in a separate file labeled "ZIP Archive Debug Binaries & Test Suite".

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with `WinDbg` or Visual Studio to debug `mysqld`.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

To use WinDbg, either install the full Windows Driver Kit (WDK) or install the standalone version.

Important

The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition) or WinDBG will complain while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.
2. Create a directory to store the generated files, such as `c:\symbols`
3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`
4. Launch `windbg.exe` giving it the paths to `mysqld.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
windbg.exe -i "C:\mysql-8.0.23-winx64\bin\" ^
-z "C:\mysql-8.0.23-winx64\data\mysqld.dmp" ^
-srcpath "E:\ade\mysql_archives\8.0\8.0.23\mysql-8.0.23" ^
-y "C:\mysql-8.0.23-winx64\bin\SRV*c:\symbols*http://msdl.microsoft.com/download/symbols" ^
-v -n -c "!analyze -vvvvv"
```

**Note**

The ^ character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.

5.9.1.4 Debugging mysqld under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time.

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for `SIGINT` (needed to stop `mysqld` with ^C to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` does not free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See [Section B.3.3.3, "What to Do If MySQL Keeps Crashing"](#).

If you are using `gdb` on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in [Section 1.6, “How to Report Bugs or Problems”](#).

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

5.9.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 5.4.2, “The Error Log”](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See [Section 5.9.1.1, “Compiling MySQL for Debugging”](#).

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
/lib/libpthread.so.0[0x7f1a5af000f0]
/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPKcS2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDP4ListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z21mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parseP3THDPKcjPS2_+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THDPcj+0xbb7)[0x67fdf8]
mysqld(_Z10do_commandP3THD+0x24d)[0x6811b6]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x67fdf8]
[0x6811b6]
[0x66e05e]
```

Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for an unexpected exit within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (`+0x9a6`) into a file name and line number, use this command:

```
shell> addr2line -file auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -file auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

5.9.1.6 Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See [Section 5.4.3, “The General Query Log”](#). When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 13.8.2, “EXPLAIN Statement”](#).

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See [Section 5.4.5, “The Slow Query Log”](#).

If you find the text `mysqld restarted` in the error log (normally a file named `host_name.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 5, MySQL Server Administration](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see [Section 1.6, “How to Report Bugs or Problems”](#).

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 5.1.7, “Server Command Options”](#).

When the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example:

Got an error from thread_id=1, mi_dynrec.c:368. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

5.9.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to `MyISAM` tables. For information about steps to take when encountering `InnoDB` table corruption, see [Section 1.6, “How to Report Bugs or Problems”](#).

If you encounter corrupted `MyISAM` tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See [Section 5.4.3, “The General Query Log”](#), and [Section 5.4.4, “The Binary Log”](#).
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restore the backup.
9. Restart the `mysqld` server *without* the binary log enabled.
10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you are a support customer, you can use the MySQL Customer Support Center (<https://www.mysql.com/support/>) to alert the MySQL team about the problem and have it fixed as soon as possible.

5.9.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1`. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See [Section 1.6, “How to Report Bugs or Problems”](#).

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

5.9.3 The LOCK_ORDER Tool

The MySQL server is a multithreaded application that uses numerous internal locking and lock-related primitives, such as mutexes, rwlocks (including prlocks and sxlocks), conditions, and files. Within the server, the set of lock-related objects changes with implementation of new features and code refactoring for performance improvements. As with any multithreaded application that uses locking primitives, there is always a risk of encountering a deadlock during execution when multiple locks are held at once. For MySQL, the effect of a deadlock is catastrophic, causing a complete loss of service.

As of MySQL 8.0.17, to enable detection of lock-acquisition deadlocks and enforcement that runtime execution is free of them, MySQL supports LOCK_ORDER tooling. This enables a lock-order dependency graph to be defined as part of server design, and server runtime checking to ensure that lock acquisition is acyclic and that execution paths comply with the graph.

This section provides information about using the LOCK_ORDER tool, but only at a basic level. For complete details, see the Lock Order section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.

The LOCK_ORDER tool is intended for debugging the server, not for production use.

To use the LOCK_ORDER tool, follow this procedure:

1. Build MySQL from source, configuring it with the `-DWITH_LOCK_ORDER=ON` CMake option so that the build includes LOCK_ORDER tooling.

**Note**

With the `WITH_LOCK_ORDER` option enabled, MySQL builds require the `flex` program.

2. To run the server with the LOCK_ORDER tool enabled, enable the `lock_order` system variable at server startup. Several other system variables for LOCK_ORDER configuration are available as well.
3. For MySQL test suite operation, `mysql-test-run.pl` has a `--lock-order` option that controls whether to enable the LOCK_ORDER tool during test case execution.

The system variables described following configure operation of the LOCK_ORDER tool, assuming that MySQL has been built to include LOCK_ORDER tooling. The primary variable is `lock_order`, which indicates whether to enable the LOCK_ORDER tool at runtime:

- If `lock_order` is disabled (the default), no other LOCK_ORDER system variables have any effect.
- If `lock_order` is enabled, the other system variables configure which LOCK_ORDER features to enable.

**Note**

In general, it is intended that the LOCK_ORDER tool be configured by executing `mysql-test-run.pl` with the `--lock-order` option, and for `mysql-test-run.pl` to set LOCK_ORDER system variables to appropriate values.

All LOCK_ORDER system variables must be set at server startup. At runtime, their values are visible but cannot be changed.

Some system variables exist in pairs, such as `lock_order_debug_loop` and `lock_order_trace_loop`. For such pairs, the variables are distinguished as follows when the condition occurs with which they are associated:

- If the `_debug_` variable is enabled, a debug assertion is raised.
- If the `_trace_` variable is enabled, an error is printed to the logs.

Table 5.7 LOCK_ORDER System Variable Summary

Variable Name	Variable Type	Variable Scope
<code>lock_order</code>	Boolean	Global
<code>lock_order_debug_loop</code>	Boolean	Global
<code>lock_order_debug_missing_arc</code>	Boolean	Global
<code>lock_order_debug_missing_key</code>	Boolean	Global
<code>lock_order_debug_missing_unlock</code>	Boolean	Global
<code>lock_order_dependencies</code>	File name	Global
<code>lock_order_extra_dependencies</code>	File name	Global
<code>lock_order_output_directory</code>	Directory name	Global
<code>lock_order_print_txt</code>	Boolean	Global
<code>lock_order_trace_loop</code>	Boolean	Global
<code>lock_order_trace_missing_arc</code>	Boolean	Global
<code>lock_order_trace_missing_key</code>	Boolean	Global
<code>lock_order_trace_missing_unlock</code>	Boolean	Global

- `lock_order`

Command-Line Format	<code>--lock-order[={OFF ON}]</code>
Introduced	8.0.17
System Variable	<code>lock_order</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to enable the LOCK_ORDER tool at runtime. If `lock_order` is disabled (the default), no other LOCK_ORDER system variables have any effect. If `lock_order` is enabled, the other system variables configure which LOCK_ORDER features to enable.

If `lock_order` is enabled, an error is raised if the server encounters a lock-acquisition sequence that is not declared in the lock-order graph.

- `lock_order_debug_loop`

Command-Line Format	<code>--lock-order-debug-loop[={OFF ON}]</code>
Introduced	8.0.17
System Variable	<code>lock_order_debug_loop</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a dependency that is flagged as a loop in the lock-order graph.

- [lock_order_debug_missing_arc](#)

Command-Line Format	<code>--lock-order-debug-missing-arc[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_debug_missing_arc
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a dependency that is not declared in the lock-order graph.

- [lock_order_debug_missing_key](#)

Command-Line Format	<code>--lock-order-debug-missing-key[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_debug_missing_key
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters an object that is not properly instrumented with the Performance Schema.

- [lock_order_debug_missing_unlock](#)

Command-Line Format	<code>--lock-order-debug-missing-unlock[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_debug_missing_unlock
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a lock that is destroyed while still held.

- [lock_order_dependencies](#)

Command-Line Format	<code>--lock-order-dependencies=file_name</code>
Introduced	8.0.17
System Variable	<code>lock_order_dependencies</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

The path to the `lock_order_dependencies.txt` file that defines the server lock-order dependency graph.

It is permitted to specify no dependencies. An empty dependency graph is used in this case.

- `lock_order_extra_dependencies`

Command-Line Format	<code>--lock-order-extra-dependencies=file_name</code>
Introduced	8.0.17
System Variable	<code>lock_order_extra_dependencies</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

The path to a file containing additional dependencies for the lock-order dependency graph. This is useful to amend the primary server dependency graph, defined in the `lock_order_dependencies.txt` file, with additional dependencies describing the behavior of third party code. (The alternative is to modify `lock_order_dependencies.txt` itself, which is not encouraged.)

If this variable is not set, no secondary file is used.

- `lock_order_output_directory`

Command-Line Format	<code>--lock-order-output-directory=dir_name</code>
Introduced	8.0.17
System Variable	<code>lock_order_output_directory</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>empty string</code>

The directory where the LOCK_ORDER tool writes its logs. If this variable is not set, the default is the current directory.

- `lock_order_print_txt`

Command-Line Format	<code>--lock-order-print-txt[={OFF ON}]</code>
---------------------	--

Introduced	8.0.17
System Variable	lock_order_print_txt
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool performs a lock-order graph analysis and prints a textual report. The report includes any lock-acquisition cycles detected.

- [lock_order_trace_loop](#)

Command-Line Format	<code>--lock-order-trace-loop[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_trace_loop
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a dependency that is flagged as a loop in the lock-order graph.

- [lock_order_trace_missing_arc](#)

Command-Line Format	<code>--lock-order-trace-missing-arc[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_trace_missing_arc
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a dependency that is not declared in the lock-order graph.

- [lock_order_trace_missing_key](#)

Command-Line Format	<code>--lock-order-trace-missing-key[={OFF ON}]</code>
Introduced	8.0.17
System Variable	lock_order_trace_missing_key
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters an object that is not properly instrumented with the Performance Schema.

- `lock_order_trace_missing_unlock`

Command-Line Format	<code>--lock-order-trace-missing-unlock[={OFF ON}]</code>
Introduced	8.0.17
System Variable	<code>lock_order_trace_missing_unlock</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a lock that is destroyed while still held.

5.9.4 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See [Section 5.9.1.2, “Creating Trace Files”](#).

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.

The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `-# [debug_options]` option. If you specify the `--debug` or `-#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysql_d.trace` on Unix and `d:t:i:O,\\mysql_d.trace` on Windows. The effect of this default is:

- `d`: Enable output for all debug macros
- `t`: Trace function calls and exits
- `i`: Add PID to output lines
- `o,/tmp/mysql_d.trace, O, \\mysql_d.trace`: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\\mysql_d.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changing the global `debug` value requires privileges sufficient to set global system variables. Changing the session `debug` value requires privileges sufficient to set restricted session system variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `-` character, and optionally followed by a comma-separated list of modifiers:

```
[+|-]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

Flag	Description
<code>d</code>	Enable output from <code>DEBUG_XXX</code> macros for the current state. May be followed by a list of keywords, which enables output only for the DBUG macros with that keyword. An empty list of keywords enables output for all macros. In MySQL, common debug macro keywords to enable are <code>enter</code> , <code>exit</code> , <code>error</code> , <code>warning</code> , <code>info</code> , and <code>loop</code> .
<code>D</code>	Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, <code>D,20</code> specifies a delay of two seconds.
<code>f</code>	Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
<code>F</code>	Identify the source file name for each line of debug or trace output.
<code>i</code>	Identify the process with the PID or thread ID for each line of debug or trace output.
<code>L</code>	Identify the source file line number for each line of debug or trace output.
<code>n</code>	Print the current function nesting depth for each line of debug or trace output.
<code>N</code>	Number each line of debug output.
<code>o</code>	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
<code>O</code>	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
<code>p</code>	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
<code>P</code>	Print the current process name for each line of debug or trace output.
<code>r</code>	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
<code>S</code>	Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0.
<code>t</code>	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

The leading `+` or `-` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `-`, the flag value is set to exactly the modifier list as given.
- With a leading `+` or `-`, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the `d` flag. An empty `d` list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the `d` value to the modifier list as given:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d       |
+-----+
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,error,warning |
+-----+
```

A leading `+` or `-` adds to or subtracts from the current `d` value:

```
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,error,warning,loop |
+-----+

mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,warning |
+-----+
```

Adding to “all macros enabled” results in no change:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d       |
+-----+

mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d       |
+-----+
```

Disabling all enabled macros disables the `d` flag entirely:

```
mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,error,loop |
+-----+

mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
|         |
+-----+
```

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 6.1, “General Security Issues”](#).
- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.10, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 6.2, “Access Control and Account Management”](#).
- The features offered by security-related plugins. See [Section 6.4, “Security Components and Plugins”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 7, Backup and Recovery](#).

6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 2.10, “Postinstallation Setup and Testing”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 8.0 FAQ: Security”](#).

6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections

between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` system database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 6.2, “Access Control and Account Management”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.10.4, “Securing the Initial MySQL Account”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()` or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 6.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another

technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. In addition, the `validate_password` plugin can be used to enforce a policy on acceptable password. See [Section 6.4.3, “The Password Validation Component”](#).

6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).
- Use a `--password=password` or `-ppassword` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

Warning

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `--password` or `-p` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
```

```
Enter password: *****
```

The `*` characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=password
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

[Section 4.2.2.2, “Using Option Files”](#), discusses option files in more detail.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 4.5.1.3, “mysql Client Logging”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER` and `ALTER USER`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` system table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See [Section 6.2.15, “Password Management”](#), and [Section 6.2.16, “Server Handling of Expired Passwords”](#).

The `validate_password` plugin can be used to enforce a policy on acceptable password. See [Section 6.4.3, “The Password Validation Component”](#).

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT` and `SET PASSWORD`. If such statements are logged by the MySQL server as written, password in them become visible to anyone with access to the logs.

Statement logging avoids writing password as cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
SET PASSWORD ...
START SLAVE ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...)
ALTER SERVER ... OPTIONS(... PASSWORD ...)
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` system table that refer to literal password are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. See [Section 6.4.5.3, “MySQL Enterprise Audit Security Considerations”](#).

Statements received by the server may be rewritten if a query rewrite plugin is installed (see [Query Rewrite Plugins](#)). In this case, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text password are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replicas store the password for the replication source server in their connection metadata repository, which by default is a table in the `mysql` database named `slave_master_info`. The use of a file in the data directory for the connection metadata repository is now deprecated, but still possible (see [Section 17.2.4, “Relay Log and Replication Metadata Repositories”](#)). Ensure that the connection metadata repository can be accessed only by the database administrator. An alternative to storing the password in the connection metadata repository is to use the `START SLAVE` or `START GROUP_REPLICATION` statement to specify credentials for connecting to the source.

Use a restricted access mode to protect database backups that include log tables or log files containing password.

6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection.

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 6.3, "Using Encrypted Connections"](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a comparison of both Open Source and Commercial SSH clients at http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 6.2.14, "Assigning Account Passwords"](#).

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.
- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 6.1.5, "How to Run MySQL as a Normal User"](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO outfile` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 5.1.8, “Server System Variables”](#).

- Encrypt binary log files and relay log files. Encryption helps to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see [Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).
- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users.

`mysqld` reserves an extra connection for users who have the `CONNECTION_ADMIN` or `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See [Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).
- Stored programs and views should be written using the security guidelines discussed in [Section 24.6, “Stored Object Access Control”](#).
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `CREATE USER` and `ALTER USER` statements also support resource control options for limiting the extent of server use permitted to an account. See [Section 13.7.1.3, “CREATE USER Statement”](#), and [Section 13.7.1.1, “ALTER USER Statement”](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

6.1.4 Security-Related mysqld Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see [Section 5.1.7, “Server Command Options”](#), and [Section 5.1.8, “Server System Variables”](#).

Table 6.1 Security Option and Variable Summary

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
allow-suspicious-udfs	Yes	Yes				
automatic_sp_privileges	Yes	Yes	Yes		Global	Yes
chroot	Yes	Yes				
local_infile	Yes	Yes	Yes		Global	Yes
safe-user-create	Yes	Yes

6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository or RPM packages, the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the MySQL repositories.

On Unix (or Linux for installations performed using `tar.gz` packages), the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.10.4, “Securing the Initial MySQL Account”](#).

6.1.6 Security Considerations for LOAD DATA LOCAL

The `LOAD DATA` statement loads a data file into a table. The statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

The `LOCAL` version of `LOAD DATA` has two potential security issues:

- Because `LOAD DATA LOCAL` is an SQL statement, parsing occurs on the server side, and transfer of the file from the client host to the server host is initiated by the MySQL server, which tells the

client the file named in the statement. In theory, a patched server could tell the client program to transfer a file of the server's choosing rather than the file named in the statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.

To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the `--ssl-mode=VERIFY_IDENTITY` option and the appropriate CA certificate.

To avoid `LOAD DATA` issues, clients should avoid using `LOCAL` unless proper client-side precautions have been taken.

For control over local data loading, MySQL permits the capability to be enabled or disabled. In addition, as of MySQL 8.0.21, MySQL enables clients to restrict local data loading operations to files located in a designated directory.

- [Enabling or Disabling Local Data Loading Capability](#)
- [Restricting Files Permitted for Local Data Loading](#)

Enabling or Disabling Local Data Loading Capability

Administrators and applications can configure whether to permit local data loading as follows:

- On the server side:
 - The `local_infile` system variable controls server-side `LOCAL` capability. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that request local data loading.
 - By default, `local_infile` is disabled. To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled. `local_infile` can also be set at runtime.
- On the client side:
 - The `ENABLED_LOCAL_INFILE` CMake option controls the compiled-in default `LOCAL` capability for the MySQL client library (see [Section 2.9.7, “MySQL Source-Configuration Options”](#)). Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.
 - By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` disabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled.
 - For client programs that use the C API, local data loading capability is determined by the default compiled into the MySQL client library. To enable or disable it explicitly, invoke the `mysql_options()` C API function to disable or enable the `MYSQL_OPT_LOCAL_INFILE` option. See [mysql_options\(\)](#).
 - For the `mysql` client, local data loading capability is determined by the default compiled into the MySQL client library. To disable or enable it explicitly, use the `--local-infile=0` or `--local-infile=1` option.

- For the `mysqlimport` client, local data loading is not used by default. To disable or enable it explicitly, use the `--local=0` or `--local[=1]` option.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add a `local-infile` option setting to that group. To prevent problems for programs that do not understand this option, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=0
```

or:

```
[client]
loose-local-infile=1
```

- In all cases, successful use of a `LOCAL` load operation by a client also requires that the server permits local loading.

If `LOCAL` capability is disabled, on either the server or client side, a client that attempts to issue a `LOAD DATA LOCAL` statement receives the following error message:

```
ERROR 3950 (42000): Loading local data is disabled; this must be
enabled on both the client and server side
```

Restricting Files Permitted for Local Data Loading

As of MySQL 8.0.21, the MySQL client library enables client applications to restrict local data loading operations to files located in a designated directory. Certain MySQL client programs take advantage of this capability.

Client programs that use the C API can control which files to permit for load data loading using the `MYSQL_OPT_LOCAL_INFILE` and `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` options of the `mysql_options()` C API function (see `mysql_options()`).

The effect of `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` depends on whether `LOCAL` data loading is enabled or disabled:

- If `LOCAL` data loading is enabled, either by default in the MySQL client library or by explicitly enabling `MYSQL_OPT_LOCAL_INFILE`, the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option has no effect.
- If `LOCAL` data loading is disabled, either by default in the MySQL client library or by explicitly disabling `MYSQL_OPT_LOCAL_INFILE`, the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option can be used to designate a permitted directory for locally loaded files. In this case, `LOCAL` data loading is permitted but restricted to files located in the designated directory. Interpretation of the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` value is as follows:
 - If the value is the null pointer (the default), it names no directory, with the result that no files are permitted for `LOCAL` data loading.
 - If the value is a directory path name, `LOCAL` data loading is permitted but restricted to files located in the named directory. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case-sensitivity of the underlying file system.

MySQL client programs use the preceding `mysql_options()` options as follows:

- The `mysql` client has a `--load-data-local-dir` option that takes a directory path or an empty string. `mysql` uses the option value to set the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option (with an empty string setting the value to the null pointer). The effect of `--load-data-local-dir` depends on whether `LOCAL` data loading is enabled:
 - If `LOCAL` data loading is enabled, either by default in the MySQL client library or by specifying `--local-infile[=1]`, the `--load-data-local-dir` option is ignored.

- If `LOCAL` data loading is disabled, either by default in the MySQL client library or by specifying `--local-infile=0`, the `--load-data-local-dir` option applies.

When `--load-data-local-dir` applies, the option value designates the directory in which local data files must be located. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case-sensitivity of the underlying file system. If the option value is the empty string, it names no directory, with the result that no files are permitted for local data loading.

- `mysqlimport` sets `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` for each file that it processes so that the directory containing the file is the permitted local loading directory.
- For data loading operations corresponding to `LOAD DATA` statements, `mysqlbinlog` extracts the files from the binary log events, writes them as temporary files to the local file system, and writes `LOAD DATA LOCAL` statements to cause the files to be loaded. By default, `mysqlbinlog` writes these temporary files to an operating system-specific directory. The `--local-load` option can be used to explicitly specify the directory where `mysqlbinlog` should prepare local temporary files.

Because other processes can write files to the default system-specific directory, it is advisable to specify the `--local-load` option to `mysqlbinlog` to designate a different directory for data files, and then designate that same directory by specifying the `--load-data-local-dir` option to `mysql` when processing the output from `mysqlbinlog`.

6.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like `; DROP DATABASE mysql;`. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Section 5.1.11, “Server SQL Modes”](#).
- Try to enter single and double quotation marks (`'` and `"`) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` (`"`), `%23` (`#`), and `%27` (`'`) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.

- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string_quote()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also [Choosing an API](#).

If the older `ext/mysql` extension must be used, then for escaping use the `mysql_real_escape_string_quote()` function and not `mysql_escape_string()` or `addslashes()` because only `mysql_real_escape_string_quote()` is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

- Perl DBI: Use placeholders or the `quote()` method.
- Ruby DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

6.2 Access Control and Account Management

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 13.7.1, “Account Management Statements”](#).

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the `mysql` system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:

Stage 1: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#), and [Section 6.2.7, “Access Control, Stage 2: Request Verification”](#). For help in diagnosing privilege-related problems, see [Section 6.2.21, “Troubleshooting Problems Connecting to MySQL”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 6.2.13, “When Privilege Changes Take Effect”](#).

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

6.2.1 Account User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see [Section 6.2.3, “Grant Tables”](#).

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See [Section 6.2.17, “Pluggable Authentication”](#).

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.
- MySQL user names are up to 32 characters long. Operating system user names may have a different maximum length.

Warning

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Section 2.11, “Upgrading MySQL”](#). Attempting to redefine MySQL's system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.

- To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the `user` table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the `user` table are encrypted using plugin-specific algorithms.
- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in [Section 10.4, “Connection Character Sets and Collations”](#). For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial `root` account, as described in [Section 2.10.4, “Securing the Initial MySQL Account”](#), which also discusses how to assign a password to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See [Section 6.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”](#), and [Section 13.7.1, “Account Management Statements”](#).

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -ppassword db_name
```

If you use the `-p` option, there must be *no space* between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). To avoid giving the password on the command line, use an option file or a login path file. See [Section 4.2.2.2, “Using Option Files”](#), and [Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about specifying user names, passwords, and other connection parameters, see [Section 4.2.4, “Connecting to the MySQL Server Using Command Options”](#).

6.2.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Privileges also differ in terms of whether they are static (built in to the server) or dynamic (defined at runtime). Whether a privilege is static or dynamic affects its availability to be granted to user accounts and roles. For information about the differences between static and dynamic privileges, see [Static Versus Dynamic Privileges](#).)

Information about account privileges is stored in the grant tables in the `mysql` system database. For a description of the structure and contents of these tables, see [Section 6.2.3, “Grant Tables”](#). The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in [Section 6.2.13, “When Privilege Changes Take Effect”](#). The server bases access-control decisions on the in-memory copies of the grant tables.

Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See [Section 2.11, “Upgrading MySQL”](#).

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

- [Summary of Available Privileges](#)
- [Static Privilege Descriptions](#)
- [Dynamic Privilege Descriptions](#)
- [Privilege-Granting Guidelines](#)
- [Static Versus Dynamic Privileges](#)
- [Migrating Accounts from SUPER to Dynamic Privileges](#)

Summary of Available Privileges

The following table shows the static privilege names used in `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

Table 6.2 Permissible Static Privileges for GRANT and REVOKE

Privilege	Grant Table Column	Context
ALL [PRIVILEGES]	Synonym for “all privileges”	Server administration
ALTER	Alter_priv	Tables
ALTER ROUTINE	Alter_routine_priv	Stored routines
CREATE	Create_priv	Databases, tables, or indexes
CREATE ROLE	Create_role_priv	Server administration
CREATE ROUTINE	Create_routine_priv	Stored routines
CREATE TABLESPACE	Create_tablespace_priv	Server administration
CREATE TEMPORARY TABLES	Create_tmp_table_priv	Tables
CREATE USER	Create_user_priv	Server administration
CREATE VIEW	Create_view_priv	Views
DELETE	Delete_priv	Tables
DROP	Drop_priv	Databases, tables, or views
DROP ROLE	Drop_role_priv	Server administration
EVENT	Event_priv	Databases
EXECUTE	Execute_priv	Stored routines
FILE	File_priv	File access on server host
GRANT OPTION	Grant_priv	Databases, tables, or stored routines
INDEX	Index_priv	Tables
INSERT	Insert_priv	Tables or columns
LOCK TABLES	Lock_tables_priv	Databases
PROCESS	Process_priv	Server administration
PROXY	See proxies_priv table	Server administration
REFERENCES	References_priv	Databases or tables
RELOAD	Reload_priv	Server administration
REPLICATION CLIENT	Repl_client_priv	Server administration
REPLICATION SLAVE	Repl_slave_priv	Server administration
SELECT	Select_priv	Tables or columns
SHOW DATABASES	Show_db_priv	Server administration
SHOW VIEW	Show_view_priv	Views
SHUTDOWN	Shutdown_priv	Server administration
SUPER	Super_priv	Server administration
TRIGGER	Trigger_priv	Tables
UPDATE	Update_priv	Tables or columns
USAGE	Synonym for “no privileges”	Server administration

The following table shows the dynamic privilege names used in `GRANT` and `REVOKE` statements, along with the context in which the privilege applies.

Table 6.3 Permissible Dynamic Privileges for GRANT and REVOKE

Privilege	Context
APPLICATION_PASSWORD_ADMIN	Dual password administration

Privilege	Context
AUDIT_ADMIN	Audit log administration
BACKUP_ADMIN	Backup administration
BINLOG_ADMIN	Backup and Replication administration
BINLOG_ENCRYPTION_ADMIN	Backup and Replication administration
CLONE_ADMIN	Clone administration
CONNECTION_ADMIN	Server administration
ENCRYPTION_KEY_ADMIN	Server administration
FIREWALL_ADMIN	Firewall administration
FIREWALL_USER	Firewall administration
GROUP_REPLICATION_ADMIN	Replication administration
INNODB_REDO_LOG_ARCHIVE	Redo log archiving administration
NDB_STORED_USER	NDB Cluster
PERSIST_RO_VARIABLES_ADMIN	Server administration
REPLICATION_APPLIER	PRIVILEGE_CHECKS_USER for a replication channel
REPLICATION_SLAVE_ADMIN	Replication administration
RESOURCE_GROUP_ADMIN	Resource group administration
RESOURCE_GROUP_USER	Resource group administration
ROLE_ADMIN	Server administration
SESSION_VARIABLES_ADMIN	Server administration
SET_USER_ID	Server administration
SHOW_ROUTINE	Server administration
SYSTEM_USER	Server administration
SYSTEM_VARIABLES_ADMIN	Server administration
TABLE_ENCRYPTION_ADMIN	Server administration
VERSION_TOKEN_ADMIN	Server administration
XA_RECOVER_ADMIN	Server administration

Static Privilege Descriptions

Static privileges are built in to the server, in contrast to dynamic privileges, which are defined at runtime. The following list describes each static privilege available in MySQL.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- [ALL, ALL PRIVILEGES](#)

These privilege specifiers are shorthand for “all privileges available at a given privilege level” (except [GRANT OPTION](#)). For example, granting [ALL](#) at the global or table level grants all global privileges or all table-level privileges, respectively.

- [ALTER](#)

Enables use of the [ALTER TABLE](#) statement to change the structure of tables. [ALTER TABLE](#) also requires the [CREATE](#) and [INSERT](#) privileges. Renaming a table requires [ALTER](#) and [DROP](#) on the old table, [CREATE](#), and [INSERT](#) on the new table.

- [ALTER ROUTINE](#)

Enables use of statements that alter or drop stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine [DEFINER](#), also enables access to routine properties other than the routine definition.

- [CREATE](#)

Enables use of statements that create new databases and tables.

- [CREATE ROLE](#)

Enables use of the [CREATE ROLE](#) statement. (The [CREATE USER](#) privilege also enables use of the [CREATE ROLE](#) statement.) See [Section 6.2.10, “Using Roles”](#).

The [CREATE ROLE](#) and [DROP ROLE](#) privileges are not as powerful as [CREATE USER](#) because they can be used only to create and drop accounts. They cannot be used as [CREATE USER](#) can be modify account attributes or rename accounts. See [User and Role Interchangeability](#).

- [CREATE ROUTINE](#)

Enables use of statements that create stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine [DEFINER](#), also enables access to routine properties other than the routine definition.

- [CREATE TABLESPACE](#)

Enables use of statements that create, alter, or drop tablespaces and log file groups.

- [CREATE TEMPORARY TABLES](#)

Enables the creation of temporary tables using the [CREATE TEMPORARY TABLE](#) statement.

After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as [DROP TABLE](#), [INSERT](#), [UPDATE](#), or [SELECT](#). For more information, see [Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”](#).

- [CREATE USER](#)

Enables use of the [ALTER USER](#), [CREATE ROLE](#), [CREATE USER](#), [DROP ROLE](#), [DROP USER](#), [RENAME USER](#), and [REVOKE ALL PRIVILEGES](#) statements.

- [CREATE VIEW](#)

Enables use of the [CREATE VIEW](#) statement.

- [DELETE](#)

Enables rows to be deleted from tables in a database.

- [DROP](#)

Enables use of statements that drop (remove) existing databases, tables, and views. The [DROP](#) privilege is required to use the [ALTER TABLE ... DROP PARTITION](#) statement on a partitioned table. The [DROP](#) privilege is also required for [TRUNCATE TABLE](#).

- [DROP ROLE](#)

Enables use of the [DROP ROLE](#) statement. (The [CREATE USER](#) privilege also enables use of the [DROP ROLE](#) statement.) See [Section 6.2.10, “Using Roles”](#).

The `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` because they can be used only to create and drop accounts. They cannot be used as `CREATE USER` can be used to modify account attributes or rename accounts. See [User and Role Interchangeability](#).

- `EVENT`

Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

- `EXECUTE`

Enables use of statements that execute stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine `DEFINER`, also enables access to routine properties other than the routine definition.

- `FILE`

Affects the following operations and server behaviors:

- Enables reading and writing files on the server host using the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.)
- Enables creating new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables.
- Enables use of the `DATA DIRECTORY` or `INDEX DIRECTORY` table option for the `CREATE TABLE` statement.

As a security measure, the server does not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system variable to a specific directory. See [Section 5.1.8, "Server System Variables"](#).

- `GRANT OPTION`

Enables you to grant to or revoke from other users those privileges that you yourself possess.

- `INDEX`

Enables use of statements that create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

- `INSERT`

Enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.

- `LOCK TABLES`

Enables use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

- `PROCESS`

The `PROCESS` privilege controls access to information about threads executing within the server (that is, information about statements being executed by sessions). Thread information available

using the `SHOW PROCESSLIST` statement, the `mysqladmin processlist` command, the `INFORMATION_SCHEMA.PROCESSLIST` table, and the Performance Schema `processlist` table is accessible as follows:

- With the `PROCESS` privilege, a user has access to information about all threads, even those belonging to other users.
- Without the `PROCESS` privilege, nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

**Note**

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See [Section 26.12.19.7, “The threads Table”](#).

The `PROCESS` privilege also enables use of the `SHOW ENGINE` statement, access to the `INFORMATION_SCHEMA.InnoDB` tables (tables with names that begin with `INNODB_`), and (as of MySQL 8.0.21) access to the `INFORMATION_SCHEMA.FILES` table.

- `PROXY`

Enables one user to impersonate or become known as another user. See [Section 6.2.18, “Proxy Users”](#).

- `REFERENCES`

Creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table.

- `RELOAD`

Enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

The `RELOAD` privilege also enables use of the `RESET MASTER` and `RESET SLAVE` statements.

- `REPLICATION CLIENT`

Enables use of the `SHOW MASTER STATUS`, `SHOW SLAVE STATUS`, and `SHOW BINARY LOGS` statements. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server.

- `REPLICATION SLAVE`

Enables the account to request updates that have been made to databases on the replication source server, using the `SHOW REPLICAS` | `SHOW SLAVE HOSTS`, `SHOW RELAYLOG EVENTS`, and `SHOW BINLOG EVENTS` statements. This privilege is also required to use the `mysqlbinlog` options `--read-from-remote-server` (`-R`) and `--read-from-remote-master`. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server.

- `SELECT`

Enables rows to be selected from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually access tables. Some `SELECT` statements do not access tables and can

be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;  
SELECT PI()*2;
```

The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

The `SELECT` privilege is needed for tables or views used with `EXPLAIN`, including any underlying tables in view definitions.

- `SHOW DATABASES`

Enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- `SHOW VIEW`

Enables use of the `SHOW CREATE VIEW` statement. This privilege is also needed for views used with `EXPLAIN`.

- `SHUTDOWN`

Enables use of the `SHUTDOWN` and `RESTART` statements, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.

- `SUPER`

`SUPER` is a powerful and far-reaching privilege and should not be granted lightly. If an account needs to perform only a subset of `SUPER` operations, it may be possible to achieve the desired privilege set

by instead granting one or more dynamic privileges, each of which confers more limited capabilities. See [Dynamic Privilege Descriptions](#).

**Note**

`SUPER` is deprecated and will be removed in a future version of MySQL. See [Migrating Accounts from SUPER to Dynamic Privileges](#).

`SUPER` affects the following operations and server behaviors:

- Enables system variable changes at runtime:
 - Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`.

The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.

- Enables setting restricted session system variables that require a special privilege.

The corresponding dynamic privilege is `SESSION_VARIABLES_ADMIN`.

See also [Section 5.1.9.1, “System Variable Privileges”](#).

- Enables changes to global transaction characteristics (see [Section 13.3.7, “SET TRANSACTION Statement”](#)).

The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.

- Enables the account to start and stop replication, including Group Replication.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN` for regular replication, `GROUP_REPLICATION_ADMIN` for Group Replication.

- Enables use of the `CHANGE MASTER TO` and `CHANGE REPLICATION FILTER` statements.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN`.

- Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

The corresponding dynamic privilege is `BINLOG_ADMIN`.

- Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.

The corresponding dynamic privilege is `SET_USER_ID`.

- Enables use of the `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.
- Enables use of the `mysqladmin debug` command.
- Enables `InnoDB` encryption key rotation.

The corresponding dynamic privilege is `ENCRYPTION_KEY_ADMIN`.

- Enables execution of Version Tokens user-defined functions.

The corresponding dynamic privilege is `VERSION_TOKEN_ADMIN`.

- Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function.

The corresponding dynamic privilege is `ROLE_ADMIN`.

- Enables control over client connections not permitted to non-`SUPER` accounts:
 - Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)
 - The server does not execute `init_connect` system variable content when `SUPER` clients connect.
 - The server accepts one connection from a `SUPER` client even if the connection limit configured by the `max_connections` system variable is reached.
 - A server in offline mode (`offline_mode` enabled) does not terminate `SUPER` client connections at the next client request, and accepts new connections from `SUPER` clients.
 - Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

The corresponding dynamic privilege for the preceding connection-control operations is `CONNECTION_ADMIN`.

You may also need the `SUPER` privilege to create or alter stored functions if binary logging is enabled, as described in [Section 24.7, “Stored Program Binary Logging”](#).

- `TRIGGER`

Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

When a trigger is activated (by a user who has privileges to execute `INSERT`, `UPDATE`, or `DELETE` statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the `TRIGGER` privilege for the table.

- `UPDATE`

Enables rows to be updated in tables in a database.

- `USAGE`

This privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to specify clauses such as `WITH GRANT OPTION` without naming specific account privileges in the privilege list. `SHOW GRANTS` displays `USAGE` to indicate that an account has no privileges at a privilege level.

Dynamic Privilege Descriptions

Dynamic privileges are defined at runtime, in contrast to static privileges, which are built in to the server. The following list describes each dynamic privilege available in MySQL.

Most dynamic privileges are defined at server startup. Others are defined by a particular server component or plugin, as indicated in the privilege descriptions. In such cases, the privilege is unavailable unless the component or plugin that defines it is enabled.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- `APPLICATION_PASSWORD_ADMIN` (added in MySQL 8.0.14)

For dual-password capability, this privilege enables use of the `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses for `ALTER USER` and `SET PASSWORD` statements that apply to

your own account. This privilege is required to manipulate your own secondary password because most users require only one password.

If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

For more information about use of dual passwords, see [Section 6.2.15, “Password Management”](#).

- `AUDIT_ADMIN`

Enables audit log configuration. This privilege is defined by the `audit_log` plugin; see [Section 6.4.5, “MySQL Enterprise Audit”](#).

- `BACKUP_ADMIN`

Enables execution of the `LOCK INSTANCE FOR BACKUP` statement and access to the Performance Schema `log_status` table.

**Note**

Besides `BACKUP_ADMIN`, the `SELECT` privilege on the `log_status` table is also needed for its access.

The `BACKUP_ADMIN` privilege is automatically granted to users with the `RELOAD` privilege when performing an in-place upgrade to MySQL 8.0 from an earlier version.

- `BINLOG_ADMIN`

Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

- `BINLOG_ENCRYPTION_ADMIN`

Enables setting the system variable `binlog_encryption`, which activates or deactivates encryption for binary log files and relay log files. This ability is not provided by the `BINLOG_ADMIN`, `SYSTEM_VARIABLES_ADMIN`, or `SESSION_VARIABLES_ADMIN` privileges. The related system variable `binlog_rotate_encryption_master_key_at_startup`, which rotates the binary log master key automatically when the server is restarted, does not require this privilege.

- `CLONE_ADMIN`

Enables execution of the `CLONE` statements. Includes `BACKUP_ADMIN` and `SHUTDOWN` privileges.

- `CONNECTION_ADMIN`

Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

Enables setting system variables related to client connections, or circumventing restrictions related to client connections. `CONNECTION_ADMIN` applies to the effects of these system variables:

- `init_connect`: The server does not execute `init_connect` system variable content when `CONNECTION_ADMIN` clients connect.
- `max_connections`: The server accepts one connection from a `CONNECTION_ADMIN` client even if the connection limit configured by the `max_connections` system variable is reached.
- `offline_mode`: A server in offline mode (`offline_mode` enabled) does not terminate `CONNECTION_ADMIN` client connections at the next client request, and accepts new connections from `CONNECTION_ADMIN` clients.
- `read_only`: Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

- `ENCRYPTION_KEY_ADMIN`

Enables InnoDB encryption key rotation.

- `FIREWALL_ADMIN`

Enables a user to administer firewall rules for any user. This privilege is defined by the `MYSQL_FIREWALL` plugin; see [Section 6.4.7, “MySQL Enterprise Firewall”](#).

- `FIREWALL_USER`

Enables users to update their own firewall rules. This privilege is defined by the `MYSQL_FIREWALL` plugin; see [Section 6.4.7, “MySQL Enterprise Firewall”](#).

- `GROUP_REPLICATION_ADMIN`

Enables the account to start and stop Group Replication using the `START GROUP REPLICATION` and `STOP GROUP REPLICATION` statements, to change the global setting for the `group_replication_consistency` system variable, and to use the `group_replication_set_write_concurrency()` and `group_replication_set_communication_protocol()` UDFs. Grant this privilege to accounts that are used to administer servers that are members of a replication group.

- `INNODB_REDO_LOG_ARCHIVE`

Enables the account to activate and deactivate redo log archiving.

- `INNODB_REDO_LOG_ENABLE`

Enables use of the `ALTER INSTANCE {ENABLE|DISABLE} INNODB REDO_LOG` statement to enable or disable redo logging. Introduced in MySQL 8.0.21.

See [Disabling Redo Logging](#).

- `NDB_STORED_USER`

Enables the user or role and its privileges to be shared and synchronized between all `NDB`-enabled MySQL servers as soon as they join a given `NDB` Cluster. This privilege is available only if the `NDB` storage engine is enabled.

Any changes to or revocations of privileges made for the given user or role are synchronized immediately with all connected MySQL servers (SQL nodes). You should be aware that there is no guarantee that multiple statements affecting privileges originating from different SQL nodes are executed on all SQL nodes in the same order. For this reason, it is highly recommended that all user administration be done from a single designated SQL node.

`NDB_STORED_USER` is a global privilege and must be granted or revoked using `ON *.*`. Trying to set any other scope for this privilege results in an error. This privilege can be given to most application and administrative users, but it cannot be granted to system reserved accounts such as `mysql.session@localhost` or `mysql.infoschema@localhost`.

A user that has been granted the `NDB_STORED_USER` privilege is stored in `NDB` (and thus shared by all SQL nodes), as is a role with this privilege. A user that is merely granted a role that has `NDB_STORED_USER` is *not* stored in `NDB`; each `NDB` stored user must be granted the privilege explicitly.

For more detailed information about how this works in `NDB`, see [Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#).

The `NDB_STORED_USER` privilege is available beginning with `NDB 8.0.18`.

- `PERSIST_RO_VARIABLES_ADMIN`

For users who also have `SYSTEM_VARIABLES_ADMIN`, `PERSIST_RO_VARIABLES_ADMIN` enables use of `SET PERSIST_ONLY` to persist global system variables to the `mysqld-auto.cnf` option file in the data directory. This statement is similar to `SET PERSIST` but does not modify the runtime global system variable value. This makes `SET PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

See also [Section 5.1.9.1, “System Variable Privileges”](#).

- `REPLICATION_APPLIER`

Enables the account to act as the `PRIVILEGE_CHECKS_USER` for a replication channel, and to execute `BINLOG` statements in `mysqlbinlog` output. Grant this privilege to accounts that are assigned using `CHANGE MASTER TO` to provide a security context for replication channels, and to handle replication errors on those channels. As well as the `REPLICATION_APPLIER` privilege, you must also give the account the required privileges to execute the transactions received by the replication channel or contained in the `mysqlbinlog` output, for example to update the affected tables. For more information, see [Section 17.3.3, “Replication Privilege Checks”](#).

- `REPLICATION_SLAVE_ADMIN`

Enables the account to connect to the replication source server, start and stop replication using the `START SLAVE` and `STOP SLAVE` statements, and use the `CHANGE MASTER TO` and `CHANGE REPLICATION FILTER` statements. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server. This privilege does not apply to Group Replication; use `GROUP_REPLICATION_ADMIN` for that.

- `RESOURCE_GROUP_ADMIN`

Enables resource group management, consisting of creating, altering, and dropping resource groups, and assignment of threads and statements to resource groups. A user with this privilege can perform any operation relating to resource groups.

- [RESOURCE_GROUP_USER](#)

Enables assigning threads and statements to resource groups. A user with this privilege can use the [SET RESOURCE GROUP](#) statement and the [RESOURCE_GROUP](#) optimizer hint.

- [ROLE_ADMIN](#)

Enables granting and revoking roles, use of the [WITH ADMIN OPTION](#) clause of the [GRANT](#) statement, and nonempty `<graphml>` element content in the result from the [ROLES_GRAPHML\(\)](#) function. Required to set the value of the [mandatory_roles](#) system variable.

- [SERVICE_CONNECTION_ADMIN](#)

Enables connections to the network interface that permits only administrative connections (see [Section 5.1.12.1, “Connection Interfaces”](#)).

- [SESSION_VARIABLES_ADMIN](#) (added in MySQL 8.0.14)

For most system variables, setting the session value requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value can have effects outside the current session and thus is a restricted operation. For these, the [SESSION_VARIABLES_ADMIN](#) privilege enables the user to set the session value.

If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include [binlog_format](#), [sql_log_bin](#), and [sql_log_off](#).

Prior to MySQL 8.0.14 when [SESSION_VARIABLES_ADMIN](#) was added, restricted session system variables can be set only by users who have the [SYSTEM_VARIABLES_ADMIN](#) or [SUPER](#) privilege.

The [SESSION_VARIABLES_ADMIN](#) privilege is a subset of the [SYSTEM_VARIABLES_ADMIN](#) and [SUPER](#) privileges. A user who has either of those privileges is also permitted to set restricted session variables and effectively has [SESSION_VARIABLES_ADMIN](#) by implication and need not be granted [SESSION_VARIABLES_ADMIN](#) explicitly.

See also [Section 5.1.9.1, “System Variable Privileges”](#).

- [SET_USER_ID](#)

Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account as the [DEFINER](#) attribute of a view or stored program.

As of MySQL 8.0.22, [SET_USER_ID](#) also enables overriding security checks designed to prevent operations that (perhaps inadvertently) cause stored objects to become orphaned or that cause adoption of stored objects that are currently orphaned. For details, see [Orphan Stored Objects](#).

- [SHOW_ROUTINE](#) (added in MySQL 8.0.20)

Enables a user to access definitions and properties of all stored routines (stored procedures and functions), even those for which the user is not named as the routine [DEFINER](#). This access includes:

- The contents of the [INFORMATION_SCHEMA.ROUTINES](#) table.
- The [SHOW CREATE FUNCTION](#) and [SHOW CREATE PROCEDURE](#) statements.
- The [SHOW FUNCTION CODE](#) and [SHOW PROCEDURE CODE](#) statements.
- The [SHOW FUNCTION STATUS](#) and [SHOW PROCEDURE STATUS](#) statements.

Prior to MySQL 8.0.20, for a user to access definitions of routines the user did not define, the user must have the global [SELECT](#) privilege, which is very broad. As of 8.0.20, [SHOW_ROUTINE](#) may be

granted instead as a privilege with a more restricted scope that permits access to routine definitions. (That is, an administrator can rescind global [SELECT](#) from users that do not otherwise require it and grant [SHOW_ROUTINE](#) instead.) This enables an account to back up stored routines without requiring a broad privilege.

- [SYSTEM_USER](#) (added in MySQL 8.0.16)

The [SYSTEM_USER](#) privilege distinguishes system users from regular users:

- A user with the [SYSTEM_USER](#) privilege is a system user.
- A user without the [SYSTEM_USER](#) privilege is a regular user.

The [SYSTEM_USER](#) privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of [SYSTEM_USER](#) to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.
- A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

For more information, see [Section 6.2.11, “Account Categories”](#).

The protection against modification by regular accounts that is afforded to system accounts by the [SYSTEM_USER](#) privilege does not apply to regular accounts that have privileges on the [mysql](#) system schema and thus can directly modify the grant tables in that schema. For full protection, do not grant [mysql](#) schema privileges to regular accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).

- [SYSTEM_VARIABLES_ADMIN](#)

Affects the following operations and server behaviors:

- Enables system variable changes at runtime:
 - Enables server configuration changes to global system variables with [SET GLOBAL](#) and [SET PERSIST](#).
 - Enables server configuration changes to global system variables with [SET PERSIST_ONLY](#), if the user also has [PERSIST_RO_VARIABLES_ADMIN](#).
 - Enables setting restricted session system variables that require a special privilege. In effect, [SYSTEM_VARIABLES_ADMIN](#) implies [SESSION_VARIABLES_ADMIN](#) without explicitly granting [SESSION_VARIABLES_ADMIN](#).

See also [Section 5.1.9.1, “System Variable Privileges”](#).

- Enables changes to global transaction characteristics (see [Section 13.3.7, “SET TRANSACTION Statement”](#)).
- [TABLE_ENCRYPTION_ADMIN](#) (added in MySQL 8.0.16)

Enables a user to override default encryption settings when [table_encryption_privilege_check](#) is enabled; see [Defining an Encryption Default for Schemas and General Tablespaces](#).

- `VERSION_TOKEN_ADMIN`

Enables execution of Version Tokens user-defined functions. This privilege is defined by the `version_tokens` plugin; see [Section 5.6.6, “Version Tokens”](#).

- `XA_RECOVER_ADMIN`

Enables execution of the `XA RECOVER` statement; see [Section 13.3.8.1, “XA Transaction SQL Statements”](#).

Prior to MySQL 8.0, any user could execute the `XA RECOVER` statement to discover the XID values for outstanding prepared XA transactions, possibly leading to commit or rollback of an XA transaction by a user other than the one who started it. In MySQL 8.0, `XA RECOVER` is permitted only to users who have the `XA_RECOVER_ADMIN` privilege, which is expected to be granted only to administrative users who have need for it. This might be the case, for example, for administrators of an XA application if it has crashed and it is necessary to find outstanding transactions started by the application so they can be rolled back. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

Privilege-Granting Guidelines

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- `FILE` can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- `GRANT OPTION` enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.
- `ALTER` may be used to subvert the privilege system by renaming tables.
- `SHUTDOWN` can be abused to deny service to other users entirely by terminating the server.
- `PROCESS` can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- `SUPER` can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` system database itself can be used to change passwords and other access privilege information:
 - Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `mysql.user` system table `authentication_string` column can change an account's password, and then connect to the MySQL server using that account.
 - `INSERT` or `UPDATE` granted for the `mysql` system database enable a user to add privileges or modify existing privileges, respectively.
 - `DROP` for the `mysql` system database enables a user to remove privilege tables, or even the database itself.

Static Versus Dynamic Privileges

MySQL supports static and dynamic privileges:

- Static privileges are built in to the server. They are always available to be granted to user accounts and cannot be unregistered.

- Dynamic privileges can be registered and unregistered at runtime. This affects their availability: A dynamic privilege that has not been registered cannot be granted.

For example, the [SELECT](#) and [INSERT](#) privileges are static and always available, whereas a dynamic privilege becomes available only if the server component that implements it has been enabled.

The remainder of this section describes how dynamic privileges work in MySQL. The discussion uses the term “components” but applies equally to plugins.

**Note**

Server administrators should be aware of which server components define dynamic privileges. For MySQL distributions, documentation of components that define dynamic privileges describes those privileges.

Third-party components may also define dynamic privileges; an administrator should understand those privileges and not install components that might conflict or compromise server operation. For example, one component conflicts with another if both define a privilege with the same name. Component developers can reduce the likelihood of this occurrence by choosing privilege names having a prefix based on the component name.

The server maintains the set of registered dynamic privileges internally in memory. Unregistration occurs at server shutdown.

Normally, a server component that defines dynamic privileges registers them when it is installed, during its initialization sequence. When uninstalled, a server component does not unregister its registered dynamic privileges. (This is current practice, not a requirement. That is, components could, but do not, unregister at any time privileges they register.)

No warning or error occurs for attempts to register an already registered dynamic privilege. Consider the following sequence of statements:

```
INSTALL COMPONENT 'my_component';
UNINSTALL COMPONENT 'my_component';
INSTALL COMPONENT 'my_component';
```

The first [INSTALL COMPONENT](#) statement registers any privileges defined by server component [my_component](#), but [UNINSTALL COMPONENT](#) does not unregister them. For the second [INSTALL COMPONENT](#) statement, the component privileges it registers are found to be already registered, but no warnings or errors occur.

Dynamic privileges apply only at the global level. The server stores information about current assignments of dynamic privileges to user accounts in the [mysql.global_grants](#) system table:

- The server automatically registers privileges named in [global_grants](#) during server startup (unless the [--skip-grant-tables](#) option is given).
- The [GRANT](#) and [REVOKE](#) statements modify the contents of [global_grants](#).
- Dynamic privilege assignments listed in [global_grants](#) are persistent. They are not removed at server shutdown.

Example: The following statement grants to user [u1](#) the privileges required to control replication (including Group Replication) on a replica, and to modify system variables:

```
GRANT REPLICATION_SLAVE_ADMIN, GROUP_REPLICATION_ADMIN, BINLOG_ADMIN
ON *.* TO 'u1'@'localhost';
```

Granted dynamic privileges appear in the output from the [SHOW GRANTS](#) statement and the [INFORMATION_SCHEMA.USER_PRIVILEGES](#) table.

For [GRANT](#) and [REVOKE](#) at the global level, any named privileges not recognized as static are checked against the current set of registered dynamic privileges and granted if found. Otherwise, an error occurs to indicate an unknown privilege identifier.

For [GRANT](#) and [REVOKE](#) the meaning of [ALL \[PRIVILEGES\]](#) at the global level includes all static global privileges, as well as all currently registered dynamic privileges:

- [GRANT ALL](#) at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the [GRANT](#) statement is not granted retroactively to any account.
- [REVOKE ALL](#) at the global level revokes all granted static global privileges and all granted dynamic privileges.

The [FLUSH PRIVILEGES](#) statement reads the [global_grants](#) table for dynamic privilege assignments and registers any unregistered privileges found there.

For descriptions of the dynamic privileges provided by MySQL Server and server components included in MySQL distributions, see [Section 6.2.2, “Privileges Provided by MySQL”](#).

Migrating Accounts from SUPER to Dynamic Privileges

In MySQL 8.0, many operations that previously required the [SUPER](#) privilege are also associated with a dynamic privilege of more limited scope. (For descriptions of these privileges, see [Section 6.2.2, “Privileges Provided by MySQL”](#).) Each such operation can be permitted to an account by granting the associated dynamic privilege rather than [SUPER](#). This change improves security by enabling DBAs to avoid granting [SUPER](#) and tailor user privileges more closely to the operations permitted. [SUPER](#) is now deprecated and will be removed in a future version of MySQL.

When removal of [SUPER](#) occurs, operations that formerly required [SUPER](#) will fail unless accounts granted [SUPER](#) are migrated to the appropriate dynamic privileges. Use the following instructions to accomplish that goal so that accounts are ready prior to [SUPER](#) removal:

1. Execute this query to identify accounts that are granted [SUPER](#):

```
SELECT GRANTEE FROM INFORMATION_SCHEMA.USER_PRIVILEGES
WHERE PRIVILEGE_TYPE = 'SUPER';
```

2. For each account identified by the preceding query, determine the operations for which it needs [SUPER](#). Then grant the dynamic privileges corresponding to those operations, and revoke [SUPER](#).

For example, if `'u1'@'localhost'` requires [SUPER](#) for binary log purging and system variable modification, these statements make the required changes to the account:

```
GRANT BINLOG_ADMIN, SYSTEM_VARIABLES_ADMIN ON *.* TO 'u1'@'localhost';
REVOKE SUPER ON *.* FROM 'u1'@'localhost';
```

After you have modified all applicable accounts, the [INFORMATION_SCHEMA](#) query in the first step should produce an empty result set.

6.2.3 Grant Tables

The `mysql` system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see [Section 5.3, “The mysql System Schema”](#).

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables directly. Modifications occur indirectly when you use account-management statements such as [CREATE USER](#), [GRANT](#), and [REVOKE](#) to set up accounts and control the privileges available to each one. See [Section 13.7.1, “Account Management Statements”](#). When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

**Note**

Direct modification of grant tables using statements such as [INSERT](#), [UPDATE](#), or [DELETE](#) is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#).

- [Grant Table Concurrency](#)

Grant Table Overview

These `mysql` database tables contain grant information:

- `user`: User accounts, static global privileges, and other nonprivilege columns.
- `global_grants`: Dynamic global privileges.
- `db`: Database-level privileges.
- `tables_priv`: Table-level privileges.
- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.
- `proxies_priv`: Proxy-user privileges.
- `default_roles`: Default user roles.
- `role_edges`: Edges for role subgraphs.
- `password_history`: Password change history.

For information about the differences between static and dynamic global privileges, see [Static Versus Dynamic Privileges](#).)

In MySQL 8.0, grant tables use the [InnoDB](#) storage engine and are transactional. Before MySQL 8.0, grant tables used the [MyISAM](#) storage engine and were nontransactional. This change of grant table

storage engine enables an accompanying change to the behavior of account-management statements such as `CREATE USER` or `GRANT`. Previously, an account-management statement that named multiple users could succeed for some users and fail for others. Now, each statement is transactional and either succeeds for all named users or rolls back and has no effect if any error occurs.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'h1.example.net'` and `'bob'` applies to authenticating connections made to the server from the host `h1.example.net` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'h1.example.net'`, `'bob'` and `'reports'` applies when `bob` connects from the host `h1.example.net` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 6.2.7, "Access Control, Stage 2: Request Verification"](#), describes the rules for this.

In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's static global privileges. Any privileges granted in this table apply to *all* databases on the server.

Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- The `global_grants` table lists current assignments of dynamic global privileges to user accounts. For each row, the scope columns determine which user has the privilege named in the privilege column.
- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The `procs_priv` table applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.
- The `proxies_priv` table indicates which users can act as proxies for other users and whether a user can grant the `PROXY` privilege to other users.
- The `default_roles` and `role_edges` tables contain information about role relationships.
- The `password_history` table retains previously chosen passwords to enable restrictions on password reuse. See [Section 6.2.15, "Password Management"](#).

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in [Section 6.2.13, “When Privilege Changes Take Effect”](#).

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the `SHOW GRANTS` statement. For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

To display nonprivilege properties of an account, use `SHOW CREATE USER`:

```
SHOW CREATE USER 'bob'@'pc84.example.com';
```

The user and db Grant Tables

The server uses the `user` and `db` tables in the `mysql` database at both the first and second stages of access control (see [Section 6.2, “Access Control and Account Management”](#)). The columns in the `user` and `db` tables are shown here.

Table 6.4 user and db Table Columns

Table Name	<code>user</code>	<code>db</code>
Scope columns	Host	Host
	User	Db
		User
Privilege columns	Select_priv	Select_priv
	Insert_priv	Insert_priv
	Update_priv	Update_priv
	Delete_priv	Delete_priv
	Index_priv	Index_priv
	Alter_priv	Alter_priv
	Create_priv	Create_priv
	Drop_priv	Drop_priv
	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv
	Alter_routine_priv	Alter_routine_priv
	Execute_priv	Execute_priv
	Trigger_priv	Trigger_priv
	Event_priv	Event_priv
	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv
	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	

Table Name	user	db
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
	Create_tablespace_priv	
	Create_role_priv	
	Drop_role_priv	
Security columns	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
	plugin	
	authentication_string	
	password_expired	
	password_last_changed	
	password_lifetime	
	account_locked	
	Password_reuse_history	
	Password_reuse_time	
	Password_require_current	
	User_attributes	
Resource control columns	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

The `user` table `plugin` and `authentication_string` columns store authentication plugin and credential information.

The server uses the plugin named in the `plugin` column of an account row to authenticate connection attempts for the account.

The `plugin` column must be nonempty. At startup, and at runtime when `FLUSH PRIVILEGES` is executed, the server checks `user` table rows. For any row with an empty `plugin` column, the server writes a warning to the error log of this form:

```
[Warning] User entry 'user_name'@'host_name' has an empty plugin
value. The user will be ignored and no one can login with this user
anymore.
```

To assign a plugin to an account that is missing one, use the `ALTER USER` statement.

The `password_expired` column permits DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is 'N', but can be set to 'Y' with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an `ALTER USER` statement to establish a new account password.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

`password_last_changed` is a `TIMESTAMP` column indicating when the password was last changed. The value is non-`NULL` only for accounts that use a MySQL built-in authentication plugin (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). The value is `NULL` for other accounts, such as those authenticated using an external authentication system.

`password_last_changed` is updated by the `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements, and by `GRANT` statements that create an account or change an account password.

`password_lifetime` indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the `password_last_changed` column), the server considers the password expired when clients connect using the account. A value of `N` greater than zero means that the password must be changed every `N` days. A value of 0 disables automatic password expiration. If the value is `NULL` (the default), the global expiration policy applies, as defined by the `default_password_lifetime` system variable.

`account_locked` indicates whether the account is locked (see [Section 6.2.19, “Account Locking”](#)).

`Password_reuse_history` is the value of the `PASSWORD HISTORY` option for the account, or `NULL` for the default history.

`Password_reuse_time` is the value of the `PASSWORD REUSE INTERVAL` option for the account, or `NULL` for the default interval.

`Password_require_current` (added in MySQL 8.0.13) corresponds to the value of the `PASSWORD REQUIRE` option for the account, as shown by the following table.

Table 6.5 Permitted `Password_require_current` Values

Password_require_current Value	Corresponding PASSWORD REQUIRE Option
'Y'	PASSWORD REQUIRE CURRENT
'N'	PASSWORD REQUIRE CURRENT OPTIONAL
NULL	PASSWORD REQUIRE CURRENT DEFAULT

`User_attributes` (added in MySQL 8.0.14) is a JSON-format column that stores account attributes not stored in other columns:

- `additional_password`: The secondary password, if any. See [Dual Password Support](#).
- `Restrictions`: Restriction lists, if any. Restrictions are added by partial-revoke operations. The attribute value is an array of elements that each have `Database` and `Restrictions` keys indicating the name of a restricted database and the applicable restrictions on it (see [Section 6.2.12, “Privilege Restriction Using Partial Revokes”](#)).
- `Password_locking`: The conditions for failed-login tracking and temporary account locking, if any (see [Failed-Login Tracking and Temporary Account Locking](#)). The `Password_locking` attribute is updated according to the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options of the `CREATE USER` and `ALTER USER` statements. The attribute value is a hash with `failed_login_attempts` and `password_lock_time_days` keys indicating the value of such options as have been specified for the account. If a key is missing, its value is implicitly 0. If a key value is implicitly or explicitly 0, the corresponding capability is disabled. This attribute was added in MySQL 8.0.19.

If no attributes apply, `User_attributes` is `NULL`.

Example: An account that has a secondary password and partially revoked database privileges has `additional_password` and `Restrictions` attributes in the column value:

```
mysql> SELECT User_attributes FROM mysql.User WHERE User = 'u'\G
***** 1. row *****
User_attributes: {"Restrictions":
                  [{"Database": "mysql", "Privileges": ["SELECT"]}],
                  "additional_password": "hashed_credentials"}
```

To determine which attributes are present, use the `JSON_KEYS()` function:

```
SELECT User, Host, JSON_KEYS(User_attributes)
FROM mysql.user WHERE User_attributes IS NOT NULL;
```

To extract a particular attribute, such as `Restrictions`, do this:

```
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
```

The `tables_priv` and `columns_priv` Grant Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the `user` and `db` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table 6.6 `tables_priv` and `columns_priv` Table Columns

Table Name	<code>tables_priv</code>	<code>columns_priv</code>
Scope columns	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
Privilege columns	Table_priv	Column_priv
	Column_priv	
Other columns	Timestamp	Timestamp
	Grantor	

The `Timestamp` and `Grantor` columns are set to the current timestamp and the `CURRENT_USER` value, respectively, but are otherwise unused.

The `procs_priv` Grant Table

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

Table 6.7 `procs_priv` Table Columns

Table Name	<code>procs_priv</code>
Scope columns	Host
	Db
	User
	Routine_name
	Routine_type

Table Name	<code>procs_priv</code>
Privilege columns	<code>Proc_priv</code>
Other columns	<code>Timestamp</code>
	<code>Grantor</code>

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

The `proxies_priv` Grant Table

The `proxies_priv` table records information about proxy accounts. It has these columns:

- `Host`, `User`: The proxy account; that is, the account that has the `PROXY` privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: The proxied account.
- `Grantor`, `Timestamp`: Unused.
- `With_grant`: Whether the proxy account can grant the `PROXY` privilege to other accounts.

For an account to be able to grant the `PROXY` privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the `'root'@'localhost'` account created during MySQL installation has a row in the `proxies_priv` table that enables granting the `PROXY` privilege for `' '@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 6.2.18, “Proxy Users”](#).

The `global_grants` Grant Table

The `global_grants` table lists current assignments of dynamic global privileges to user accounts. The table has these columns:

- `USER`, `HOST`: The user name and host name of the account to which the privilege is granted.
- `PRIV`: The privilege name.
- `WITH_GRANT_OPTION`: Whether the account can grant the privilege to other accounts.

The `default_roles` Grant Table

The `default_roles` table lists default user roles. It has these columns:

- `HOST`, `USER`: The account or role to which the default role applies.
- `DEFAULT_ROLE_HOST`, `DEFAULT_ROLE_USER`: The default role.

The `role_edges` Grant Table

The `role_edges` table lists edges for role subgraphs. It has these columns:

- `FROM_HOST`, `FROM_USER`: The account that is granted a role.
- `TO_HOST`, `TO_USER`: The role that is granted to the account.
- `WITH_ADMIN_OPTION`: Whether the account can grant the role to and revoke it from other accounts by using `WITH ADMIN OPTION`.

The password_history Grant Table

The `password_history` table contains information about password changes. It has these columns:

- `Host, User`: The account for which the password change occurred.
- `Password_timestamp`: The time when the password change occurred.
- `Password`: The new password hash value.

The `password_history` table accumulates a sufficient number of nonempty passwords per account to enable MySQL to perform checks against both the account password history length and reuse interval. Automatic pruning of entries that are outside both limits occurs when password-change attempts occur.

Note

The empty password does not count in the password history and is subject to reuse at any time.

If an account is renamed, its entries are renamed to match. If an account is dropped or its authentication plugin is changed, its entries are removed.

Grant Table Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

Table 6.8 Grant Table Scope Column Lengths

Column Name	Maximum Permitted Characters
<code>Host, Proxied_host</code>	255 (60 prior to MySQL 8.0.17)
<code>User, Proxied_user</code>	32
<code>Db</code>	64
<code>Table_name</code>	64
<code>Column_name</code>	64
<code>Routine_name</code>	64

`Host` and `Proxied_host` values are converted to lowercase before being stored in the grant tables.

For access-checking purposes, comparisons of `User`, `Proxied_user`, `authentication_string`, `Db`, and `Table_name` values are case-sensitive. Comparisons of `Host`, `Proxied_host`, `Column_name`, and `Routine_name` values are not case-sensitive.

Grant Table Privilege Column Properties

The `user` and `db` tables list each privilege in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

The `tables_priv`, `columns_priv`, and `procs_priv` tables declare the privilege columns as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table 6.9 Set-Type Privilege Column Values

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Table_priv</code>	'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop',

Table Name	Column Name	Possible Set Elements
		'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'
tables_priv	Column_priv	'Select', 'Insert', 'Update', 'References'
columns_priv	Column_priv	'Select', 'Insert', 'Update', 'References'
procs_priv	Proc_priv	'Execute', 'Alter Routine', 'Grant'

Only the `user` and `global_grants` tables specify administrative privileges, such as `RELOAD`, `SHUTDOWN`, and `SYSTEM_VARIABLES_ADMIN`. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the `user` and `global_grants` tables to determine whether a user can perform an administrative operation.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but a user's ability to read or write files on the server host is independent of the database being accessed.

Grant Table Concurrency

As of MySQL 8.0.22, to permit concurrent DML and DDL operations on MySQL grant tables, read operations that previously acquired row locks on MySQL grant tables are executed as non-locking reads. Operations that are performed as non-locking reads on MySQL grant tables include:

- `SELECT` statements and other read-only statements that read data from grant tables through join lists and subqueries, including `SELECT ... FOR SHARE` statements, using any transaction isolation level.
- DML operations that read data from grant tables (through join lists or subqueries) but do not modify them, using any transaction isolation level.

Statements that no longer acquire row locks when reading data from grant tables report a warning if executed while using statement-based replication.

When using `-binlog_format=mixed`, DML operations that read data from grant tables are written to the binary log as row events to make the operations safe for mixed-mode replication.

`SELECT ... FOR SHARE` statements that read data from grant tables report a warning. With the `FOR SHARE` clause, read locks are not supported on grant tables.

DML operations that read data from grant tables and are executed using the `SERIALIZABLE` isolation level report a warning. Read locks that would normally be acquired when using the `SERIALIZABLE` isolation level are not supported on grant tables.

6.2.4 Specifying Account Names

MySQL account names consist of a user name and a host name, which enables creation of distinct accounts for users with the same user name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

MySQL role names are similar to account names, with some differences described at [Section 6.2.5, “Specifying Role Names”](#).

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names follow these rules:

- Account name syntax is `'user_name'@'host_name'`.

- An account name consisting only of a user name is equivalent to `'user_name'@' % '`. For example, `'me'` is equivalent to `'me'@' % '`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as space or `-`), or a `host_name` string containing special characters or wildcard characters (such as `.` or `%`). For example, in the account name `'test-user'@' % .com'`, both the user name and host name parts require quotes.
- Quote user names and host names as identifiers or as strings, using either backticks (```), single quotation marks (`'`), or double quotation marks (`"`). For string-quoting and identifier-quoting guidelines, see [Section 9.1.1, “String Literals”](#), and [Section 9.2, “Schema Object Names”](#).
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`. The latter is actually equivalent to `'me@localhost'@' % '`.
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case sensitive.

For additional detail about the properties of user names and host names as stored in the grant tables, such as maximum length, see [Grant Table Scope Column Properties](#).

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `:::1` indicates the IPv6 loopback interface.
- The `%` and `_` wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of `' % '` matches any host name, whereas a value of `' % .mysql.com'` matches any host in the `mysql.com` domain. `'198.51.100. % '` matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, `'198.51.100. % '` to match every host on a subnet), someone could try to exploit this capability by naming a host `198.51.100.somewhere.com`. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 198.51.100.0
```

IP addresses that satisfy this condition range from `198.51.100.0` to `198.51.100.255`.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- `198.0.0.0/255.0.0.0`: Any host on the 198 class A network
- `198.51.100.0/255.255.0.0`: Any host on the 198.51 class B network
- `198.51.100.0/255.255.255.0`: Any host on the 198.51.100 class C network
- `198.51.100.1`: Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.
- If DNS returns the IP address for a given host as `198.51.100.2`, that will match an account host value of `198.51.100.2` but not `198.051.100.2`. Similarly, it will match an account host pattern like `198.51.100.%` but not `198.051.100.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

6.2.5 Specifying Role Names

MySQL role names refer to roles, which are named collections of privileges. For role usage examples, see [Section 6.2.10, “Using Roles”](#).

Role names have syntax and semantics similar to account names; see [Section 6.2.4, “Specifying Account Names”](#). As stored in the grant tables, they have the same properties as account names, which are described in [Grant Table Scope Column Properties](#).

Role names differ from account names in these respects:

- The user part of role names cannot be blank. Thus, there is no “anonymous role” analogous to the concept of “anonymous user.”
- As for an account name, omitting the host part of a role name results in a host part of `'%'`. But unlike `'%'` in an account name, a host part of `'%'` in a role name has no wildcard properties. For example, for a name `'me'@'%'` used as a role name, the host part (`'%'`) is just a literal value; it has no “any host” matching property.

- Netmask notation in the host part of a role name has no significance.
- An account name is permitted to be `CURRENT_USER()` in several contexts. A role name is not.

It is possible for a row in the `mysql.user` system table to serve as both an account and a role. In this case, any special user or host name matching properties do not apply in contexts for which the name is used as a role name. For example, you cannot execute the following statement with the expectation that it will set the current session roles using all roles that have a user part of `myrole` and any host name:

```
SET ROLE 'myrole'@'%';
```

Instead, the statement sets the active role for the session to the role with exactly the name `'myrole'@'%'`.

For this reason, role names are often specified using only the user name part and letting the host name part implicitly be `'%'`. Specifying a role with a non-`'%'` host part can be useful if you intend to create a name that works both as a role and as a user account that is permitted to connect from the given host.

6.2.6 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify your identity by supplying the correct password
- Whether your account is locked or unlocked

The server checks credentials first, then account locking state. A failure for either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Credential checking is performed using the three `user` table scope columns (`Host`, `User`, and `authentication_string`). Locking state is recorded in the `user` table `account_locked` column. The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name, the client supplies the password specified in that row, and the `account_locked` value is `'N'`. The rules for permissible `Host` and `User` values are given in [Section 6.2.4, “Specifying Account Names”](#). Account locking can be changed with the `ALTER USER` statement.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `authentication_string` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `authentication_string` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank `authentication_string` values in the `user` table represent encrypted passwords. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented

by the account authentication plugin). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See [Section 6.2.1, “Account User Names and Passwords”](#).

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` system database*.

The following table shows how various combinations of `User` and `Host` values in the `user` table apply to incoming connections.

User Value	Host Value	Permissible Connections
'fred'	'h1.example.net'	fred, connecting from h1.example.net
' '	'h1.example.net'	Any user, connecting from h1.example.net
'fred'	'%'	fred, connecting from any host
' '	'%'	Any user, connecting from any host
'fred'	'%.example.net'	fred, connecting from any host in the example.net domain
'fred'	'x.example.%'	fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful
'fred'	'198.51.100.177'	fred, connecting from the host with IP address 198.51.100.177
'fred'	'198.51.100.%'	fred, connecting from any host in the 198.51.100 class C subnet
'fred'	'198.51.100.0/255.255.255.0'	Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from h1.example.net by fred.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so 198.51.100.13 and 198.51.100.0/255.255.255.0 are considered equally specific.) The pattern '%' means “any host” and is least specific. The empty string '' also means “any host” but sorts after '%'. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific). For rows with equally-specific `Host` and `User` values, the order is nondeterministic.

To see how this works, suppose that the `user` table looks like this:

```
+-----+-----+
| Host   | User   | ...
+-----+-----+
| %      | root   | ...
| %      | jeffrey | ...
| localhost | root   | ...
| localhost |       | ...
+-----+-----+
```

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

Host	User	...
localhost	root	...
localhost		...
%	jeffrey	...
%	root	...

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of '`localhost`' and '', and the one with values of '%' and '`jeffrey`'. The '`localhost`' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

Host	User	...
%	jeffrey	...
h1.example.net		...

The sorted table looks like this:

Host	User	...
h1.example.net		...
%	jeffrey	...

A connection by `jeffrey` from `h1.example.net` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `h1.example.net` by `jeffrey` is first matched not by the row containing '`jeffrey`' as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See [Section 12.16, “Information Functions”](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost     |
+-----+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

6.2.7 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `global_grants`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 6.2.3, “Grant Tables”](#), which lists the columns present in each grant table.)

The `user` and `global_grants` tables grant global privileges. The rows in these tables for a given account indicate the account privileges that apply on a global basis no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only (for particular databases, tables, columns, or routines). It is also possible to grant database privileges globally but use partial revokes to restrict them from being exercised on specific databases (see [Section 6.2.12, “Privilege Restriction Using Partial Revokes”](#)).

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `%` and `_` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`_`) as part of a database name, specify it as `_` in the `GRANT` statement.
- A `'%'` or blank `Host` value means “any host.”
- A `'%'` or blank `Db` value means “any database.”

The server reads the `db` table into memory and sorts it at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters `%` and `_` can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A `'%'` or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` and `global_privilege` tables because those are the only tables that specify administrative privileges. The server grants access if a row for the account in those tables permits the requested operation and

denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` table. (The latter table contains no `Shutdown_priv` column, so there is no need to check it.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges in the `user` table row (less any privilege restrictions imposed by partial revokes). If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges from the `db` table:

The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.

After determining the database-specific privileges granted by the `db` table rows, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege global and the `db` table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

6.2.8 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:

- `CREATE USER` and `DROP USER` create and remove accounts.
- `GRANT` and `REVOKE` assign privileges to and revoke privileges from accounts.
- `SHOW GRANTS` displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in [Section 6.2.3, “Grant Tables”](#).

Note

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the

tables to the expected structure, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#).

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. [phpMyAdmin](#) is one such program.

This section discusses the following topics:

- [Creating Accounts and Granting Privileges](#)
- [Checking Account Privileges and Properties](#)
- [Revoking Account Privileges](#)
- [Dropping Accounts](#)

For additional information about the statements discussed here, see [Section 13.7.1, “Account Management Statements”](#).

Creating Accounts and Granting Privileges

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that the MySQL `root` account has the `CREATE USER` privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL `root` user, supplying the appropriate password at the password prompt:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```

After connecting to the server, you can add new accounts. The following example uses `CREATE USER` and `GRANT` statements to set up four accounts (where you see `'password'`, substitute an appropriate password):

```
CREATE USER 'finley'@'localhost'
  IDENTIFIED BY 'password';
GRANT ALL
  ON *.*
  TO 'finley'@'localhost'
  WITH GRANT OPTION;

CREATE USER 'finley'@'%.example.com'
  IDENTIFIED BY 'password';
GRANT ALL
  ON *.*
  TO 'finley'@'%.example.com'
  WITH GRANT OPTION;

CREATE USER 'admin'@'localhost'
  IDENTIFIED BY 'password';
GRANT RELOAD,PROCESS
  ON *.*
  TO 'admin'@'localhost';

CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

- Two accounts have a user name of `finley`. Both are superuser accounts with full global privileges to do anything. The `'finley'@'localhost'` account can be used only when connecting from the local host. The `'finley'@'%.example.com'` account uses the `'%'` wildcard in the host part, so it can be used to connect from any host in the `example.com` domain.

The `'finley'@'localhost'` account is necessary if there is an anonymous-user account for `localhost`. Without the `'finley'@'localhost'` account, that anonymous-user account takes

precedence when `finley` connects from the local host and `finley` is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'finley'@'%'` account and thus comes earlier in the `user` table sort order. (For information about `user` table sorting, see [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#).)

- The `'admin'@'localhost'` account can be used only by `admin` to connect from the local host. It is granted the global `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges using `GRANT` statements.
- The `'dummy'@'localhost'` account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account using `GRANT` statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of `custom`, but the host name parts differ:

```
CREATE USER 'custom'@'localhost'
  IDENTIFIED BY 'password';
GRANT ALL
  ON bankaccount.*
  TO 'custom'@'localhost';

CREATE USER 'custom'@'host47.example.com'
  IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
  ON expenses.*
  TO 'custom'@'host47.example.com';

CREATE USER 'custom'@'%.example.com'
  IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
  ON customer.addresses
  TO 'custom'@'%.example.com';
```

The three accounts can be used as follows:

- The `'custom'@'localhost'` account has all database-level privileges to access the `bankaccount` database. The account can be used to connect to the server only from the local host.
- The `'custom'@'host47.example.com'` account has specific database-level privileges to access the `expenses` database. The account can be used to connect to the server only from the host `host47.example.com`.
- The `'custom'@'%.example.com'` account has specific table-level privileges to access the `addresses` table in the `customer` database, from any host in the `example.com` domain. The account can be used to connect to the server from all machines in the domain due to use of the `%` wildcard character in the host part of the account name.

Checking Account Privileges and Properties

To see the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----+
```

To see nonprivilege properties for an account, use `SHOW CREATE USER`:

```
mysql> SET print_identified_with_as_hex = ON;
```

```
mysql> SHOW CREATE USER 'admin'@'localhost'\G
***** 1. row *****
CREATE USER for admin@localhost: CREATE USER 'admin'@'localhost'
IDENTIFIED WITH 'caching_sha2_password'
AS 0x24412430303524301D0E17054E2241362B1419313C3E44326F294133734B30792F436E77764270373039612E3244525078
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
PASSWORD HISTORY DEFAULT
PASSWORD REUSE INTERVAL DEFAULT
PASSWORD REQUIRE CURRENT DEFAULT
```

Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes `SHOW CREATE USER` to display hash values that contain unprintable characters as hexadecimal strings rather than as regular string literals.

Revoking Account Privileges

To revoke account privileges, use the `REVOKE` statement. Privileges can be revoked at different levels, just as they can be granted at different levels.

Revoke global privileges:

```
REVOKE ALL
ON *.*
FROM 'finley'@'%example.com';

REVOKE RELOAD
ON *.*
FROM 'admin'@'localhost';
```

Revoke database-level privileges:

```
REVOKE CREATE,DROP
ON expenses.*
FROM 'custom'@'host47.example.com';
```

Revoke table-level privileges:

```
REVOKE INSERT,UPDATE,DELETE
ON customer.addresses
FROM 'custom'@'%example.com';
```

To check the effect of privilege revocation, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT PROCESS ON *.* TO 'admin'@'localhost' |
+-----+
```

Dropping Accounts

To remove an account, use the `DROP USER` statement. For example, to drop some of the accounts created previously:

```
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

6.2.9 Reserved Accounts

One part of the MySQL installation process is data directory initialization (see [Section 2.10.1, “Initializing the Data Directory”](#)). During data directory initialization, MySQL creates user accounts that should be considered reserved:

- `'root'@'localhost'`: Used for administrative purposes. This account has all privileges, is a system account, and can perform any operation.

Strictly speaking, this account name is not reserved, in the sense that some installations rename the `root` account to something else to avoid exposing a highly privileged account with a well-known name.

- `'mysql.sys'@'localhost'`: Used as the `DEFINER` for `sys` schema objects. Use of the `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account. This account is locked so that it cannot be used for client connections.
- `'mysql.session'@'localhost'`: Used internally by plugins to access the server. This account is locked so that it cannot be used for client connections. The account is a system account.
- `'mysql.infoschema'@'localhost'`: Used as the `DEFINER` for `INFORMATION_SCHEMA` views. Use of the `mysql.infoschema` account avoids problems that occur if a DBA renames or removes the root account. This account is locked so that it cannot be used for client connections.

6.2.10 Using Roles

A MySQL role is a named collection of privileges. Like user accounts, roles can have privileges granted to and revoked from them.

A user account can be granted roles, which grants to the account the privileges associated with each role. This enables assignment of sets of privileges to accounts and provides a convenient alternative to granting individual privileges, both for conceptualizing desired privilege assignments and implementing them.

The following list summarizes role-management capabilities provided by MySQL:

- `CREATE ROLE` and `DROP ROLE` create and remove roles.
- `GRANT` and `REVOKE` assign privileges to revoke privileges from user accounts and roles.
- `SHOW GRANTS` displays privilege and role assignments for user accounts and roles.
- `SET DEFAULT ROLE` specifies which account roles are active by default.
- `SET ROLE` changes the active roles within the current session.
- The `CURRENT_ROLE()` function displays the active roles within the current session.
- The `mandatory_roles` and `activate_all_roles_on_login` system variables enable defining mandatory roles and automatic activation of granted roles when users log in to the server.

For descriptions of individual role-manipulation statements (including the privileges required to use them), see [Section 13.7.1, “Account Management Statements”](#). The following discussion provides examples of role usage. Unless otherwise specified, SQL statements shown here should be executed using a MySQL account with sufficient administrative privileges, such as the `root` account.

- [Creating Roles and Granting Privileges to Them](#)
- [Defining Mandatory Roles](#)
- [Checking Role Privileges](#)
- [Activating Roles](#)
- [Revoking Roles or Role Privileges](#)
- [Dropping Roles](#)
- [User and Role Interchangeability](#)

Creating Roles and Granting Privileges to Them

Consider this scenario:

- An application uses a database named `app_db`.
- Associated with the application, there can be accounts for developers who create and maintain the application, and for users who interact with it.
- Developers need full access to the database. Some users need only read access, others need read/write access.

To avoid granting privileges individually to possibly many user accounts, create roles as names for the required privilege sets. This makes it easy to grant the required privileges to user accounts, by granting the appropriate roles.

To create the roles, use the `CREATE ROLE` statement:

```
CREATE ROLE 'app_developer', 'app_read', 'app_write';
```

Role names are much like user account names and consist of a user part and host part in `'user_name'@'host_name'` format. The host part, if omitted, defaults to `'%'`. The user and host parts can be unquoted unless they contain special characters such as `-` or `%`. Unlike account names, the user part of role names cannot be blank. For additional information, see [Section 6.2.5, “Specifying Role Names”](#).

To assign privileges to the roles, execute `GRANT` statements using the same syntax as for assigning privileges to user accounts:

```
GRANT ALL ON app_db.* TO 'app_developer';
GRANT SELECT ON app_db.* TO 'app_read';
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now suppose that initially you require one developer account, two user accounts that need read-only access, and one user account that needs read/write access. Use `CREATE USER` to create the accounts:

```
CREATE USER 'dev1'@'localhost' IDENTIFIED BY 'dev1pass';
CREATE USER 'read_user1'@'localhost' IDENTIFIED BY 'read_user1pass';
CREATE USER 'read_user2'@'localhost' IDENTIFIED BY 'read_user2pass';
CREATE USER 'rw_user1'@'localhost' IDENTIFIED BY 'rw_user1pass';
```

To assign each user account its required privileges, you could use `GRANT` statements of the same form as just shown, but that requires enumerating individual privileges for each user. Instead, use an alternative `GRANT` syntax that permits granting roles rather than privileges:

```
GRANT 'app_developer' TO 'dev1'@'localhost';
GRANT 'app_read' TO 'read_user1'@'localhost', 'read_user2'@'localhost';
GRANT 'app_read', 'app_write' TO 'rw_user1'@'localhost';
```

The `GRANT` statement for the `rw_user1` account grants the read and write roles, which combine to provide the required read and write privileges.

The `GRANT` syntax for granting roles to an account differs from the syntax for granting privileges: There is an `ON` clause to assign privileges, whereas there is no `ON` clause to assign roles. Because the syntaxes are distinct, you cannot mix assigning privileges and roles in the same statement. (It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.) As of MySQL 8.0.16, roles cannot be granted to anonymous users.

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the `ALTER USER` statement, by users who have the global `CREATE USER` privilege.)

While locked, a role cannot be used to authenticate to the server. If unlocked, a role can be used to authenticate. This is because roles and users are both authorization identifiers with much in common and little to distinguish them. See also [User and Role Interchangeability](#).

Defining Mandatory Roles

It is possible to specify roles as mandatory by naming them in the value of the `mandatory_roles` system variable. The server treats a mandatory role as granted to all users, so that it need not be granted explicitly to any account.

To specify mandatory roles at server startup, define `mandatory_roles` in your server `my.cnf` file:

```
[mysqld]
mandatory_roles='role1,role2@localhost,r3@%.example.com'
```

To set and persist `mandatory_roles` at runtime, use a statement like this:

```
SET PERSIST mandatory_roles = 'role1,role2@localhost,r3@%.example.com' ;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

Setting `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see [Activating Roles](#)). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

If a role named in `mandatory_roles` is not present in the `mysql.user` system table, the role is not granted to users. When the server attempts role activation for a user, it does not treat the nonexistent role as mandatory and writes a warning to the error log. If the role is created later and thus becomes valid, `FLUSH PRIVILEGES` may be necessary to cause the server to treat it as mandatory.

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 13.7.7.21, “SHOW GRANTS Statement”](#).

Checking Role Privileges

To verify the privileges assigned to an account, use `SHOW GRANTS`. For example:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost';
+-----+
| Grants for dev1@localhost |
+-----+
| GRANT USAGE ON *.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-----+
```

However, that shows each granted role without “expanding” it to the privileges the role represents. To show role privileges as well, add a `USING` clause naming the granted roles for which to display privileges:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost' USING 'app_developer';
+-----+
| Grants for dev1@localhost |
+-----+
| GRANT USAGE ON *.* TO `dev1`@`localhost` |
| GRANT ALL PRIVILEGES ON `app_db`.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-----+
```

Verify each other type of user similarly:

```
mysql> SHOW GRANTS FOR 'read_user1'@'localhost' USING 'app_read';
+-----+
| Grants for read_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `read_user1`@`localhost` |
| GRANT SELECT ON `app_db`.* TO `read_user1`@`localhost` |
| GRANT `app_read`@`%` TO `read_user1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
+-----+
| Grants for rw_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost` |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost` |
+-----+
```

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 13.7.7.21, “SHOW GRANTS Statement”](#).

Activating Roles

Roles granted to a user account can be active or inactive within account sessions. If a granted role is active within a session, its privileges apply; otherwise, they do not. To determine which roles are active within the current session, use the `CURRENT_ROLE()` function.

By default, granting a role to an account or naming it in the `mandatory_roles` system variable value does not automatically cause the role to become active within account sessions. For example, because thus far in the preceding discussion no `rw_user1` roles have been activated, if you connect to the server as `rw_user1` and invoke the `CURRENT_ROLE()` function, the result is `NONE` (no active roles):

```
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| NONE           |
+-----+
```

To specify which roles should become active each time a user connects to the server and authenticates, use `SET DEFAULT ROLE`. To set the default to all assigned roles for each account created earlier, use this statement:

```
SET DEFAULT ROLE ALL TO
  'dev1'@'localhost',
  'read_user1'@'localhost',
  'read_user2'@'localhost',
  'rw_user1'@'localhost';
```

Now if you connect as `rw_user1`, the initial value of `CURRENT_ROLE()` reflects the new default role assignments:

```
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%`,`app_write`@`%` |
+-----+
```

To cause all explicitly granted and mandatory roles to be automatically activated when users connect to the server, enable the `activate_all_roles_on_login` system variable. By default, automatic role activation is disabled.

Within a session, a user can execute `SET ROLE` to change the set of active roles. For example, for `rw_user1`:

```
mysql> SET ROLE NONE; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| NONE           |
+-----+
mysql> SET ROLE ALL EXCEPT 'app_write'; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%` |
+-----+
mysql> SET ROLE DEFAULT; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%`, `app_write`@`%` |
+-----+
```

The first `SET ROLE` statement deactivates all roles. The second makes `rw_user1` effectively read only. The third restores the default roles.

The effective user for stored program and view objects is subject to the `DEFINER` and `SQL SECURITY` attributes, which determine whether execution occurs in invoker or definer context (see [Section 24.6, “Stored Object Access Control”](#)):

- Stored program and view objects that execute in invoker context execute with the roles that are active within the current session.
- Stored program and view objects that execute in definer context execute with the default roles of the user named in their `DEFINER` attribute. If `activate_all_roles_on_login` is enabled, such objects execute with all roles granted to the `DEFINER` user, including mandatory roles. For stored programs, if execution should occur with roles different from the default, the program body should execute `SET ROLE` to activate the required roles.

Revoking Roles or Role Privileges

Just as roles can be granted to an account, they can be revoked from an account:

```
REVOKE role FROM user;
```

Roles named in the `mandatory_roles` system variable value cannot be revoked.

`REVOKE` can also be applied to a role to modify the privileges granted to it. This affects not only the role itself, but any account granted that role. Suppose that you want to temporarily make all application users read only. To do this, use `REVOKE` to revoke the modification privileges from the `app_write` role:

```
REVOKE INSERT, UPDATE, DELETE ON app_db.* FROM 'app_write';
```

As it happens, that leaves the role with no privileges at all, as can be seen using `SHOW GRANTS` (which demonstrates that this statement can be used with roles, not just users):

```
mysql> SHOW GRANTS FOR 'app_write';
+-----+
| Grants for app_write@% |
+-----+
| GRANT USAGE ON *.* TO `app_write`@`%` |
+-----+
```

Because revoking privileges from a role affects the privileges for any user who is assigned the modified role, `rw_user1` now has no table modification privileges (`INSERT`, `UPDATE`, and `DELETE` are no longer present):

```
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost'
      USING 'app_read', 'app_write';
+-----+
| Grants for rw_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost` |
| GRANT SELECT ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost` |
+-----+
```

In effect, the `rw_user1` read/write user has become a read-only user. This also occurs for any other accounts that are granted the `app_write` role, illustrating how use of roles makes it unnecessary to modify privileges for individual accounts.

To restore modification privileges to the role, simply re-grant them:

```
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now `rw_user1` again has modification privileges, as do any other accounts granted the `app_write` role.

Dropping Roles

To drop roles, use `DROP ROLE`:

```
DROP ROLE 'app_read', 'app_write';
```

Dropping a role revokes it from every account to which it was granted.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

User and Role Interchangeability

As has been hinted at earlier for `SHOW GRANTS`, which displays grants for user accounts or roles, accounts and roles can be used interchangeably.

One difference between roles and users is that `CREATE ROLE` creates an authorization identifier that is locked by default, whereas `CREATE USER` creates an authorization identifier that is unlocked by default. However, distinction is not immutable because a user with appropriate privileges can lock or unlock roles or users after they have been created.

If a database administrator has a preference that a specific authorization identifier must be a role, a name scheme can be used to communicate this intention. For example, you could use a `r_` prefix for all authorization identifiers that you intend to be roles and nothing else.

Another difference between roles and users lies in the privileges available for administering them:

- The `CREATE ROLE` and `DROP ROLE` privileges enable only use of the `CREATE ROLE` and `DROP ROLE` statements, respectively.
- The `CREATE USER` privilege enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

Thus, the `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` and may be granted to users who should only be permitted to create and drop roles, and not perform more general account manipulation.

With regard to privileges and interchangeability of users and roles, you can treat a user account like a role and grant that account to another user or a role. The effect is to grant the account's privileges and roles to the other user or role.

This set of statements demonstrates that you can grant a user to a user, a role to a user, a user to a role, or a role to a role:

```
CREATE USER 'u1';
CREATE ROLE 'r1';
GRANT SELECT ON db1.* TO 'u1';
GRANT SELECT ON db2.* TO 'r1';
CREATE USER 'u2';
CREATE ROLE 'r2';
GRANT 'u1', 'r1' TO 'u2';
GRANT 'u1', 'r1' TO 'r2';
```

The result in each case is to grant to the grantee object the privileges associated with the granted object. After executing those statements, each of `u2` and `r2` have been granted privileges from a user (`u1`) and a role (`r1`):

```
mysql> SHOW GRANTS FOR 'u2' USING 'u1', 'r1';
+-----+
| Grants for u2@% |
+-----+
| GRANT USAGE ON *.* TO `u2`@`%` |
| GRANT SELECT ON `db1`.`*` TO `u2`@`%` |
| GRANT SELECT ON `db2`.`*` TO `u2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `u2`@`%` |
+-----+
mysql> SHOW GRANTS FOR 'r2' USING 'u1', 'r1';
+-----+
| Grants for r2@% |
+-----+
| GRANT USAGE ON *.* TO `r2`@`%` |
| GRANT SELECT ON `db1`.`*` TO `r2`@`%` |
| GRANT SELECT ON `db2`.`*` TO `r2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `r2`@`%` |
+-----+
```

The preceding example is illustrative only, but interchangeability of user accounts and roles has practical application, such as in the following situation: Suppose that a legacy application development project began before the advent of roles in MySQL, so all user accounts associated with the project are granted privileges directly (rather than granted privileges by virtue of being granted roles). One of these accounts is a developer account that was originally granted privileges as follows:

```
CREATE USER 'old_app_dev'@'localhost' IDENTIFIED BY 'old_app_devpass';
GRANT ALL ON old_app.* TO 'old_app_dev'@'localhost';
```

If this developer leaves the project, it becomes necessary to assign the privileges to another user, or perhaps multiple users if development activities have expanded. Here are some ways to deal with the issue:

- Without using roles: Change the account password so the original developer cannot use it, and have a new developer use the account instead:

```
ALTER USER 'old_app_dev'@'localhost' IDENTIFIED BY 'new_password';
```

- Using roles: Lock the account to prevent anyone from using it to connect to the server:

```
ALTER USER 'old_app_dev'@'localhost' ACCOUNT LOCK;
```

Then treat the account as a role. For each developer new to the project, create a new account and grant to it the original developer account:

```
CREATE USER 'new_app_dev1'@'localhost' IDENTIFIED BY 'new_password';
GRANT 'old_app_dev'@'localhost' TO 'new_app_dev1'@'localhost';
```

The effect is to assign the original developer account privileges to the new account.

6.2.11 Account Categories

As of MySQL 8.0.16, MySQL incorporates the concept of user account categories, based on the `SYSTEM_USER` privilege.

- [System and Regular Accounts](#)
- [Operations Affected by the SYSTEM_USER Privilege](#)
- [System and Regular Sessions](#)
- [Protecting System Accounts Against Manipulation by Regular Accounts](#)

System and Regular Accounts

MySQL incorporates the concept of user account categories, with system and regular users distinguished according to whether they have the `SYSTEM_USER` privilege:

- A user with the `SYSTEM_USER` privilege is a system user.
- A user without the `SYSTEM_USER` privilege is a regular user.

The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER` to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.
- A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

If a user has the appropriate privileges to perform a given operation on regular accounts, `SYSTEM_USER` enables the user to also perform the operation on system accounts. `SYSTEM_USER` does not imply any other privilege, so the ability to perform a given account operation remains predicated on possession of any other required privileges. For example, if a user can grant the `SELECT` and `UPDATE` privileges to regular accounts, then with `SYSTEM_USER` the user can also grant `SELECT` and `UPDATE` to system accounts.

The distinction between system and regular accounts enables better control over certain account administration issues by protecting accounts that have the `SYSTEM_USER` privilege from accounts that do not have the privilege. For example, the `CREATE USER` privilege enables not only creation of new accounts, but modification and removal of existing accounts. Without the system user concept, a user who has the `CREATE USER` privilege can modify or drop any existing account, including the `root` account. The concept of system user enables restricting modifications to the `root` account (itself a system account) so they can be made only by system users. Regular users with the `CREATE USER` privilege can still modify or drop existing accounts, but only regular accounts.

Operations Affected by the SYSTEM_USER Privilege

The `SYSTEM_USER` privilege affects these operations:

- Account manipulation.

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements such as `CREATE USER` and `GRANT`. To prevent an account from modifying system accounts this way, make it a regular account by not granting it the `SYSTEM_USER` privilege. (However, to fully protect system accounts against regular accounts, you must also withhold

modification privileges for the `mysql` system schema from regular accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).)

- Killing current sessions and statements executing within them.

To kill a session or statement that is executing with the `SYSTEM_USER` privilege, your own session must have the `SYSTEM_USER` privilege, in addition to any other required privilege (`CONNECTION_ADMIN` or the deprecated `SUPER` privilege).

Prior to MySQL 8.0.16, `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege) is sufficient to kill any session or statement.

- Setting the `DEFINER` attribute for stored objects.

To set the `DEFINER` attribute for a stored object to an account that has the `SYSTEM_USER` privilege, you must have the `SYSTEM_USER` privilege, in addition to any other required privilege (`SET_USER_ID` or the deprecated `SUPER` privilege).

Prior to MySQL 8.0.16, the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege) is sufficient to specify any `DEFINER` value for stored objects.

- Specifying mandatory roles.

A role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable.

Prior to MySQL 8.0.16, any role can be listed in `mandatory_roles`.

System and Regular Sessions

Sessions executing within the server are distinguished as system or regular sessions, similar to the distinction between system and regular users:

- A session that possesses the `SYSTEM_USER` privilege is a system session.
- A session that does not possess the `SYSTEM_USER` privilege is a regular session.

A regular session is able to perform only operations permitted to regular users. A system session is additionally able to perform operations permitted only to system users.

The privileges possessed by a session are those granted directly to its underlying account, plus those granted to all roles currently active within the session. Thus, a session may be a system session because its account has been granted the `SYSTEM_USER` privilege directly, or because the session has activated a role that has the `SYSTEM_USER` privilege. Roles granted to an account that are not active within the session do not affect session privileges.

Because activating and deactivating roles can change the privileges possessed by sessions, a session may change from a regular session to a system session or vice versa. If a session activates or deactivates a role that has the `SYSTEM_USER` privilege, the appropriate change between regular and system session takes place immediately, for that session only:

- If a regular session activates a role with the `SYSTEM_USER` privilege, the session becomes a system session.
- If a system session deactivates a role with the `SYSTEM_USER` privilege, the session becomes a regular session, unless some other role with the `SYSTEM_USER` privilege remains active.

These operations have no effect on existing sessions:

- If the `SYSTEM_USER` privilege is granted to or revoked from an account, existing sessions for the account do not change between regular and system sessions. The grant or revoke operation affects only sessions for subsequent connections by the account.

- Statements executed by a stored object invoked within a session execute with the system or regular status of the parent session, even if the object `DEFINER` attribute names a system account.

Because role activation affects only sessions and not accounts, granting a role that has the `SYSTEM_USER` privilege to a regular account does not protect that account against regular users. The role protects only sessions for the account in which the role has been activated, and protects the session only against being killed by regular sessions.

Protecting System Accounts Against Manipulation by Regular Accounts

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

Account manipulation can be done two ways:

- By using account-management statements such as `CREATE USER` and `GRANT`. This is the preferred method.
- By direct grant-table modification using statements such as `INSERT` and `UPDATE`. This method is discouraged but possible for users with the appropriate privileges on the `mysql` system schema that contains the grant tables.

To fully protect system accounts against modification by a given account, make it a regular account and do not grant it modification privileges for the `mysql` schema:

- The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements. To prevent an account from modifying system accounts this way, make it a regular account by not granting `SYSTEM_USER` to it. This includes not granting `SYSTEM_USER` to any roles granted to the account.
- Privileges for the `mysql` schema enable manipulation of system accounts through direct modification of the grant tables, even if the modifying account is a regular account. To restrict unauthorized direct modification of system accounts by a regular account, do not grant modification privileges for the `mysql` schema to the account (or any roles granted to the account). If a regular account must have global privileges that apply to all schemas, `mysql` schema modifications can be prevented using privilege restrictions imposed using partial revokes. See [Section 6.2.12, “Privilege Restriction Using Partial Revokes”](#).

Note

Unlike withholding the `SYSTEM_USER` privilege, which prevents an account from modifying system accounts but not regular accounts, withholding `mysql` schema privileges prevents an account from modifying system accounts as well as regular accounts. This should not be an issue because, as mentioned, direct grant-table modification is discouraged.

Suppose that you want to create a user `u1` who has all privileges on all schemas, except that `u1` should be a regular user without the ability to modify system accounts. Assuming that the `partial_revokes` system variable is enabled, configure `u1` as follows:

```
CREATE USER u1 IDENTIFIED BY 'password';

GRANT ALL ON *.* TO u1 WITH GRANT OPTION;
-- GRANT ALL includes SYSTEM_USER, so at this point
-- u1 can manipulate system or regular accounts

REVOKE SYSTEM_USER ON *.* FROM u1;
-- Revoking SYSTEM_USER makes u1 a regular user;
-- now u1 can use account-management statements
-- to manipulate only regular accounts

REVOKE ALL ON mysql.* FROM u1;
```

```
-- This partial revoke prevents u1 from directly
-- modifying grant tables to manipulate accounts
```

To prevent all `mysql` system schema access by an account, revoke all its privileges on the `mysql` schema, as just shown. It is also possible to permit partial `mysql` schema access, such as read-only access. The following example creates an account that has `SELECT`, `INSERT`, `UPDATE`, and `DELETE` privileges globally for all schemas, but only `SELECT` for the `mysql` schema:

```
CREATE USER u2 IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u2;
REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u2;
```

Another possibility is to revoke all `mysql` schema privileges but grant access to specific `mysql` tables or columns. This can be done even with a partial revoke on `mysql`. The following statements enable read-only access to `u1` within the `mysql` schema, but only for the `db` table and the `Host` and `User` columns of the `user` table:

```
CREATE USER u3 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u3;
REVOKE ALL ON mysql.* FROM u3;
GRANT SELECT ON mysql.db TO u3;
GRANT SELECT(Host,User) ON mysql.user TO u3;
```

6.2.12 Privilege Restriction Using Partial Revokes

Prior to MySQL 8.0.16, it is not possible to grant privileges that apply globally except for certain schemas. As of MySQL 8.0.16, that is possible if the `partial_revokes` system variable is enabled. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. Privilege restrictions thus imposed may be useful for administration of accounts that have global privileges but should not be permitted to access certain schemas. For example, it is possible to permit an account to modify any table except those in the `mysql` system schema.

- [Using Partial Revokes](#)
- [Partial Revokes Versus Explicit Schema Grants](#)
- [Disabling Partial Revokes](#)
- [Partial Revokes and Replication](#)

Note

For brevity, `CREATE USER` statements shown here do not include passwords. For production use, always assign account passwords.

Using Partial Revokes

The `partial_revokes` system variable controls whether privilege restrictions can be placed on accounts. By default, `partial_revokes` is disabled and attempts to partially revoke global privileges produce an error:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> REVOKE INSERT ON world.* FROM u1;
ERROR 1141 (42000): There is no such grant defined for user 'u1' on host '%'
```

To permit the `REVOKE` operation, enable `partial_revokes`:

```
SET PERSIST partial_revokes = ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

With `partial_revokes` enabled, the partial revoke succeeds:

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
| REVOKE INSERT ON `world`.* FROM `u1`@`%` |
+-----+
```

`SHOW GRANTS` lists partial revokes as `REVOKE` statements in its output. The result indicates that `u1` has global `SELECT` and `INSERT` privileges, except that `INSERT` cannot be exercised for tables in the `world` schema. That is, access by `u1` to `world` tables is read only.

The server records privilege restrictions implemented through partial revokes in the `mysql.user` system table. If an account has partial revokes, its `User_attributes` column value has a `Restrictions` attribute:

```
mysql> SELECT User, Host, User_attributes->'$.Restrictions'
FROM mysql.user WHERE User_attributes->'$.Restrictions' <> '';
+-----+-----+-----+
| User | Host | User_attributes->'$.Restrictions' |
+-----+-----+-----+
| u1   | %    | [{"Database": "world", "Privileges": ["INSERT"]}]] |
+-----+-----+-----+
```

Note

Although partial revokes can be imposed for any schema, privilege restrictions on the `mysql` system schema in particular are useful as part of a strategy for preventing regular accounts from modifying system accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).

Partial revoke operations are subject to these conditions:

- Partial revokes must name the schema literally. Schema names that contain the `%` or `_` SQL wildcard characters (for example, `myschema%`) are not permitted.
- It is possible to use partial revokes to place restrictions on nonexistent schemas, but only if the revoked privilege is granted globally. If a privilege is not granted globally, revoking it for a nonexistent schema produces an error.
- Partial revokes apply at the schema level only. You cannot use partial revokes for privileges that apply only globally (such as `FILE` or `BINLOG_ADMIN`), or for table, column, or routine privileges.

As mentioned previously, partial revokes of schema-level privileges appear in `SHOW GRANTS` output as `REVOKE` statements. This differs from how `SHOW GRANTS` represents “plain” schema-level privileges:

- When granted, schema-level privileges are represented by their own `GRANT` statements in the output:

```
mysql> CREATE USER u1;
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> GRANT DELETE ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT USAGE ON *.* TO `u1`@`%` |
| GRANT UPDATE ON `mysql`.* TO `u1`@`%` |
| GRANT DELETE ON `world`.* TO `u1`@`%` |
+-----+
```

- When revoked, schema-level privileges simply disappear from the output. They do not appear as `REVOKE` statements:

```
mysql> REVOKE UPDATE ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT USAGE ON *.* TO `u1`@`%` |
+-----+
```

When a user grants a privilege, any restriction the grantor has on the privilege is inherited by the grantee, unless the grantee already has the privilege without the restriction. Consider the following two users, one of whom has the global `SELECT` privilege:

```
CREATE USER u1, u2;
GRANT SELECT ON *.* TO u2;
```

Suppose that an administrative user `admin` has a global but partially revoked `SELECT` privilege:

```
mysql> CREATE USER admin;
mysql> GRANT SELECT ON *.* TO admin WITH GRANT OPTION;
mysql> REVOKE SELECT ON mysql.* FROM admin;
mysql> SHOW GRANTS FOR admin;
+-----+
| Grants for admin@% |
+-----+
| GRANT SELECT ON *.* TO `admin`@`%` WITH GRANT OPTION |
| REVOKE SELECT ON `mysql`.* FROM `admin`@`%` |
+-----+
```

If `admin` grants `SELECT` globally to `u1` and `u2`, the result differs for each user:

- If `admin` grants `SELECT` globally to `u1`, who has no `SELECT` privilege to begin with, `u1` inherits the `admin` privilege restriction:

```
mysql> GRANT SELECT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT ON *.* TO `u1`@`%` |
| REVOKE SELECT ON `mysql`.* FROM `u1`@`%` |
+-----+
```

- On the other hand, `u2` already holds a global `SELECT` privilege without restriction. `GRANT` can only add to a grantee's existing privileges, not reduce them, so if `admin` grants `SELECT` globally to `u2`, `u2` does not inherit the `admin` restriction:

```
mysql> GRANT SELECT ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
+-----+
| Grants for u2@% |
+-----+
| GRANT SELECT ON *.* TO `u2`@`%` |
+-----+
```

If a `GRANT` statement includes an `AS user` clause, the privilege restrictions applied are those on the user/role combination specified by the clause, rather than those on the user who executes the statement. For information about the `AS` clause, see [Section 13.7.1.6, "GRANT Statement"](#).

Restrictions on new privileges granted to an account are added to any existing restrictions for that account:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
```

```
| Grants for u1@%
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE INSERT ON `mysql`.* FROM `u1`@`%` |
+-----+
mysql> REVOKE DELETE, UPDATE ON db2.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@%
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE UPDATE, DELETE ON `db2`.* FROM `u1`@`%` |
| REVOKE INSERT ON `mysql`.* FROM `u1`@`%` |
+-----+
```

Aggregation of privilege restrictions applies both when privileges are partially revoked explicitly (as just shown) and when restrictions are inherited implicitly from the user who executes the statement or the user mentioned in an `AS user` clause.

If an account has a privilege restriction on a schema:

- The account cannot grant to other accounts a privilege on the restricted schema or any object within it.
- Another account that does not have the restriction can grant privileges to the restricted account for the restricted schema or objects within it. Suppose that an unrestricted user executes these statements:

```
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE SELECT, INSERT, UPDATE ON mysql.* FROM u1;
GRANT SELECT ON mysql.user TO u1; -- grant table privilege
GRANT SELECT(Host,User) ON mysql.db TO u1; -- grant column privileges
```

The resulting account has these privileges, with the ability to perform limited operations within the restricted schema:

```
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@%
+-----+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u1`@`%` |
| REVOKE SELECT, INSERT, UPDATE ON `mysql`.* FROM `u1`@`%` |
| GRANT SELECT (`Host`, `User`) ON `mysql`.`db` TO `u1`@`%` |
| GRANT SELECT ON `mysql`.`user` TO `u1`@`%` |
+-----+
```

If an account has a restriction on a global privilege, the restriction is removed by any of these actions:

- Granting the privilege globally to the account by an account that has no restriction on the privilege.
- Granting the privilege at the schema level.
- Revoking the privilege globally.

Consider a user `u1` who holds several privileges globally, but with restrictions on `INSERT`, `UPDATE` and `DELETE`:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@%
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE INSERT, UPDATE, DELETE ON `mysql`.* FROM `u1`@`%` |
+-----+
```

Granting a privilege globally to `u1` from an account with no restriction removes the privilege restriction. For example, to remove the `INSERT` restriction:

```
mysql> GRANT INSERT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE UPDATE, DELETE ON `mysql`.* FROM `u1`@`%` |
+-----+
```

Granting a privilege at the schema level to `u1` removes the privilege restriction. For example, to remove the `UPDATE` restriction:

```
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE DELETE ON `mysql`.* FROM `u1`@`%` |
+-----+
```

Revoking a global privilege removes the privilege, including any restrictions on it. For example, to remove the `DELETE` restriction (at the cost of removing all `DELETE` access):

```
mysql> REVOKE DELETE ON *.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u1`@`%` |
+-----+
```

If an account has a privilege at both the global and schema levels, you must revoke it at the schema level twice to effect a partial revoke. Suppose that `u1` has these privileges, where `INSERT` is held both globally and on the `world` schema:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> GRANT INSERT ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
| GRANT INSERT ON `world`.* TO `u1`@`%` |
+-----+
```

Revoking `INSERT` on `world` revokes the schema-level privilege (`SHOW GRANTS` no longer displays the schema-level `GRANT` statement):

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
+-----+
```

Revoking `INSERT` on `world` again performs a partial revoke of the global privilege (`SHOW GRANTS` now includes a schema-level `REVOKE` statement):

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
+-----+
```

```
| REVOKE INSERT ON `world`.* FROM `u1`@`%` |
+-----+
```

Partial Revokes Versus Explicit Schema Grants

To provide access to accounts for some schemas but not others, partial revokes provide an alternative to the approach of explicitly granting schema-level access without granting global privileges. The two approaches have different advantages and disadvantages.

Granting schema-level privileges and not global privileges:

- Adding a new schema: The schema is inaccessible to existing accounts by default. For any account to which the schema should be accessible, the DBA must grant schema-level access.
- Adding a new account: The DBA must grant schema-level access for each schema to which the account should have access.

Granting global privileges in conjunction with partial revokes:

- Adding a new schema: The schema is accessible to existing accounts that have global privileges. For any such account to which the schema should be inaccessible, the DBA must add a partial revoke.
- Adding a new account: The DBA must grant the global privileges, plus a partial revoke on each restricted schema.

The approach that uses explicit schema-level grant is more convenient for accounts for which access is limited to a few schemas. The approach that uses partial revokes is more convenient for accounts with broad access to all schemas except a few.

Disabling Partial Revokes

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.
- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` when restrictions exist, the restrictions first must be removed:

1. Determine which accounts have partial revokes:

```
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
```

2. For each such account, remove its privilege restrictions. Suppose that the previous step shows account `u1` to have these restrictions:

```
[{"Database": "world", "Privileges": ["INSERT", "DELETE"]}]
```

Restriction removal can be done various ways:

- Grant the privileges globally, without restrictions:

```
GRANT INSERT, DELETE ON *.* TO u1;
```

- Grant the privileges at the schema level:

```
GRANT INSERT, DELETE ON world.* TO u1;
```

- Revoke the privileges globally (assuming that they are no longer needed):

```
REVOKE INSERT, DELETE ON *.* FROM ul;
```

- Remove the account itself (assuming that it is no longer needed):

```
DROP USER ul;
```

After all privilege restrictions are removed, it is possible to disable partial revokes:

```
SET PERSIST partial_revokes = OFF;
```

Partial Revokes and Replication

In replication scenarios, if `partial_revokes` is enabled on any host, it must be enabled on all hosts. Otherwise, `REVOKE` statements to partially revoke a global privilege do not have the same effect for all hosts on which replication occurs, potentially resulting in replication inconsistencies or errors.

6.2.13 When Privilege Changes Take Effect

If the `mysqld` server is started without the `--skip-grant-tables` option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are described in [Section 13.7.1, “Account Management Statements”](#). Examples include `GRANT`, `REVOKE`, `SET PASSWORD`, and `RENAME USER`.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE` (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

Note

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections.

Changes to the set of active roles within a session take effect immediately, for that session only. The `SET ROLE` statement performs session role activation and deactivation (see [Section 13.7.1.11, “SET ROLE Statement”](#)).

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

6.2.14 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `ALTER USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see [Section 13.7.1.3, “CREATE USER Statement”](#), [Section 13.7.1.1, “ALTER USER Statement”](#), and [Section 13.7.1.10, “SET PASSWORD Statement”](#).

MySQL uses plugins to perform client authentication; see [Section 6.2.17, “Pluggable Authentication”](#). In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to storing them in the `mysql.user` system table. For the statements described here, MySQL automatically hashes the password specified. There are also syntax for `CREATE USER` and `ALTER USER` that permits hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

`CREATE USER` also supports syntax for specifying the account authentication plugin. See [Section 13.7.1.3, “CREATE USER Statement”](#).

To assign or change a password for an existing account, use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```
ALTER USER USER() IDENTIFIED BY 'password';
```

To change an account password from the command line, use the `mysqladmin` command:

```
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the `mysql.user` system table that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

Warning

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that, currently, a password used by a replica as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by MySQL Server

generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

6.2.15 Password Management

MySQL supports these password-management capabilities:

- Password expiration, to require passwords to be changed periodically.
- Password reuse restrictions, to prevent old passwords from being chosen again.
- Password verification, to require that password changes also specify the current password to be replaced.
- Dual passwords, to enable clients to connect using either a primary or secondary password.
- Password strength assessment, to require strong passwords.
- Random password generation, as an alternative to requiring explicit administrator-specified literal passwords.
- Password failure tracking, to enable temporary account locking after too many consecutive incorrect-password login failures.

The following sections describe these capabilities, except password strength assessment, which is implemented using the `validate_password` component and is described in [Section 6.4.3, “The Password Validation Component”](#).

- [Internal Versus External Credentials Storage](#)
- [Password Expiration Policy](#)
- [Password Reuse Policy](#)
- [Password Verification-Required Policy](#)
- [Dual Password Support](#)
- [Random Password Generation](#)
- [Failed-Login Tracking and Temporary Account Locking](#)

Important

MySQL implements password-management capabilities using tables in the `mysql` system database. If you upgrade MySQL from an earlier version, your system tables might not be up to date. In that case, the server writes messages similar to these to the error log during the startup process (the exact numbers may vary):

```
[ERROR] Column count of mysql.user is wrong. Expected
49, found 47. The table is probably corrupted
[Warning] ACL table mysql.password_history missing.
Some operations may fail.
```

To correct the issue, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#). Until this is done, *password changes are not possible*.

Internal Versus External Credentials Storage

Some authentication plugins store account credentials internally to MySQL, in the `mysql.user` system table:

- `mysql_native_password`

- [caching_sha2_password](#)
- [sha256_password](#)

Most discussion in this section applies to such authentication plugins because most password-management capabilities described here are based on internal credentials storage handled by MySQL itself. Other authentication plugins store account credentials externally to MySQL. For accounts that use plugins that perform authentication against an external credentials system, password management must be handled externally against that system as well.

The exception is that the options for failed-login tracking and temporary account locking apply to all accounts, not just accounts that use internal credentials storage, because MySQL is able to assess the status of login attempts for any account no matter whether it uses internal or external credentials storage.

For information about individual authentication plugins, see [Section 6.4.1, “Authentication Plugins”](#).

Password Expiration Policy

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration. Expiration policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

To expire an account password manually, use the [ALTER USER](#) statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding row in the [mysql.user](#) system table.

Password expiration according to policy is automatic and is based on password age, which for a given account is assessed from the date and time of its most recent password change. The [mysql.user](#) system table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if its age is greater than its permitted lifetime. This works with no explicit manual password expiration.

To establish automatic password-expiration policy globally, use the [default_password_lifetime](#) system variable. Its default value is 0, which disables automatic password expiration. If the value of [default_password_lifetime](#) is a positive integer *N*, it indicates the permitted password lifetime, such that passwords must be changed every *N* days.

Examples:

- To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in a server [my.cnf](#) file:

```
[mysqld]  
default_password_lifetime=180
```

- To establish a global policy such that passwords never expire, set [default_password_lifetime](#) to 0:

```
[mysqld]  
default_password_lifetime=0
```

- [default_password_lifetime](#) can also be set and persisted at runtime:

```
SET PERSIST default_password_lifetime = 180;  
SET PERSIST default_password_lifetime = 0;
```

[SET PERSIST](#) sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the [GLOBAL](#) keyword rather than [PERSIST](#).

The global password-expiration policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD EXPIRE` option of the `CREATE USER` and `ALTER USER` statements. See [Section 13.7.1.3, “CREATE USER Statement”](#), and [Section 13.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require the password to be changed every 90 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
```

This expiration option overrides the global policy for all accounts named by the statement.

- Disable password expiration:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

This expiration option overrides the global policy for all accounts named by the statement.

- Defer to the global expiration policy for all accounts named by the statement:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

When a client successfully connects, the server determines whether the account password has expired:

- The server checks whether the password has been manually expired.
- Otherwise, the server checks whether the password age is greater than its permitted lifetime according to the automatic password expiration policy. If so, the server considers the password expired.

If the password is expired (whether manually or automatically), the server either disconnects the client or restricts the operations permitted to it (see [Section 6.2.16, “Server Handling of Expired Passwords”](#)). Operations performed by a restricted client result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.

mysql> ALTER USER USER() IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set (0.00 sec)
```

After the client resets the password, the server restores normal access for the session, as well as for subsequent connections that use the account. It is also possible for an administrative user to reset the account password, but any existing restricted sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

Password Reuse Policy

MySQL enables restrictions to be placed on reuse of previous passwords. Reuse restrictions can be established based on number of password changes, time elapsed, or both. Reuse policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

The password history for an account consists of passwords it has been assigned in the past. MySQL can restrict new passwords from being chosen from this history:

- If an account is restricted on the basis of number of password changes, a new password cannot be chosen from a specified number of the most recent passwords. For example, if the minimum number of password changes is set to 3, a new password cannot be the same as any of the most recent 3 passwords.
- If an account is restricted based on time elapsed, a new password cannot be chosen from passwords in the history that are newer than a specified number of days. For example, if the password reuse interval is set to 60, a new password must not be among those previously chosen within the last 60 days.

Note

The empty password does not count in the password history and is subject to reuse at any time.

To establish password-reuse policy globally, use the `password_history` and `password_reuse_interval` system variables.

Examples:

- To prohibit reusing any of the last 6 passwords or passwords newer than 365 days, put these lines in the server `my.cnf` file:

```
[mysqld]
password_history=6
password_reuse_interval=365
```

- To set and persist the variables at runtime, use statements like this:

```
SET PERSIST password_history = 6;
SET PERSIST password_reuse_interval = 365;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-reuse policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options of the `CREATE USER` and `ALTER USER` statements. See [Section 13.7.1.3, “CREATE USER Statement”](#), and [Section 13.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require a minimum of 5 password changes before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
```

This history-length option overrides the global policy for all accounts named by the statement.

- Require a minimum of 365 days elapsed before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
```

This time-elapsed option overrides the global policy for all accounts named by the statement.

- To combine both types of reuse restrictions, use `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` together:

```
CREATE USER 'jeffrey'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'jeffrey'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
```

These options override both global policy reuse restrictions for all accounts named by the statement.

- Defer to the global policy for both types of reuse restrictions:

```
CREATE USER 'jeffrey'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
ALTER USER 'jeffrey'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
```

Password Verification-Required Policy

As of MySQL 8.0.13, it is possible to require that attempts to change an account password be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing a password without proving that they know the current password. Such changes could otherwise occur, for example, if one user walks away from a terminal session temporarily without logging out, and a malicious user uses the session to change the original user's MySQL password. This can have unfortunate consequences:

- The original user becomes unable to access MySQL until the account password is reset by an administrator.
- Until the password reset occurs, the malicious user can access MySQL with the benign user's changed credentials.

Password-verification policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

For each account, its `mysql.user` row indicates whether there is an account-specific setting requiring verification of the current password for password change attempts. The setting is established by the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements:

- If the account setting is `PASSWORD REQUIRE CURRENT`, password changes must specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT OPTIONAL`, password changes may but need not specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT DEFAULT`, the `password_require_current` system variable determines the verification-required policy for the account:
 - If `password_require_current` is enabled, password changes must specify the current password.
 - If `password_require_current` is disabled, password changes may but need not specify the current password.

In other words, if the account setting is not `PASSWORD REQUIRE CURRENT DEFAULT`, the account setting takes precedence over the global policy established by the `password_require_current` system variable. Otherwise, the account defers to the `password_require_current` setting.

By default, password verification is optional: `password_require_current` is disabled and accounts created with no `PASSWORD REQUIRE` option default to `PASSWORD REQUIRE CURRENT DEFAULT`.

The following table shows how per-account settings interact with `password_require_current` system variable values to determine account password verification-required policy.

Table 6.10 Password-Verification Policy

Per-Account Setting	<code>password_require_current</code> System Variable	Password Changes Require Current Password?
<code>PASSWORD REQUIRE CURRENT</code>	<code>OFF</code>	Yes
<code>PASSWORD REQUIRE CURRENT</code>	<code>ON</code>	Yes
<code>PASSWORD REQUIRE CURRENT OPTIONAL</code>	<code>OFF</code>	No
<code>PASSWORD REQUIRE CURRENT OPTIONAL</code>	<code>ON</code>	No
<code>PASSWORD REQUIRE CURRENT DEFAULT</code>	<code>OFF</code>	No
<code>PASSWORD REQUIRE CURRENT DEFAULT</code>	<code>ON</code>	Yes

Note

Privileged users can change any account password without specifying the current password, regardless of the verification-required policy. A privileged user is one who has the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` system database.

To establish password-verification policy globally, use the `password_require_current` system variable. Its default value is `OFF`, so it is not required that account password changes specify the current password.

Examples:

- To establish a global policy that password changes must specify the current password, start the server with these lines in a server `my.cnf` file:

```
[mysqld]
password_require_current=ON
```

- To set and persist `password_require_current` at runtime, use a statement such as one of these:

```
SET PERSIST password_require_current = ON;
SET PERSIST password_require_current = OFF;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password verification-required policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD REQUIRE` options of the `CREATE USER` and `ALTER USER` statements. See [Section 13.7.1.3, “CREATE USER Statement”](#), and [Section 13.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require that password changes specify the current password:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
```

This verification option overrides the global policy for all accounts named by the statement.

- Do not require that password changes specify the current password (the current password may but need not be given):

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

This verification option overrides the global policy for all accounts named by the statement.

- Defer to the global password verification-required policy for all accounts named by the statement:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

Verification of the current password comes into play when a user changes a password using the [ALTER USER](#) or [SET PASSWORD](#) statement. The examples use [ALTER USER](#), which is preferred over [SET PASSWORD](#), but the principles described here are the same for both statements.

In password-change statements, a [REPLACE](#) clause specifies the current password to be replaced. Examples:

- Change the current user's password:

```
ALTER USER USER() IDENTIFIED BY 'auth_string' REPLACE 'current_auth_string';
```

- Change a named user's password:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'auth_string'
  REPLACE 'current_auth_string';
```

- Change a named user's authentication plugin and password:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH caching_sha2_password BY 'auth_string'
  REPLACE 'current_auth_string';
```

The [REPLACE](#) clause works like this:

- [REPLACE](#) must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
- [REPLACE](#) is optional if password changes for the account may but need not specify the current password.
- If [REPLACE](#) is specified, it must specify the correct current password, or an error occurs. This is true even if [REPLACE](#) is optional.
- [REPLACE](#) can be specified only when changing the account password for the current user. (This means that in the examples just shown, the statements that explicitly name the account for [jeffrey](#) fail unless the current user is [jeffrey](#).) This is true even if the change is attempted for another user by a privileged user; however, such a user can change any password without specifying [REPLACE](#).
- [REPLACE](#) is omitted from the binary log to avoid writing cleartext passwords to it.

Dual Password Support

As of MySQL 8.0.14, user accounts are permitted to have dual passwords, designated as primary and secondary passwords. Dual-password capability makes it possible to seamlessly perform credential changes in scenarios like this:

- A system has a large number of MySQL servers, possibly involving replication.
- Multiple applications connect to different MySQL servers.
- Periodic credential changes must be made to the account or accounts used by the applications to connect to the servers.

Consider how a credential change must be performed in the preceding type of scenario when an account is permitted only a single password. In this case, there must be close cooperation in the timing of when the account password change is made and propagated throughout all servers, and when all applications that use the account are updated to use the new password. This process may involve downtime during which servers or applications are unavailable.

With dual passwords, credential changes can be made more easily, in phases, without requiring close cooperation, and without downtime:

1. For each affected account, establish a new primary password on the servers, retaining the current password as the secondary password. This enables servers to recognize either the primary or secondary password for each account, while applications can continue to connect to the servers using the same password as previously (which is now the secondary password).
2. After the password change has propagated to all servers, modify applications that use any affected account to connect using the account primary password.
3. After all applications have been migrated from the secondary passwords to the primary passwords, the secondary passwords are no longer needed and can be discarded. After this change has propagated to all servers, only the primary password for each account can be used to connect. The credential change is now complete.

MySQL implements dual-password capability with syntax that saves and discards secondary passwords:

- The `RETAIN CURRENT PASSWORD` clause for the `ALTER USER` and `SET PASSWORD` statements saves an account current password as its secondary password when you assign a new primary password.
- The `DISCARD OLD PASSWORD` clause for `ALTER USER` discards an account secondary password, leaving only the primary password.

Suppose that, for the previously described credential-change scenario, an account named `'appuser1'@'host1.example.com'` is used by applications to connect to servers, and that the account password is to be changed from `'password_a'` to `'password_b'`.

To perform this change of credentials, use `ALTER USER` as follows:

1. On each server that is not a replica, establish `'password_b'` as the new `appuser1` primary password, retaining the current password as the secondary password:

```
ALTER USER 'appuser1'@'host1.example.com'
  IDENTIFIED BY 'password_b'
  RETAIN CURRENT PASSWORD;
```

2. Wait for the password change to replicate throughout the system to all replicas.
3. Modify each application that uses the `appuser1` account so that it connects to the servers using a password of `'password_b'` rather than `'password_a'`.

- At this point, the secondary password is no longer needed. On each server that is not a replica, discard the secondary password:

```
ALTER USER 'appuser1'@'host1.example.com'
DISCARD OLD PASSWORD;
```

- After the discard-password change has replicated to all replicas, the credential change is complete.

The `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses have the following effects:

- `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `ALTER USER` or `SET PASSWORD` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)
- If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.
- If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.
- For `ALTER USER`, if you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify `RETAIN CURRENT PASSWORD`, the statement fails.
- For `ALTER USER`, `DISCARD OLD PASSWORD` discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

Statements that modify secondary passwords require these privileges:

- The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` and `SET PASSWORD` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.
- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

Random Password Generation

As of MySQL 8.0.18, the `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements have the capability of generating random passwords for user accounts, as an alternative to requiring explicit administrator-specified literal passwords. See the description of each statement for details about the syntax. This section describes the characteristics common to generated random passwords.

By default, generated random passwords have a length of 20 characters. This length is controlled by the `generated_random_password_length` system variable, which has a range from 5 to 255.

For each account for which a statement generates a random password, the statement stores the password in the `mysql.user` system table, hashed appropriately for the account authentication plugin. The statement also returns the cleartext password in a row of a result set to make it available to the user or application executing the statement. The result set columns are named `user`, `host`, and `generated password`, indicating the user name and host name values that identify the affected row in the `mysql.user` system table, and the cleartext generated password.

```
mysql> CREATE USER
      'u1'@'localhost' IDENTIFIED BY RANDOM PASSWORD,
      'u2'@'%.example.com' IDENTIFIED BY RANDOM PASSWORD,
      'u3'@'%.org' IDENTIFIED BY RANDOM PASSWORD;
```

```

+-----+-----+-----+
| user | host          | generated password |
+-----+-----+-----+
| u1   | localhost     | BA;42VpXgQ@i+y{&TDF |
| u2   | %.example.com | YX5>XRAJRP@>sn9azmD4 |
| u3   | %.org         | ;GfD441, )C}PI/6)4TwZ |
+-----+-----+-----+
mysql> ALTER USER
      'u1'@'localhost' IDENTIFIED BY RANDOM PASSWORD,
      'u2'@'%.example.com' IDENTIFIED BY RANDOM PASSWORD;
+-----+-----+-----+
| user | host          | generated password |
+-----+-----+-----+
| u1   | localhost     | yhXBrBp.;Y6abB)e_UWr |
| u2   | %.example.com | >M-vmjp9DTY6}hkp,RcC |
+-----+-----+-----+
mysql> SET PASSWORD FOR 'u3'@'%.org' TO RANDOM;
+-----+-----+-----+
| user | host | generated password |
+-----+-----+-----+
| u3   | %.org | o(. _oNn)d;FC<vJIDg9M |
+-----+-----+-----+
    
```

A `CREATE USER`, `ALTER USER`, or `SET PASSWORD` statement that generates a random password for an account is written to the binary log as a `CREATE USER` or `ALTER USER` statement with an `IDENTIFIED WITH auth_plugin AS 'auth_string'` clause, where *auth_plugin* is the account authentication plugin and *auth_string* is the account hashed password value.

If the `validate_password` component is installed, the policy that it implements has no effect on generated passwords. (The purpose of password validation is to help humans create better passwords.)

Failed-Login Tracking and Temporary Account Locking

As of MySQL 8.0.19, administrators can configure user accounts such that too many consecutive login failures cause temporary account locking.

“Login failure” in this context means failure of the client to provide a correct password during a connection attempt. It does not include failure to connect for reasons such as unknown user or network issues. For accounts that have dual passwords (see [Dual Password Support](#)), either account password counts as correct.

The required number of login failures and the lock time are configurable per account, using the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options of the `CREATE USER` and `ALTER USER` statements. Examples:

```

CREATE USER 'u1'@'localhost' IDENTIFIED BY 'password'
      FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 3;

ALTER USER 'u2'@'localhost'
      FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME UNBOUNDED;
    
```

When too many consecutive login failures occur, the client receives an error that looks like this:

```

ERROR 3957 (HY000): Access denied for user 'user'.
Account is blocked for D day(s) (R day(s) remaining)
due to N consecutive failed logins.
    
```

Use the options as follows:

- `FAILED_LOGIN_ATTEMPTS N`

This option indicates whether to track account login attempts that specify an incorrect password. The number *N* specifies how many consecutive incorrect passwords cause temporary account locking.

- `PASSWORD_LOCK_TIME {N | UNBOUNDED}`

This option indicates how long to lock the account after too many consecutive login attempts provide an incorrect password. The value is a number *N* to specify the number of days the account remains locked, or **UNBOUNDED** to specify that when an account enters the temporarily locked state, the duration of that state is unbounded and does not end until the account is unlocked. The conditions under which unlocking occurs are described later.

Permitted values of *N* for each option are in the range from 0 to 32767. A value of 0 disables the option.

Failed-login tracking and temporary account locking have these characteristics:

- For failed-login tracking and temporary locking to occur for an account, its **FAILED_LOGIN_ATTEMPTS** and **PASSWORD_LOCK_TIME** options both must be nonzero.
- For **CREATE USER**, if **FAILED_LOGIN_ATTEMPTS** or **PASSWORD_LOCK_TIME** is not specified, its implicit default value is 0 for all accounts named by the statement. This means that failed-login tracking and temporary account locking are disabled. (These implicit defaults also apply to accounts created prior to the introduction of failed-login tracking.)
- For **ALTER USER**, if **FAILED_LOGIN_ATTEMPTS** or **PASSWORD_LOCK_TIME** is not specified, its value remains unchanged for all accounts named by the statement.
- For temporary account locking to occur, password failures must be consecutive. Any successful login that occurs prior to reaching the **FAILED_LOGIN_ATTEMPTS** value for failed logins causes failure counting to reset. For example, if **FAILED_LOGIN_ATTEMPTS** is 4 and three consecutive password failures have occurred, one more failure is necessary for locking to begin. But if the next login succeeds, failed-login counting for the account is reset so that four consecutive failures are again required for locking.
- Once temporary locking begins, successful login cannot occur even with the correct password until either the lock duration has passed or the account is unlocked by one of the account-reset methods listed in the following discussion.

When the server reads the grant tables, it initializes state information for each account regarding whether failed-login tracking is enabled, whether the account is currently temporarily locked and when locking began if so, and the number of failures before temporary locking occurs if the account is not locked.

An account's state information can be reset, which means that failed-login counting is reset, and the account is unlocked if currently temporarily locked. Account resets can be global for all accounts or per account:

- A global reset of all accounts occurs for any of these conditions:
 - A server restart.
 - Execution of **FLUSH PRIVILEGES**. (Starting the server with **--skip-grant-tables** causes the grant tables not to be read, which disables failed-login tracking. In this case, the first execution of **FLUSH PRIVILEGES** causes the server to read the grant tables and enable failed-login tracking, in addition to resetting all accounts.)
- A per-account reset occurs for any of these conditions:
 - Successful login for the account.
 - The lock duration passes. In this case, failed-login counting resets at the time of the next login attempt.
 - Execution of an **ALTER USER** statement for the account that sets either **FAILED_LOGIN_ATTEMPTS** or **PASSWORD_LOCK_TIME** (or both) to any value (including the current option value), or execution of an **ALTER USER . . . UNLOCK** statement for the account.

Other `ALTER USER` statements for the account have no effect on its current failed-login count or its locking state.

Failed-login tracking is tied to the login account that is used to check credentials. If user proxying is in use, tracking occurs for the proxy user, not the proxied user. That is, tracking is tied to the account indicated by `USER()`, not the account indicated by `CURRENT_USER()`. For information about the distinction between proxy and proxied users, see [Section 6.2.18, “Proxy Users”](#).

6.2.16 Server Handling of Expired Passwords

MySQL provides password-expiration capability, which enables database administrators to require that users reset their password. Passwords can be expired manually, and on the basis of a policy for automatic expiration (see [Section 6.2.15, “Password Management”](#)).

The `ALTER USER` statement enables account password expiration. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
shell> mysql -u myuser -p
Password: *****
ERROR 1862 (HY000): Your password has expired. To log in you must
change it using a client that supports expired passwords.
```

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

- The client can use the `SET` statement.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```
mysql> USE performance_schema;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.

mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.
```

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay

connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

Note

This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

```
bool arg = 1;
mysql_options(mysql,
              MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
              &arg);
```

This is the technique used within the `mysql` client, which enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or with the `--connect-expired-password` option.

- Pass the `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_real_connect()` at connect time:

```
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql,
                        host, user, password, db,
                        port, unix_socket,
                        CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
{
    ... handle error ...
}
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- If `disconnect_on_expired_password` is enabled (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` error.
- If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

6.2.17 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

- If the server cannot find the plugin, an error occurs and the connection attempt is rejected.

- Otherwise, the server invokes that plugin to authenticate the user, and the plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:

- **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.
- **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.
- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see [Section 6.2.18, “Proxy Users”](#).

**Note**

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, if the server is started with the `--skip-grant-tables` option, it also disables remote connections by enabling `skip_networking`.

- [Authentication Plugin Usage](#)
- [Authentication Plugin Client/Server Compatibility](#)
- [Authentication Plugin Connector-Writing Considerations](#)
- [Restrictions on Pluggable Authentication](#)

Available Authentication Plugins

MySQL 8.0 provides these authentication plugins:

- A plugin that performs native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication in MySQL. The `mysql_native_password` plugin implements authentication based on this native password hashing method. See [Section 6.4.1.1, “Native Pluggable Authentication”](#).
- Plugins that perform authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).
- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).
- A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See [Section 6.4.1.5, “PAM Pluggable Authentication”](#).
- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See [Section 6.4.1.6, “Windows Pluggable Authentication”](#).

- Plugins that perform authentication using LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. These plugins support proxy users as well. See [Section 6.4.1.7, “LDAP Pluggable Authentication”](#).
- A plugin that prevents all client connections to any account that uses it. Use cases for this plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users. See [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).
- A plugin that authenticates clients that connect from the local host through the Unix socket file. See [Section 6.4.1.9, “Socket Peer-Credential Pluggable Authentication”](#).
- A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See [Section 6.4.1.10, “Test Pluggable Authentication”](#).

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see [Restrictions on Pluggable Authentication](#).

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see [Writing Authentication Plugins](#).

Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under [Section 6.4.1, “Authentication Plugins”](#).

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

- If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.
- For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The `default_authentication_plugin` system variable configures the default authentication plugin.
- When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.

In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided.

For standard MySQL clients such as `mysql` and `mysqladmin`, the `--default-auth=plugin_name` option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server will override this if the server-side plugin associated with the user account requires a different client-side plugin.

If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

Authentication Plugin Client/Server Compatibility

Pluggable authentication enables flexibility in the choice of authentication methods for MySQL accounts, but in some cases client connections cannot be established due to authentication plugin incompatibility between the client and server.

The general compatibility principle for a successful client connection to a given account on a given server is that the client and server both must support the authentication *method* required by the account. Because authentication methods are implemented by authentication plugins, the client and server both must support the authentication *plugin* required by the account.

Authentication plugin incompatibilities can arise in various ways. Examples:

- Connect using a MySQL 5.7 client from 5.7.22 or lower to a MySQL 8.0 server account that authenticates with `caching_sha2_password`. This fails because the 5.7 client does not recognize the plugin, which was introduced in MySQL 8.0. (This issue is addressed in MySQL 5.7 as of 5.7.23, when `caching_sha2_password` client-side support was added to the MySQL client library and client programs.)
- Connect using a MySQL 5.5 client to a MySQL 5.6 server account that authenticates with `sha256_password`. This fails because the 5.5 client does not recognize the plugin, which was introduced in MySQL 5.6.
- Connect using a MySQL 5.7 client to a pre-5.7 server account that authenticates with `mysql_old_password`. This fails for multiple reasons. First, such a connection requires `--secure-auth=0`, which is no longer a supported option. Even were it supported, the 5.7 client does not recognize the plugin because it was removed in MySQL 5.7.
- Connect using a MySQL 5.7 client from a Community distribution to a MySQL 5.7 Enterprise server account that authenticates using one of the Enterprise-only LDAP authentication plugins. This fails because the Community client does not have access to the Enterprise plugin.

In general, these compatibility issues do not arise when connections are made between a client and server from the same MySQL distribution. When connections are made between a client and server from different MySQL series, issues can arise. These issues are inherent in the development process when MySQL introduces new authentication plugins or removes old ones. To minimize the potential for incompatibilities, regularly upgrade the server, clients, and connectors on a timely basis.

Authentication Plugin Connector-Writing Considerations

Various implementations of the MySQL client/server protocol exist. The `libmysqlclient` C API client library is one implementation. Some MySQL connectors (typically those not written in C) provide their own implementation. However, not all protocol implementations handle plugin authentication the same way. This section describes an authentication issue that protocol implementors should take into account.

In the client/server protocol, the server tells connecting clients which authentication plugin it considers the default. If the protocol implementation used by the client tries to load the default plugin and that plugin does not exist on the client side, the load operation fails. This is an unnecessary failure if the default plugin is not the plugin actually required by the account to which the client is trying to connect.

If a client/server protocol implementation does not have its own notion of default authentication plugin and always tries to load the default plugin specified by the server, it will fail with an error if that plugin is not available.

To avoid this problem, the protocol implementation used by the client should have its own default plugin and should use it as its first choice (or, alternatively, fall back to this default in case of failure to load the default plugin specified by the server). Example:

- In MySQL 5.7, `libmysqlclient` uses as its default choice either `mysql_native_password` or the plugin specified through the `MYSQL_DEFAULT_AUTH` option for `mysql_options()`.

- When a 5.7 client tries to connect to an 8.0 server, the server specifies `caching_sha2_password` as its default authentication plugin, but the client still sends credential details per either `mysql_native_password` or whatever is specified through `MYSQL_DEFAULT_AUTH`.
- The only time the client loads the plugin specified by the server is for a change-plugin request, but in that case it can be any plugin depending on the user account. In this case, the client must try to load the plugin, and if that plugin is not available, an error is not optional.

Restrictions on Pluggable Authentication

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at [Section 6.2.17, “Pluggable Authentication”](#). The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the `mysql.user` system table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

- [General Pluggable Authentication Restrictions](#)
- [Pluggable Authentication and Third-Party Connectors](#)

General Pluggable Authentication Restrictions

- **Connector/C++:** Clients that use this connector can connect to the server only through accounts that use native authentication.

Exception: A connector supports pluggable authentication if it was built to link to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed, or if the connector is recompiled from source to link against the current `libmysqlclient`.

For information about writing connectors to handle information from the server about the default server-side authentication plugin, see [Authentication Plugin Connector-Writing Considerations](#).

- **Connector/NET:** Clients that use Connector/NET can connect to the server through accounts that use native authentication or Windows native authentication.
- **Connector/PHP:** Clients that use this connector can connect to the server only through accounts that use native authentication, when compiled using the MySQL native driver for PHP (`mysqlnd`).
- **Windows native authentication:** Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.
- **Proxy users:** Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user name different from that of the connecting user). For example, the PAM and Windows plugins support proxy users. The `mysql_native_password` and `sha256_password` authentication plugins do not support proxy users by default, but can be configured to do so; see [Server Support for Proxy User Mapping](#).
- **Replication:** Replicas can not only employ replication user accounts using native authentication, but can also connect through replication user accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise, the plugin must be installed on the replica side in the directory named by the replica's `plugin_dir` system variable.

- **FEDERATED tables:** A `FEDERATED` table can access the remote table only through accounts on the remote server that use native authentication.

Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. *However, you should test the connector against a recent version of the server to verify that such connections still work without problem.*

Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections through accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server's `plugin_dir` system variable).

If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/NET uses this approach to provide support for Windows native authentication.
- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also [C API Client Plugin Functions](#).
- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

6.2.18 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see [Section 6.2.17, “Pluggable Authentication”](#). For information about specific plugins, see [Section 6.4.1, “Authentication Plugins”](#). For information about writing authentication plugins that support proxy users, see [Implementing Proxy User Support in Authentication Plugins](#).

- [Granting and Revoking the PROXY Privilege](#)
- [Default Proxy Users](#)
- [Default Proxy User and Anonymous User Conflicts](#)
- [Server Support for Proxy User Mapping](#)
- [Proxy User System Variables](#)

**Note**

One administrative benefit to be gained by proxying is that the DBA can set up a single account with a set of privileges and then enable multiple proxy users to have those privileges without having to assign the privileges individually to each of those users. As an alternative to proxy users, DBAs may find that roles provide a suitable way to map users onto specific sets of named privileges. Each user can be granted a given single role to, in effect, be granted the appropriate set of privileges. See [Section 6.2.10, “Using Roles”](#).

Requirements for Proxy User Support

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- Proxying must be supported, either by the plugin itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see [Server Support for Proxy User Mapping](#).
- The account for the external proxy user must be set up to be authenticated by the plugin. Use the `CREATE USER` statement to associate an account with an authentication plugin, or `ALTER USER` to change its plugin.
- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the `CREATE USER` and `GRANT` statements for this.
- Normally, the proxied user is configured so that it can be used only in proxying scenarios and not for direct logins.
- The proxy user account must have the `PROXY` privilege for the proxied account. Use the `GRANT` statement for this.
- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.

Alternatively, for plugins that are provided proxy mapping by the server, the proxied user is determined from the `PROXY` privilege held by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

- When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.
- If that account is a proxy account, the server attempts to determine the appropriate proxied account by finding a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

Simple Proxy User Example

Consider the following account definitions:

```
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
  IDENTIFIED WITH my_auth_plugin
  AS 'my_auth_string';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'employee'@'localhost'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL
  ON employees.*
  TO 'employee'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
  ON 'employee'@'localhost'
  TO 'employee_ext'@'localhost';
```

When a client connects as `employee_ext` from the local host, MySQL uses the plugin named `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `'my_auth_string'` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` external user, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied user). If this privilege has not been granted, an error occurs. Otherwise, `employee_ext` assumes the privileges of `employee`. The server checks statements executed during the client session by `employee_ext` against the privileges granted to `employee`. In this case, `employee_ext` can access tables in the `employees` database.

The proxied account, `employee`, uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly. (This assumes that the plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| employee_ext@localhost | employee@localhost |
+-----+-----+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

Preventing Direct Login to Proxied Accounts

Proxied accounts generally are intended to be used only by means of proxy accounts. That is, clients connect using a proxy account, then are mapped onto and assume the privileges of the appropriate proxied user.

There are multiple ways to ensure that a proxied account cannot be used directly:

- Associate the account with the `mysql_no_login` authentication plugin. In this case, the account cannot be used for direct logins under any circumstances. This assumes that the plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).
- Include the `ACCOUNT LOCK` option when you create the account. See [Section 13.7.1.3, “CREATE USER Statement”](#). With this method, also include a password so that if the account is unlocked later, it cannot be accessed with no password. (If the `validate_password` component is enabled, it will not permit creating an account without a password, even if the account is locked. See [Section 6.4.3, “The Password Validation Component”](#).)
- Create the account with a password but do not tell anyone else the password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

Granting and Revoking the PROXY Privilege

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

The statement creates a row in the `mysql.proxies_priv` grant table.

At connect time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. Examples:

```
-- grant PROXY to multiple accounts
GRANT PROXY ON 'a' TO 'b', 'c', 'd';

-- revoke PROXY from multiple accounts
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';

-- grant PROXY to an account and enable the account to grant
-- PROXY to the proxied account
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;

-- grant PROXY to default proxy account
GRANT PROXY ON 'a' TO '@';
```

The `PROXY` privilege can be granted in these cases:

- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.
- By `proxied_user` for itself: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial `root` account created during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost'
  IDENTIFIED BY 'admin_password';
GRANT PROXY
  ON ''@''
  TO 'admin'@'localhost'
  WITH GRANT OPTION;
```

Those statements create an `admin` user that can manage all `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account with an empty user name and host name (`''@''`), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). Suppose that there exists a plugin named `ldap_auth` that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy account
CREATE USER ''@''
  IDENTIFIED WITH ldap_auth
  AS 'O=Oracle, OU=MySQL';

-- create proxied accounts; use
-- mysql_no_login plugin to prevent direct login
CREATE USER 'developer'@'localhost'
  IDENTIFIED WITH mysql_no_login;
CREATE USER 'manager'@'localhost'
  IDENTIFIED WITH mysql_no_login;

-- grant to default proxy account the
-- PROXY privilege for proxied accounts
GRANT PROXY
  ON 'manager'@'localhost'
  TO ''@'';
GRANT PROXY
  ON 'developer'@'localhost'
  TO ''@'';
```

Now assume that a client connects as follows:

```
shell> mysql --user=myuser --password ...
Enter password: myuser_password
```

The server will not find `myuser` defined as a MySQL user. But because there is a blank user account (`''@''`) that matches the client user name and host name, the server authenticates the client against that account: The server invokes the `ldap_auth` authentication plugin and passes `myuser` and `myuser_password` to it as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_password` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. Returning a user name different from the client user name of `myuser` signals to the server that it should treat `myuser` as a proxy. The server verifies that `''@''` can authenticate as `developer` (because `''@''` has the `PROXY` privilege to do so) and accepts the connection. The session proceeds with `myuser` having the privileges of the `developer` proxied user. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` and `CURRENT_USER()` functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
```

```
| myuser@localhost | developer@localhost |
+-----+-----+
```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of the `manager` proxied user.

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| myuser@localhost | manager@localhost |
+-----+-----+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the `developer` or `manager` account, which is why those proxied accounts should be protected against direct login (see [Preventing Direct Login to Proxied Accounts](#)).

Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user because they can prevent that user from working as intended.

In the preceding discussion, the default proxy user account has `' '` in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and `' % '` in the host part, because `' % '` also matches any host, but has precedence over `' '` by the rules that the server uses to sort account rows internally (see [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#)).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy account
CREATE USER ''@''
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
-- create anonymous account
CREATE USER ''@%'
  IDENTIFIED BY 'anon_user_password';
```

The first account (`' '@''`) is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account (`' '@%'`) is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (`' '`), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of `' % '` ahead of `' '`. For accounts that do not match any more-specific account, the server attempts to authenticate them against `' '@%'` (the anonymous user) rather than `' '@''` (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:

- Remove the anonymous account so that it does not conflict with the default proxy user.
- Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only `localhost` proxy connections, use `' '@'localhost'`:

```
CREATE USER ''@'localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
```

In addition, modify any `GRANT PROXY` statements to name `' '@'localhost'` rather than `' '@''` as the proxy user.

Be aware that this strategy prevents anonymous-user connections from `localhost`.

- Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the `authentication_windows` plugin. See [Section 6.4.1.6, “Windows Pluggable Authentication”](#).
- Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```
-- create proxy user for local connections
CREATE USER '@'localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
-- create proxy user for remote connections
CREATE USER '@%'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
```

Create the proxied users:

```
-- create proxied user for local connections
CREATE USER 'developer'@'localhost'
  IDENTIFIED WITH mysql_no_login;
-- create proxied user for remote connections
CREATE USER 'developer'@%'
  IDENTIFIED WITH mysql_no_login;
```

Grant to each proxy account the `PROXY` privilege for the corresponding proxied account:

```
GRANT PROXY
  ON 'developer'@'localhost'
  TO '@'localhost';
GRANT PROXY
  ON 'developer'@%'
  TO '@%';
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the `some_plugin`/`'some_auth_string'` combination causes `some_plugin` to map the client user name to `developer`. Local connections match the `'@'localhost'` proxy user, which maps to the `'developer'@'localhost'` proxied user. Remote connections match the `'@%'` proxy user, which maps to the `'developer'@%'` proxied user.

Server Support for Proxy User Mapping

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`. If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request:

- By default, `check_proxy_users` is disabled, so the server performs no proxy user mapping even for authentication plugins that request server support for proxy users.
- If `check_proxy_users` is enabled, it may also be necessary to enable a plugin-specific system variable to take advantage of server proxy user mapping support:
 - For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
 - For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

For example, to enable all the preceding capabilities, start the server with these lines in the `my.cnf` file:

```
[mysqld]
check_proxy_users=ON
mysql_native_password_proxy_users=ON
sha256_password_proxy_users=ON
```

Assuming that the relevant system variables have been enabled, create the proxy user as usual using `CREATE USER`, then grant it the `PROXY` privilege to a single other account to be treated as the proxied user. When the server receives a successful connection request for the proxy user, it finds that the user has the `PROXY` privilege and uses it to determine the proper proxied user.

```
-- create proxy account
CREATE USER 'proxy_user'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
  ON ...
  TO 'proxied_user'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
  ON 'proxied_user'@'localhost'
  TO 'proxy_user'@'localhost';
```

To use the proxy account, connect to the server using its name and password:

```
shell> mysql -u proxy_user -p
Enter password: (enter proxy_user password here)
```

Authentication succeeds, the server finds that `proxy_user` has the `PROXY` privilege for `proxied_user`, and the session proceeds with `proxy_user` having the privileges of `proxied_user`.

Proxy user mapping performed by the server is subject to these restrictions:

- The server will not proxy to or from an anonymous user, even if the associated `PROXY` privilege is granted.
- When a single account has been granted proxy privileges for more than one proxied account, server proxy user mapping is nondeterministic. Therefore, granting to a single account proxy privileges for multiple proxied accounts is discouraged.

Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user`: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `' '@'` proxy account, this variable is set as follows:

```
mysql> SELECT @@proxy_user;
+-----+
| @@proxy_user |
+-----+
| ' '@'       |
+-----+
```

- `external_user`: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that

authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

6.2.19 Account Locking

MySQL supports locking and unlocking user accounts using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` clauses for the `CREATE USER` and `ALTER USER` statements:

- When used with `CREATE USER`, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.

If the `validate_password` component is enabled, it will not permit creating an account without a password, even if the account is locked. See [Section 6.4.3, “The Password Validation Component”](#).

- When used with `ALTER USER`, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.

As of MySQL 8.0.19, `ALTER USER ... UNLOCK` unlocks any account named by the statement that is temporarily locked due to too many failed logins. See [Section 6.2.15, “Password Management”](#).

Account locking state is recorded in the `account_locked` column of the `mysql.user` system table. The output from `SHOW CREATE USER` indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the `Locked_connects` status variable that indicates the number of attempts to connect to a locked account, returns an `ER_ACCOUNT_HAS_BEEN_LOCKED` error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a `DEFINER` attribute naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the `account_locked` column in the `mysql.user` system table. For upgrades from MySQL versions older than 5.7.6, perform the MySQL upgrade procedure to ensure that this column exists. See [Section 2.11, “Upgrading MySQL”](#). For nonupgraded installations that have no `account_locked` column, the server treats all accounts as unlocked, and using the `ACCOUNT LOCK` or `ACCOUNT UNLOCK` clauses produces an error.

6.2.20 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` system table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%.example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account at account-creation time, use the `CREATE USER` statement. To modify the limits for an existing account, use `ALTER USER`. Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
->     WITH MAX_QUERIES_PER_HOUR 20
->         MAX_UPDATES_PER_HOUR 10
->         MAX_CONNECTIONS_PER_HOUR 5
->         MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use an `ALTER USER` statement. The following statement changes the query limit for `francis` to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a `MAX_USER_CONNECTIONS` limit of zero. `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and

the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 6.2.3, “Grant Tables”](#).)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

6.2.21 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it will not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable

set to `127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM and DEB distributions on Linux), the installation process initializes the MySQL data directory, including the `mysql` system database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see [Section 2.10, “Postinstallation Setup and Testing”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, initialize the data directory. After doing so and starting the server, you should be able to connect to the server.

- After a fresh installation, if you try to log on to the server as `root` without using a password, you might get the following error message.

```
shell> mysql -u root
ERROR 1045 (28000): Access denied for user 'root'@'localhost' (using password: NO)
```

It means a root password has already been assigned during installation and it has to be supplied. See [Section 2.10.4, “Securing the Initial MySQL Account”](#) on the different ways the password could have been assigned and, in some cases, how to find it. If you need to reset the root password, see instructions in [Section B.3.3.2, “How to Reset the Root Password”](#). After you have found or reset your password, log on again as `root` using the `--password` (or `-p`) option:

```
shell> mysql -u root -p
Enter password:
```

However, the server is going to let you connect as `root` without using a password if you have initialized MySQL using `mysqld --initialize-insecure` (see [Section 2.10.1, “Initializing the Data Directory”](#) for details). That is a security risk, so you should set a password for the `root` account; see [Section 2.10.4, “Securing the Initial MySQL Account”](#) for instructions.

- If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Section 2.11, “Upgrading MySQL”](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 4.2.2.2, “Using Option Files”](#). Environment variables are listed in [Section 4.9, “Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pXXXX ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see [Section 6.2.14, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section B.3.3.2, “How to Reset the Root Password”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pxxxx -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [Section 5.1.12.3, “DNS Lookups and the Host Cache”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `skip_name_resolve` system variable enabled.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see [Section 4.2.4, “Connecting to the MySQL Server Using Command Options”](#).
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root` works but `mysql -h your_hostname -u root` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host `'pluto'` in the `user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the row does not work. Try adding a row to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add a row to the `user` table with a `Host` value that contains a wildcard (for example, `'pluto.%'`). However, use of `Host` values ending with `%` is *insecure* and is *not* recommended!)
- If `mysql -u user_name` works but `mysql -u user_name some_db` does not, you have not granted access to the given user for the database named `some_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all rows that have `Host` values containing wildcards (rows that contain `'%'` or `'_'` characters). A very common error is to insert a new row with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include a row with `Host='localhost'` and `User=''`. Because that

row has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new row when connecting from `localhost`! The correct procedure is to insert a second row with `Host='localhost'` and `User='some_user'`, or to delete the row with `Host='localhost'` and `User=''`. After deleting the row, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#).

- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA` statement, your row in the `user` table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 6.2.13, “When Privilege Changes Take Effect”](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -ppassword db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=password` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `SHOW GRANTS` statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See [Section 5.9.4, “The DEBUG Package”](#).
- If you have any other problems with the MySQL grant tables and ask on the [MySQL Community Slack](#), always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.6, “How to Report Bugs or Problems”](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

6.2.22 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@localhost'` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost      |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER '@localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
```

```

| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1 |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost |
+-----+

```

6.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#)).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

Support for encrypted connections in MySQL is provided using OpenSSL. For information about the encryption protocols and ciphers that OpenSSL supports, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

Note

From MySQL 8.0.11 to 8.0.17, it was possible to compile MySQL using wolfSSL as an alternative to OpenSSL. As of MySQL 8.0.18, support for wolfSSL is removed and all MySQL builds use OpenSSL.

By default, MySQL programs attempt to connect using encryption if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. For information about options that affect use of encrypted connections, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#) and [Command Options for Encrypted Connections](#).

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the `REQUIRE` clause of the `CREATE USER` statement in [Section 13.7.1.3, “CREATE USER Statement”](#). See also the description of the `require_secure_transport` system variable at [Section 5.1.8, “Server System Variables”](#).

Encrypted connections can be used between source and replica servers. See [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

For information about using encrypted connections from the MySQL C API, see [C API Support for Encrypted Connections](#).

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see [Section 6.3.4, “Connecting to MySQL Remotely from Windows with SSH”](#).

6.3.1 Configuring MySQL to Use Encrypted Connections

Several configuration parameters are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- [Server-Side Startup Configuration for Encrypted Connections](#)
- [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#)
- [Client-Side Configuration for Encrypted Connections](#)
- [Configuring Encrypted Connections as Mandatory](#)

Encrypted connections also can be used in these contexts:

- Between source and replica replication servers. See [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- Among Group Replication servers. See [Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).
- By client programs that are based on the MySQL C API. See [C API Support for Encrypted Connections](#).

Instructions for creating any required certificate and key files are available in [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).

Server-Side Startup Configuration for Encrypted Connections

On the server side, the `--ssl` option specifies that the server permits but does not require encrypted connections. This option is enabled by default, so it need not be specified explicitly.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. See [Configuring Encrypted Connections as Mandatory](#).

These system variables on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`ssl_capath` is similar but specifies the path name of a directory of CA certificate files.)
- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `ssl_key`: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To specify in addition that clients are required to use encrypted connections, enable the `require_secure_transport` system variable:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
require_secure_transport=ON
```

Each certificate and key system variable names a file in PEM format. Should you need to create the required certificate and key files, see [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#). MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See [Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#). Alternatively, if you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

The server performs certificate and key file autodiscovery. If no explicit encrypted-connection options are given other than `--ssl` (possibly along with `ssl_cipher`) to configure encrypted connections, the server attempts to enable encrypted-connection support automatically at startup:

- If the server discovers valid certificate and key files named `ca.pem`, `server-cert.pem`, and `server-key.pem` in the data directory, it enables support for encrypted connections by clients. (The files need not have been generated automatically; what matters is that they have those names and are valid.)
- If the server does not find valid certificate and key files in the data directory, it continues executing but without support for encrypted connections.

If the server automatically enables encrypted connection support, it writes a note to the error log. If the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server or manually using `mysql_ssl_rsa_setup`.)

MySQL also provides these system variables for server-side encrypted-connection control:

- `ssl_cipher`: The list of permissible ciphers for connection encryption.
- `ssl_crl`: The path name of the file containing certificate revocation lists. (`ssl_crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `tls_version`, `tls_ciphersuites`: Which encryption protocols and ciphersuites the server permits for encrypted connections; see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). For example, you can set `tls_version` to prevent clients from using less-secure protocols.

If the server cannot create a valid TLS context from the system variables for server-side encrypted-connection control, the server does not support encrypted connections.

Server-Side Runtime Configuration and Monitoring for Encrypted Connections

Prior to MySQL 8.0.16, the `tls_xxx` and `ssl_xxx` system variables that configure encrypted-connection support can be set only at server startup. These system variables therefore determine the TLS context the server uses for all new connections.

As of MySQL 8.0.16, the `tls_xxx` and `ssl_xxx` system variables are dynamic and can be set at runtime, not just at startup. If changed with `SET GLOBAL`, the new values apply only until server restart. If changed with `SET PERSIST`, the new values also carry over to subsequent server restarts. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#). However, runtime changes to these variables do not immediately affect the TLS context for new connections, as explained later in this section.

Along with the change in MySQL 8.0.16 that enables runtime changes to the TLS context-related system variables, the server enables runtime updates to the actual TLS context used for new

connections. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired.

To create the initial TLS context, the server uses the values that the context-related system variables have at startup. To expose the context values, the server also initializes a set of corresponding status variables. The following table shows the system variables that define the TLS context and the corresponding status variables that expose the currently active context values.

Table 6.11 System and Status Variables for Server Main Connection Interface TLS Context

System Variable Name	Corresponding Status Variable Name
<code>ssl_ca</code>	<code>Current_tls_ca</code>
<code>ssl_capath</code>	<code>Current_tls_capath</code>
<code>ssl_cert</code>	<code>Current_tls_cert</code>
<code>ssl_cipher</code>	<code>Current_tls_cipher</code>
<code>ssl_crl</code>	<code>Current_tls_crl</code>
<code>ssl_crlpath</code>	<code>Current_tls_crlpath</code>
<code>ssl_key</code>	<code>Current_tls_key</code>
<code>tls_ciphersuites</code>	<code>Current_tls_ciphersuites</code>
<code>tls_version</code>	<code>Current_tls_version</code>

To reconfigure the TLS context at runtime, use this procedure:

1. For any TLS context-related system variables that should be changed, set them to their new values.
2. Execute `ALTER INSTANCE RELOAD TLS`. This statement reconfigures the active TLS context from the current values of the TLS context-related system variables. It also sets the context-related status variables to reflect the new active context values. The statement requires the `CONNECTION_ADMIN` privilege.
3. New connections established after execution of `ALTER INSTANCE RELOAD TLS` use the new TLS context. Existing connections remain unaffected. If existing connections should be terminated, use the `KILL` statement.

The members of each pair of system and status variables may have different values temporarily due to the way the reconfiguration procedure works:

- Changes to the system variables prior to `ALTER INSTANCE RELOAD TLS` do not change the TLS context. At this point, those changes have no effect on new connections, and corresponding context-related system and status variables may have different values. This enables you to make any changes required to individual system variables, then update the active TLS context atomically with `ALTER INSTANCE RELOAD TLS` after all system variable changes have been made.
- After `ALTER INSTANCE RELOAD TLS`, corresponding system and status variables have the same values. This remains true until the next change to the system variables.

In some cases, `ALTER INSTANCE RELOAD TLS` by itself may suffice to reconfigure the TLS context, without changing any system variables. Suppose that the certificate in the file named by `ssl_cert` has expired. It is sufficient to replace the existing file contents with a nonexpired certificate and execute `ALTER INSTANCE RELOAD TLS` to cause the new file contents to be read and used for new connections.

As of MySQL 8.0.21, the server implements independent connection-encryption configuration for the administrative connection interface. See [Administrative Interface Support for Encrypted Connections](#). In addition, `ALTER INSTANCE RELOAD TLS` is extended with a `FOR CHANNEL` clause that enables specifying the channel (interface) for which to reload the TLS context. See [Section 13.1.5, “ALTER INSTANCE Statement”](#). There are no status variables to expose the administrative interface TLS

context, but the Performance Schema `tls_channel_status` table exposes TLS properties for both the main and administrative interfaces. See [Section 26.12.19.8, “The `tls_channel_status` Table”](#).

Updating the main interface TLS context has these effects:

- The update changes the TLS context used for new connections on the main connection interface.
- The update also changes the TLS context used for new connections on the administrative interface unless some nondefault TLS parameter value is configured for that interface.
- The update does not affect the TLS context used by other enabled server plugins or components such as Group Replication or X Plugin:
 - To apply the main interface reconfiguration to Group Replication's group communication connections, which take their settings from the server's TLS context-related system variables, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to stop and restart Group Replication.
 - X Plugin initializes its TLS context at plugin initialization as described at [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#). This context does not change thereafter.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

Options that enable or disable encrypted connections on a connection interface have an effect only at startup. For example, the `--ssl` and `--admin-ssl` options affect only at startup whether the main and administrative interfaces support encrypted connections. Such options are ignored and have no effect on the operation of `ALTER INSTANCE RELOAD TLS` at runtime. For example, you can use `--ssl=OFF` to start the server with encrypted connections disabled on the main interface, then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS` to enable encrypted connections at runtime.

Client-Side Configuration for Encrypted Connections

For a complete list of client options related to establishment of encrypted connections, see [Command Options for Encrypted Connections](#).

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the `--ssl-mode` option:

- In the absence of an `--ssl-mode` option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established. This is also the behavior with an explicit `--ssl-mode=PREFERRED` option.
- With `--ssl-mode=REQUIRED`, clients require an encrypted connection and fail if one cannot be established.
- With `--ssl-mode=DISABLED`, clients use an unencrypted connection.
- With `--ssl-mode=VERIFY_CA` or `--ssl-mode=VERIFY_IDENTITY`, clients require an encrypted connection, and also perform verification against the server CA certificate and (with `VERIFY_IDENTITY`) against the server host name in its certificate.

Attempts to establish an unencrypted connection fail if the `require_secure_transport` system variable is enabled on the server side to cause the server to require encrypted connections. See [Configuring Encrypted Connections as Mandatory](#).

The following options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the `ssl_ca`, `ssl_cert`, and

`ssl_key` system variables used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`), and specify `--ssl-mode=VERIFY_CA`.
- To enable host name identity verification as well, use `--ssl-mode=VERIFY_IDENTITY` rather than `--ssl-mode=VERIFY_CA`.

Note

Host name identity verification with `VERIFY_IDENTITY` does not work with self-signed certificates that are created automatically by the server or manually using `mysql_ssl_rsa_setup` (see [Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)). Such self-signed certificates do not contain the server name as the Common Name value.

Host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.

MySQL also provides these options for client-side SSL control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `--tls-version`, `--tls-ciphersuites`: The permitted encryption protocols and ciphersuites; see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `CREATE USER` statement that included the `REQUIRE SSL` clause. Assuming that the server supports encrypted connections, a client can connect using encryption with no `--ssl-mode` option or with an explicit `--ssl-mode=PREFERRED` option:

```
mysql
```

Or:

```
mysql --ssl-mode=PREFERRED
```

For an account created with a `REQUIRE SSL` clause, the connection attempt fails if an encrypted connection cannot be established. For an account with no special encryption requirements, the attempt falls back to an unencrypted connection if an encrypted connection cannot be established. To prevent fallback and fail if an encrypted connection cannot be obtained, connect like this:

```
mysql --ssl-mode=REQUIRED
```

If the account has more stringent security requirements, other options must be specified to establish an encrypted connection:

- For accounts created with a `REQUIRE X509` clause, clients must specify at least `--ssl-cert` and `--ssl-key`. In addition, `--ssl-ca` (or `--ssl-capath`) is recommended so that the public certificate provided by the server can be verified. For example (enter the command on a single line):

```
mysql --ssl-ca=ca.pem
      --ssl-cert=client-cert.pem
      --ssl-key=client-key.pem
```

- For accounts created with a `REQUIRE ISSUER` or `REQUIRE SUBJECT` clause, the encryption requirements are the same as for `REQUIRE X509`, but the certificate must match the issue or subject, respectively, specified in the account definition.

For additional information about the `REQUIRE` clause, see [Section 13.7.1.3, “CREATE USER Statement”](#).

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl-mode=DISABLED`:

```
mysql --ssl-mode=DISABLED
```

To determine whether the current connection with the server uses encryption, check the session value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256         |
+-----+-----+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL: Not in use
...
```

Or:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES128-GCM-SHA256
...
```

Configuring Encrypted Connections as Mandatory

For some MySQL deployments it may be not only desirable but mandatory to use encrypted connections (for example, to satisfy regulatory requirements). This section discusses configuration settings that enable you to do this. These levels of control are available:

- You can configure the server to require that clients connect using encrypted connections.
- You can invoke individual client programs to require an encrypted connection, even if the server permits but does not require encryption.
- You can configure individual MySQL accounts to be usable only over encrypted connections.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
```

```
require_secure_transport=ON
```

Alternatively, to set and persist the value at runtime, use this statement:

```
SET PERSIST require_secure_transport=ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

With `require_secure_transport` enabled, client connections to the server are required to use some form of secure transport, and the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

To invoke a client program such that it requires an encrypted connection whether or not the server requires encryption, use an `--ssl-mode` option value of `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`. For example:

```
mysql --ssl-mode=REQUIRED
mysqldump --ssl-mode=VERIFY_CA
mysqladmin --ssl-mode=VERIFY_IDENTITY
```

To configure a MySQL account to be usable only over encrypted connections, include a `REQUIRE` clause in the `CREATE USER` statement that creates the account, specifying in that clause the encryption characteristics you require. For example, to require an encrypted connection and the use of a valid X.509 certificate, use `REQUIRE X509`:

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For additional information about the `REQUIRE` clause, see [Section 13.7.1.3, “CREATE USER Statement”](#).

To modify existing accounts that have no encryption requirements, use the `ALTER USER` statement.

6.3.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports multiple TLS protocols and ciphers, and enables configuring which protocols and ciphers to permit for encrypted connections. It is also possible to determine which protocol and cipher the current session uses.

- [Supported Connection TLS Protocols](#)
- [Connection TLS Protocol Configuration](#)
- [Connection Cipher Configuration](#)
- [Connection TLS Protocol Negotiation](#)
- [Monitoring Current Client Session TLS Protocol and Cipher](#)

Supported Connection TLS Protocols

MySQL supports encrypted connections using the TLSv1, TLSv1.1, TLSv1.2, and TLSv1.3 protocols, listed in order from less secure to more secure. The set of protocols actually permitted for connections is subject to multiple factors:

- MySQL configuration. Permitted TLS protocols can be configured on both the server side and client side to include only a subset of the supported TLS protocols. The configuration on both sides must include at least one protocol in common or connection attempts cannot negotiate a protocol to use. For details, see [Connection TLS Protocol Negotiation](#).
- System-wide host configuration. The host system may permit only certain TLS protocols, which means that MySQL connections cannot use nonpermitted protocols even if MySQL itself permits them:

- Suppose that MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.2 or higher. In this case, you cannot establish MySQL connections that use TLSv1 or TLSv1.1, even though MySQL is configured to permit them, because the host system does not permit them.
- If MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.3 or higher, you cannot establish MySQL connections at all, because no protocol permitted by MySQL is permitted by the host system.

Workarounds for this issue include:

- Change the system-wide host configuration to permit additional TLS protocols. Consult your operating system documentation for instructions. For example, your system may have an `/etc/ssl/openssl.cnf` file that contains these lines to restrict TLS protocols to TLSv1.2 or higher:

```
[system_default_sect]
MinProtocol = TLSv1.2
```

Changing the value to a lower protocol version or `None` makes the system more permissive. This workaround has the disadvantage that permitting lower (less secure) protocols may have adverse security consequences.

- If you cannot or prefer not to change the host system TLS configuration, change MySQL applications to use higher (more secure) TLS protocols that are permitted by the host system. This may not be possible for older versions of MySQL that support only lower protocol versions. For example, TLSv1 is the only supported protocol prior to MySQL 5.6.46, so attempts to connect to a pre-5.6.46 server fail even if the client is from a newer MySQL version that supports higher protocol versions. In such cases, an upgrade to a version of MySQL that supports additional TLS versions may be required.
- The SSL library. If the SSL library does not support a particular protocol, neither does MySQL, and any parts of the following discussion that specify that protocol do not apply.

Note

Support for the TLSv1.3 protocol is available as of MySQL 8.0.16 (as of MySQL 8.0.18 for the Group Replication component). In addition, to use TLSv1.3, both the MySQL server and the client application must be compiled using OpenSSL 1.1.1 or higher.

Connection TLS Protocol Configuration

On the server side, the value of the `tls_version` system variable determines which TLS protocols a MySQL server permits for encrypted connections. The `tls_version` value applies to connections from clients, regular source/replica replication connections where this server instance is the source, Group Replication group communication connections, and Group Replication distributed recovery connections where this server instance is the donor. The variable value is a list of one or more comma-separated protocol versions from this list (not case-sensitive): TLSv1, TLSv1.1, TLSv1.2, and (if available) TLSv1.3. By default, this variable lists all protocols supported by the SSL library used to compile MySQL. To determine the value of `tls_version` at runtime, use this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| tls_version   | TLSv1,TLSv1.1,TLSv1.2             |
+-----+-----+
```

To change the value of `tls_version`, set it at server startup. For example, to permit connections that use the TLSv1.1 or TLSv1.2 protocol, but prohibit connections that use the less-secure TLSv1 protocol, use these lines in the server `my.cnf` file:

```
[mysqld]
tls_version=TLSv1.1,TLSv1.2
```

To be even more restrictive and permit only TLSv1.2 connections, set `tls_version` like this:

```
[mysqld]
tls_version=TLSv1.2
```

As of MySQL 8.0.16, `tls_version` can also be changed at runtime. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

On the client side, the `--tls-version` option specifies which TLS protocols a client program permits for connections to the server. The format of the option value is the same as for the `tls_version` system variable described previously (a list of one or more comma-separated protocol versions).

For source/replica replication connections where this server instance is the replica, the `MASTER_TLS_VERSION` option for the `CHANGE MASTER TO` statement specifies which TLS protocols the replica permits for connections to the source. The format of the option value is the same as for the `tls_version` system variable described previously. See [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

The protocols that can be specified for `MASTER_TLS_VERSION` depend on the SSL library. This option is independent of and not affected by the server `tls_version` value. For example, a server that acts as a replica can be configured with `tls_version` set to TLSv1.3 to permit only incoming connections that use TLSv1.3, but also configured with `MASTER_TLS_VERSION` set to TLSv1.2 to permit only TLSv1.2 for outgoing replica connections to the source.

For Group Replication distributed recovery connections where this server instance is the joining member that initiates distributed recovery (that is, the client), the `group_replication_recovery_tls_version` system variable specifies which protocols are permitted by the client. This option is independent of and not affected by the server `tls_version` value, which applies when this server instance is the donor. A Group Replication server generally participates in distributed recovery both as a donor and as a joining member over the course of its group membership, so both these system variables should be set. See [Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

TLS protocol configuration affects which protocol a given connection uses, as described in [Connection TLS Protocol Negotiation](#).

Permitted protocols should be chosen such as not to leave “holes” in the list. For example, these server configuration values do not have holes:

```
tls_version=TLSv1,TLSv1.1,TLSv1.2,TLSv1.3
tls_version=TLSv1.1,TLSv1.2,TLSv1.3
tls_version=TLSv1.2,TLSv1.3
tls_version=TLSv1.3
```

These values do have holes and should not be used:

```
tls_version=TLSv1,TLSv1.2      (TLSv1.1 is missing)
tls_version=TLSv1.1,TLSv1.3   (TLSv1.2 is missing)
```

The prohibition on holes also applies in other configuration contexts, such as for clients or replicas.

The list of permitted protocols should not be empty. If you set a TLS version parameter to the empty string, encrypted connections cannot be established:

- `tls_version`: The server does not permit encrypted incoming connections.
- `--tls-version`: The client does not permit encrypted outgoing connections to the server.
- `MASTER_TLS_VERSION`: The replica does not permit encrypted outgoing connections to the source.

Connection Cipher Configuration

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers applicable for encrypted connections that use TLS protocols up through TLSv1.2:

- Set the `ssl_cipher` system variable on the server side, and use the `--ssl-cipher` option for client programs.
- For regular source/replica replication connections, where this server instance is the source, set the `ssl_cipher` system variable. Where this server instance is the replica, use the `MASTER_SSL_CIPHER` option for the `CHANGE MASTER TO` statement. See [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, set the `ssl_cipher` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_ssl_cipher` system variable. See [Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

For encrypted connections that use TLSv1.3, OpenSSL 1.1.1 and higher supports the following ciphersuites, the first three of which are enabled by default:

```
TLS_AES_128_GCM_SHA256
TLS_AES_256_GCM_SHA384
TLS_CHACHA20_POLY1305_SHA256
TLS_AES_128_CCM_SHA256
TLS_AES_128_CCM_8_SHA256
```

To configure the permitted TLSv1.3 ciphersuites explicitly, set the following parameters. In each case, the configuration value is a list of zero or more colon-separated ciphersuite names.

- On the server side, use the `tls_ciphersuites` system variable. If this variable is not set, its default value is `NULL`, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.
- On the client side, use the `--tls-ciphersuites` option. If this option is not set, the client permits the default set of ciphersuites. If the option is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.
- For regular source/replica replication connections, where this server instance is the source, use the `tls_ciphersuites` system variable. Where this server instance is the replica, use the `MASTER_TLS_CIPHERSUITES` option for the `CHANGE MASTER TO` statement. See [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, use the `tls_ciphersuites` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_tls_ciphersuites` system variable. See [Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

Note

Ciphersuite support is available as of MySQL 8.0.16, but requires that both the MySQL server and the client application be compiled using OpenSSL 1.1.1 or higher.

In MySQL 8.0.16 through 8.0.18, the `MASTER_TLS_CIPHERSUITES` option for the `CHANGE MASTER TO` statement and the `group_replication_recovery_tls_ciphersuites` system variable are not available. In these releases, if TLSv1.3 is used for source/replica replication connections, or in Group Replication for distributed recovery (supported from MySQL 8.0.18), the replication source or Group Replication donor servers must permit the use of at least one TLSv1.3 ciphersuite that is enabled by default. From MySQL 8.0.19, you can use the options to configure client support for any selection of ciphersuites, including only non-default ciphersuites if you want.

A given cipher may work only with particular TLS protocols, which affects the TLS protocol negotiation process. See [Connection TLS Protocol Negotiation](#).

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites.

For encrypted connections that use TLS.v1.3, MySQL uses the SSL library default ciphersuite list.

For encrypted connections that use TLS protocols up through TLSv1.2, MySQL passes the following default cipher list to the SSL library.

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES128-SHA256
ECDHE-RSA-AES128-SHA256
ECDHE-ECDSA-AES256-SHA384
ECDHE-RSA-AES256-SHA384
DHE-RSA-AES128-GCM-SHA256
DHE-DSS-AES128-GCM-SHA256
DHE-RSA-AES128-SHA256
DHE-DSS-AES128-SHA256
DHE-DSS-AES256-GCM-SHA384
DHE-RSA-AES256-SHA256
DHE-DSS-AES256-SHA256
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-GCM-SHA256
DH-DSS-AES128-GCM-SHA256
ECDH-ECDSA-AES128-GCM-SHA256
AES256-GCM-SHA384
DH-DSS-AES256-GCM-SHA384
ECDH-ECDSA-AES256-GCM-SHA384
AES128-SHA256

ECDH-ECDSA-AES128-SHA256
AES256-SHA256
DH-DSS-AES256-SHA256
ECDH-ECDSA-AES256-SHA384
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
ECDH-ECDSA-AES256-SHA
DHE-RSA-AES256-GCM-SHA384
```

```
DH-RSA-AES128-GCM-SHA256
ECDH-RSA-AES128-GCM-SHA256
DH-RSA-AES256-GCM-SHA384
ECDH-RSA-AES256-GCM-SHA384
DH-RSA-AES128-SHA256
ECDH-RSA-AES128-SHA256
DH-RSA-AES256-SHA256
ECDH-RSA-AES256-SHA384
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
ECDH-ECDSA-AES256-SHA
DH-RSA-AES128-SHA
ECDH-RSA-AES128-SHA
DH-RSA-AES256-SHA
ECDH-RSA-AES256-SHA
DES-CBC3-SHA
```

These cipher restrictions are in place:

- The following ciphers are permanently restricted:

```
!DHE-DSS-DES-CBC3-SHA
!DHE-RSA-DES-CBC3-SHA
!ECDH-RSA-DES-CBC3-SHA
!ECDH-ECDSA-DES-CBC3-SHA
!ECDHE-RSA-DES-CBC3-SHA
!ECDHE-ECDSA-DES-CBC3-SHA
```

- The following categories of ciphers are permanently restricted:

```
!aNULL
!eNULL
!EXPORT
!LOW
!MD5
!DES
!RC2
!RC4
!PSK
!SSLv3
```

If the server is started with the `ssl_cert` system variable set to a certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for encrypted connections disabled.

Connection TLS Protocol Negotiation

Connection attempts in MySQL negotiate use of the highest TLS protocol version available on both sides for which a protocol-compatible encryption cipher is available on both sides. The negotiation process depends on factors such as the SSL library used to compile the server and client, the TLS protocol and encryption cipher configuration, and which key size is used:

- For a connection attempt to succeed, the server and client TLS protocol configuration must permit some protocol in common.
- Similarly, the server and client encryption cipher configuration must permit some cipher in common. A given cipher may work only with particular TLS protocols, so a protocol available to the negotiation process is not chosen unless there is also a compatible cipher.

- If TLSv1.3 is available, it is used if possible. (This means that server and client configuration both must permit TLSv1.3, and both must also permit some TLSv1.3-compatible encryption cipher.) Otherwise, MySQL continues through the list of available protocols, using TLSv1.2 if possible, and so forth. Negotiation proceeds from more secure protocols to less secure. Negotiation order is independent of the order in which protocols are configured. For example, negotiation order is the same regardless of whether `tls_version` has a value of `TLSv1`, `TLSv1.1`, `TLSv1.2`, `TLSv1.3` or `TLSv1.3`, `TLSv1.2`, `TLSv1.1`, `TLSv1`.
- TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, set the `ssl_cipher` system variable on the server side or use the `--ssl-cipher` client option to specify the cipher name explicitly:

```
AES128-SHA
AES128-SHA256
AES256-SHA
AES256-SHA256
CAMELLIA128-SHA
CAMELLIA256-SHA
DES-CBC3-SHA
DHE-RSA-AES256-SHA
RC4-MD5
RC4-SHA
SEED-SHA
```

- For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client do not have a permitted protocol in common, and a protocol-compatible cipher in common, the server terminates the connection request. Examples:

- If the server is configured with `tls_version=TLSv1.1,TLSv1.2`:
 - Connection attempts fail for clients invoked with `--tls-version=TLSv1`, and for older clients that support only TLSv1.
 - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1'`, and for older replicas that support only TLSv1.
- If the server is configured with `tls_version=TLSv1` or is an older server that supports only TLSv1:
 - Connection attempts fail for clients invoked with `--tls-version=TLSv1.1,TLSv1.2`.
 - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1.1,TLSv1.2'`.

MySQL permits specifying a list of protocols to support. This list is passed directly down to the underlying SSL library and is ultimately up to that library what protocols it actually enables from the supplied list. Please refer to the MySQL source code and the OpenSSL `SSL_CTX_new()` documentation for information about how the SSL library handles this.

Monitoring Current Client Session TLS Protocol and Cipher

To determine which encryption TLS protocol and cipher the current client session uses, check the session values of the `Ssl_version` and `Ssl_cipher` status variables:

```
mysql> SELECT * FROM performance_schema.session_status
      WHERE VARIABLE_NAME IN ('Ssl_version','Ssl_cipher');
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256 |
| Ssl_version   | TLSv1.2        |
+-----+-----+
```

If the connection is not encrypted, both variables have an empty value.

6.3.3 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the `openssl` command directly.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin. See [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

6.3.3.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides these ways to create the SSL certificate and key files and RSA key-pair files required to support encrypted connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup, for MySQL distributions.
- Users can invoke the `mysql_ssl_rsa_setup` utility manually.
- For some distribution types, such as RPM and DEB packages, `mysql_ssl_rsa_setup` invocation occurs during data directory initialization. In this case, the MySQL distribution need not have been compiled using OpenSSL as long as the `openssl` command is available.

Important

Server autogeneration and `mysql_ssl_rsa_setup` help lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by these methods are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

- [Automatic SSL and RSA File Generation](#)
- [Manual SSL and RSA File Generation Using `mysql_ssl_rsa_setup`](#)
- [SSL and RSA File Characteristics](#)

Automatic SSL and RSA File Generation

For MySQL distributions compiled using OpenSSL, the MySQL server has the capability of automatically generating missing SSL and RSA files at startup. The `auto_generate_certs`, `sha256_password_auto_generate_rsa_keys`, and `caching_sha2_password_auto_generate_rsa_keys` system variables control automatic generation of these files. These variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable encrypted client connections using SSL; see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

1. The server checks the data directory for SSL files with the following names:

```
ca.pem
server-cert.pem
```

```
server-key.pem
```

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

ca.pem	Self-signed CA certificate
ca-key.pem	CA private key
server-cert.pem	Server certificate
server-key.pem	Server private key
client-cert.pem	Client certificate
client-key.pem	Client private key

3. If the server autogenerates SSL files, it uses the names of the `ca.pem`, `server-cert.pem`, and `server-key.pem` files to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

1. The server checks the data directory for RSA files with the following names:

private_key.pem	Private member of private/public key pair
public_key.pem	Public member of private/public key pair

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.
3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (`sha256_password_private_key_path` and `sha256_password_public_key_path`; `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`).

Manual SSL and RSA File Generation Using `mysql_ssl_rsa_setup`

MySQL distributions include a `mysql_ssl_rsa_setup` utility that can be invoked manually to generate SSL and RSA files. This utility is included with all MySQL distributions, but it does require that the `openssl` command be available. For usage instructions, see [Section 4.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

SSL and RSA File Characteristics

SSL and RSA files created automatically by the server or by invoking `mysql_ssl_rsa_setup` have these characteristics:

- SSL and RSA keys are have a size of 2048 bits.
- The SSL CA certificate is self signed.
- The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.
- SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

ca.pem:	MySQL_Server_ <i>suffix</i> _Auto_Generated_CA_Certificate
server-cert.pm:	MySQL_Server_ <i>suffix</i> _Auto_Generated_Server_Certificate
client-cert.pm:	MySQL_Server_ <i>suffix</i> _Auto_Generated_Client_Certificate

The *suffix* value is based on the MySQL version number. For files generated by `mysql_ssl_rsa_setup`, the suffix can be specified explicitly using the `--suffix` option.

For files generated by the server, if the resulting CN values exceed 64 characters, the `_suffix` portion of the name is omitted.

- SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.
- SSL files created by the server or by `mysql_ssl_rsa_setup` are valid for ten years from the time of generation.
- RSA files do not expire.
- SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).
- Files created automatically by the server are owned by the account that runs the server. Files created using `mysql_ssl_rsa_setup` are owned by the user who invoked that program. This can be changed on systems that support the `chown()` system call if the program is invoked by `root` and the `--uid` option is given to specify the user who should own the files.
- On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke `openssl` directly:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

It is also possible to check SSL certificate expiration information using this SQL statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2027 GMT |
| Ssl_server_not_before | May 1 14:16:39 2017 GMT |
+-----+-----+
```

6.3.3.2 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Note

There are easier alternatives to generating the files required for SSL than the procedure described here: Let the server autogenerate them or use the `mysql_ssl_rsa_setup` program. See [Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

Important

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
```

```
error:00000001:lib(0):func(0):reason(1)
```

- [Example 1: Creating SSL Files from the Command Line on Unix](#)
- [Example 2: Creating SSL Files Using a Script on Unix](#)
- [Example 3: Creating SSL Files on Windows](#)

Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 \
    -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
```

You should see a response like this:

```
server-cert.pem: OK
client-cert.pem: OK
```

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

Now you have a set of files that can be used as follows:

- `ca.pem`: Use this to set the `ssl_ca` system variable on the server side and the `--ssl-ca` option on the client side. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these to set the `ssl_cert` and `ssl_key` system variables on the server side.
- `client-cert.pem`, `client-key.pem`: Use these as the arguments to the `--ssl-cert` and `--ssl-key` options on the client side.

For additional usage instructions, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

```

DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/jones/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/jones/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:
# -----
# You are about to be asked to enter information that will be
# incorporated into your certificate request.
# What you are about to enter is what is called a Distinguished Name
# or a DN.
# There are quite a few fields but you can leave some blank
# For some fields there will be a default value,
# If you enter '.', the field will be left blank.

# (365 days)
# Sign the certificate? [y/n]:y
#
#
# 1 out of 1 certificate requests certified, commit? [y/n]y
# Write out database with 1 new entries
# Data Base Updated

#
# Create a my.cnf file that you can use to test the certificates
#

cat <<EOF > $DIR/my.cnf
[client]
ssl-ca=$DIR/ca.pem
ssl-cert=$DIR/client-cert.pem
ssl-key=$DIR/client-key.pem
[mysqld]
ssl_ca=$DIR/ca.pem
ssl_cert=$DIR/server-cert.pem
ssl_key=$DIR/server-key.pem
EOF
```

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '`...critical component is missing: Microsoft Visual C++ 2008 Redistributables`', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):

1. On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
2. Select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select **Path**, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add '`;C:\OpenSSL-Win32\bin`' to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
md c:\newcerts
cd c:\newcerts
```

- When a '`\`' character is shown at the end of a command line, this '`\`' character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see [Section 6.3.1, "Configuring MySQL to Use Encrypted Connections"](#).

6.3.3.3 Creating RSA Keys Using openssl

This section describes how to use the `openssl` command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` and `caching_sha2_password` plugins.

Note

There are easier alternatives to generating the files required for RSA than the procedure described here: Let the server autogenerate them or use the `mysql_ssl_rsa_setup` program. See [Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so the files will be owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```
chmod 400 private_key.pem
chmod 444 public_key.pem
```

6.3.4 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

6.4 Security Components and Plugins

MySQL includes several components and plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see [Section 6.2.17, “Pluggable Authentication”](#). For characteristics of specific authentication plugins, see [Section 6.4.1, “Authentication Plugins”](#).

- A password-validation component for implementing password strength policies and assessing the strength of potential passwords. See [Section 6.4.3, “The Password Validation Component”](#).
- Keyring plugins that provide secure storage for sensitive information. See [Section 6.4.4, “The MySQL Keyring”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See [Section 6.4.5, “MySQL Enterprise Audit”](#).
- A user-defined function enables applications to add their own message events to the audit log. See [Section 6.4.6, “The Audit Message Component”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. See [Section 6.4.7, “MySQL Enterprise Firewall”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. See [Section 6.5, “MySQL Enterprise Data Masking and De-Identification”](#).

6.4.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see [Section 6.2.17, “Pluggable Authentication”](#).

The default plugin is indicated by the value of the `default_authentication_plugin` system variable.

6.4.1.1 Native Pluggable Authentication

MySQL includes a `mysql_native_password` plugin that implements native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication.

The following table shows the plugin names on the server and client sides.

Table 6.12 Plugin and Library Names for Native Password Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>mysql_native_password</code>
Client-side plugin	<code>mysql_native_password</code>
Library file	None (plugins are built in)

The following sections provide installation and usage information specific to native pluggable authentication:

- [Installing Native Pluggable Authentication](#)

- [Using Native Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Installing Native Pluggable Authentication

The `mysql_native_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using Native Pluggable Authentication

MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_native_password ...
```

6.4.1.2 Caching SHA-2 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- `sha256_password`: Implements basic SHA-256 authentication.
- `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the caching SHA-2 authentication plugin. For information about the original basic (noncaching) plugin, see [Section 6.4.1.3, “SHA-256 Pluggable Authentication”](#).

Important

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see [caching_sha2_password as the Preferred Authentication Plugin](#).

Important

To connect to the server using an account that authenticates with the `caching_sha2_password` plugin, you must use either a secure connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `caching_sha2_password` plugin uses MySQL's encryption capabilities. See [Section 6.3, “Using Encrypted Connections”](#).

Note

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The `caching_sha2_password` plugin has these advantages, compared to `sha256_password`:

- On the server side, an in-memory cache enables faster reauthentication of users who have connected previously when they connect again.
- RSA-based password exchange is available regardless of the SSL library against which MySQL is linked.
- Support is provided for client connections that use the Unix socket-file and shared-memory protocols.

The following table shows the plugin names on the server and client sides.

Table 6.13 Plugin and Library Names for SHA-2 Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>caching_sha2_password</code>
Client-side plugin	<code>caching_sha2_password</code>
Library file	None (plugins are built in)

The following sections provide installation and usage information specific to caching SHA-2 pluggable authentication:

- [Installing SHA-2 Pluggable Authentication](#)
- [Using SHA-2 Pluggable Authentication](#)
- [Cache Operation for SHA-2 Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Installing SHA-2 Pluggable Authentication

The `caching_sha2_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

The server-side plugin uses the `sha2_cache_cleaner` audit plugin as a helper to perform password cache management. `sha2_cache_cleaner`, like `caching_sha2_password`, is built in and need not be installed.

Using SHA-2 Pluggable Authentication

To set up an account that uses the `caching_sha2_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha2user'@'localhost'  
IDENTIFIED WITH caching_sha2_password BY 'password';
```

The server assigns the `caching_sha2_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `caching_sha2_password` is the default authentication plugin. If `caching_sha2_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `caching_sha2_password`, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=caching_sha2_password
```

That causes the `caching_sha2_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```
CREATE USER 'sha2user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `caching_sha2_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:

```
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'password';
```

`caching_sha2_password` supports connections over secure transport. If you follow the RSA configuration procedure given later in this section, it also supports encrypted password exchange using RSA over unencrypted connections. RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
- The server uses the `caching_sha2_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
- The `Caching_sha2_password_rsa_public_key` status variable displays the RSA public key value used by the `caching_sha2_password` authentication plugin.
- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.
- For connections by accounts that authenticate with `caching_sha2_password` and RSA key pair-based password exchange, the server does not send the RSA public key to clients by default. Clients can use a client-side copy of the required public key, or request the public key from the server.

Use of a trusted local copy of the public key enables the client to avoid a round trip in the client/server protocol, and is more secure than requesting the public key from the server. On the other hand, requesting the public key from the server is more convenient (it requires no management of a client-side file) and may be acceptable in secure network environments.

- For command-line clients, use the `--server-public-key-path` option to specify the RSA public key file. Use the `--get-server-public-key` option to request the public key from the server. The following programs support the two options: `mysql`, `mysqlsh`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`, `mysqlshow`, `mysqlslap`, `mysqltest`, `mysql_upgrade`.
- For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file, or request the public key from the server by passing the `MYSQL_OPT_GET_SERVER_PUBLIC_KEY` option.
- For replicas, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file, or the `GET_MASTER_PUBLIC_KEY` option to request the public key from the source. For Group Replication, the `group_replication_recovery_public_key_path` and `group_replication_recovery_get_public_key` system variables serve the same purpose.

In all cases, if the option is given to specify a valid public key file, it takes precedence over the option to request the public key from the server.

For clients that use the `caching_sha2_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to TCP connections encrypted using TLS, as well as Unix socket-file and shared-memory connections. The password is sent as cleartext but cannot be snooped because the connection is secure.
- If the connection is not secure, an RSA key pair is used. This applies to TCP connections not encrypted using without TLS and named-pipe connections. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

To enable use of an RSA key pair for password exchange during the client connection process, use the following procedure:

1. Create the RSA private and public key-pair files using the instructions in [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
caching_sha2_password_private_key_path=myprivkey.pem
caching_sha2_password_public_key_path=mypubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```
[mysqld]
caching_sha2_password_private_key_path=/usr/local/mysql/myprivkey.pem
caching_sha2_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Caching_sha2_password_rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'\G
***** 1. row *****
Variable_name: Caching_sha2_password_rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCsGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUdd+KvSZgY7cNBZMNpwX6
MvElPbJFXO7u18nJ9lwc99Du/E7lw6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBcIDmNVnyU54OT/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `caching_sha2_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not

used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p
Enter password: password
```

For this connection attempt by `sha2user`, the server determines that `caching_sha2_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. However, the server does not send the public key to the client, and the client provided no public key, so it cannot encrypt the password and the connection fails:

```
ERROR 2061 (HY000): Authentication plugin 'caching_sha2_password'
reported error: Authentication requires secure connection.
```

To request the RSA public key from the server, specify the `--get-server-public-key` option:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p --get-server-public-key
Enter password: password
```

In this case, the server sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

Alternatively, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p --server-public-key-path=file_name
Enter password: password
```

In this case, the client uses the public key to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `caching_sha2_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'` statement and save the returned key value in a file.

Cache Operation for SHA-2 Pluggable Authentication

On the server side, the `caching_sha2_password` plugin uses an in-memory cache for faster authentication of clients who have connected previously. Entries consist of account-name/password-hash pairs. The cache works like this:

1. When a client connects, `caching_sha2_password` checks whether the client and password match some cache entry. If so, authentication succeeds.
2. If there is no matching cache entry, the plugin attempts to verify the client against the credentials in the `mysql.user` system table. If this succeeds, `caching_sha2_password` adds an entry for the client to the hash. Otherwise, authentication fails and the connection is rejected.

In this way, when a client first connects, authentication against the `mysql.user` system table occurs. When the client connects subsequently, faster authentication against the cache occurs.

Password cache operations other than adding entries are handled by the `sha2_cache_cleaner` audit plugin, which performs these actions on behalf of `caching_sha2_password`:

- It clears the cache entry for any account that is renamed or dropped, or any account for which the credentials or authentication plugin are changed.
- It empties the cache when the `FLUSH PRIVILEGES` statement is executed.
- It empties the cache at server shutdown. (This means the cache is not persistent across server restarts.)

Cache clearing operations affect the authentication requirements for subsequent client connections. For each user account, the first client connection for the user after any of the following operations must use a secure connection (made using TCP using TLS credentials, a Unix socket file, or shared memory) or RSA key pair-based password exchange:

- After account creation.
- After a password change for the account.
- After `RENAME USER` for the account.
- After `FLUSH PRIVILEGES`.

`FLUSH PRIVILEGES` clears the entire cache and affects all accounts that use the `caching_sha2_password` plugin. The other operations clear specific cache entries and affect only accounts that are part of the operation.

Once the user authenticates successfully, the account is entered into the cache and subsequent connections do not require a secure connection or the RSA key pair, until another cache clearing event occurs that affects the account. (When the cache can be used, the server uses a challenge-response mechanism that does not use cleartext password transmission and does not require a secure connection.)

6.4.1.3 SHA-256 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- `sha256_password`: Implements basic SHA-256 authentication.
- `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the original noncaching SHA-2 authentication plugin. For information about the caching plugin, see [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

Important

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see [caching_sha2_password as the Preferred Authentication Plugin](#).

Because `caching_sha2_password` is the default authentication plugin in MySQL 8.0 and provides a superset of the capabilities of the `sha256_password` authentication plugin, `sha256_password` is deprecated and will be removed in a future MySQL version. MySQL accounts that authenticate using `sha256_password` should be migrated to use `caching_sha2_password` instead.

**Important**

To connect to the server using an account that authenticates with the `sha256_password` plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `sha256_password` plugin uses MySQL's encryption capabilities. See [Section 6.3, “Using Encrypted Connections”](#).

**Note**

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The following table shows the plugin names on the server and client sides.

Table 6.14 Plugin and Library Names for SHA-256 Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>sha256_password</code>
Client-side plugin	<code>sha256_password</code>
Library file	None (plugins are built in)

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- [Installing SHA-256 Pluggable Authentication](#)
- [Using SHA-256 Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Installing SHA-256 Pluggable Authentication

The `sha256_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using SHA-256 Pluggable Authentication

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha256user'@'localhost'
IDENTIFIED WITH sha256_password BY 'password';
```

The server assigns the `sha256_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `sha256_password` is the default authentication plugin. If `sha256_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `sha256_password`, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=sha256_password
```

That causes the `sha256_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `sha256_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:

```
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'password';
```

`sha256_password` supports connections over secure transport. `sha256_password` also supports encrypted password exchange using RSA over unencrypted connections if MySQL is compiled using OpenSSL, and the MySQL server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `sha256_password_private_key_path` and `sha256_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
- The server uses the `sha256_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
- The `Rsa_public_key` status variable displays the RSA public key value used by the `sha256_password` authentication plugin.
- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.
- For connections by accounts that authenticate with `sha256_password` and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:
 - For these command-line clients, use the `--server-public-key-path` option to specify the RSA public key file: `mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`, `mysqlshow`, `mysqlslap`, `mysqltest`, `mysql_upgrade`.
 - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file.
 - For replicas, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file. For Group Replication, the `group_replication_recovery_get_public_key` system variable serves the same purpose.

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to connections encrypted using TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.

**Note**

Unlike `caching_sha2_password`, the `sha256_password` plugin does not treat shared-memory connections as secure, even though share-memory transport is secure by default.

- If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to connections not encrypted using TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.
- If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

**Note**

To use RSA password encryption with `sha256_password`, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
sha256_password_private_key_path=myprivkey.pem
sha256_password_public_key_path=mypubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```
[mysqld]
sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Rsa_public_key'\G
***** 1. row *****
Variable_name: Rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCsQGIb3DQEBQUAA4GNADCBiQKBgQD09nRUDd+KvSZgY7cNBZMNpwX6
MvElPbJFXO7u18nJ9lwc99Du/E7lw6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBCIDmNVnyU54OT/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `sha256_password` plugin have the option of using those key files to connect to the server. As

mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

6.4.1.4 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

Table 6.15 Plugin and Library Names for Cleartext Authentication

Plugin or File	Plugin or File Name
Server-side plugin	None, see discussion
Client-side plugin	<code>mysql_clear_password</code>
Library file	None (plugin is built in)

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used, which enables the client to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, `mysql_clear_password` can be used on the client side in concert with any server-side plugin that needs a cleartext password. (Examples are the PAM and simple LDAP authentication plugins; see [Section 6.4.1.5, “PAM Pluggable Authentication”](#), and [Section 6.4.1.7, “LDAP Pluggable Authentication”](#).)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Note

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 6.3, “Using Encrypted Connections”](#)), IPsec, or a private network.

To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqldump`, `mysqlshow`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

6.4.1.5 PAM Pluggable Authentication

Note

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- External authentication: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named `joe` can connect and have the privileges of a MySQL user named `developer`.

PAM pluggable authentication has been tested on Linux and macOS.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing PAM Pluggable Authentication](#).

Table 6.16 Plugin and Library Names for PAM Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_pam</code>

Plugin or File	Plugin or File Name
Client-side plugin	<code>mysql_clear_password</code>
Library file	<code>authentication_pam.so</code>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- [How PAM Authentication of MySQL Users Works](#)
- [Installing PAM Pluggable Authentication](#)
- [Uninstalling PAM Pluggable Authentication](#)
- [Using PAM Pluggable Authentication](#)
- [PAM Unix Password Authentication without Proxy Users](#)
- [PAM LDAP Authentication without Proxy Users](#)
- [PAM Unix Password Authentication with Proxy Users and Group Mapping](#)
- [PAM Authentication Access to Unix Password Store](#)
- [PAM Authentication Debugging](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#). For information about the `mysql_clear_password` plugin, see [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#). For proxy user information, see [Section 6.2.18, “Proxy Users”](#).

How PAM Authentication of MySQL Users Works

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see [Using PAM Pluggable Authentication](#).

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:
 - The client user name is the external user name.
 - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.
2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:
 - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.
 - Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns '[Authentication succeeded, Username is user_name](#)' or '[Authentication failed](#)'. The password must be appropriate for the password store used by the PAM service. Examples:

- For traditional Unix passwords, the service looks up passwords stored in the [/etc/shadow](#) file.
- For LDAP, the service looks up passwords stored in an LDAP directory.

If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.
5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:

- For traditional Unix passwords, groups are Unix groups defined in the [/etc/group](#) file, possibly supplemented with additional PAM information in a file such as [/etc/security/group.conf](#).
- For LDAP, groups are LDAP groups defined in an LDAP directory.

If the proxy user (the external user) has the [PROXY](#) privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

Installing PAM Pluggable Authentication

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the [plugin_dir](#) system variable). If necessary, configure the plugin directory location by setting the value of [plugin_dir](#) at server startup.

The plugin library file base name is [authentication_pam](#). The file name suffix differs per platform (for example, [.so](#) for Unix and Unix-like systems, [.dll](#) for Windows).

To load the plugin at server startup, use the [--plugin-load-add](#) option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server [my.cnf](#) file, adjusting the [.so](#) suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying [my.cnf](#), restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the [.so](#) suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

[INSTALL PLUGIN](#) loads the plugin immediately, and also registers it in the [mysql.plugins](#) system table to cause the server to load it for each subsequent normal startup without the need for [--plugin-load-add](#).

To verify plugin installation, examine the [INFORMATION_SCHEMA.PLUGINS](#) table or use the [SHOW PLUGINS](#) statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE '%pam%';
```

PLUGIN_NAME	PLUGIN_STATUS
authentication_pam	ACTIVE

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see [Using PAM Pluggable Authentication](#).

Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_pam;
```

Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in [Installing PAM Pluggable Authentication](#).

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see [How PAM Authentication of MySQL Users Works](#)). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.
- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the `mysql-unix` PAM service name and should map operating system users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

```
pam_service_name[ ,pam_group_name=mysql_user_name]...
```

The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

- Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`\`). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

- If the authentication string contains no PAM group mapping list, the plugin returns the external name.
- If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `'user_name'@'host_name'` to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 32 characters (see [Section 6.2.3, “Grant Tables”](#)), which limits PAM nonproxy authentication to Unix accounts with names of at most 32 characters.

- Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible:

- You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.
- You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the `mysql-unix` PAM service for some users, and `mysql-ldap` for others.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The login name and password are `antonio` and `antonio_password`, respectively. Change these to correspond to the user you want to authenticate.
- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name corresponds to the authentication method (`mysql-unix` or `mysql-ldap` in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must name the PAM service in the authentication string of the `CREATE USER` statement for any account that authenticates using that PAM service.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related issues that occur when the plugin performs authentication. For more information, see [PAM Authentication Debugging](#).

PAM Unix Password Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a `mysql-unix` PAM service file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
#%PAM-1.0
auth            include      password-auth
account         include      password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-unix` PAM service:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL         |
+-----+-----+-----+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

PAM LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

Note

Another way to use LDAP for MySQL user authentication is to use the LDAP-specific authentication plugins. See [Section 6.4.1.7, “LDAP Pluggable Authentication”](#).

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using LDAP by creating a `mysql-ldap` PAM service file named `/etc/pam.d/mysql-ldap`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-ldap` file might look like this:

```

#%PAM-1.0
auth        required    pam_ldap.so
account     required    pam_ldap.so

```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-ldap` PAM service:

```

CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-ldap';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';

```

Here, the authentication string contains only the PAM service name, `mysql-ldap`, which authenticates using LDAP.

4. Connecting to the server is the same as described in [PAM Unix Password Authentication without Proxy Users](#).

PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [PAM LDAP Authentication without Proxy Users](#).

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Verify that `antonio` is a member of the `root` or `users` PAM group.
3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```

#%PAM-1.0
auth        include     password-auth
account     include     password-auth

```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
```

```
@include common-account
@include common-session-noninteractive
```

4. Create a default proxy user (`'@'`) that maps external PAM users to the proxied accounts:

```
CREATE USER '@'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix, root=developer, users=data_entry';
```

Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

5. Create the proxied accounts and grant to each one the privileges it should have:

```
CREATE USER 'developer'@'localhost'
  IDENTIFIED WITH mysql_no_login;
CREATE USER 'data_entry'@'localhost'
  IDENTIFIED WITH mysql_no_login;

GRANT ALL PRIVILEGES
  ON mydevdb.*
  TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'data_entry'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using PAM will use the `developer` or `data_entry` account by proxy based on their PAM group. (This assumes that the plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

6. Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY
  ON 'developer'@'localhost'
  TO '@';
GRANT PROXY
  ON 'data_entry'@'localhost'
  TO '@';
```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server authenticates the connection using the default `'@'` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `'@'` has the `PROXY` privilege for `developer` and permits the connection. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
+-----+-----+-----+
```

```

| USER()          | CURRENT_USER()   | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | '@'         |
+-----+-----+-----+

```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `developer` MySQL user, and that proxying occurs through the default proxy account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` PAM group, a similar process occurs, but the plugin maps `user` PAM group membership to the `data_entry` MySQL user name and returns that name to the server:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()   | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | data_entry@localhost | '@'         |
+-----+-----+-----+

```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges of the `data_entry` MySQL user, and that proxying occurs through the default proxy account.

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

PAM Authentication Access to Unix Password Store

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read `/etc/shadow`) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the `mysql` operating system account, put that account in the `shadow` group that has `/etc/shadow` access:
 1. Create a `shadow` group in `/etc/group`.
 2. Add the `mysql` operating system user to the `shadow` group in `/etc/group`.
 3. Assign `/etc/group` to the `shadow` group and enable the group read permission:

```

chgrp shadow /etc/shadow
chmod g+r /etc/shadow

```

4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

```
chmod u-s /usr/sbin/unix_chkpwd
setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
```

Adjust the path to `unix_chkpwd` as necessary for your platform.

PAM Authentication Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a *temporary* basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
##PAM-1.0
auth        required    pam_permit.so
account     required    pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

6.4.1.6 Windows Pluggable Authentication

Note

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- **External authentication:** Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.
- **Proxy user support:** Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.17 Plugin and Library Names for Windows Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_windows</code>
Client-side plugin	<code>authentication_windows_client</code>
Library file	<code>authentication_windows.dll</code>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 8.0 (see <https://www.mysql.com/support/supportedplatforms/database.html>).

The following sections provide installation and usage information specific to Windows pluggable authentication:

- [Installing Windows Pluggable Authentication](#)
- [Uninstalling Windows Pluggable Authentication](#)
- [Using Windows Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#). For proxy user information, see [Section 6.2.18, “Proxy Users”](#).

Installing Windows Pluggable Authentication

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE '%windows%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_windows | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see [Using Windows Pluggable Authentication](#). Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See [Section 5.1.8, “Server System Variables”](#).

Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_windows;
```

In addition, remove any startup options that set Windows plugin-related system variables.

Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in [Installing Windows Pluggable Authentication](#). Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the

`Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is a member of the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=mysql_user_name  
win_user_or_group_name
```

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin  
  IDENTIFIED WITH authentication_windows  
  AS 'Rafal, Tasha, Administrators, "Power Users";  
  
CREATE USER sql_admin  
  IDENTIFIED WITH authentication_windows  
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,  
      "Power Users"=sql_admin';
```

- Each backslash character (`\`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user  
.\user  
domain\\group  
.\group  
BUILTIN\\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
  AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 6.2.18, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
    MyDomain\\domain_user = local_wlad,
    MyDomain\\Developers = local_dev,
    BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_dev
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_admin
  IDENTIFIED WITH mysql_no_login;
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using Windows will use the `win_proxy` proxy account. (This assumes that the plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

- Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string (in this case, `local_wlad`). A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account (`' '@'`) for `win_proxy` in the preceding instructions. For information about default proxy accounts, see [Section 6.2.18, “Proxy Users”](#).

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

To use the Windows authentication plugin with Connector/NET connection strings in Connector/NET 6.4.4 and higher, see [Using the Windows Native Authentication Plugin](#).

6.4.1.7 LDAP Pluggable Authentication

Note

LDAP pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. MySQL uses LDAP to fetch user, credential, and group information.

LDAP pluggable authentication provides these capabilities:

- External authentication: LDAP authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables in LDAP directories.
- Proxy user support: LDAP authentication can return to MySQL a user name different from the external user name passed by the client program, based on the LDAP groups the external user is a member of. This means that an LDAP plugin can return the MySQL user that defines the privileges the external LDAP-authenticated user should have. For example, an LDAP user named `joe` can connect and have the privileges of a MySQL user named `developer`, if the LDAP group for `joe` is `developer`.
- Security: Using TLS, connections to the LDAP server can be secure.

The following tables show the plugin and library file names for simple and SASL-based LDAP authentication. The file name suffix might differ on your system. The files must be located in the directory named by the `plugin_dir` system variable.

Table 6.18 Plugin and Library Names for Simple LDAP Authentication

Plugin or File	Plugin or File Name
Server-side plugin name	<code>authentication_ldap_simple</code>
Client-side plugin name	<code>mysql_clear_password</code>
Library file name	<code>authentication_ldap_simple.so</code>

Table 6.19 Plugin and Library Names for SASL-Based LDAP Authentication

Plugin or File	Plugin or File Name
Server-side plugin name	<code>authentication_ldap_sasl</code>
Client-side plugin name	<code>authentication_ldap_sasl_client</code>
Library file names	<code>authentication_ldap_sasl.so</code> , <code>authentication_ldap_sasl_client.so</code>

The library files include only the `authentication_ldap_XXX` authentication plugins. The client-side `mysql_clear_password` plugin is built into the `libmysqlclient` client library.

Each server-side LDAP plugin works with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.
- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

The following sections provide installation and usage information specific to LDAP pluggable authentication:

- [Prerequisites for LDAP Pluggable Authentication](#)
- [How LDAP Authentication of MySQL Users Works](#)
- [Installing LDAP Pluggable Authentication](#)
- [Uninstalling LDAP Pluggable Authentication](#)
- [LDAP Pluggable Authentication and `ldap.conf`](#)
- [Using LDAP Pluggable Authentication](#)
- [Simple LDAP Authentication](#)
- [SASL-Based LDAP Authentication](#)
- [LDAP Authentication with Proxying](#)
- [LDAP Authentication Group Preference and Mapping Specification](#)
- [LDAP Authentication User DN Suffixes](#)
- [LDAP Authentication Methods](#)
- [The GSSAPI/Kerberos Authentication Method](#)
- [LDAP Search Referral](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#). For information about the `mysql_clear_password` plugin, see [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#). For proxy user information, see [Section 6.2.18, “Proxy Users”](#).

**Note**

If your system supports PAM and permits LDAP as a PAM authentication method, another way to use LDAP for MySQL user authentication is to use the server-side [authentication_pam](#) plugin. See [Section 6.4.1.5, “PAM Pluggable Authentication”](#).

Prerequisites for LDAP Pluggable Authentication

To use LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the LDAP authentication plugins to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.
- An LDAP client library must be available on systems where the server-side [authentication_ldap_sasl](#) or [authentication_ldap_simple](#) plugin is used. Currently, supported libraries are the Windows native LDAP library, or the OpenLDAP library on non-Windows systems.
- To use SASL-based LDAP authentication:
 - The LDAP server must be configured to communicate with a SASL server.
 - A SASL client library must be available on systems where the client-side [authentication_ldap_sasl_client](#) plugin is used. Currently, the only supported library is the Cyrus SASL library.
 - To use a particular SASL authentication method, any other services required by that method must be available. For example, to use GSSAPI/Kerberos, a GSSAPI library and Kerberos services must be available.

How LDAP Authentication of MySQL Users Works

This section provides a general overview of how MySQL and LDAP work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific LDAP authentication plugins, see [Using LDAP Pluggable Authentication](#). For information about authentication methods available to the LDAP plugins, see [LDAP Authentication Methods](#).

The client connects to the MySQL server, providing the MySQL client user name and a password:

- For simple LDAP authentication, the client-side and server-side plugins communicate the password as cleartext. A secure connection between the MySQL client and server is recommended to prevent password exposure.
- For SASL-based LDAP authentication, the client-side and server-side plugins avoid sending the cleartext password between the MySQL client and server. For example, the plugins might use SASL messages for secure transmission of credentials within the LDAP protocol. For the GSSAPI authentication method, the client-side and server-side plugins communicate securely using Kerberos without using LDAP messages directly.

If the client user name and host name match no MySQL account, the connection is rejected.

If there is a matching MySQL account, authentication against LDAP occurs. The LDAP server looks for an entry matching the user and authenticates the entry against the LDAP password:

- If the MySQL account names an LDAP user distinguished name (DN), LDAP authentication uses that value and the LDAP password provided by the client. (To associate an LDAP user DN with a MySQL account, include a [BY](#) clause that specifies an authentication string in the [CREATE USER](#) statement that creates the account.)

- If the MySQL account names no LDAP user DN, LDAP authentication uses the user name and LDAP password provided by the client. In this case, the authentication plugin first binds to the LDAP server using the root DN and password as credentials to find the user DN based on the client user name, then authenticates that user DN against the LDAP password. This bind using the root credentials fails if the root DN and password are set to incorrect values, or are empty (not set) and the LDAP server does not permit anonymous connections.

If the LDAP server finds no match or multiple matches, authentication fails and the client connection is rejected.

If the LDAP server finds a single match, LDAP authentication succeeds (assuming that the password is correct), the LDAP server returns the LDAP entry, and the authentication plugin determines the name of the authenticated user based on that entry:

- If the LDAP entry has a group attribute (by default, the `cn` attribute), the plugin returns its value as the authenticated user name.
- If the LDAP entry has no group attribute, the authentication plugin returns the client user name as the authenticated user name.

The MySQL server compares the client user name with the authenticated user name to determine whether proxying occurs for the client session:

- If the names are the same, no proxying occurs: The MySQL account matching the client user name is used for privilege checking.
- If the names differ, proxying occurs: MySQL looks for an account matching the authenticated user name. That account becomes the proxied user, which is used for privilege checking. The MySQL account that matched the client user name is treated as the external proxy user.

Installing LDAP Pluggable Authentication

This section describes how to install the LDAP authentication plugins. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library files must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base names are `authentication_ldap_simple` and `authentication_ldap_sasl`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use `--plugin-load-add` options to name the library files that contain them. With this plugin-loading method, the options must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure.

Each server-side LDAP plugin exposes a set of system variables that enable its operation to be configured. Setting most of these is optional, but you must set the variables that specify the LDAP server host (so the plugin knows where to connect) and base distinguished name for LDAP bind operations (to limit the scope of searches and obtain faster searches). For details about all LDAP system variables, see [Section 6.4.1.11, “Pluggable Authentication System Variables”](#).

To load the plugins and set the LDAP server host and base distinguished name for LDAP bind operations, put lines such as these in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_ldap_simple.so
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
plugin-load-add=authentication_ldap_sasl.so
```

```
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_ldap_simple
  SONAME 'authentication_ldap_simple.so';
INSTALL PLUGIN authentication_ldap_sasl
  SONAME 'authentication_ldap_sasl.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

After installing the plugins at runtime, their system variables become available and you can add settings for them to your `my.cnf` file to configure the plugins for subsequent restarts. For example:

```
[mysqld]
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to set and persist the values at runtime, use these statements:

```
SET PERSIST authentication_ldap_simple_server_host='127.0.0.1';
SET PERSIST authentication_ldap_simple_bind_base_dn='dc=example,dc=com';
SET PERSIST authentication_ldap_sasl_server_host='127.0.0.1';
SET PERSIST authentication_ldap_sasl_bind_base_dn='dc=example,dc=com';
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
  FROM INFORMATION_SCHEMA.PLUGINS
  WHERE PLUGIN_NAME LIKE '%ldap%';
```

PLUGIN_NAME	PLUGIN_STATUS
authentication_ldap_sasl	ACTIVE
authentication_ldap_simple	ACTIVE

If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with an LDAP plugin, see [Using LDAP Pluggable Authentication](#).

Additional Notes for SELinux

On systems running EL6 or EL that have SELinux enabled, changes to the SELinux policy are required to enable the MySQL LDAP plugins to communicate with the LDAP service:

1. Create a file `mysqlldap.te` with these contents:

```
module mysqlldap 1.0;
```

```
require {
    type ldap_port_t;
    type mysqld_t;
    class tcp_socket name_connect;
}

#===== mysqld_t =====

allow mysqld_t ldap_port_t:tcp_socket name_connect;
```

2. Compile the security policy module into a binary representation:

```
checkmodule -M -m mysqlldap.te -o mysqlldap.mod
```

3. Create an SELinux policy module package:

```
semodule_package -m mysqlldap.mod -o mysqlldap.pp
```

4. Install the module package:

```
semodule -i mysqlldap.pp
```

5. When the SELinux policy changes have been made, restart the MySQL server:

```
service mysqld restart
```

Uninstalling LDAP Pluggable Authentication

The method used to uninstall the LDAP authentication plugins depends on how you installed them:

- If you installed the plugins at server startup using `--plugin-load-add` options, restart the server without those options.
- If you installed the plugins at runtime using `INSTALL PLUGIN`, they remain installed across server restarts. To uninstall them, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_ldap_simple;
UNINSTALL PLUGIN authentication_ldap_sasl;
```

In addition, remove from your `my.cnf` file any startup options that set LDAP plugin-related system variables. If you used `SET PERSIST` to persist LDAP system variables, use `RESET PERSIST` to remove the settings.

LDAP Pluggable Authentication and `ldap.conf`

For installations that use OpenLDAP, the `ldap.conf` file provides global defaults for LDAP clients. Options can be set in this file to affect LDAP clients, including the LDAP authentication plugins. OpenLDAP uses configuration options in this order of precedence:

- Configuration specified by the LDAP client.
- Configuration specified in the `ldap.conf` file. To disable use of this file, set the `LDAPNOINIT` environment variable.
- OpenLDAP library built-in defaults.

If the library defaults or `ldap.conf` values do not yield appropriate option values, an LDAP authentication plugin may be able to set related variables to affect the LDAP configuration directly. For example, LDAP plugins can override `ldap.conf` for parameters such as these:

- TLS configuration: System variables are available to enable TLS and control CA configuration, such as `authentication_ldap_simple_tls` and `authentication_ldap_simple_ca_path` for simple LDAP authentication, and `authentication_ldap_sasl_tls` and `authentication_ldap_sasl_ca_path` for SASL LDAP authentication.

- LDAP referral. See [LDAP Search Referral](#).

For more information about `ldap.conf` consult the `ldap.conf(5)` man page.

Using LDAP Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using LDAP pluggable authentication. It is assumed that the server is running with the appropriate server-side plugins enabled, as described in [Installing LDAP Pluggable Authentication](#), and that the appropriate client-side plugins are available on the client host.

This section does not describe LDAP configuration or administration. You are assumed to be familiar with those topics.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.
- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

Overall requirements for LDAP authentication of MySQL users:

- There must be an LDAP directory entry for each user to be authenticated.
- There must be a MySQL user account that specifies a server-side LDAP authentication plugin and optionally names the associated LDAP user distinguished name (DN). (To associate an LDAP user DN with a MySQL account, include a `BY` clause in the `CREATE USER` statement that creates the account.) If an account names no LDAP string, LDAP authentication uses the user name specified by the client to find the LDAP entry.
- Client programs connect using the connection method appropriate for the server-side authentication plugin the MySQL account uses. For LDAP authentication, connections require the MySQL user name and LDAP password. In addition, for accounts that use the server-side `authentication_ldap_simple` plugin, invoke client programs with the `--enable-cleartext-plugin` option to enable the client-side `mysql_clear_password` plugin.

The instructions here assume the following scenario:

- MySQL users `betsy` and `boris` authenticate to the LDAP entries for `betsy_ldap` and `boris_ldap`, respectively. (It is not necessary that the MySQL and LDAP user names differ. The use of different names in this discussion helps clarify whether an operation context is MySQL or LDAP.)
- LDAP entries use the `uid` attribute to specify user names. This may vary depending on LDAP server. Some LDAP servers use the `cn` attribute for user names rather than `uid`. To change the attribute, modify the `authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr` system variable appropriately.
- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
uid=boris_ldap,ou=People,dc=example,dc=com
```

- `CREATE USER` statements that create MySQL accounts name an LDAP user in the `BY` clause, to indicate which LDAP entry the MySQL account authenticates against.

The instructions for setting up an account that uses LDAP authentication depend on which server-side LDAP plugin is used. The following sections describe several usage scenarios.

Simple LDAP Authentication

To configure a MySQL account for simple LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_simple` plugin, and optionally names the LDAP user distinguished name (DN):

```
CREATE USER user
  IDENTIFIED WITH authentication_ldap_simple
  [BY 'LDAP user DN'];
```

Suppose that MySQL user `betsy` has this entry in the LDAP directory:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `betsy` looks like this:

```
CREATE USER 'betsy'@'localhost'
  IDENTIFIED WITH authentication_ldap_simple
  AS 'uid=betsy_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password, and by enabling the client-side `mysql_clear_password` plugin:

```
shell> mysql --user=betsy --password --enable-cleartext-plugin
Enter password: betsy_password (betsy_ldap LDAP password)
```

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to the LDAP server. A cleartext password is necessary to use the server-side LDAP library without SASL, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

The authentication process occurs as follows:

1. The client-side plugin sends `betsy` and `betsy_password` as the client user name and LDAP password to the MySQL server.
2. The connection attempt matches the `'betsy'@'localhost'` account. The server-side LDAP plugin finds that this account has an authentication string of `'uid=betsy_ldap,ou=People,dc=example,dc=com'` to name the LDAP user DN. The plugin sends this string and the LDAP password to the LDAP server.

3. The LDAP server finds the LDAP entry for `betsy_ldap` and the password matches, so LDAP authentication succeeds.
4. The LDAP entry has no group attribute, so the server-side plugin returns the client user name (`betsy`) as the authenticated user. This is the same user name supplied by the client, so no proxying occurs and the client session uses the `'betsy'@'localhost'` account for privilege checking.

Had the matching LDAP entry contained a group attribute, that attribute value would have been the authenticated user name and, if the value differed from `betsy`, proxying would have occurred. For examples that use the group attribute, see [LDAP Authentication with Proxying](#).

Had the `CREATE USER` statement contained no `BY` clause to specify the `betsy_ldap` LDAP distinguished name, authentication attempts would use the user name provided by the client (in this case, `betsy`). In the absence of an LDAP entry for `betsy`, authentication would fail.

SASL-Based LDAP Authentication

To configure a MySQL account for SASL LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_sasl` plugin, and optionally names the LDAP user distinguished name (DN):

```
CREATE USER user
  IDENTIFIED WITH authentication_ldap_sasl
  [BY 'LDAP user DN'];
```

Suppose that MySQL user `boris` has this entry in the LDAP directory:

```
uid=boris_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `boris` looks like this:

```
CREATE USER 'boris'@'localhost'
  IDENTIFIED WITH authentication_ldap_sasl
  AS 'uid=boris_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password:

```
shell> mysql --user=boris --password
Enter password: boris_password (boris_ldap LDAP password)
```

For the server-side `authentication_ldap_sasl` plugin, clients use the client-side `authentication_ldap_sasl_client` plugin. If a client program does not find the client-side plugin, specify a `--plugin-dir` option that names the directory where the plugin library file is installed.

The authentication process for `boris` is similar to that previously described for `betsy` with simple LDAP authentication, except that the client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

LDAP Authentication with Proxying

LDAP authentication plugins support proxying, enabling a user to connect to the MySQL server as one user but assume the privileges of a different user. This section describes basic LDAP plugin proxy support. The LDAP plugins also support specification of group preference and proxy user mapping; see [LDAP Authentication Group Preference and Mapping Specification](#).

The proxying implementation described here is based on use of LDAP group attribute values to map connecting MySQL users who authenticate using LDAP onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the

privileges. Instead, they connect through a default proxy account authenticated with LDAP, such that all external logins are mapped to the proxied MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those proxied MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The instructions here assume the following scenario:

- LDAP entries use the `uid` and `cn` attributes to specify user name and group values, respectively. To use different user and group attribute names, set the appropriate plugin-specific system variables:
 - For the `authentication_ldap_simple` plugin: Set `authentication_ldap_simple_user_search_attr` and `authentication_ldap_simple_group_search_attr`.
 - For the `authentication_ldap_sasl` plugin: Set `authentication_ldap_sasl_user_search_attr` and `authentication_ldap_sasl_group_search_attr`.
- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=basha,ou=People,dc=example,dc=com,cn=accounting
uid=basil,ou=People,dc=example,dc=com,cn=front_office
```

At connect time, the group attribute values become the authenticated user names, so they name the `accounting` and `front_office` proxied accounts.

- The examples assume use of SASL LDAP authentication. Make the appropriate adjustments for simple LDAP authentication.

Create the default proxy MySQL account:

```
CREATE USER ''@'%'
  IDENTIFIED WITH authentication_ldap_sasl;
```

The proxy account definition has no `AS 'auth_string'` clause to name an LDAP user DN. Thus:

- When a client connects, the client user name becomes the LDAP user name to search for.
- The matching LDAP entry is expected to include a group attribute naming the proxied MySQL account that defines the privileges the client should have.

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

Create the proxied accounts and grant to each one the privileges it should have:

```
CREATE USER 'accounting'@'localhost'
  IDENTIFIED WITH mysql_no_login;
CREATE USER 'front_office'@'localhost'
  IDENTIFIED WITH mysql_no_login;

GRANT ALL PRIVILEGES
  ON accountingdb.*
  TO 'accounting'@'localhost';
GRANT ALL PRIVILEGES
  ON frontdb.*
  TO 'front_office'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using LDAP will use the default `''@'%'` proxy account. (This assumes that the `mysql_no_login`

plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY
  ON 'accounting'@'localhost'
  TO ' '%' ;
GRANT PROXY
  ON 'front_office'@'localhost'
  TO ' '%' ;
```

Use the `mysql` command-line client to connect to the MySQL server as `basha`.

```
shell> mysql --user=basha --password
Enter password: basha_password (basha LDAP password)
```

Authentication occurs as follows:

1. The server authenticates the connection using the default `' '%'` proxy account, for client user `basha`.
2. The matching LDAP entry is:

```
uid=basha,ou=People,dc=example,dc=com,cn=accounting
```

3. The matching LDAP entry has group attribute `cn=accounting`, so `accounting` becomes the authenticated proxied user.
4. The authenticated user differs from the client user name `basha`, with the result that `basha` is treated as a proxy for `accounting`, and `basha` assumes the privileges of the proxied `accounting` account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| basha@localhost | accounting@localhost | ' '%' |
+-----+-----+-----+
```

This demonstrates that `basha` uses the privileges granted to the proxied `accounting` MySQL account, and that proxying occurs through the default proxy user account.

Now connect as `basil` instead:

```
shell> mysql --user=basil --password
Enter password: basil_password (basil LDAP password)
```

The authentication process for `basil` is similar to that previously described for `basha`:

1. The server authenticates the connection using the default `' '%'` proxy account, for client user `basil`.
2. The matching LDAP entry is:

```
uid=basil,ou=People,dc=example,dc=com,cn=front_office
```

3. The matching LDAP entry has group attribute `cn=front_office`, so `front_office` becomes the authenticated proxied user.
4. The authenticated user differs from the client user name `basil`, with the result that `basil` is treated as a proxy for `front_office`, and `basil` assumes the privileges of the proxied `front_office` account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
```

USER()	CURRENT_USER()	@@proxy_user
basil@localhost	front_office@localhost	' '@' %'

This demonstrates that `basil` uses the privileges granted to the proxied `front_office` MySQL account, and that proxying occurs through the default proxy user account.

LDAP Authentication Group Preference and Mapping Specification

As described in [LDAP Authentication with Proxying](#), basic LDAP authentication proxying works by the principle that the plugin uses the first group name returned by the LDAP server as the MySQL proxied user account name. This simple capability does not enable specifying any preference about which group name to use if the LDAP server returns multiple group names, or specifying any name other than the group name as the proxied user name.

As of MySQL 8.0.14, for MySQL accounts that use LDAP authentication, the authentication string can specify the following information to enable greater proxying flexibility:

- A list of groups in preference order, such that the plugin uses the first group name in the list that matches a group returned by the LDAP server.
- A mapping from group names to proxied user names, such that a group name when matched can provide a specified name to use as the proxied user. This provides an alternative to using the group name as the proxied user.

Consider the following MySQL proxy account definition:

```
CREATE USER '@' %'
  IDENTIFIED WITH authentication_ldap_sasl
  AS '+ou=People,dc=example,dc=com#grp1=usera,grp2,grp3=userc';
```

The authentication string has a user DN suffix `ou=People,dc=example,dc=com` prefixed by the `+` character. Thus, as described in [LDAP Authentication User DN Suffixes](#), the full user DN is constructed from the user DN suffix as specified, plus the client user name as the `uid` attribute.

The remaining part of the authentication string begins with `#`, which signifies the beginning of group preference and mapping information. This part of the authentication string lists group names in the order `grp1`, `grp2`, `grp3`. The LDAP plugin compares that list with the set of group names returned by the LDAP server, looking in list order for a match against the returned names. The plugin uses the first match, or if there is no match, authentication fails.

Suppose that the LDAP server returns groups `grp3`, `grp2`, and `grp7`. The LDAP plugin uses `grp2` because it is the first group in the authentication string that matches, even though it is not the first group returned by the LDAP server. If the LDAP server returns `grp4`, `grp2`, and `grp1`, the plugin uses `grp1` even though `grp2` also matches. `grp1` has a precedence higher than `grp2` because it is listed earlier in the authentication string.

Assuming that the plugin finds a group name match, it performs mapping from that group name to the MySQL proxied user name, if there is one. For the example proxy account, mapping occurs as follows:

- If the matching group name is `grp1` or `grp3`, those are associated in the authentication string with user names `usera` and `userc`, respectively. The plugin uses the corresponding associated user name as the proxied user name.
- If the matching group name is `grp2`, there is no associated user name in the authentication string. The plugin uses `grp2` as the proxied user name.

If the LDAP server returns a group in DN format, the LDAP plugin parses the group DN to extract the group name from it.

To specify LDAP group preference and mapping information, these principles apply:

- Begin the group preference and mapping part of the authentication string with a `#` prefix character.
- The group preference and mapping specification is a list of one or more items, separated by commas. Each item has the form `group_name=user_name` or `group_name`. Items should be listed in group name preference order. For a group name selected by the plugin as a match from set of group names returned by the LDAP server, the two syntaxes differ in effect as follows:
 - For an item specified as `group_name=user_name` (with a user name), the group name maps to the user name, which is used as the MySQL proxied user name.
 - For an item specified as `group_name` (with no user name), the group name is used as the MySQL proxied user name.
- To quote a group or user name that contains special characters such as space, surround it by double quote (") characters. For example, if an item has group and user names of `my group name` and `my user name`, it must be written in a group mapping using quotes:

```
"my group name"="my user name"
```

If an item has group and user names of `my_group_name` and `my_user_name` (which contain no special characters), it may but need not be written using quotes. Any of the following are valid:

```
my_group_name=my_user_name
my_group_name="my_user_name"
"my_group_name"=my_user_name
"my_group_name"="my_user_name"
```

- To escape a character, precede it by a backslash (`\`). This is useful particularly to include a literal double quote or backslash, which are otherwise not included literally.
- A user DN need not be present in the authentication string, but if present, it must precede the group preference and mapping part. A user DN can be given as a full user DN, or as a user DN suffix with a `+` prefix character. (See [LDAP Authentication User DN Suffixes](#).)

LDAP Authentication User DN Suffixes

LDAP authentication plugins permit the authentication string that provides user DN information to begin with a `+` prefix character:

- In the absence of a `+` character, the authentication string value is treated as is without modification.
- If the authentication string begins with `+`, the plugin constructs the full user DN value from the user name sent by the client, together with the DN specified in the authentication string (with the `+` removed). In the constructed DN, the client user name becomes the value of the attribute that specifies LDAP user names. This is `uid` by default; to change the attribute, modify the appropriate system variable (`authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr`). The authentication string is stored as given in the `mysql.user` system table, with the full user DN constructed on the fly before authentication.

This account authentication string does not have `+` at the beginning, so it is taken as the full user DN:

```
CREATE USER 'baldwin'
  IDENTIFIED WITH authentication_ldap_simple
  AS 'uid=admin,ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`baldwin`). In this case, that name is not used because the authentication string has no prefix and thus fully specifies the user DN.

This account authentication string does have `+` at the beginning, so it is taken as just part of the user DN:

```
CREATE USER 'accounting'
  IDENTIFIED WITH authentication_ldap_simple
  AS '+ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`accounting`), which in this case is used as the `uid` attribute together with the authentication string to construct the user DN: `uid=accounting,ou=People,dc=example,dc=com`

The accounts in the preceding examples have a nonempty user name, so the client always connects to the MySQL server using the same name as specified in the account definition. If an account has an empty user name, such as the default anonymous `'@'%'` proxy account described in [LDAP Authentication with Proxying](#), clients might connect to the MySQL server with varying user names. But the principle is the same: If the authentication string begins with `+`, the plugin uses the user name sent by the client together with the authentication string to construct the user DN.

LDAP Authentication Methods

The LDAP authentication plugins use a configurable authentication method. The appropriate system variable and available method choices are plugin-specific:

- For the `authentication_ldap_simple` plugin: Set the `authentication_ldap_simple_auth_method_name` system variable to configure the method. The permitted choices are `SIMPLE` and `AD-FOREST`.
- For the `authentication_ldap_sasl` plugin: Set the `authentication_ldap_sasl_auth_method_name` system variable to configure the method. The permitted choices are `SCRAM-SHA-1` and `GSSAPI`. (To determine which SASL LDAP methods are actually available on the host system, check the value of the `Authentication_ldap_sasl_supported_methods` status variable.)

See the system variable descriptions for information about each permitted method. Also, depending on the method, additional configuration may be needed, as described in the following sections.

The GSSAPI/Kerberos Authentication Method

Generic Security Service Application Program Interface (GSSAPI) is a security abstraction interface. Kerberos is an instance of a specific security protocol that can be used through that abstract interface. Using GSSAPI, applications authenticate to Kerberos to obtain service credentials, then use those credentials in turn to enable secure access to other services.

One such service is LDAP, which is used by the client-side and server-side SASL LDAP authentication plugins. When the `authentication_ldap_sasl_auth_method_name` system variable is set to `GSSAPI`, these plugins use the GSSAPI/Kerberos authentication method. In this case, the plugins communicate securely using Kerberos without using LDAP messages directly. The server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

GSSAPI/Kerberos is supported as an authentication method for MySQL clients and servers only on Linux. It is useful in Linux environments where applications access LDAP using Microsoft Active Directory, which has Kerberos enabled by default.

The following discussion provides information about the configuration requirements for using the GSSAPI method. Familiarity is assumed with Kerberos concepts and operation, such as these common Kerberos terms:

- Principal = A named entity, such as a user or service.
- KDC = The Key Distribution Center, comprising the AS and TGS.
- AS = The Authentication Server, part of the KDC. Provides the initial ticket needed to obtain a TGT.
- TGS = The ticket-granting service, part of the KDC.
- TGT = The ticket-granting ticket, presented to the TGS to obtain service tickets for service access.

Kerberos authentication requires both a KDC server and an LDAP server. This requirement can be satisfied in different ways:

- Active Directory includes both servers, with Kerberos authentication enabled by default in the Active Directory LDAP server.
- OpenLDAP provides an LDAP server, but a separate KDC server may be needed, with additional Kerberos setup required.

Kerberos must also be available on the client host. A client contacts the AS using a password to obtain a TGT. The client then uses the TGT to obtain access from the TGS to other services, such as LDAP.

The following sections discuss the configuration steps to use GSSAPI/Kerberos for SASL LDAP authentication in MySQL:

- [Check the Kerberos Setup](#)
- [Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos](#)
- [Create a MySQL Account That Uses GSSAPI/Kerberos](#)
- [Use the MySQL Account to Connect to the MySQL Server](#)
- [/etc/krb5.conf Client Configuration Parameters](#)

Check the Kerberos Setup

The following example shows how to test availability of Kerberos in Active Directory. The example makes these assumptions:

- Active Directory is running on the host named `ldap_auth.example.com` with IP address `198.51.100.10`.
- The `MYSQL.LOCAL` domain is used for MySQL-related Kerberos authentication and LDAP lookups.
- A principal named `bredon@MYSQL.LOCAL` is registered with the KDC. (In later discussion, this principal name is also used for the MySQL user that uses GSSAPI/Kerberos to authenticate to the MySQL server.)

With those assumptions satisfied, follow this procedure:

1. Verify that the Kerberos library is installed and configured correctly in the operating system. For example, to configure a `MYSQL.LOCAL` domain for use during MySQL authentication, the Kerberos configuration file, `/etc/krb5.conf`, should contain something like this:

```
[realms]
  MYSQL.LOCAL = {
    kdc = ldap_auth.example.com
    admin_server = ldap_auth.example.com
    default_domain = MYSQL.LOCAL
  }
```

2. You may need to add an entry to `/etc/hosts` for the server host:

```
198.51.100.10 ldap_auth ldap_auth.example.com
```

3. Check whether Kerberos authentication works correctly:

- a. Use `kinit` to authenticate to Kerberos:

```
kinit bredon@MYSQL.LOCAL
```

The command authenticates for the Kerberos principal named `bredon@MYSQL.LOCAL`. Enter the principal's password when the command prompts for it. The KDC returns a TGT that is cached on the client side for use by other Kerberos-aware applications.

- b. Use `klist` to check whether the TGT was obtained correctly. The output should be similar to this:

```
Ticket cache: FILE:/tmp/krb5cc_244306
Default principal: bredon@MYSQL.LOCAL

Valid starting          Expires              Service principal
03/23/2020 08:18:33    03/23/2020 18:18:33    krbtgt/MYSQL.LOCAL@MYSQL.LOCAL
```

4. Check whether `ldapsearch` works with the Kerberos TGT using this command, which searches for users in the `MYSQL.LOCAL` domain:

```
ldapsearch -h 198.51.100.10 -Y GSSAPI -b "dc=MYSQL,dc=LOCAL"
```

Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos

Assuming that the LDAP server is accessible through Kerberos as just described, configure the server-side SASL LDAP authentication plugin to use the GSSAPI/Kerberos authentication method. (For general LDAP plugin installation information, see [Installing LDAP Pluggable Authentication](#).) Here is an example of plugin-related settings the server `my.cnf` file might contain:

```
[mysqld]
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_auth_method_name="GSSAPI"
authentication_ldap_sasl_server_host=198.51.100.10
authentication_ldap_sasl_server_port=389
authentication_ldap_sasl_bind_root_dn="cn=admin,cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_bind_root_pwd="password"
authentication_ldap_sasl_bind_base_dn="cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_user_search_attr="sAMAccountName"
```

Those option file settings configure the SASL LDAP plugin as follows:

- The `--plugin-load-add` option loads the plugin (adjust the `.so` suffix for your platform as necessary). If you loaded the plugin previously using an `INSTALL PLUGIN` statement, this option is unnecessary.
- `authentication_ldap_sasl_auth_method_name` must be set to `GSSAPI` to use GSSAPI/Kerberos as the SASL LDAP authentication method.
- `authentication_ldap_sasl_server_host` and `authentication_ldap_sasl_server_port` indicate the IP address and port number of the Active Directory server host for authentication.
- `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd` configure the root DN and password for group search capability. This capability is required, but users may not have privileges to search. In such cases, it is necessary to provide root DN information:
 - In the DN option value, `admin` should be the name of an administrative LDAP account that has privileges to perform user searches.
 - In the password option value, `password` should be the `admin` account password.
- `authentication_ldap_sasl_bind_base_dn` indicates the user DN base path, so that searches look for users in the `MYSQL.LOCAL` domain.
- `authentication_ldap_sasl_user_search_attr` specifies a standard Active Directory search attribute, `sAMAccountName`. This attribute is used in searches to match logon names; attribute values are not the same as the user DN values.

Create a MySQL Account That Uses GSSAPI/Kerberos

MySQL authentication using the SASL LDAP authentication plugin with the GSSAPI/Kerberos method is based on a user that is a Kerberos principal. The following discussion uses a principal named `bredon@MYSQL.LOCAL` as this user, which must be registered in several places:

- The Kerberos administrator should register the user name as a Kerberos principal. This name should include a domain name. The principal name and password will be used by clients to authenticate with Kerberos and obtain a TGT.
- The LDAP administrator should register the user name in an LDAP entry. For example:

```
uid=bredon,dc=MYSQL,dc=LOCAL
```

Note

In Active Directory (which uses Kerberos as the default authentication method), creating a user creates both the Kerberos principal and the LDAP entry.

- The MySQL DBA should create an account that has the Kerberos principal name as the user name, and that authenticates using the SASL LDAP plugin.

Assuming that the Kerberos principal and LDAP entry have been registered by the appropriate service administrators, and that the MySQL server has been started using the `my.cnf` settings previously described, create a MySQL account that corresponds to the Kerberos principal name, including the domain name.

Note

The SASL LDAP plugin uses a constant user DN for Kerberos authentication and ignores any user DN configured from MySQL. This has certain implications:

- For any MySQL account that uses GSSAPI/Kerberos authentication, the authentication string in `CREATE USER` or `ALTER USER` statements should contain no user DN because it has no effect.
- Because the authentication string contains no user DN, it should contain group mapping information, to enable the user to be handled as a proxy user that is mapped onto the desired proxied user. For information about proxying with the LDAP authentication plugin, see [LDAP Authentication with Proxying](#).

The following statements create a proxy user named `bredon@MYSQL.LOCAL` that assumes the privileges of the proxied user named `proxied_krb_usr`. Other GSSAPI/Kerberos users that should have the same privileges can similarly be created as proxy users for the same proxied user.

```
-- create proxy account
CREATE USER 'bredon@MYSQL.LOCAL'
  IDENTIFIED WITH authentication_ldap_sasl
  BY '#krb_grp=proxied_krb_user';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_krb_user'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL
  ON krb_user_db.*
  TO 'proxied_krb_user';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
  ON 'proxied_krb_user'
  TO 'bredon@MYSQL.LOCAL';
```

Observe closely the quoting for the proxy account name in the first `CREATE USER` statement and the `GRANT PROXY` statement:

- For most MySQL accounts, the user and host are separate parts of the account name, and thus are quoted separately as `'user_name'@'host_name'`.

- For Kerberos authentication, the user part of the account name includes the principal domain, so 'bredon@MYSQL.LOCAL' is quoted as a single value. Because no host part is given, the full MySQL account name uses the default of '%' as the host part: 'bredon@MYSQL.LOCAL'@'%'

The proxied account uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly to the MySQL server. Instead, it is expected that users who authenticate using LDAP use the `bredon@MYSQL.LOCAL` proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see [Section 6.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

Use the MySQL Account to Connect to the MySQL Server

After a MySQL account that uses GSSAPI/Kerberos has been set up, clients can authenticate to Kerberos and use the account to connect to the MySQL server. Kerberos authentication can take place either prior to or at the time of MySQL client program invocation:

- The client user can obtain a TGT independently of MySQL prior to invoking the MySQL client program. For example, the client user can use `kinit` to authenticate to Kerberos by providing a Kerberos principal name and the principal password. The TGT is cached and becomes available for use by other Kerberos-aware applications, such as the client-side SASL LDAP authentication plugin. In this case, the MySQL client program authenticates to the MySQL server using the TGT, so invoke the client without specifying a user name or password:

```
shell> kinit bredon@MYSQL.LOCAL
Password for bredon@MYSQL.LOCAL: (enter password here)
shell> mysql --default-auth=authentication_ldap_sasl_client
```

If the MySQL client command does include credentials, they are handled as follows:

- If the command includes a user name, authentication fails if that name does not match the principal name in the TGT.
- If the command includes a password, the password is ignored. Because authentication is based on the TGT, it can succeed *even if the user-provided password is incorrect*. For this reason, the plugin produces a warning if a valid TGT is found that causes a password to be ignored.
- If there is no TGT, the client-side SASL LDAP authentication plugin itself can obtain the TGT from the KDC. In this case, to invoke the client, specify the name and password of the Kerberos principal associated with the MySQL account (enter the command on a single line, then enter the principal password at the prompt):

```
shell> mysql --default-auth=authentication_ldap_sasl_client
--user=bredon@MYSQL.LOCAL
--password
Enter password: (enter password here)
```

- If the client command specifies no principal name as the user name and the client-side plugin finds the Kerberos cache empty because there is no TGT, authentication fails.

If you are uncertain whether a TGT exists, you can use `klist` to check.

Authentication occurs as follows:

1. The client uses the TGT to authenticate using Kerberos.
2. The server finds the LDAP entry for the principal and uses it to authenticate the connection for the `bredon@MYSQL.LOCAL` MySQL proxy account.
3. The group mapping information in the proxy account authentication string (`'#krb_grp=proxied_krb_user'`) indicates that the authenticated proxied user should be `proxied_krb_user`.

4. `bredon@MYSQL.LOCAL` is treated as a proxy for `proxied_krb_user`, and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| bredon@MYSQL.LOCAL@localhost | proxied_krb_user@% | 'bredon@MYSQL.LOCAL'@'%' |
+-----+-----+-----+
```

The `USER()` value indicates the user name used for the client command (`bredon@MYSQL.LOCAL`) and the host from which the client connected (`localhost`).

The `CURRENT_USER()` value is the full name of the proxied user account, which consists of the `proxied_krb_user` user part and the `%` host part.

The `@@proxy_user` value indicates the full name of the account used to make the connection to the MySQL server, which consists of the `bredon@MYSQL.LOCAL` user part and the `%` host part.

This demonstrates that proxying occurs through the `bredon@MYSQL.LOCAL` proxy user account, and that `bredon@MYSQL.LOCAL` assumes the privileges granted to the `proxied_krb_user` proxied user account.

A TGT once obtained is cached on the client side and can be used until it expires without specifying the password again. However the TGT is obtained, the client-side plugin uses it to acquire service tickets and communicate with the server-side plugin.

When the client-side plugin itself obtains the TGT, the client user may not want the TGT to be reused. As described in [/etc/krb5.conf Client Configuration Parameters](#), the local `/etc/krb5.conf` file can be used to cause the client-side plugin to destroy the TGT when done with it.

The server-side plugin has no access to the TGT itself or the Kerberos password used to obtain it.

The LDAP authentication plugins have no control over the caching mechanism (storage in a local file, in memory, and so forth), but Kerberos utilities such as `kswitch` may be available for this purpose.

/etc/krb5.conf Client Configuration Parameters

The client-side SASL LDAP plugin reads the local `/etc/krb5.conf` file. If this file is missing or inaccessible, an error occurs. Assuming that the file is accessible, the optional `[appdefaults]` group can be used to provide information used by the plugin. Place such information within the `MySQL` section of the group. For example:

```
[appdefaults]
MySQL = {
    ldap_server_host = "ldap_host.example.com"
    ldap_destroy_tgt = true
}
```

The client-side plugin recognizes these parameters in the `MySQL` section:

- The `ldap_server_host` value specifies the LDAP server host and can be useful when that host differs from the KDC server host specified in the `[realms]` group. By default, the plugin uses the KDC server host as the LDAP server host.
- The `ldap_destroy_tgt` value indicates whether the client-side plugin destroys the TGT after obtaining and using it. By default, `ldap_destroy_tgt` is `false`, but can be set to `true` to avoid TGT reuse. (This setting applies only to TGTs created by the client-side plugin, not TGTs created externally to MySQL.)

LDAP Search Referral

An LDAP server can be configured to delegate LDAP searches to another LDAP server, a functionality known as LDAP referral. Suppose that the server `a.example.com` holds a `"dc=example,dc=com"`

root DN and wishes to delegate searches to another server [b.example.com](#). To enable this, [a.example.com](#) would be configured with a named referral object having these attributes:

```
dn: dc=subtree,dc=example,dc=com
objectClass: referral
objectClass: extensibleObject
dc: subtree
ref: ldap://b.example.com/dc=subtree,dc=example,dc=com
```

An issue with enabling LDAP referral is that searches can fail with LDAP operation errors when the search base DN is the root DN, and referral objects are not set. A MySQL DBA might wish to avoid such referral errors for the LDAP authentication plugins, even though LDAP referral might be set globally in the [ldap.conf](#) configuration file. To configure on a plugin-specific basis whether the LDAP server should use LDAP referral when communicating with each plugin, set the [authentication_ldap_simple_referral](#) and [authentication_ldap_sasl_referral](#) system variables. Setting either variable to **ON** or **OFF** causes the corresponding LDAP authentication plugin to tell the LDAP server whether to use referral during MySQL authentication. Each variable has a plugin-specific effect and does not affect other applications that communicate with the LDAP server. Both variables are **OFF** by default.

6.4.1.8 No-Login Pluggable Authentication

The [mysql_no_login](#) server-side authentication plugin prevents all client connections to any account that uses it. Use cases for this plugin include:

- Accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users.
- Proxied accounts that should never permit direct login but are intended to be accessed only through proxy accounts.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the [plugin_dir](#) system variable.

Table 6.20 Plugin and Library Names for No-Login Authentication

Plugin or File	Plugin or File Name
Server-side plugin	mysql_no_login
Client-side plugin	None
Library file	mysql_no_login.so

The following sections provide installation and usage information specific to no-login pluggable authentication:

- [Installing No-Login Pluggable Authentication](#)
- [Uninstalling No-Login Pluggable Authentication](#)
- [Using No-Login Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#). For proxy user information, see [Section 6.2.18, “Proxy Users”](#).

Installing No-Login Pluggable Authentication

This section describes how to install the no-login authentication plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the [plugin_dir](#) system variable). If necessary, configure the plugin directory location by setting the value of [plugin_dir](#) at server startup.

The plugin library file base name is `mysql_no_login`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=mysql_no_login.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN mysql_no_login SONAME 'mysql_no_login.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE '%login%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| mysql_no_login | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the no-login plugin, see [Using No-Login Pluggable Authentication](#).

Uninstalling No-Login Pluggable Authentication

The method used to uninstall the no-login authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN mysql_no_login;
```

Using No-Login Pluggable Authentication

This section describes how to use the no-login authentication plugin to prevent accounts from being used for connecting from MySQL client programs to the server. It is assumed that the server is running with the no-login plugin enabled, as described in [Installing No-Login Pluggable Authentication](#).

To refer to the no-login authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `mysql_no_login`.

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.

The following example illustrates these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` system table:

```
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.*
  TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user
  TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost'
  SQL SECURITY DEFINER
  VIEW nologindb.myview
  AS SELECT User, Host FROM mysql.user;
```

To provide protected access to the view to an ordinary user, do this:

```
GRANT SELECT ON nologindb.myview
  TO 'ordinaryuser'@'localhost';
```

Now the ordinary user can use the view to access the limited information it presents:

```
SELECT * FROM nologindb.myview;
```

Attempts by the user to access columns other than those exposed by the view result in an error, as do attempts to select from the view by users not granted access to it.

Note

Because the `nologin` account cannot be used directly, the operations required to set up objects that it uses must be performed by `root` or similar account that has the privileges required to create the objects and set `DEFINER` values.

The `mysql_no_login` plugin is also useful in proxying scenarios. (For a discussion of concepts involved in proxying, see [Section 6.2.18, “Proxy Users”](#).) An account that authenticates using `mysql_no_login` may be used as a proxied user for proxy accounts:

```
-- create proxied account
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
  ON ...
  TO 'proxied_user'@'localhost';
-- permit proxy_user to be a proxy account for proxied account
GRANT PROXY
  ON 'proxied_user'@'localhost'
  TO 'proxy_user'@'localhost';
```

This enables clients to access MySQL through the proxy account (`proxy_user`) but not to bypass the proxy mechanism by connecting directly as the proxied user (`proxied_user`). A client who connects using the `proxy_user` account has the privileges of the `proxied_user` account, but `proxied_user` itself cannot be used to connect.

For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

6.4.1.9 Socket Peer-Credential Pluggable Authentication

The server-side `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCRECRED` socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the `SO_PEERCRECRED` option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.21 Plugin and Library Names for Socket Peer-Credential Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>auth_socket</code>
Client-side plugin	None, see discussion
Library file	<code>auth_socket.so</code>

The following sections provide installation and usage information specific to socket pluggable authentication:

- [Installing Socket Pluggable Authentication](#)
- [Uninstalling Socket Pluggable Authentication](#)
- [Using Socket Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=auth_socket.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
        FROM INFORMATION_SCHEMA.PLUGINS
        WHERE PLUGIN_NAME LIKE '%socket%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| auth_socket | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see [Using Socket Pluggable Authentication](#).

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN auth_socket;
```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server. If the names do not match, the plugin checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` system table row. If a match is found, the plugin permits the connection. The `authentication_string` value can be specified using an `IDENTIFIED ...AS` clause with `CREATE USER` or `ALTER USER`.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

To permit both the `valerie` and `stefanie` operating system users to access MySQL through socket file connections that use the account, this can be done two ways:

- Name both users at account-creation time, one following `CREATE USER`, and the other in the authentication string:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stefanie';
```

- If you have already used `CREATE USER` to create the account for a single user, use `ALTER USER` to add the second user:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
ALTER USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stefanie';
```

To access the account, both `valerie` and `stefanie` specify `--user=valerie` at connect time.

6.4.1.10 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

Note

This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.22 Plugin and Library Names for Test Authentication

Plugin or File	Plugin or File Name
Server-side plugin	<code>test_plugin_server</code>
Client-side plugin	<code>auth_test_plugin</code>
Library file	<code>auth_test_plugin.so</code>

The following sections provide installation and usage information specific to test pluggable authentication:

- [Installing Test Pluggable Authentication](#)
- [Uninstalling Test Pluggable Authentication](#)
- [Using Test Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.17, “Pluggable Authentication”](#).

Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE '%test_plugin%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| test_plugin_server | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see [Using Test Pluggable Authentication](#).

Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN test_plugin_server;
```

Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH test_plugin_server
BY 'testpassword';
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
shell> mysql --user=testuser --password
Enter password: testpassword
```

The plugin fetches the password as received from the client and compares it with the value stored in the `authentication_string` column of the account row in the `mysql.user` system table. If the two values match, the plugin returns the `authentication_string` value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the “user”):

```
[Note] Plugin test_plugin_server reported:
'successfully authenticated user testpassword'
```

6.4.1.11 Pluggable Authentication System Variables

These variables are unavailable unless the appropriate server-side plugin is installed:

- `authentication_ldap_sasl` for system variables with names of the form `authentication_ldap_sasl_XXX`
- `authentication_ldap_simple` for system variables with names of the form `authentication_ldap_simple_XXX`

Table 6.23 Authentication Plugin System Variable Summary

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dyn. Var
authentication_ldap_sasl_auth_method	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_bind_base_dn	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_bind_root_dn	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_bind_root_pwd	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_ca_path	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_group_search_base	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_group_search_filter	Yes	Yes	Yes		Global	Yes

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
authentication_ldap_sasl_init_pool_size	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_log_status	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_max_pool_size	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_referral	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_server_host	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_server_port	Yes	Yes	Yes		Global	Yes

authentication_ldap_sasl_server_host	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_server_port	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_tls	Yes	Yes	Yes		Global	Yes
authentication_ldap_sasl_user_search_attr	Yes	Yes	Yes		Global	Yes
authentication_windows_log_level	Yes	Yes	Yes		Global	No
authentication_windows_session_principal_name	Yes	Yes	Yes		Global	No

- [authentication_ldap_sasl_auth_method_name](#)

Command-Line Format	<code>--authentication-ldap-sasl-auth-method-name=value</code>
System Variable	authentication_ldap_sasl_auth_method_name
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>SCRAM-SHA-1</code>
Valid Values (\geq 8.0.20)	<code>SCRAM-SHA-1</code> <code>GSSAPI</code>
Valid Values (\leq 8.0.19)	<code>SCRAM-SHA-1</code>

For SASL LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method to ensure password security.

These authentication method values are permitted:

- [SCRAM-SHA-1](#): Use a SASL challenge-response mechanism.

The client-side [authentication_ldap_sasl_client](#) plugin communicates with the SASL server, using the password to create a challenge and obtain a SASL request buffer, then passes this buffer to the server-side [authentication_ldap_sasl](#) plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

- [GSSAPI](#): Use Kerberos, a passwordless and ticket-based protocol.

GSSAPI/Kerberos is supported as an authentication method for MySQL clients and servers only on Linux. It is useful in Linux environments where applications access LDAP using Microsoft Active Directory, which has Kerberos enabled by default.

The client-side [authentication_ldap_sasl_client](#) plugin obtains a service ticket using the ticket-granting ticket (TGT) from Kerberos, but does not use LDAP services directly. The server-side [authentication_ldap_sasl](#) plugin routes Kerberos messages between the client-side plugin and the LDAP server. Using the credentials thus obtained, the server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

- [authentication_ldap_sasl_bind_base_dn](#)

Command-Line Format	<code>--authentication-ldap-sasl-bind-base-dn=value</code>
System Variable	authentication_ldap_sasl_bind_base_dn
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

For SASL LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user\_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user\_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is [ou=People,dc=example,dc=com](#): Searches find user entries only in the first set.
- If the base DN is [ou=Admin,dc=example,dc=com](#): Searches find user entries only in the second set.
- If the base DN is [ou=dc=example,dc=com](#): Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- [authentication_ldap_sasl_bind_root_dn](#)

Command-Line Format	<code>--authentication-ldap-sasl-bind-root-dn=value</code>
---------------------	--

System Variable	<code>authentication_ldap_sasl_bind_root_dn</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For SASL LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_sasl_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_sasl` performs an initial LDAP binding using `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_sasl` performs a second bind using the user DN and client-supplied password.
- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_sasl` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.
- `authentication_ldap_sasl_bind_root_pwd`

Command-Line Format	<code>--authentication-ldap-sasl-bind-root-pwd=value</code>
System Variable	<code>authentication_ldap_sasl_bind_root_pwd</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For SASL LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_sasl_bind_root_dn`. See the description of that variable.

- `authentication_ldap_sasl_ca_path`

Command-Line Format	<code>--authentication-ldap-sasl-ca-path=value</code>
System Variable	<code>authentication_ldap_sasl_ca_path</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	<code>NULL</code>
---------------	-------------------

For SASL LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

Note

In addition to setting the `authentication_ldap_sasl_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_sasl_tls` system variable. These variables can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_sasl_group_search_attr`

Command-Line Format	<code>--authentication-ldap-sasl-group-search-attr=value</code>
System Variable	<code>authentication_ldap_sasl_group_search_attr</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>cn</code>

For SASL LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_sasl_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

This variable should be the empty string if you want no group or proxy authentication.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- `authentication_ldap_sasl_group_search_filter`

Command-Line Format	<code>--authentication-ldap-sasl-group-search-filter=value</code>
System Variable	<code>authentication_ldap_sasl_group_search_filter</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>((&(objectClass=posixGroup)(memberUid=%s)) (&(objectClass=group)(member=%s)))</code>

For SASL LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as `"admin"`, whereas `{UD}`

is replaced with a use full DN such as `"uid=admin,ou=People,dc=example,dc=com"`. The following value is the default, which supports both OpenLDAP and Active Directory:

```
( | (&(objectClass=posixGroup)(memberUid={UA}))
  (&(objectClass=group)(member={UD})))
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}memberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- `authentication_ldap_sasl_init_pool_size`

Command-Line Format	<code>--authentication-ldap-sasl-init-pool-size=#</code>
System Variable	<code>authentication_ldap_sasl_init_pool_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	32767

For SASL LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_sasl_init_pool_size` and `authentication_ldap_sasl_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_sasl_init_pool_size` connections, unless `authentication_ldap_sasl_max_pool_size=0` to disable pooling.
- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_sasl_max_pool_size`.
- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.
- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_sasl_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_sasl_log_status`

Command-Line Format	<code>--authentication-ldap-sasl-log-status=#</code>
System Variable	<code>authentication_ldap_sasl_log_status</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value (\geq 8.0.18)	6
Maximum Value (\leq 8.0.17)	5

For SASL LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

Table 6.24 Log Levels for `authentication_ldap_sasl_log_status`

Option Value	Types of Messages Logged
1	No messages
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages
5	Same as previous level plus debugging messages from MySQL
6	Same as previous level plus debugging messages from LDAP library

Log level 6 is available as of MySQL 8.0.18.

On the client side, messages can be logged to the standard output by setting the `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable. The permitted and default values are the same as for `authentication_ldap_sasl_log_status`.

The `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable applies only to SASL LDAP authentication. It has no effect for simple LDAP authentication because the client plugin in that case is `mysql_clear_password`, which knows nothing about LDAP operations.

- `authentication_ldap_sasl_max_pool_size`

Command-Line Format	<code>--authentication-ldap-sasl-max-pool-size=#</code>
System Variable	<code>authentication_ldap_sasl_max_pool_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	32767

For SASL LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with `authentication_ldap_sasl_init_pool_size`. See the description of that variable.

- `authentication_ldap_sasl_referral`

Command-Line Format	<code>--authentication-ldap-sasl-referral[={OFF ON}]</code>
Introduced	8.0.20
System Variable	<code>authentication_ldap_sasl_referral</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

For SASL LDAP authentication, whether to enable LDAP search referral. See [LDAP Search Referral](#).

This variable can be set to override the default OpenLDAP referral configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_sasl_server_host`

Command-Line Format	<code>--authentication-ldap-sasl-server-host=host_name</code>
System Variable	<code>authentication_ldap_sasl_server_host</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

For SASL LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_sasl_auth_method_name=SCRAM-SHA-1`: The LDAP server host can be a host name or IP address.
- `authentication_ldap_sasl_server_port`

Command-Line Format	<code>--authentication-ldap-sasl-server-port=port_num</code>
System Variable	<code>authentication_ldap_sasl_server_port</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>389</code>
Minimum Value	<code>1</code>
Maximum Value	<code>32376</code>

For SASL LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_sasl_tls`

Command-Line Format	<code>--authentication-ldap-sasl-tls[={OFF ON}]</code>
---------------------	--

System Variable	<code>authentication_ldap_sasl_tls</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

For SASL LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#). If you enable this variable, you may also wish to set the `authentication_ldap_sasl_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

As of MySQL 8.0.14, LDAPS can be used by setting the `authentication_ldap_sasl_server_port` system variable.

- `authentication_ldap_sasl_user_search_attr`

Command-Line Format	<code>--authentication-ldap-sasl-user-search-attr=value</code>
System Variable	<code>authentication_ldap_sasl_user_search_attr</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>uid</code>

For SASL LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_sasl_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

- `authentication_ldap_simple_auth_method_name`

Command-Line Format	<code>--authentication-ldap-simple-auth-method-name=value</code>
System Variable	<code>authentication_ldap_simple_auth_method_name</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>SIMPLE</code>
Valid Values	<code>SIMPLE</code>

AD-FOREST

For simple LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method.

**Note**

For all simple LDAP authentication methods, it is recommended to also set TLS parameters to require that communication with the LDAP server take place over secure connections.

These authentication method values are permitted:

- **SIMPLE**: Use simple LDAP authentication. This method uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user distinguished name. See the description of `authentication_ldap_simple_bind_root_dn`.
- **AD-FOREST**: A variation on **SIMPLE**, such that authentication searches all domains in the Active Directory forest, performing an LDAP bind to each Active Directory domain until the user is found in some domain.
- `authentication_ldap_simple_bind_base_dn`

Command-Line Format	<code>--authentication-ldap-simple-bind-base-dn=value</code>
System Variable	<code>authentication_ldap_simple_bind_base_dn</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For simple LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_simple_bind_root_dn`

Command-Line Format	<code>--authentication-ldap-simple-bind-root-dn=value</code>
System Variable	<code>authentication_ldap_simple_bind_root_dn</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

For simple LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_simple_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_simple` performs an initial LDAP binding using `authentication_ldap_simple_bind_root_dn` and `authentication_ldap_simple_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_simple` performs a second bind using the user DN and client-supplied password.
 - If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_simple` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.
- `authentication_ldap_simple_bind_root_pwd`

Command-Line Format	<code>--authentication-ldap-simple-bind-root-pwd=value</code>
System Variable	<code>authentication_ldap_simple_bind_root_pwd</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

For simple LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_simple_bind_root_dn`. See the description of that variable.

- `authentication_ldap_simple_ca_path`

Command-Line Format	<code>--authentication-ldap-simple-ca-path=value</code>
System Variable	<code>authentication_ldap_simple_ca_path</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Default Value	NULL
---------------	------

For simple LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

Note

In addition to setting the `authentication_ldap_simple_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_simple_tls` system variable. These variables can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_simple_group_search_attr`

Command-Line Format	<code>--authentication-ldap-simple-group-search-attr=value</code>
System Variable	<code>authentication_ldap_simple_group_search_attr</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>cn</code>

For simple LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_simple_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- `authentication_ldap_simple_group_search_filter`

Command-Line Format	<code>--authentication-ldap-simple-group-search-filter=value</code>
System Variable	<code>authentication_ldap_simple_group_search_filter</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Default Value	<code>((&(objectClass=posixGroup)(memberUid=%s)) (&(objectClass=group)(member=%s)))</code>
---------------	--

For simple LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
( | (&(objectClass=posixGroup)(memberUid={UA}))
  (&(objectClass=group)(member={UD})) )
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}memberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- `authentication_ldap_simple_init_pool_size`

Command-Line Format	<code>--authentication-ldap-simple-init-pool-size=#</code>
System Variable	<code>authentication_ldap_simple_init_pool_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	32767

For simple LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_simple_init_pool_size` and `authentication_ldap_simple_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_simple_init_pool_size` connections, unless `authentication_ldap_simple_max_pool_size=0` to disable pooling.
- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_simple_max_pool_size`.
- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.
- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not

be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_simple_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_simple_log_status`

Command-Line Format	<code>--authentication-ldap-simple-log-status=#</code>
System Variable	<code>authentication_ldap_simple_log_status</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value (≥ 8.0.18)	6
Maximum Value (≤ 8.0.17)	5

For simple LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

Table 6.25 Log Levels for `authentication_ldap_simple_log_status`

Option Value	Types of Messages Logged
1	No messages
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages
5	Same as previous level plus debugging messages from MySQL
6	Same as previous level plus debugging messages from LDAP library

Log level 6 is available as of MySQL 8.0.18.

- `authentication_ldap_simple_max_pool_size`

Command-Line Format	<code>--authentication-ldap-simple-max-pool-size=#</code>
System Variable	<code>authentication_ldap_simple_max_pool_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0

Maximum Value	32767
---------------	-------

For simple LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with `authentication_ldap_simple_init_pool_size`. See the description of that variable.

- `authentication_ldap_simple_referral`

Command-Line Format	<code>--authentication-ldap-simple-referral[={OFF ON}]</code>
Introduced	8.0.20
System Variable	<code>authentication_ldap_simple_referral</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

For simple LDAP authentication, whether to enable LDAP search referral. See [LDAP Search Referral](#).

- `authentication_ldap_simple_server_host`

Command-Line Format	<code>--authentication-ldap-simple-server-host=host_name</code>
System Variable	<code>authentication_ldap_simple_server_host</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

For simple LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_simple_auth_method_name=SIMPLE`: The LDAP server host can be a host name or IP address.
- For `authentication_ldap_simple_auth_method_name=AD-FOREST`: The LDAP server host can be an Active Directory domain name. For example, for an LDAP server URL of `ldap://example.mem.local:389`, the server name can be `mem.local`.

An Active Directory forest setup can have multiple domains (LDAP server IPs), which can be discovered using DNS. On Unix and Unix-like systems, some additional setup may be required to

configure your DNS server with SRV records that specify the LDAP servers for the Active Directory domain. For information about DNS SRV, see [RFC 2782](#).

Suppose that your configuration has these properties:

- The name server that provides information about Active Directory domains has IP address [10.172.166.100](#).
- The LDAP servers have names [ldap1.mem.local](#) through [ldap3.mem.local](#) and IP addresses [10.172.166.101](#) through [10.172.166.103](#).

You want the LDAP servers to be discoverable using SRV searches. For example, at the command line, a command like this should list the LDAP servers:

```
host -t SRV _ldap._tcp.mem.local
```

Perform the DNS configuration as follows:

1. Add a line to [/etc/resolv.conf](#) to specify the name server that provides information about Active Directory domains:

```
nameserver 10.172.166.100
```

2. Configure the appropriate zone file for the name server with SRV records for the LDAP servers:

```
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap1.mem.local.
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap2.mem.local.
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap3.mem.local.
```

3. It may also be necessary to specify the IP address for the LDAP servers in [/etc/hosts](#) if the server host cannot be resolved. For example, add lines like this to the file:

```
10.172.166.101 ldap1.mem.local
10.172.166.102 ldap2.mem.local
10.172.166.103 ldap3.mem.local
```

With the DNS configured as just described, the server-side LDAP plugin can discover the LDAP servers and will try to authenticate in all domains until authentication succeeds or there are no more servers.

Windows needs no such settings as just described. Given the LDAP server host in the [authentication_ldap_simple_server_host](#) value, the Windows LDAP library searches all domains and attempts to authenticate.

- [authentication_ldap_simple_server_port](#)

Command-Line Format	--authentication-ldap-simple-server-port=port_num
System Variable	authentication_ldap_simple_server_port
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	389
Minimum Value	1

Maximum Value	32376
---------------	-------

For simple LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_simple_tls`

Command-Line Format	<code>--authentication-ldap-simple-tls[={OFF ON}]</code>
System Variable	<code>authentication_ldap_simple_tls</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

For simple LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#). If you enable this variable, you may also wish to set the `authentication_ldap_simple_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

As of MySQL 8.0.14, LDAPS can be used by setting the `authentication_ldap_simple_server_port` system variable.

- `authentication_ldap_simple_user_search_attr`

Command-Line Format	<code>--authentication-ldap-simple-user-search-attr=value</code>
System Variable	<code>authentication_ldap_simple_user_search_attr</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>uid</code>

For simple LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_simple_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

6.4.2 The Connection-Control Plugins

MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to connection attempts after a configurable number of consecutive failed attempts. This capability provides a deterrent that slows down brute force attacks against MySQL user accounts. The plugin library contains two plugins:

- `CONNECTION_CONTROL` checks incoming connection attempts and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

The `CONNECTION_CONTROL` plugin uses the audit plugin interface (see [Writing Audit Plugins](#)). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and `MYSQL_AUDIT_CONNECTION_CHANGE_USER` subevents to check whether the server should introduce a delay before responding to connection attempts.

- `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` implements an `INFORMATION_SCHEMA` table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, see [Section 25.53.1, “The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table”](#).

6.4.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, `CONNECTION_CONTROL` and `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS`. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `connection_control`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load-add` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN CONNECTION_CONTROL
  SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS
  SONAME 'connection_control.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE 'connection%';
+-----+-----+
| PLUGIN_NAME                                | PLUGIN_STATUS |
+-----+-----+
| CONNECTION_CONTROL                        | ACTIVE        |
| CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS | ACTIVE        |
+-----+-----+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-login-attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

Note

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin is of little use because without the `CONNECTION_CONTROL` plugin to provide the data that populates the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, retrievals from the table will always be empty.

- [Connection Delay Configuration](#)
- [Connection Failure Assessment](#)
- [Connection Failure Monitoring](#)

Connection Delay Configuration

To enable configuring its operation, the `CONNECTION_CONTROL` plugin exposes these system variables:

- `connection_control_failed_connections_threshold`: The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts. To disable failed-connection counting, set `connection_control_failed_connections_threshold` to zero.
- `connection_control_min_connection_delay`: The minimum delay in milliseconds for connection failures above the threshold.
- `connection_control_max_connection_delay`: The maximum delay in milliseconds for connection failures above the threshold.

If `connection_control_failed_connections_threshold` is nonzero, failed-connection counting is enabled and has these properties:

- The delay is zero up through `connection_control_failed_connections_threshold` consecutive failed connection attempts.
- Thereafter, the server adds an increasing delay for subsequent consecutive attempts, until a successful connection occurs. The initial unadjusted delays begin at 1000 milliseconds (1 second) and increase by 1000 milliseconds per attempt. That is, once delay has been activated for an account, the unadjusted delays for subsequent failed attempts are 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.
- The actual delay experienced by a client is the unadjusted delay, adjusted to lie within the values of the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables, inclusive.

- Once delay has been activated for an account, the first successful connection thereafter by the account also experiences a delay, but failure counting is reset for subsequent connections.

For example, with the default `connection_control_failed_connections_threshold` value of 3, there is no delay for the first three consecutive failed connection attempts by an account. The actual adjusted delays experienced by the account for the fourth and subsequent failed connections depend on the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` values:

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1000 and 20000, the adjusted delays are the same as the unadjusted delays, up to a maximum of 20000 milliseconds. The fourth and subsequent failed connections are delayed by 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.
- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1500 and 20000, the adjusted delays for the fourth and subsequent failed connections are 1500 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth, up to a maximum of 20000 milliseconds.
- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 2000 and 3000, the adjusted delays for the fourth and subsequent failed connections are 2000 milliseconds, 2000 milliseconds, and 3000 milliseconds, with all subsequent failed connections also delayed by 3000 milliseconds.

You can set the `CONNECTION_CONTROL` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, with a minimum delay of 2000 milliseconds. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=2000
```

To set and persist the variables at runtime, use these statements:

```
SET PERSIST connection_control_failed_connections_threshold = 4;
SET PERSIST connection_control_min_connection_delay = 2000;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables both have minimum and maximum values of 1000 and 2147483647. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000.

Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

- If the client user proxies another user, the account for failed-connection counting is the proxying user, not the proxied user. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see [Section 6.2.18, “Proxy Users”](#)).
- If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1@%.example.com`, `user1@%.com`, or `user1@%` entry instead, counting uses `user1@%.example.com`, `user1@%.com`, or `user1@%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

Note

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not
allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `CONNECTION_CONTROL` does not see it, and does not count it.

Connection Failure Monitoring

To monitor failed connections, use these information sources:

- The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

- The `INFORMATION_SCHEMA.CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per account (user/host combination). This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime has these effects:

- All accumulated failed-connection counters are reset to zero.
- The `Connection_control_delay_generated` status variable is reset to zero.
- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

6.4.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- [Connection-Control System Variables](#)
- [Connection-Control Status Variables](#)

Connection-Control System Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes these system variables:

- `connection_control_failed_connections_threshold`

Command-Line Format	<code>--connection-control-failed-connections-threshold=#</code>
System Variable	<code>connection_control_failed_connections_threshold</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	2147483647

The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value *N*, the server adds a delay beginning with consecutive failed attempt *N*+1. If an account has reached the point where connection responses are delayed, a delay also occurs for the next subsequent successful connection.
- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see [Section 6.4.2.1, “Connection-Control Plugin Installation”](#).

- `connection_control_max_connection_delay`

Command-Line Format	<code>--connection-control-max-connection-delay=#</code>
System Variable	<code>connection_control_max_connection_delay</code>
Scope	Global

Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2147483647
Minimum Value	1000
Maximum Value	2147483647
Unit	milliseconds

The maximum delay in milliseconds for server response to failed connection attempts, if [connection_control_failed_connections_threshold](#) is greater than zero.

For information about how [connection_control_max_connection_delay](#) interacts with other connection-control system and status variables, see [Section 6.4.2.1, “Connection-Control Plugin Installation”](#).

- [connection_control_min_connection_delay](#)

Command-Line Format	--connection-control-min-connection-delay=#
System Variable	connection_control_min_connection_delay
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	1000
Maximum Value	2147483647
Unit	milliseconds

The minimum delay in milliseconds for server response to failed connection attempts, if [connection_control_failed_connections_threshold](#) is greater than zero.

For information about how [connection_control_min_connection_delay](#) interacts with other connection-control system and status variables, see [Section 6.4.2.1, “Connection-Control Plugin Installation”](#).

Connection-Control Status Variables

If the [CONNECTION_CONTROL](#) plugin is installed, it exposes this status variable:

- [Connection_control_delay_generated](#)

The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the [connection_control_failed_connections_threshold](#) system variable.

This variable provides a simple counter. For more detailed connection-control monitoring information, examine the [INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS](#) table; see [Section 25.53.1, “The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table”](#).

Assigning a value to [connection_control_failed_connections_threshold](#) at runtime resets [Connection_control_delay_generated](#) to zero.

6.4.3 The Password Validation Component

The `validate_password` component serves to improve security by requiring account passwords and enabling strength testing of potential passwords. This component exposes system variables that enable you to configure password policy, and status variables for component monitoring.

Note

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. (For general information about server components, see [Section 5.5, “MySQL Server Components”](#).) The following instructions describe how to use the component, not the plugin. For instructions on using the plugin form of `validate_password`, see [The Password Validation Plugin in MySQL 5.7 Reference Manual](#).

The plugin form of `validate_password` is still available but is deprecated and will be removed in a future version of MySQL. MySQL installations that use the plugin should make the transition to using the component instead. See [Section 6.4.3.3, “Transitioning to the Password Validation Component”](#).

The `validate_password` component implements these capabilities:

- For SQL statements that assign a password supplied as a cleartext value, `validate_password` checks the password against the current password policy and rejects the password if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This applies to the `ALTER USER`, `CREATE USER`, and `SET PASSWORD` statements.
- For `CREATE USER` statements, `validate_password` requires that a password be given, and that it satisfies the password policy. This is true even if an account is locked initially because otherwise unlocking the account later would cause it to become accessible without a password that satisfies the policy.
- `validate_password` implements a `VALIDATE_PASSWORD_STRENGTH()` SQL function that assesses the strength of potential passwords. This function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

Note

For statements that assign or modify account passwords (`ALTER USER`, `CREATE USER`, and `SET PASSWORD`), the `validate_password` capabilities described here apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use plugins that perform authentication against a credentials system external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see [Section 6.2.15, “Password Management”](#).

The preceding restriction does not apply to use of the `VALIDATE_PASSWORD_STRENGTH()` function because it does not affect accounts directly.

Examples:

- `validate_password` checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

```
mysql> ALTER USER USER() IDENTIFIED BY 'abc';
ERROR 1819 (HY000): Your password does not satisfy the current
policy requirements
```

- Passwords specified as hashed values are not checked because the original password value is not available for checking:

```
mysql> ALTER USER 'jeffrey'@'localhost'
```

```
IDENTIFIED WITH mysql_native_password
AS '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

- This account-creation statement fails, even though the account is locked initially, because it does not include a password that satisfies the current password policy:

```
mysql> CREATE USER 'juanita'@'localhost' ACCOUNT LOCK;
ERROR 1819 (HY000): Your password does not satisfy the current
policy requirements
```

- To check a password, use the `VALIDATE_PASSWORD_STRENGTH()` function:

```
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
+-----+
| VALIDATE_PASSWORD_STRENGTH('weak') |
+-----+
| 25 |
+-----+
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
+-----+
| VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
+-----+
| 50 |
+-----+
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!');
+-----+
| VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!') |
+-----+
| 100 |
+-----+
```

To configure password checking, modify the system variables having names of the form `validate_password.xxx`; these are the parameters that control password policy. See [Section 6.4.3.2, “Password Validation Options and Variables”](#).

If `validate_password` is not installed, the `validate_password.xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH()` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters, or no password at all.

Assuming that `validate_password` is installed, it implements three levels of password checking: `LOW`, `MEDIUM`, and `STRONG`. The default is `MEDIUM`; to change this, modify the value of `validate_password.policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- `LOW` policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password.length`.
- `MEDIUM` policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character. To change these values, modify `validate_password.number_count`, `validate_password.mixed_case_count`, and `validate_password.special_char_count`.
- `STRONG` policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password.dictionary_file`.

In addition, `validate_password` supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To provide control over this capability, `validate_password` exposes a `validate_password.check_user_name` system variable, which is enabled by default.

6.4.3.1 Password Validation Component Installation and Uninstallation

This section describes how to install and uninstall the `validate_password` password-validation component. For general information about installing and uninstalling components, see [Section 5.5, “MySQL Server Components”](#).

Note

If you install MySQL 8.0 using the [MySQL Yum repository](#), [MySQL SLES Repository](#), or [RPM packages provided by Oracle](#), the `validate_password` component is enabled by default after you start your MySQL Server for the first time.

Upgrades to MySQL 8.0 from 5.7 using Yum or RPM packages leave the `validate_password` plugin in place. To make the transition from the `validate_password` plugin to the `validate_password` component, see [Section 6.4.3.3, “Transitioning to the Password Validation Component”](#).

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `validate_password` component, use this statement:

```
INSTALL COMPONENT 'file://component_validate_password';
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `validate_password` component, use this statement:

```
UNINSTALL COMPONENT 'file://component_validate_password';
```

`UNINSTALL COMPONENT` unloads the component, and deregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

6.4.3.2 Password Validation Options and Variables

This section describes the system and status variables that `validate_password` provides to enable its operation to be configured and monitored.

- [Password Validation Component System Variables](#)
- [Password Validation Component Status Variables](#)
- [Password Validation Plugin Options](#)
- [Password Validation Plugin System Variables](#)
- [Password Validation Plugin Status Variables](#)

Password Validation Component System Variables

If the `validate_password` component is enabled, it exposes several system variables that enable configuration of password checking:

```
mysql> SHOW VARIABLES LIKE 'validate_password.%';
```

Variable_name	Value
<code>validate_password.check_user_name</code>	ON
<code>validate_password.dictionary_file</code>	
<code>validate_password.length</code>	8
<code>validate_password.mixed_case_count</code>	1
<code>validate_password.number_count</code>	1
<code>validate_password.policy</code>	MEDIUM

```
| validate_password.special_char_count | 1 |
+-----+-----+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- `validate_password.check_user_name`

Command-Line Format	<code>--validate-password.check-user-name[={OFF ON}]</code>
System Variable	<code>validate_password.check_user_name</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether `validate_password` compares passwords to the user name part of the effective user account for the current session and rejects them if they match. This variable is unavailable unless `validate_password` is installed.

By default, `validate_password.check_user_name` is enabled. This variable controls user name matching independent of the value of `validate_password.policy`.

When `validate_password.check_user_name` is enabled, it has these effects:

- Checking occurs in all contexts for which `validate_password` is invoked, which includes use of statements such as `ALTER USER` or `SET PASSWORD` to change the current user's password, and invocation of functions such as `VALIDATE_PASSWORD_STRENGTH()`.
- The user names used for comparison are taken from the values of the `USER()` and `CURRENT_USER()` functions for the current session. An implication is that a user who has sufficient privileges to set another user's password can set the password to that user's name, and cannot set that user's password to the name of the user executing the statement. For example, `'root'@'localhost'` can set the password for `'jeffrey'@'localhost'` to `'jeffrey'`, but cannot set the password to `'root'`.
- Only the user name part of the `USER()` and `CURRENT_USER()` function values is used, not the host name part. If a user name is empty, no comparison occurs.
- If a password is the same as the user name or its reverse, a match occurs and the password is rejected.
- User-name matching is case-sensitive. The password and user name values are compared as binary strings on a byte-by-byte basis.
- If a password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.
- `validate_password.dictionary_file`

Command-Line Format	<code>--validate-password.dictionary-file=file_name</code>
System Variable	<code>validate_password.dictionary_file</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name

The path name of the dictionary file that `validate_password` uses for checking passwords. This variable is unavailable unless `validate_password` is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is interpreted relative to the server data directory. File contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (`STRONG`); see the description of the `validate_password.policy` system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case sensitive.

For `VALIDATE_PASSWORD_STRENGTH()`, the password is checked against all policies, including `STRONG`, so the strength assessment includes the dictionary check regardless of the `validate_password.policy` value.

`validate_password.dictionary_file` can be set at runtime and assigning a value causes the named file to be read without a server restart.

- `validate_password.length`

Command-Line Format	<code>--validate-password.length=#</code>
System Variable	<code>validate_password.length</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0

The minimum number of characters that `validate_password` requires passwords to have. This variable is unavailable unless `validate_password` is installed.

The `validate_password.length` minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

```
validate_password.number_count
+ validate_password.special_char_count
+ (2 * validate_password.mixed_case_count)
```

If `validate_password` adjusts the value of `validate_password.length` due to the preceding constraint, it writes a message to the error log.

- `validate_password.mixed_case_count`

Command-Line Format	<code>--validate-password.mixed-case-count=#</code>
System Variable	<code>validate_password.mixed_case_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of lowercase and uppercase characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

For a given `validate_password.mixed_case_count` value, the password must have that many lowercase characters, and that many uppercase characters.

- `validate_password.number_count`

Command-Line Format	<code>--validate-password.number-count=#</code>
System Variable	<code>validate_password.number_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of numeric (digit) characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

- `validate_password.policy`

Command-Line Format	<code>--validate-password.policy=value</code>
System Variable	<code>validate_password.policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1 2

The password policy enforced by `validate_password`. This variable is unavailable unless `validate_password` is installed.

`validate_password.policy` affects how `validate_password` uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by `validate_password.check_user_name`.

The `validate_password.policy` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password.length` system variable. Similarly, the required values for the other tests are given by other `validate_password.xxx` variables.

Policy	Tests Performed
0 or <code>LOW</code>	Length

Policy	Tests Performed
1 or <code>MEDIUM</code>	Length; numeric, lowercase/uppercase, and special characters
2 or <code>STRONG</code>	Length; numeric, lowercase/uppercase, and special characters; dictionary file

- `validate_password.special_char_count`

Command-Line Format	<code>--validate-password.special-char-count=#</code>
System Variable	<code>validate_password.special_char_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of nonalphanumeric characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

Password Validation Component Status Variables

If the `validate_password` component is enabled, it exposes status variables that provide operational information:

```
mysql> SHOW STATUS LIKE 'validate_password.%';
```

Variable_name	Value
<code>validate_password.dictionary_file_last_parsed</code>	2019-10-03 08:33:49
<code>validate_password.dictionary_file_words_count</code>	1902

The following list describes the meaning of each status variable.

- `validate_password.dictionary_file_last_parsed`

When the dictionary file was last parsed. This variable is unavailable unless `validate_password` is installed.

- `validate_password.dictionary_file_words_count`

The number of words read from the dictionary file. This variable is unavailable unless `validate_password` is installed.

Password Validation Plugin Options

Note

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated and will be removed in a future version of MySQL. Consequently, its options are also deprecated and will be removed. MySQL installations that use the plugin should make the transition to using the component instead. See [Section 6.4.3.3, “Transitioning to the Password Validation Component”](#).

To control activation of the `validate_password` plugin, use this option:

- `--validate-password[=value]`

Command-Line Format	<code>--validate-password[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON OFF FORCE FORCE_PLUS_PERMANENT

This option controls how the server loads the deprecated `validate_password` plugin at startup. The value should be one of those available for plugin-loading options, as described in [Section 5.6.1, “Installing and Uninstalling Plugins”](#). For example, `--validate-password=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the `validate_password` plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`. See [Section 6.4.3.1, “Password Validation Component Installation and Uninstallation”](#).

Password Validation Plugin System Variables

Note

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated and will be removed in a future version of MySQL. Consequently, its system variables are also deprecated and will be removed. Use the corresponding system variables of the `validate_password` component; see [Password Validation Component System Variables](#). MySQL installations that use the plugin should make the transition to using the component instead. See [Section 6.4.3.3, “Transitioning to the Password Validation Component”](#).

- `validate_password_check_user_name`

Command-Line Format	<code>--validate-password-check-user-name[={OFF ON}]</code>
System Variable	<code>validate_password_check_user_name</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.check_user_name` system variable of the `validate_password` component instead.

- `validate_password_dictionary_file`

Command-Line Format	<code>--validate-password-dictionary-file=file_name</code>
System Variable	<code>validate_password_dictionary_file</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	File name

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file` system variable of the `validate_password` component instead.

- `validate_password_length`

Command-Line Format	<code>--validate-password-length=#</code>
System Variable	<code>validate_password_length</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.length` system variable of the `validate_password` component instead.

- `validate_password_mixed_case_count`

Command-Line Format	<code>--validate-password-mixed-case-count=#</code>
System Variable	<code>validate_password_mixed_case_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.mixed_case_count` system variable of the `validate_password` component instead.

- `validate_password_number_count`

Command-Line Format	<code>--validate-password-number-count=#</code>
System Variable	<code>validate_password_number_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1

Minimum Value	0
---------------	---

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.number_count` system variable of the `validate_password` component instead.

- `validate_password_policy`

Command-Line Format	<code>--validate-password-policy=value</code>
System Variable	<code>validate_password_policy</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1 2

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.policy` system variable of the `validate_password` component instead.

- `validate_password_special_char_count`

Command-Line Format	<code>--validate-password-special-char-count=#</code>
System Variable	<code>validate_password_special_char_count</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.special_char_count` system variable of the `validate_password` component instead.

Password Validation Plugin Status Variables

Note

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated and will be removed in a future version of MySQL. Consequently, its status variables are also deprecated and will be removed. Use the corresponding status variables of the `validate_password` component; see [Password Validation Component Status Variables](#). MySQL installations that use the plugin should make the transition to using the component instead. See [Section 6.4.3.3, “Transitioning to the Password Validation Component”](#).

- `validate_password_dictionary_file_last_parsed`

This `validate_password` plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_last_parsed` status variable of the `validate_password` component instead.

- `validate_password_dictionary_file_words_count`

This `validate_password` plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_words_count` status variable of the `validate_password` component instead.

6.4.3.3 Transitioning to the Password Validation Component

Note

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated and will be removed in a future version of MySQL.

MySQL installations that currently use the `validate_password` plugin should make the transition to using the `validate_password` component instead. To do so, use the following procedure. The procedure installs the component before uninstalling the plugin, to avoid having a time window during which no password validation occurs. (The component and plugin can be installed simultaneously. In this case, the server attempts to use the component, falling back to the plugin if the component is unavailable.)

1. Install the `validate_password` component:

```
INSTALL COMPONENT 'file://component_validate_password';
```

2. Test the `validate_password` component to ensure that it works as expected. If you need to set any `validate_password.xxx` system variables, you can do so at runtime using `SET GLOBAL`. (Any option file changes that must be made are performed in the next step.)
3. Adjust any references to the plugin system and status variables to refer to the corresponding component system and status variables. Suppose that previously you had configured the plugin at startup using an option file like this:

```
[mysqld]
validate_password=FORCE_PLUS_PERMANENT
validate_password_dictionary_file=/usr/share/dict/words
validate_password_length=10
validate_password_number_count=2
```

Those settings are appropriate for the plugin, but must be modified to apply to the component. To adjust the option file, omit the `--validate_password` option (it applies only to the plugin, not the component), and modify the system variable references from no-dot names appropriate for the plugin to dotted names appropriate for the component:

```
[mysqld]
validate_password.dictionary_file=/usr/share/dict/words
validate_password.length=10
validate_password.number_count=2
```

Similar adjustments are needed for applications that refer at runtime to `validate_password` plugin system and status variables. Change the no-dot plugin variable names to the corresponding dotted component variable names.

4. Uninstall the `validate_password` plugin:

```
UNINSTALL PLUGIN validate_password;
```

If the `validate_password` plugin is loaded at server startup using a `--plugin-load` or `--plugin-load-add` option, omit that option from the server startup procedure. For example, if the option is listed in a server option file, remove it from the file.

5. Restart the server.

6.4.4 The MySQL Keyring

MySQL Server supports a keyring that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation comprises these elements:

- Keyring plugins that manage a backing store or communicate with a storage back end. These keyring plugins are available:
 - `keyring_file` stores keyring data in a file local to the server host. This plugin is available in MySQL Community Edition and MySQL Enterprise Edition distributions. See [Section 6.4.4.2, “Using the keyring_file File-Based Plugin”](#).
 - `keyring_encrypted_file` stores keyring data in an encrypted file local to the server host. This plugin is available in MySQL Enterprise Edition distributions. See [Section 6.4.4.3, “Using the keyring_encrypted_file Keyring Plugin”](#).
 - `keyring_okv` is a KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. This plugin is available in MySQL Enterprise Edition distributions. See [Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”](#).
 - `keyring_aws` communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. This plugin is available in MySQL Enterprise Edition distributions. See [Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”](#).
 - `keyring_hashicorp` communicates with HashiCorp Vault for back end storage. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 8.0.18. See [Section 6.4.4.6, “Using the HashiCorp Vault Keyring Plugin”](#).
- A key migration capability. A MySQL server operational mode enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#).
- A keyring service interface for keyring key management, accessible at two levels:
 - SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
 - C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).
- Key metadata access. In MySQL 8.0.16 and higher, the Performance Schema `keyring_keys` table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The `keyring_keys` table does not expose any sensitive keyring data such as key contents. See [Section 26.12.19.3, “The keyring_keys table”](#).

Warning

The `keyring_file` and `keyring_encrypted_file` plugins for encryption key management are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

Within MySQL, uses of the keyring include:

- The [InnoDB](#) storage engine uses the keyring to store its key for tablespace encryption. [InnoDB](#) can use any supported keyring plugin. See [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).
- MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. The audit log plugin can use any supported keyring plugin. See [Encrypting Audit Log Files](#).
- Binary log and relay log management supports keyring-based encryption of log files. With log file encryption activated, the keys used to encrypt passwords for the binary log files and relay log files are stored in the keyring. This capability can use any supported keyring plugin. See [Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

For general keyring installation instructions, see [Section 6.4.4.1, “Keyring Plugin Installation”](#). For installation and configuration information specific to a given keyring plugin, see the section describing that plugin.

For information about using the keyring UDFs, see [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).

Keyring plugins and UDFs access a keyring service that provides the interface for server components to the keyring. For information about accessing the keyring plugin service and writing keyring plugins, see [Section 5.6.8.2, “The Keyring Service”](#), and [Writing Keyring Plugins](#).

6.4.4.1 Keyring Plugin Installation

Keyring service consumers require a keyring plugin to be installed. MySQL provides these plugin choices:

- [keyring_file](#): Stores keyring data in a file local to the server host. Available in all MySQL distributions.
- [keyring_encrypted_file](#): Stores keyring data in an encrypted file local to the server host. Available in MySQL Enterprise Edition distributions.
- [keyring_okv](#): Uses KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions.
- [keyring_aws](#): Communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.
- [keyring_hashicorp](#): Communicates with HashiCorp Vault for back end storage. Available in MySQL Enterprise Edition distributions.

This section describes how to install the keyring plugin of your choosing. For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

If you intend to use keyring user-defined functions (UDFs) in conjunction with the keyring plugin, install the UDFs after installing the plugin, using the instructions in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the [plugin_dir](#) system variable). If necessary, configure the plugin directory location by setting the value of [plugin_dir](#) at server startup.

Installation for each keyring plugin is similar. The following instructions use [keyring_file](#). Users of a different keyring plugin can substitute its name for [keyring_file](#).

The [keyring_file](#) plugin library file base name is [keyring_file](#). The file name suffix differs per platform (for example, [.so](#) for Unix and Unix-like systems, [.dll](#) for Windows).

**Note**

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is unsupported and results may not be as anticipated.

The keyring plugin must be loaded early during the server startup sequence so that server components can access it as necessary during their own initialization. For example, the [InnoDB](#) storage engine uses the keyring for tablespace encryption, so the keyring plugin must be loaded and available prior to [InnoDB](#) initialization.

To load the plugin, use the `--early-plugin-load` option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is `.so`, use these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
```

Before starting the server, check the notes for your chosen keyring plugin to see whether it permits or requires additional configuration:

- `keyring_file`: [Section 6.4.4.2, “Using the keyring_file File-Based Plugin”](#).
- `keyring_encrypted_file`: [Section 6.4.4.3, “Using the keyring_encrypted_file Keyring Plugin”](#).
- `keyring_okv`: [Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”](#).
- `keyring_aws`: [Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”](#)
- `keyring_hashicorp`: [Section 6.4.4.6, “Using the HashiCorp Vault Keyring Plugin”](#)

After performing any plugin-specific configuration, verify plugin installation. With the MySQL server running, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Plugins can be loaded by methods other than `--early-plugin-load`, such as the `--plugin-load` or `--plugin-load-add` option or the `INSTALL PLUGIN` statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain server components, such as [InnoDB](#):

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after [InnoDB](#) initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an [InnoDB](#) table, any plugins named in it can be loaded during startup only after [InnoDB](#) initialization.

If no keyring plugin is available when a server component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if [InnoDB](#) finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, [InnoDB](#) can access only unencrypted tablespaces. To ensure that [InnoDB](#) can access encrypted tablespaces as well, use `--early-plugin-load` to load the keyring plugin.

6.4.4.2 Using the keyring_file File-Based Plugin

The `keyring_file` keyring plugin stores keyring data in a file local to the server host.

Warning

The `keyring_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_file` plugin, use the general keyring installation instructions found in [Section 6.4.4.1, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_file` found [here](#).

To be usable during the server startup process, `keyring_file` must be loaded using the `--early-plugin-load` option. The `keyring_file_data` system variable optionally configures the location of the file used by the `keyring_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring
```

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

For additional information about `keyring_file_data`, see [Section 6.4.4.12, “Keyring System Variables”](#).

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_file` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_file`, see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

6.4.4.3 Using the `keyring_encrypted_file` Keyring Plugin

Note

The `keyring_encrypted_file` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `keyring_encrypted_file` keyring plugin stores keyring data in an encrypted file local to the server host.

**Warning**

The `keyring_encrypted_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_encrypted_file` plugin, use the general keyring installation instructions found in [Section 6.4.4.1, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_encrypted_file` found [here](#).

To be usable during the server startup process, `keyring_encrypted_file` must be loaded using the `--early-plugin-load` option. To specify the password for encrypting the keyring data file, set the `keyring_encrypted_file_password` system variable. (The password is mandatory; if not specified at server startup, `keyring_encrypted_file` initialization fails.) The `keyring_encrypted_file_data` system variable optionally configures the location of the file used by the `keyring_encrypted_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary and substituting your chosen password:

```
[mysqld]
early-plugin-load=keyring_encrypted_file.so
keyring_encrypted_file_data=/usr/local/mysql/mysql-keyring/keyring-encrypted
keyring_encrypted_file_password=password
```

Because the `my.cnf` file stores a password when written as shown, it should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

For additional information about the system variables used to configure the `keyring_encrypted_file` plugin, see [Section 6.4.4.12, “Keyring System Variables”](#).

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_encrypted_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum. In addition, `keyring_encrypted_file` encrypts file contents using AES before writing the file, and decrypts file contents after reading the file.

The `keyring_encrypted_file` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_encrypted_file`, see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

6.4.4.4 Using the `keyring_okv` KMIP Plugin

**Note**

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys between a key management server and its clients. The `keyring_okv` keyring plugin uses the KMIP 1.1 protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively by the back end, not by `keyring_okv`. The plugin works with these KMIP-compatible products:

- Oracle Key Vault
- Gemalto SafeNet KeySecure Appliance
- Townsend Alliance Key Manager

The `keyring_okv` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_okv`, [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

To install the `keyring_okv` plugin, use the general keyring installation instructions found in [Section 6.4.4.1, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_okv` found [here](#).

- [General keyring_okv Configuration](#)
- [Configuring keyring_okv for Oracle Key Vault](#)
- [Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance](#)
- [Configuring keyring_okv for Townsend Alliance Key Manager](#)
- [Password-Protecting the keyring_okv Key File](#)

General keyring_okv Configuration

Regardless of which KMIP back end the `keyring_okv` plugin uses for keyring storage, the `keyring_okv_conf_dir` system variable configures the location of the directory used by `keyring_okv` for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, `keyring_okv` writes a message to the error log during server startup that it cannot communicate:

```
[Warning] Plugin keyring_okv reported: 'For keyring_okv to be
initialized, please point the keyring_okv_conf_dir variable to a directory
containing Oracle Key Vault configuration file and ssl materials'
```

The `keyring_okv_conf_dir` variable must name a directory that contains the following items:

- `okvclient.ora`: A file that contains details of the KMIP back end with which `keyring_okv` will communicate.
- `ssl`: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: `CA.pem`, `cert.pem`, and `key.pem`. If the key file is password-protected, the `ssl` directory can contain a single-line text file named `password.txt` containing the password needed to decrypt the key file.

Both the `okvclient.ora` file and `ssl` directory with the certificate and key files are required for `keyring_okv` to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with `keyring_okv`, as described elsewhere.

The configuration directory used by `keyring_okv` as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

To be usable during the server startup process, `keyring_okv` must be loaded using the `--early-plugin-load` option. Also, set the `keyring_okv_conf_dir` system variable to tell `keyring_okv` where to find its configuration directory. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and directory location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```

For additional information about `keyring_okv_conf_dir`, see [Section 6.4.4.12, “Keyring System Variables”](#).

Configuring `keyring_okv` for Oracle Key Vault

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- [Oracle Key Vault site](#)
- [Oracle Key Vault documentation](#)

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.
2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the [Oracle Key Vault](#) site and consult the Oracle Key Vault Administrator's Guide.

1. Create the configuration directory that will contain the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see [General keyring_okv Configuration](#)).
2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
3. Select the Endpoints tab to arrive at the Endpoints page. On the Endpoints page, click Add.
4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
5. Log out from the Oracle Key Vault server.
6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.
7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

```
java -jar okvclient.jar -d dir_name [-v]
```

The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password will be required when the endpoint connects to Oracle Key Vault.)

8. The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

```
install_dir/conf/okvclient.ora
```

The file contents include lines that look something like this:

```
SERVER=host_ip:port_num
STANDBY_SERVER=host_ip:port_num
```

The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails:

- For the `SERVER` variable, a setting in the `okvclient.ora` file is mandatory.
- For the `STANDBY_SERVER` variable, a setting in the `okvclient.ora` file is optional.

9. Go to the Oracle Key Vault installer directory and test the setup by running this command:

```
okvutil/bin/okvutil list
```

The output should look something like this:

Unique ID	Type	Identifier
255AB8DE-C97F-482C-E053-0100007F28B9	Symmetric Key -	
264BF6E0-A20E-7C42-E053-0100007FB29C	Symmetric Key -	

For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

```
no objects found
```

10. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

```
jar xf okvclient.jar ssl
```

11. Copy the Oracle Key Vault support files (the `okvclient.ora` file and the `ssl` directory) into the configuration directory.
12. (Optional) If you wish to password-protect the key file, use the instructions in [Password-Protecting the keyring_okv Key File](#).

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with Oracle Key Vault.

Configuring `keyring_okv` for Gemalto SafeNet KeySecure Appliance

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). The `keyring_okv` keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure `keyring_okv` and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the [KeySecure User Guide](#).

1. Create the configuration directory that will contain the KeySecure support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see [General keyring_okv Configuration](#)).
2. In the configuration directory, create a subdirectory named `ssl` to use for storing the required SSL certificate and key files.
3. In the configuration directory, create a file named `okvclient.ora`. It should have following format:

```
SERVER=host_ip:port_num
STANDBY_SERVER=host_ip:port_num
```

For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, the `okvclient.ora` file looks like this:

```
SERVER=198.51.100.20:9002
STANDBY_SERVER=198.51.100.20:9002
```

4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.
5. Navigate to Security >> Local CAs and create a local certificate authority (CA).
6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.
7. Download the CA and save it in the `ssl` directory as a file named `CA.pem`.
8. Navigate to Security >> Certificate Requests and create a certificate. Then you will be able to download a compressed `tar` file containing certificate PEM files.
9. Extract the PEM files from in the downloaded file. For example, if the file name is `csr_w_pk_pkcs8.gz`, decompress and unpack it using this command:

```
tar zxvf csr_w_pk_pkcs8.gz
```

Two files result from the extraction operation: `certificate_request.pem` and `private_key_pkcs8.pem`.

10. Use this `openssl` command to decrypt the private key and create a file named `key.pem`:

```
openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
```

11. Copy the `key.pem` file into the `ssl` directory.

12. Copy the certificate request in `certificate_request.pem` into the clipboard.
13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the `CA.pem` file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.
14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named `cert.pem` in the `ssl` directory.
15. (Optional) If you wish to password-protect the key file, use the instructions in [Password-Protecting the keyring_okv Key File](#).

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with KeySecure.

Configuring keyring_okv for Townsend Alliance Key Manager

Townsend Alliance Key Manager uses the KMIP protocol. The `keyring_okv` keyring plugin can use Alliance Key Manager as its KMIP back end for keyring storage. For additional information, see [Alliance Key Manager for MySQL](#).

Password-Protecting the keyring_okv Key File

You can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To do so, change location to the `ssl` directory and perform these steps:

1. Encrypt the `key.pem` key file. For example, use a command like this, and enter the encryption password at the prompts:

```
shell> openssl rsa -des3 -in key.pem -out key.pem.new
Enter PEM pass phrase:
Verifying - Enter PEM pass phrase:
```

2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.
3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

```
shell> openssl rsa -in key.pem.new -passin file:password.txt
```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.
5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

6.4.4.5 Using the keyring_aws Amazon Web Services Keyring Plugin

Note

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `keyring_aws` keyring plugin communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

`keyring_aws` is available on these platforms:

- EL7
- macOS 10.13 and 10.14

- SLES 12
- Ubuntu 14.04 and 16.04
- Windows

The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- [AWS site](#)
- [KMS documentation](#)

The following sections provide configuration and usage information for the `keyring_aws` keyring plugin:

- [keyring_aws Configuration](#)
- [keyring_aws Operation](#)
- [keyring_aws Credential Changes](#)

keyring_aws Configuration

To install the `keyring_aws` plugin, use the general keyring installation instructions found in [Section 6.4.4.1, “Keyring Plugin Installation”](#), together with the plugin-specific configuration information found here.

The plugin library file contains the `keyring_aws` plugin and two user-defined functions (UDFs), `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()`.

To configure `keyring_aws`, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.
2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.
3. Use the AWS KMS account to create a customer master key (CMK) ID. At MySQL startup, set the `keyring_aws_cmk_id` system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using `SET GLOBAL`.)
4. If necessary, create the directory in which the configuration file will be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring/keyring_aws_conf` as the file name, the following commands (executed as `root`) create its parent directory and set the directory mode and ownership:

```
shell> cd /usr/local/mysql
shell> mkdir mysql-keyring
shell> chmod 750 mysql-keyring
shell> chown mysql mysql-keyring
shell> chgrp mysql mysql-keyring
```

At MySQL startup, set the `keyring_aws_conf_file` system variable to `/usr/local/mysql/mysql-keyring/keyring_aws_conf` to indicate the configuration file location to the server.

5. Prepare the `keyring_aws` configuration file, which should contain two lines:
 - Line 1: The secret access key ID
 - Line 2: The secret access key

For example, if the key ID is `wwwwwwwwwwwwEXAMPLE` and the key is `xxxxxxxxxxxxxx/yyy/zzzzzzzEXAMPLEKEY`, the configuration file looks like this:

```
wwwwwwwwwwwwEXAMPLE
xxxxxxxxxxxxxx/yyy/zzzzzzzEXAMPLEKEY
```

To be usable during the server startup process, `keyring_aws` must be loaded using the `--early-plugin-load` option. The `keyring_aws_cmk_id` system variable is mandatory and configures the customer master key (CMK) ID obtained from the AWS KMS server. The `keyring_aws_conf_file` and `keyring_aws_data_file` system variables optionally configure the locations of the files used by the `keyring_aws` plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_aws.so
keyring_aws_cmk_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
```

For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, `keyring_aws` attempts to create it (as well as its parent directory, if necessary).

For additional information about the system variables used to configure the `keyring_aws` plugin, see [Section 6.4.4.12, “Keyring System Variables”](#).

Start the MySQL server and install the UDFs associated with the `keyring_aws` plugin. This is a one-time operation, performed by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION keyring_aws_rotate_cmk RETURNS INTEGER
  SONAME 'keyring_aws.so';
CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER
  SONAME 'keyring_aws.so';
```

For additional information about the `keyring_aws` UDFs, see [Section 6.4.4.10, “Plugin-Specific Keyring Key-Management Functions”](#).

keyring_aws Operation

At plugin startup, the `keyring_aws` plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.

During operation, `keyring_aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring_aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_aws` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()` UDFs “extend” the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling the UDFs. There are no corresponding C-language key service functions.

For information about the key types permitted by `keyring_aws`, see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

keyring_aws Credential Changes

Assuming that the `keyring_aws` plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.
2. Store the new credentials in the configuration file (the file named by the `keyring_aws_conf_file` system variable). The file format is as described previously.
3. Reinitialize the `keyring_aws` plugin so that it rereads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- Restart the server. This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.
- Reinitialize the plugin without restarting the server by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```
UNINSTALL PLUGIN keyring_aws;
INSTALL PLUGIN keyring_aws SONAME 'keyring_aws.so';
```

Note

In addition to loading a plugin at runtime, `INSTALL PLUGIN` has the side effect of registering the plugin in the `mysql.plugin` system table. Because of this, if you decide to stop using `keyring_aws`, it is not sufficient to remove the `--early-plugin-load` option from the set of options used to start the server. That stops the plugin from loading early, but the server still attempts to load it when it gets to the point in the startup sequence where it loads the plugins registered in `mysql.plugin`.

Consequently, if you execute the `UNINSTALL PLUGIN` plus `INSTALL PLUGIN` sequence just described to change the AWS KMS credentials, then to stop using `keyring_aws`, it is necessary to execute `UNINSTALL PLUGIN` again to unregister the plugin in addition to removing the `--early-plugin-load` option.

6.4.4.6 Using the HashiCorp Vault Keyring Plugin

Note

The `keyring_hashicorp` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `keyring_hashicorp` keyring plugin communicates with HashiCorp Vault for back end storage. The plugin supports HashiCorp Vault AppRole authentication. No key information is

permanently stored in MySQL server local storage. (An optional in-memory key cache may be used as intermediate storage.) Random key generation is performed on the MySQL server side, and the keys are subsequently stored to Hashicorp Vault.

The `keyring_hashicorp` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 5.6.8.2, “The Keyring Service”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_hashicorp`, see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

To install the `keyring_hashicorp` plugin, use the general keyring installation instructions found in [Section 6.4.4.1, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_hashicorp` found here. Plugin-specific configuration includes preparation of the certificate and key files needed for connecting to HashiCorp Vault, as well as configuring Vault itself. The following sections provide the necessary instructions.

- [Certificate and Key Preparation](#)
- [HashiCorp Vault Setup](#)
- [keyring_hashicorp Configuration](#)

Certificate and Key Preparation

The `keyring_hashicorp` plugin requires a secure connection to the HashiCorp Vault server, employing the HTTPS protocol. A typical setup includes a set of certificate and key files:

- `company.crt`: A custom CA certificate belonging to the organization. This file is used both by HashiCorp Vault server and the `keyring_hashicorp` plugin.
- `vault.key`: The private key of the HashiCorp Vault server instance. This file is used by HashiCorp Vault server.
- `vault.crt`: The certificate of the HashiCorp Vault server instance. This file must be signed by the organization CA certificate.

The following instructions describe how to create the certificate and key files using OpenSSL. (If you already have the files, proceed to [HashiCorp Vault Setup](#).) The instructions as shown apply to Linux platforms and may require adjustment for other platforms.

Important

Certificates generated by these instructions are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

1. Prepare the company and HashiCorp Vault server keys.

Use the following commands to generate the key files:

```
openssl genrsa -aes256 -out company.key 4096
```

```
openssl genrsa -aes256 -out vault.key 2048
```

The commands produce files holding the company private key (`company.key`) and the Vault server private key (`vault.key`). The keys are randomly generated RSA keys of 4,096 and 2,048 bits, respectively.

Each command prompts for a password. (For testing purposes, the password is not required. To disable it, omit the `-aes256` argument.)

The key files hold sensitive information and should be stored in a secure location. The password (also sensitive) is required later, so write it down and store it in a secure location.

(Optional) To check key file content and validity, use the following commands:

```
openssl rsa -in company.key -check
openssl rsa -in vault.key -check
```

2. Create the company CA certificate.

Use the following command to create a company CA certificate file named `company.crt` that is valid for 365 days (enter the command on a single line):

```
openssl req -x509 -new -nodes -key company.key
-sha256 -days 365 -out company.crt
```

You will be prompted for the company key password during CA certificate creation, if you used the `-aes256` argument to perform key encryption during key generation. You will also be prompted for information about the certificate holder (that is, you or your company), as shown here:

```
Country Name (2 letter code) [AU]:
State or Province Name (full name) [Some-State]:
Locality Name (eg, city) []:
Organization Name (eg, company) [Internet Widgits Pty Ltd]:
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:
Email Address []:
```

Answer the prompts with appropriate values.

3. Create a certificate signing request.

To create a HashiCorp Vault server certificate, a Certificate Signing Request (CSR) must be prepared for the newly created server key. Create a configuration file named `request.conf` containing the following lines. If the HashiCorp Vault server does not run on the local host, substitute appropriate CN and IP values, and make any other changes required.

```
[req]
distinguished_name = vault
x509_extensions = v3_req
prompt = no

[vault]
C = US
ST = CA
L = RWC
O = Company
CN = 127.0.0.1

[v3_req]
subjectAltName = @alternatives
authorityKeyIdentifier = keyid,issuer
basicConstraints = CA:TRUE

[alternatives]
IP = 127.0.0.1
```

Use this command to create the signing request:

```
openssl req -new -key vault.key -config request.conf -out request.csr
```

The output file (`request.csr`) is an intermediate file that serves as input for creation of the server certificate.

4. Create the HashiCorp Vault server certificate.

Sign the combined information from the HashiCorp Vault server key (`vault.key`) and the CSR (`request.csr`) with the company certificate (`company.crt`) to create the HashiCorp Vault server certificate (`vault.crt`). Use the following command to do this (enter the command on a single line):

```
openssl x509 -req -in request.csr
  -CA company.crt -CAkey company.key -CAcreateserial
  -out vault.crt -days 365 -sha256
```

To make the `vault.crt` server certificate useful, append the contents of the `company.crt` company certificate to it. This is required so that the company certificate is delivered along with the server certificate in requests.

```
cat company.crt >> vault.crt
```

If you open the `vault.crt` file with a text editor, its content should look like this:

```
-----BEGIN CERTIFICATE-----
... content of HashiCorp Vault server certificate ...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... content of company certificate ...
-----END CERTIFICATE-----
```

HashiCorp Vault Setup

The following instructions describe how to create a HashiCorp Vault setup that facilitates testing the `keyring_hashicorp` plugin.

Important

A test setup is similar to a production setup, but production use of HashiCorp Vault entails additional security considerations such as use of non-self-signed certificates and storing the company certificate in the system trust store. It is assumed that you will implement whatever additional security steps are needed to satisfy your operational requirements.

These instructions assume availability of the certificate and key files created in [Certificate and Key Preparation](#). See that section if you do not have the files.

1. Fetch the HashiCorp Vault binary.

Download the HashiCorp Vault binary appropriate for your platform from <https://www.vaultproject.io/downloads.html>.

Extract the content of the archive to produce the executable `vault` command, which is used to perform HashiCorp Vault operations. If necessary, add the directory where you install the command to the system path.

(Optional) HashiCorp Vault supports autocomplete options that make it easier to use. For more information, see <https://learn.hashicorp.com/vault/getting-started/install#command-completion>.

2. Create the HashiCorp Vault server configuration file.

Prepare a configuration file named `config.hcl` with the following content. For the `tls_cert_file`, `tls_key_file`, and `path` values, substitute path names appropriate for your system.

```
listener "tcp" {
  address="127.0.0.1:8200"
  tls_cert_file="/home/username/certificates/vault.crt"
  tls_key_file="/home/username/certificates/vault.key"
}

storage "file" {
  path = "/home/username/vaultstorage/storage"
}

ui = true
```

3. Start the HashiCorp Vault server.

To start the Vault server, use the following command, where the `-config` option specifies the path to the configuration file just created:

```
vault server -config=config.hcl
```

During this step, you may be prompted for a password for the Vault server private key stored in the `vault.key` file.

The server should start, displaying some information on the console (IP, port, and so forth).

So that you can enter the remaining commands, put the `vault server` command in the background or open another terminal before continuing.

4. Initialize the HashiCorp Vault server.

Note

The operations described in this step are required only when starting Vault the first time, to obtain the unseal key and root token. Subsequent Vault instance restarts require only unsealing using the unseal key.

Issue the following commands (assuming Bourne shell syntax):

```
export VAULT_SKIP_VERIFY=1
vault operator init -n 1 -t 1
```

The first command enables the `vault` command to temporarily ignore the fact that no company certificate has been added to the system trust store. It compensates for the fact that our self-signed CA is not added to that store. (For production use, such a certificate should be added.)

The second command creates a single unseal key with a requirement for a single unseal key to be present for unsealing. (For production use, an instance would have multiple unseal keys with up to that many keys required to be entered to unseal it. The unseal keys should be delivered to key custodians within the company. Use of a single key might be considered a security issue because that permits the vault to be unsealed by a single key custodian.)

Vault should reply with information about the unseal key and root token, plus some additional text (the actual unseal key and root token values will differ from those shown here):

```
...
Unseal Key 1: I2xwcFQc89200Nt2pBiRNlnkHhZTUrWS+JybL39BjcOE=
Initial Root Token: s.vTvXeo3tPEYehfcd9WH7oUKz
...
```

Store the unseal key and root token in a secure location.

5. Unseal the HashiCorp Vault server.

Use this command to unseal the Vault server:

```
vault operator unseal
```

When prompted to enter the unseal key, use the key obtained previously during Vault initialization.

Vault should produce output indicating that setup is complete and the vault is unsealed.

6. Log in to the HashiCorp Vault server and verify its status.

Prepare the environment variables required for logging in as root:

```
vault login s.vTvXeo3tPEYehfcd9WH7oUKz
```

For the token value in that command, substitute the content of the root token obtained previously during Vault initialization.

Verify the Vault server status:

```
vault status
```

The output should contain these lines (among others):

```
...
Initialized      true
Sealed           false
...
```

7. Set up HashiCorp Vault authentication and storage.

Note

The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

Enable the AppRole authentication method and verify that it is in the authentication method list:

```
vault auth enable approle
vault auth list
```

Enable the Vault KeyValue storage engine:

```
vault secrets enable -version=1 kv
```

Create and set up a role for use with the `keyring_hashicorp` plugin (enter the command on a single line):

```
vault write auth/approle/role/mysql token_num_uses=0
token_ttl=20m token_max_ttl=30m secret_id_num_uses=0
```

8. Add an AppRole security policy.

Note

The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

Prepare a policy that to permit the previously created role to access appropriate secrets. Create a new file named `mysql.hcl` with the following content:

```
path "kv/mysql/*" {
  capabilities = ["create", "read", "update", "delete", "list"]
}
```

```
}
```

Import the policy file to the Vault server to create a policy named `mysql-policy`, then assign the policy to the new role:

```
vault policy write mysql-policy mysql.hcl
vault write auth/approle/role/mysql policies=mysql-policy
```

Obtain the ID of the newly created role and store it in a secure location:

```
vault read auth/approle/role/mysql/role-id
```

Generate a secret ID for the role and store it in a secure location:

```
vault write -f auth/approle/role/mysql/secret-id
```

After these AppRole role ID and secret ID credentials are generated, they are expected to remain valid indefinitely. They need not be generated again and the `keyring_hashicorp` plugin can be configured with them for use on an ongoing basis. For more information about AuthRole authentication, visit <https://www.vaultproject.io/docs/auth/approle.html>.

keyring_hashicorp Configuration

The plugin library file contains the `keyring_hashicorp` plugin and a user-defined function (UDF), `keyring_hashicorp_update_config()`. When the plugin initializes and terminates, it automatically loads and unloads the UDF, so there is no need to load and unload the UDF manually.

The `keyring_hashicorp` plugin supports the configuration parameters shown in the following table. Specify these parameters by assigning values to the corresponding system variables.

Configuration Parameter	System Variable	Mandatory
HashiCorp Server URL	<code>keyring_hashicorp_server_url</code>	No
AppRole role ID	<code>keyring_hashicorp_role_id</code>	Yes
AppRole secret ID	<code>keyring_hashicorp_secret_id</code>	Yes
Store path	<code>keyring_hashicorp_store_path</code>	Yes
Authorization Path	<code>keyring_hashicorp_auth_path</code>	No
CA certificate file path	<code>keyring_hashicorp_ca_path</code>	No
Cache control	<code>keyring_hashicorp_caching</code>	No

To be usable during the server startup process, `keyring_hashicorp` must be loaded using the `--early-plugin-load` option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_hashicorp.so
keyring_hashicorp_role_id='ee3b495c-d0c9-11e9-8881-8444c71c32aa'
keyring_hashicorp_secret_id='0512af29-d0ca-11e9-95ee-0010e00dd718'
keyring_hashicorp_store_path='/v1/kv/mysql'
```

MySQL Server authenticates against HashiCorp Vault using AppRole authentication. Successful authentication requires that two secrets be provided to Vault, a role ID and a secret ID, which are similar in concept to user name and password. The role ID and secret ID values to use are those obtained during the HashiCorp Vault setup procedure performed previously. To specify the two IDs, assign their respective values to the `keyring_hashicorp_role_id` and `keyring_hashicorp_secret_id` system variables. The setup procedure also results in a store path of `/v1/kv/mysql`, which is the value to assign to `keyring_hashicorp_commit_store_path`.

At plugin initialization time, `keyring_hashicorp` attempts to connect to the HashiCorp Vault server using the configuration values. If the connection is successful, the plugin stores the values in corresponding system variables that have `_commit_` in their name. For example,

upon successful connection, the plugin stores the values of `keyring_hashicorp_role_id` and `keyring_hashicorp_store_path` in `keyring_hashicorp_commit_role_id` and `keyring_hashicorp_commit_store_path`.

Reconfiguration at runtime can be performed with the assistance of the `keyring_hashicorp_update_config()` UDF:

1. Use `SET` statements to assign the desired new values to the configuration system variables shown in the preceding table. These assignments in themselves have no effect on ongoing plugin operation.
2. Invoke `keyring_hashicorp_update_config()` to cause the plugin to reconfigure and reconnect to the HashiCorp Vault server using the new variable values.
3. If the connection is successful, the plugin stores the updated configuration values in corresponding system variables that have `_commit_` in their name.

For example, if you have reconfigured HashiCorp Vault to listen on port 8201 rather than the default 8200, reconfigure `keyring_hashicorp` like this:

```
mysql> SET GLOBAL keyring_hashicorp_server_url = 'https://127.0.0.1:8201';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT keyring_hashicorp_update_config();
+-----+
| keyring_hashicorp_update_config() |
+-----+
| Configuration update was successful. |
+-----+
1 row in set (0.03 sec)
```

If the plugin is not able to connect to HashiCorp Vault during initialization or reconfiguration and there was no existing connection, the `_commit_` system variables are set to `'Not committed'` for string-valued variables, and `OFF` for Boolean-valued variables. If the plugin is not able to connect but there was an existing connection, that connection remains active and the `_commit_` variables reflect the values used for it.

Note

If you do not set the mandatory system variables at server startup, or if some other plugin initialization error occurs, initialization fails. In this case, you can use the runtime reconfiguration procedure to initialize the plugin without restarting the server.

For additional information about the `keyring_hashicorp` plugin-specific system variables and UDF, see [Section 6.4.4.12, “Keyring System Variables”](#), and [Section 6.4.4.10, “Plugin-Specific Keyring Key-Management Functions”](#).

6.4.4.7 Supported Keyring Key Types and Lengths

MySQL Keyring supports keys of different types (encryption algorithms) and lengths:

- The available key types depend on which keyring plugin is installed.
- The permitted key lengths are subject to multiple factors:
 - General keyring UDF interface limits (for keys managed using one of the keyring UDFs described in [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#)), or limits from backend implementations. These length limits can vary by key operation type.
 - In addition to the general limits, individual plugins may impose restrictions on key lengths per key type.

[Table 6.26, “General Keyring Key Length Limits”](#) shows the general key length limits. (The lower limits for `keyring_aws` are imposed by the AWS KMS interface, not the keyring UDFs.) [Table 6.27,](#)

“[Keyring Plugin Key Types and Lengths](#)” shows for each keyring plugin the key types it permits, as well as any plugin-specific key-length restrictions.

Table 6.26 General Keyring Key Length Limits

Key Operation	Maximum Key Length
Generate key	16,384 bytes (2,048 prior to MySQL 8.0.18); 1,024 for keyring_aws
Store key	16,384 bytes (2,048 prior to MySQL 8.0.18); 4,096 for keyring_aws
Fetch key	16,384 bytes (2,048 prior to MySQL 8.0.18); 4,096 for keyring_aws

Table 6.27 Keyring Plugin Key Types and Lengths

Plugin Name	Permitted Key Type	Plugin-Specific Length Restrictions
keyring_aws	AES	16, 24, or 32 bytes
	SECRET	None
keyring_encrypted_file	AES	None
	DSA	None
	RSA	None
	SECRET	None
keyring_file	AES	None
	DSA	None
	RSA	None
	SECRET	None
keyring_hashicorp	AES	None
	DSA	None
	RSA	None
	SECRET	None
keyring_okv	AES	16, 24, or 32 bytes
	SECRET	None

The [SECRET](#) key type, available as of MySQL 8.0.19, is intended for general-purpose storage of sensitive data using the MySQL keyring, and is supported by all keyring plugins. The keyring encrypts and decrypts [SECRET](#) data as a byte stream upon storage and retrieval.

Example keyring operations involving the [SECRET](#) key type:

```
SELECT keyring_key_generate('MySecret1', 'SECRET', 20);
SELECT keyring_key_remove('MySecret1');

SELECT keyring_key_store('MySecret2', 'SECRET', 'MySecretData');
SELECT keyring_key_fetch('MySecret2');
SELECT keyring_key_length_fetch('MySecret2');
SELECT keyring_key_type_fetch('MySecret2');
SELECT keyring_key_remove('MySecret2');
```

6.4.4.8 Migrating Keys Between Keyring Keystores

The MySQL server supports an operational mode that enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. A migration server (that is, a server started in key migration mode) does not accept client connections.

Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

It is possible to perform offline or online key migration:

- If you are sure that no running server on the local host is using the source or destination keystore, an offline migration is possible. In this case, the migration server can modify the keystores without possibility of a running server modifying keystore content during the migration.
- If a running server on the local host is using the source or destination keystore, an online migration must be performed. In this case, the migration server connects to the running server and instructs it to pause keyring operations while key migration is in progress.

The result of a key migration operation is that the destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore. The source keystore is the same before and after the migration because keys are copied, not moved. If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.

The user who invokes the server in key-migration mode must not be the `root` operating system user, and must have permission to read and write the keyring files.

To perform a key migration operation, determine which key migration options are needed. Migration options indicate which keyring plugins are involved, and whether to perform an offline or online migration:

- To indicate the source and destination keyring plugins, specify these options:
 - `--keyring-migration-source`: The source keyring plugin that manages the keys to be migrated.
 - `--keyring-migration-destination`: The destination keyring plugin to which the migrated keys are to be copied.

These options tell the server to run in key migration mode. Both options are mandatory for all key migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- For an offline migration, no additional key migration options are needed.

**Warning**

Do not perform offline migration involving a keystore that is in use by a running server.

- For an online migration, some running server currently is using the source or destination keystore. Specify the key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.

Use of any of the following options signifies an online migration:

- `--keyring-migration-host`: The host where the running server is located. This is always the local host.
- `--keyring-migration-user`, `--keyring-migration-password`: The user name and password for the account to use to connect to the running server.
- `--keyring-migration-port`: For TCP/IP connections, the port number to connect to on the running server.
- `--keyring-migration-socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For additional details about the key migration options, see [Section 6.4.4.11, “Keyring Command Options”](#).

Start the migration server with the key migration options determined as just described, possibly with other options. Keep the following considerations in mind:

- Other server options might be required, such as other configuration parameters for the two keyring plugins. For example, if `keyring_file` is one of the plugins, you must set the `keyring_file_data` system variable if the keyring data file location is not the default location. Other non-keyring options may be required as well. One way to specify these options is by using `--defaults-file` to name an option file that contains the required options.
- If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server will be owned by `isabel`. Subsequent startup will fail when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, start the migration server as the `root` operating system user and provide a `--user=user_name` option, where `user_name` is the system account normally used to run MySQL.

- The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.

Example command line for offline key migration:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_file.so
--keyring-migration-destination=keyring_encrypted_file.so
--keyring_encrypted_file_password=password
```

Example command line for online key migration:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_file.so
--keyring-migration-destination=keyring_encrypted_file.so
--keyring_encrypted_file_password=password
--keyring-migration-host=localhost
--keyring-migration-user=root
--keyring-migration-password=root_password
```

The key migration server performs the migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options. The account used to connect must have the privileges required to modify the global `keyring_operations` system variable (`ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or the deprecated `SUPER` privilege).
2. (Online migration only) Disable `keyring_operations` on the running server. (The running server must support `keyring_operations`.)
3. Load the source and destination keyring plugins.
4. Copy keys from the source keyring to the destination keyring.
5. Unload the keyring plugins.
6. (Online migration only) Enable `keyring_operations` on the running server.
7. (Online migration only) Disconnect from the running server.
8. Exit.

If an error occurs during key migration, any keys that were copied to the destination plugin are removed, leaving the destination keystore unchanged.

**Important**

For an online migration operation, the migration server takes care of enabling and disabling `keyring_operations` on the running server. However, if the migration server exits abnormally (for example, if someone forcibly terminates it), it is possible that `keyring_operations` will not have been re-enabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore, it need not be restarted after the migration.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keyring plugin and restarted.
- If the running server was using the destination keystore and will continue to use it, it should be restarted after the migration to load all keys migrated into the destination keystore.

**Note**

MySQL server key migration mode supports pausing a single running server. To perform a key migration if multiple key servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set `keyring_operations=OFF`.
2. Use the migration server to perform an offline key migration.
3. Connect to each running server manually and set `keyring_operations=ON`.

All running servers must support the `keyring_operations=ON` system variable.

6.4.4.9 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval.

MySQL Server also includes an SQL interface for keyring key management, implemented as a set of general-purpose user-defined functions (UDFs) that access the functions provided by the internal keyring service. The keyring UDFs are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to UDF invocation. For these UDFs to be used, a keyring plugin such as `keyring_file` or `keyring_okv` must be enabled.

The UDFs described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have UDFs of its own that are intended for use only with that plugin; see [Section 6.4.4.10, “Plugin-Specific Keyring Key-Management Functions”](#).

The following sections provide installation instructions for the keyring UDFs and demonstrate how to use them. For information about the keyring service functions invoked by the UDFs, see [Section 5.6.8.2, “The Keyring Service”](#). For general keyring information, see [Section 6.4.4, “The MySQL Keyring”](#).

- [Installing or Uninstalling General-Purpose Keyring Functions](#)

- [Using General-Purpose Keyring Functions](#)
- [General-Purpose Keyring Function Reference](#)

Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring user-defined functions (UDFs), which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and UDFs, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#), and [Section 5.7.1, “Installing and Uninstalling User-Defined Functions”](#).

The keyring UDFs enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the UDFs will not work correctly without it. Attempts to use the UDFs without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER
  SONAME 'keyring_udf.so';
```

If the plugin and UDFs are used on a source replication server, install them on all replicas as well to avoid replication issues.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

Using General-Purpose Keyring Functions

Before using the keyring user-defined functions (UDFs), install them according to the instructions provided in [Installing or Uninstalling General-Purpose Keyring Functions](#).

The keyring UDFs are subject to these constraints:

- To use any keyring UDF, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see [Installing or Uninstalling General-Purpose Keyring Functions](#).

- The keyring UDFs invoke keyring service functions (see [Section 5.6.8.2, “The Keyring Service”](#)). The service functions in turn use whatever keyring plugin is installed (for example, `keyring_file` or `keyring_okv`). Therefore, to use any keyring UDF, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

```
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
```

To install a keyring plugin, see [Section 6.4.4.1, “Keyring Plugin Installation”](#).

- To use any keyring UDF, a user must possess the global `EXECUTE` privilege. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to
have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

- A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring UDFs for manipulation of instance-wide keys, such as those created by `InnoDB` to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

- Keyring UDFs support the key types and lengths supported by the underlying keyring plugin. For information about keys specific to a particular keyring plugin, see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-----+
| keyring_key_generate('MyKey', 'DSA', 256) |
+-----+
|                                           1 |
+-----+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified combination of key type and key length; see [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
```

underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.

```
mysql> SELECT @x;
+-----+
| @x    |
+-----+
| NULL  |
+-----+
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1     |
+-----+
```

This technique also applies to other keyring UDFs that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent UDF calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```
mysql> SELECT keyring_key_type_fetch('MyKey');
+-----+
| keyring_key_type_fetch('MyKey') |
+-----+
| DSA                             |
+-----+
mysql> SELECT keyring_key_length_fetch('MyKey');
+-----+
| keyring_key_length_fetch('MyKey') |
+-----+
| 256                               |
+-----+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+-----+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
+-----+
| 1                                             |
+-----+
mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+-----+
| HEX(keyring_key_fetch('MyShortKey')) |
+-----+
| 1DB3B0FC3328A24C                     |
+-----+
```

Keyring UDFs treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

```
mysql> SELECT keyring_key_remove('MyKey');
+-----+
| keyring_key_remove('MyKey') |
+-----+
| 1                             |
+-----+
```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```
mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+-----+
```

```
| keyring_key_store('AES_key', 'AES', 'Secret string') |
+-----+
|                                     1 |
+-----+
```

As indicated previously, a user must have the global `EXECUTE` privilege to call keyring UDFs, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each UDF call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.
2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.
3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account (`'root'@'localhost'` in this example), create the administrative schema and the stored function to access the key:

```
mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost'
      FUNCTION key_schema.get_shared_key()
      RETURNS BLOB READS SQL DATA
      RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
+-----+
| keyring_key_generate('SharedKey', 'DSA', 8) |
+-----+
|                                     1 |
+-----+
```

From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost'
      IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
for routine 'key_schema.get_shared_key'
```

From the administrative account, grant `EXECUTE` to `key_user` for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
      TO 'key_user'@'localhost';
```

From the `key_user` account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
+-----+
| HEX(key_schema.get_shared_key()) |
+-----+
| 9BAFB9E75CEE013 |
+-----+
```

General-Purpose Keyring Function Reference

For each general-purpose keyring user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see [Using General-Purpose Keyring Functions](#).

- `keyring_key_fetch(key_id)`

Given a key ID, deobfuscates and returns the key value.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key value as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Note

Key values retrieved using `keyring_key_fetch()` are subject to the general keyring UDF limits described in [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#). A key value longer than that length can be stored using a keyring service function (see [Section 5.6.8.2, “The Keyring Service”](#)), but if retrieved using `keyring_key_fetch()` is truncated to the general keyring UDF limit.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 16) |
+-----+
| 1 |
+-----+
mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
+-----+
| HEX(keyring_key_fetch('RSA_key')) |
+-----+
| 91C2253B696064D3556984B6630F891A |
+-----+
mysql> SELECT keyring_key_type_fetch('RSA_key');
+-----+
| keyring_key_type_fetch('RSA_key') |
+-----+
| RSA |
+-----+
mysql> SELECT keyring_key_length_fetch('RSA_key');
+-----+
| keyring_key_length_fetch('RSA_key') |
+-----+
| 16 |
+-----+
```

The example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- `keyring_key_generate(key_id, key_type, key_length)`

Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin. See [Section 6.4.4.7, “Supported Keyring Key Types and Lengths”](#).

Arguments:

- *key_id*: A string that specifies the key ID.
- *key_type*: A string that specifies the key type.
- *key_length*: An integer that specifies the key length in bytes.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 384) |
+-----+
|                                           1 |
+-----+
```

- `keyring_key_length_fetch(key_id)`

Given a key ID, returns the key length.

Arguments:

- *key_id*: A string that specifies the key ID.

Return value:

Returns the key length in bytes as an integer for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

- `keyring_key_remove(key_id)`

Removes the key with a given ID from the keyring.

Arguments:

- *key_id*: A string that specifies the key ID.

Return value:

Returns 1 for success, or `NULL` for failure.

Example:

```
mysql> SELECT keyring_key_remove('AES_key');
+-----+
| keyring_key_remove('AES_key') |
+-----+
|                               1 |
+-----+
```

- `keyring_key_store(key_id, key_type, key)`

Obfuscates and stores a key in the keyring.

Arguments:

- `key_id`: A string that specifies the key ID.
- `key_type`: A string that specifies the key type.
- `key`: A string that specifies the key value.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----+
| keyring_key_store('new key', 'DSA', 'My key value') |
+-----+
|                                                    1 |
+-----+
```

- `keyring_key_type_fetch(key_id)`

Given a key ID, returns the key type.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

6.4.4.10 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring UDFs, see [Section 6.4.4.9, “General-Purpose Keyring Key-Management Functions”](#).

- `keyring_aws_rotate_cmk()`

Associated keyring plugin: `keyring_aws`

`keyring_aws_rotate_cmk()` rotates the customer master key (CMK). Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.

Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

This UDF requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

- `keyring_aws_rotate_keys()`

Associated keyring plugin: `keyring_aws`

`keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

`keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

- After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` UDF
- After changing the `keyring_aws_cmk_id` system variable to a different key value

This UDF requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

- `keyring_hashicorp_update_config()`

Associated keyring plugin: `keyring_hashicorp`

When invoked, the `keyring_hashicorp_update_config()` UDF causes `keyring_hashicorp` to perform a runtime reconfiguration, as described in [keyring_hashicorp Configuration](#).

This UDF requires the `SYSTEM_VARIABLES_ADMIN` privilege because it modifies global system variables.

Arguments:

None.

Return value:

Returns the string `'Configuration update was successful.'` for success, or `'Configuration update failed.'` for failure.

6.4.4.11 Keyring Command Options

MySQL supports the following keyring-related command-line options:

- `--keyring-migration-destination=plugin`

Command-Line Format	<code>--keyring-migration-destination=plugin_name</code>
Type	String

The destination keyring plugin for key migration. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#). The format and interpretation of the option value is the same as described for the `--keyring-migration-source` option.

**Note**

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- `--keyring-migration-host=host_name`

Command-Line Format	<code>--keyring-migration-host=host_name</code>
Type	String
Default Value	<code>localhost</code>

The host location of the running server that is currently using one of the key migration keystores. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#). Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as `localhost`, `127.0.0.1`, `:::1`, or the local host IP address or host name.

- `--keyring-migration-password[=password]`

Command-Line Format	<code>--keyring-migration-password[=password]</code>
Type	String

The password for connecting to the running server that is currently using one of the key migration keystores. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#). If you omit the `password` value following the option name on the command line, the server prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

- `--keyring-migration-port=port_num`

Command-Line Format	<code>--keyring-migration-port=port_num</code>
Type	Numeric
Default Value	<code>3306</code>

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-socket=path`

Command-Line Format	<code>--keyring-migration-socket={file_name pipe_name}</code>
Type	String

For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-source=plugin`

Command-Line Format	<code>--keyring-migration-source=plugin_name</code>
---------------------	---

Type	String
------	--------

The source keyring plugin for key migration. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#).

The option value is similar to that for `--plugin-load`, except that only one plugin library can be specified. The value is given as `name=plugin_library` or `plugin_library`. The `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If the plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Note

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- `--keyring-migration-user=user_name`

Command-Line Format	<code>--keyring-migration-user=user_name</code>
Type	String

The user name for connecting to the running server that is currently using one of the key migration keystores. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#).

6.4.4.12 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see [Section 6.4.4.1, “Keyring Plugin Installation”](#)).

- `keyring_aws_cmk_id`

Command-Line Format	<code>--keyring-aws-cmk-id=value</code>
System Variable	<code>keyring_aws_cmk_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The customer master key (CMK) ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_aws` initialization fails.

- `keyring_aws_conf_file`

Command-Line Format	<code>--keyring-aws-conf-file=file_name</code>
System Variable	<code>keyring_aws_conf_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

Default Value	platform specific
---------------	-------------------

The location of the configuration file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described in [Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”](#).

The default file name is `keyring_aws_conf`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

- `keyring_aws_data_file`

Command-Line Format	<code>--keyring-aws-data-file</code>
System Variable	<code>keyring_aws_data_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	platform specific

The location of the storage file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, if the value assigned to `keyring_aws_data_file` specifies a file that does not exist, the `keyring_aws` plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, `keyring_aws` reads any encrypted keys contained in the file into its in-memory cache. `keyring_aws` does not cache unencrypted keys in memory.

The default file name is `keyring_aws_data`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

- `keyring_aws_region`

Command-Line Format	<code>--keyring-aws-region=value</code>
System Variable	<code>keyring_aws_region</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>us-east-1</code>
Valid Values	<code>ap-northeast-1</code> <code>ap-northeast-2</code> <code>ap-south-1</code> <code>ap-southeast-1</code>

	ap-southeast-2
	eu-central-1
	eu-west-1
	sa-east-1
	us-east-1
	us-west-1
	us-west-2

The AWS region for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

- `keyring_encrypted_file_data`

Command-Line Format	<code>--keyring-encrypted-file-data=file_name</code>
System Variable	<code>keyring_encrypted_file_data</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	platform specific

The path name of the data file used for secure data storage by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_encrypted_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring_encrypted`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT CMake` option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR CMake` option.

INSTALL_LAYOUT Value	Default <code>keyring_encrypted_file_data</code> Value
DEB, RPM, SVR4	<code>/var/lib/mysql-keyring/keyring_encrypted</code>
Otherwise	<code>keyring/keyring_encrypted</code> under the <code>CMAKE_INSTALL_PREFIX</code> value

At plugin startup, if the value assigned to `keyring_encrypted_file_data` specifies a file that does not exist, the `keyring_encrypted_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the

`/usr/local/mysql/mysql-keyring` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_encrypted_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_encrypted_file_data` results in an error, the variable value remains unchanged.

Important

Once the `keyring_encrypted_file` plugin has created its data file and started to use it, it is important not to remove the file. Loss of the file will cause data encrypted using its keys to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_encrypted_file_data` to match.)

- `keyring_encrypted_file_password`

Command-Line Format	<code>--keyring-encrypted-file-password=password</code>
System Variable	<code>keyring_encrypted_file_password</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The password used by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_encrypted_file` initialization fails.

If this variable is specified in an option file, the file should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Important

Once the `keyring_encrypted_file_password` value has been set, changing it does not rotate the keyring password and could make the server inaccessible. If an incorrect password is provided, the `keyring_encrypted_file` plugin cannot load keys from the encrypted keyring file.

The password value cannot be displayed at runtime with `SHOW VARIABLES` or the Performance Schema `global_variables` table because the display value is obfuscated.

- `keyring_file_data`

Command-Line Format	<code>--keyring-file-data=file_name</code>
System Variable	<code>keyring_file_data</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name

Default Value	platform specific
---------------	-------------------

The path name of the data file used for secure data storage by the `keyring_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<code>INSTALL_LAYOUT</code> Value	Default <code>keyring_file_data</code> Value
DEB, RPM, SVR4	<code>/var/lib/mysql-keyring/keyring</code>
Otherwise	<code>keyring/keyring</code> under the <code>CMAKE_INSTALL_PREFIX</code> value

At plugin startup, if the value assigned to `keyring_file_data` specifies a file that does not exist, the `keyring_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_file_data` results in an error, the variable value remains unchanged.

Important

Once the `keyring_file` plugin has created its data file and started to use it, it is important not to remove the file. For example, `InnoDB` uses the file to store the master key used to decrypt the data in tables that use `InnoDB` tablespace encryption; see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#). Loss of the file will cause data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_file_data` to match.) It is recommended that you create a separate backup of the keyring data file immediately after you create the first encrypted table and before and after master key rotation.

- `keyring_hashicorp_auth_path`

Command-Line Format	<code>--keyring-hashicorp-auth-path=value</code>
Introduced	8.0.18
System Variable	<code>keyring_hashicorp_auth_path</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>/v1/auth/approle/login</code>

The authentication path where AppRole authentication is enabled within the HashiCorp Vault server, for use by the [keyring_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed.

- [keyring_hashicorp_ca_path](#)

Command-Line Format	<code>--keyring-hashicorp-ca-path=file_name</code>
Introduced	8.0.18
System Variable	keyring_hashicorp_ca_path
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

The absolute path name of a local file accessible to the MySQL server that contains a properly formatted TLS certificate authority for use by the [keyring_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed.

If this variable is not set, the [keyring_hashicorp](#) plugin opens an HTTPS connection without using server certificate verification, and trusts any certificate delivered by the HashiCorp Vault server. For this to be safe, it must be assumed that the Vault server is not malicious and that no man-in-the-middle attack is possible. If those assumptions are invalid, set [keyring_hashicorp_ca_path](#) to the path of a trusted CA certificate. (For example, for the instructions in [Certificate and Key Preparation](#), this is the `company.crt` file.)

- [keyring_hashicorp_caching](#)

Command-Line Format	<code>--keyring-hashicorp-caching[={OFF ON}]</code>
Introduced	8.0.18
System Variable	keyring_hashicorp_caching
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to enable the optional in-memory key cache used by the [keyring_hashicorp](#) plugin to cache keys from the HashiCorp Vault server. This variable is unavailable unless that plugin is installed. If the cache is enabled, the plugin populates it during initialization. Otherwise, the plugin populates only the key list during initialization.

Enabling the cache is a compromise: It improves performance, but maintains a copy of sensitive key information in memory, which may be undesirable for security purposes.

- [keyring_hashicorp_commit_auth_path](#)

Introduced	8.0.18
System Variable	keyring_hashicorp_commit_auth_path
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

This variable is associated with [keyring_hashicorp_auth_path](#), from which it takes its value during [keyring_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- [keyring_hashicorp_commit_ca_path](#)

Introduced	8.0.18
System Variable	keyring_hashicorp_commit_ca_path
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

This variable is associated with [keyring_hashicorp_ca_path](#), from which it takes its value during [keyring_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- [keyring_hashicorp_commit_caching](#)

Introduced	8.0.18
System Variable	keyring_hashicorp_commit_caching
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

This variable is associated with [keyring_hashicorp_caching](#), from which it takes its value during [keyring_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- [keyring_hashicorp_commit_role_id](#)

Introduced	8.0.18
System Variable	keyring_hashicorp_commit_role_id
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Type	String
------	--------

This variable is associated with `keyring_hashicorp_role_id`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- `keyring_hashicorp_commit_server_url`

Introduced	8.0.18
System Variable	<code>keyring_hashicorp_commit_server_url</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable is associated with `keyring_hashicorp_server_url`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- `keyring_hashicorp_commit_store_path`

Introduced	8.0.18
System Variable	<code>keyring_hashicorp_commit_store_path</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable is associated with `keyring_hashicorp_store_path`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring_hashicorp Configuration](#).

- `keyring_hashicorp_role_id`

Command-Line Format	<code>--keyring-hashicorp-role-id=value</code>
Introduced	8.0.18
System Variable	<code>keyring_hashicorp_role_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The HashiCorp Vault AppRole authentication role ID, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, `keyring_hashicorp` initialization fails.

- [keyring_hashicorp_secret_id](#)

Command-Line Format	<code>--keyring-hashicorp-secret-id=value</code>
Introduced	8.0.18
System Variable	keyring_hashicorp_secret_id
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The HashiCorp Vault AppRole authentication secret ID, for use by the [keyring_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, [keyring_hashicorp](#) initialization fails.

The value of this variable is sensitive, so its value is masked by * characters when displayed.

- [keyring_hashicorp_server_url](#)

Command-Line Format	<code>--keyring-hashicorp-server-url=value</code>
Introduced	8.0.18
System Variable	keyring_hashicorp_server_url
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>https://127.0.0.1:8200</code>

The HashiCorp Vault server URL, for use by the [keyring_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed. The value must begin with `https://`.

- [keyring_hashicorp_store_path](#)

Command-Line Format	<code>--keyring-hashicorp-store-path=value</code>
Introduced	8.0.18
System Variable	keyring_hashicorp_store_path
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

A store path within the HashiCorp Vault server that is writeable when appropriate AppRole AppRole credentials are provided by the [keyring_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed. To specify the credentials, set the [keyring_hashicorp_role_id](#) and [keyring_hashicorp_secret_id](#) system variables (for example, as shown in [keyring_hashicorp Configuration](#)).

This variable is mandatory. If not specified, [keyring_hashicorp](#) initialization fails.

- `keyring_okv_conf_dir`

Command-Line Format	<code>--keyring-okv-conf-dir=dir_name</code>
System Variable	<code>keyring_okv_conf_dir</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>empty string</code>

The path name of the directory that stores configuration information used by the `keyring_okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring_okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring_okv_conf_dir` value is empty. For the `keyring_okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see [Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”](#).

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to `keyring_okv_conf_dir` specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, `keyring_okv` writes an error message to the error log. If an attempted runtime assignment to `keyring_okv_conf_dir` results in an error, the variable value and keyring operation remain unchanged.

- `keyring_operations`

System Variable	<code>keyring_operations</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether keyring operations are enabled. This variable is used during key migration operations. See [Section 6.4.4.8, “Migrating Keys Between Keyring Keystores”](#). The privileges required to modify this variable are `ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or the deprecated `SUPER` privilege.

6.4.5 MySQL Enterprise Audit

**Note**

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the audit plugin (see [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see [Section 6.4.5.4, “Audit Log File Formats”](#).

For more information about controlling how logging occurs, including audit log file naming and format selection, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#). To perform filtering of audited events, see [Section 6.4.5.7, “Audit Log Filtering”](#). For descriptions of the parameters used to configure the audit log plugin, see [Audit Log Options and Variables](#).

If the audit log plugin is enabled, the Performance Schema (see [Chapter 26, MySQL Performance Schema](#)) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '%alog/%';
```

6.4.5.1 Elements of MySQL Enterprise Audit

MySQL Enterprise Audit is based on the audit log plugin and related elements:

- A server-side plugin named `audit_log` examines auditable events and determines whether to write them to the audit log.
- User-defined functions enable manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.
- Tables in the `mysql` system database provide persistent storage of filter and user account data.
- System variables enable audit log configuration and status variables provide runtime operational information.
- An `AUDIT_ADMIN` privilege enable users to administer the audit log.

6.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related elements described in [Section 6.4.5.1, “Elements of MySQL Enterprise Audit”](#). For general information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

**Important**

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

**Note**

If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `audit_log_filter_win_install.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `audit_log_filter_linux_install.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

Run the script as follows. The example here uses the Linux installation script. Make the appropriate substitution for your system.

```
shell> mysql -u root -p < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

**Note**

Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL 8.0, perform the MySQL upgrade procedure, making sure to use the option that forces an update (see [Section 2.11, “Upgrading MySQL”](#)). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

As of MySQL 8.0.12, for new MySQL installations, the `USER` and `HOST` columns in the `audit_log_user` table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the `User` and `Host` columns in the `mysql.user` system table. For upgrades to an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```
ALTER TABLE mysql.audit_log_user
  DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
  ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);
```

**Note**

To use MySQL Enterprise Audit in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statement in the script is not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statement from the installation script and execute it manually.
2. On the source node, run the installation script as described previously.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE 'audit%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| audit_log   | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

Important

By default, rule-based audit log filtering logs no auditable events for any users. This differs from legacy audit log behavior, which logs all auditable events for all users (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)). Should you wish to produce log-everything behavior with rule-based filtering, create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

Once installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it, execute the following statements:

```
DROP TABLE IF EXISTS mysql.audit_log_user;
DROP TABLE IF EXISTS mysql.audit_log_filter;
UNINSTALL PLUGIN audit_log;
DROP FUNCTION audit_log_filter_set_filter;
DROP FUNCTION audit_log_filter_remove_filter;
DROP FUNCTION audit_log_filter_set_user;
DROP FUNCTION audit_log_filter_remove_user;
DROP FUNCTION audit_log_filter_flush;
DROP FUNCTION audit_log_encryption_password_get;
DROP FUNCTION audit_log_encryption_password_set;
DROP FUNCTION audit_log_read;
DROP FUNCTION audit_log_read_bookmark;
```

6.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See [Encrypting Audit Log Files](#).

6.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- New-style XML format (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 8.0 uses new-style XML format by default.
- Old-style XML format (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series.
- JSON format (`audit_log_format=JSON`)

By default, audit log file contents are written in new-style XML format, without compression or encryption.

Note

For information about issues to consider when changing the log format, see [Selecting Audit Log File Format](#).

The following sections describe the available audit logging formats:

- [New-Style XML Audit Log File Format](#)
- [Old-Style XML Audit Log File Format](#)
- [JSON Audit Log File Format](#)

New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
      --socket=/usr/local/mysql/mysql.sock
      --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
  </AUDIT_RECORD>
  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>2_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Connect</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>connect</COMMAND_CLASS>
    <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

```

<CONNECTION_ATTRIBUTES>
  <ATTRIBUTE>
    <NAME>_pid</NAME>
    <VALUE>42794</VALUE>
  </ATTRIBUTE>
  ...
  <ATTRIBUTE>
    <NAME>program_name</NAME>
    <VALUE>mysqladmin</VALUE>
  </ATTRIBUTE>
</CONNECTION_ATTRIBUTES>
<PRIV_USER>root</PRIV_USER>
<PROXY_USER/>
<DB>test</DB>
</AUDIT_RECORD>

...

<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
  <RECORD_ID>6_2019-10-03T14:06:33</RECORD_ID>
  <NAME>Query</NAME>
  <CONNECTION_ID>5</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root[root] @ localhost [127.0.0.1]</USER>
  <OS_LOGIN/>
  <HOST>localhost</HOST>

  <SQLTEXT>DROP TABLE IF EXISTS t</SQLTEXT>
</AUDIT_RECORD>

...

<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:39 UTC</TIMESTAMP>
  <RECORD_ID>8_2019-10-03T14:06:33</RECORD_ID>
  <NAME>Quit</NAME>
  <CONNECTION_ID>5</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root</USER>
  <OS_LOGIN/>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>connect</COMMAND_CLASS>
  <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>

...

<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:43 UTC</TIMESTAMP>
  <RECORD_ID>11_2019-10-03T14:06:33</RECORD_ID>
  <NAME>Quit</NAME>
  <CONNECTION_ID>6</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root</USER>
  <OS_LOGIN/>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>connect</COMMAND_CLASS>
  <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>
<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
  <RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
  <NAME>NoAudit</NAME>
  <SERVER_ID>1</SERVER_ID>
</AUDIT_RECORD>

```

```
</AUDIT>
```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

Audit	When auditing starts, which may be server startup time
Connect	When a client connects, also known as logging in
Query	An SQL statement (executed directly)
Prepare	Preparation of an SQL statement; usually followed by Execute
Execute	Execution of an SQL statement; usually follows Prepare
Shutdown	Server shutdown
Quit	When a client disconnects
NoAudit	Auditing has been turned off

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `TableDelete`, `TableInsert`, `TableRead`, `TableUpdate`, `Time`.

Many of these values correspond to the `COM_xxx` command values listed in the `my_command.h` header file. For example, `Create DB` and `Change user` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

Events having `<NAME>` values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event contains `<DB>` and `<TABLE>` elements to identify the table to which the event refers.

- `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
```

- `<TIMESTAMP>`

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss` UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` element values.

- `<COMMAND_CLASS>`

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `<CONNECTION_ATTRIBUTES>`

As of MySQL 8.0.19, events with a `<COMMAND_CLASS>` value of `connect` may include a `<CONNECTION_ATTRIBUTES>` element to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see [Section 26.12.9, “Performance Schema Connection Attribute Tables”](#).)

The `<CONNECTION_ATTRIBUTES>` element contains one `<ATTRIBUTE>` element per attribute, each of which contains `<NAME>` and `<VALUE>` elements to indicate the attribute name and value, respectively.

Example:

```
<CONNECTION_ATTRIBUTES>
  <ATTRIBUTE>
    <NAME>_pid</NAME>
    <VALUE>42794</VALUE>
  </ATTRIBUTE>
  <ATTRIBUTE>
    <NAME>_os</NAME>
    <VALUE>osx10.14</VALUE>
  </ATTRIBUTE>
```

```

<ATTRIBUTE>
  <NAME>_platform</NAME>
  <VALUE>x86_64</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
  <NAME>_client_version</NAME>
  <VALUE>8.0.19</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
  <NAME>_client_name</NAME>
  <VALUE>libmysql</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
  <NAME>program_name</NAME>
  <VALUE>mysqladmin</VALUE>
</ATTRIBUTE>
</CONNECTION_ATTRIBUTES>

```

If no connection attributes are present in the event, none are logged and no `<CONNECTION_ATTRIBUTES>` element appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- `<CONNECTION_ID>`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- `<CONNECTION_TYPE>`

The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

Example:

```
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

- `<DB>`

A string representing the default database name.

Example:

```
<DB>test</DB>
```

- `<HOST>`

A string representing the client host name.

Example:

```
<HOST>localhost</HOST>
```

- `<IP>`

A string representing the client IP address.

Example:

```
<IP>127.0.0.1</IP>
```

- `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```
<MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
```

- `<OS_LOGIN>`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see [Section 6.2.18, “Proxy Users”](#)).

Example:

```
<OS_LOGIN>jeffrey</OS_LOGIN>
```

- `<OS_VERSION>`

A string representing the operating system on which the server was built or is running.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

Example:

```
<PRIV_USER>jeffrey</PRIV_USER>
```

- `<PROXY_USER>`

A string representing the proxy user (see [Section 6.2.18, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example:

```
<PROXY_USER>developer</PROXY_USER>
```

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- `<STARTUP_OPTIONS>`

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
--port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

- `<STATUS>`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example:

```
<STATUS>1051</STATUS>
```

- `<STATUS_CODE>`

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- `<TABLE>`

A string representing a table name.

Example:

```
<TABLE>t3</TABLE>
```

- `<USER>`

A string representing the user name sent by the client. This may differ from the `<PRIV_USER>` value.

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- `<VERSION>`

An unsigned integer representing the version of the audit log file format.

Example:

```
<VERSION>1</VERSION>
```

Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (`audit_log_format=OLD`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:00 UTC"
    RECORD_ID="1_2019-10-03T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.7.21-log" />
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="2_2019-10-03T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=" "
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    CONNECTION_TYPE="SSL/TLS"
    PRIV_USER="root"
    PROXY_USER=" "
    DB="test" />
  ...
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="6_2019-10-03T14:25:00"
    NAME="Query"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root[root] @ localhost [127.0.0.1]"
    OS_LOGIN=" "
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="drop_table"
    SQLTEXT="DROP TABLE IF EXISTS t" />
  ...
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="8_2019-10-03T14:25:00"
    NAME="Quit"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=" "
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    CONNECTION_TYPE="SSL/TLS" />
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:32 UTC"
    RECORD_ID="12_2019-10-03T14:25:00"
    NAME="NoAudit"
    SERVER_ID="1" />
</AUDIT>
```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- `NAME`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example: `NAME="Query"`

Some common `NAME` values:

Audit	When auditing starts, which may be server startup time
Connect	When a client connects, also known as logging in
Query	An SQL statement (executed directly)
Prepare	Preparation of an SQL statement; usually followed by Execute
Execute	Execution of an SQL statement; usually follows Prepare
Shutdown	Server shutdown
Quit	When a client disconnects
NoAudit	Auditing has been turned off

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `TableDelete`, `TableInsert`, `TableRead`, `TableUpdate`, `Time`.

Many of these values correspond to the `COM_xxx` command values listed in the `my_command.h` header file. For example, `"Create DB"` and `"Change user"` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

Events having `NAME` values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event has `DB` and `TABLE` attributes to identify the table to which the event refers.

`Connect` events for old-style XML audit log format do not include connection attributes.

- `RECORD_ID`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example: `RECORD_ID="12_2019-10-03T14:25:00"`

- `TIMESTAMP`

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `TIMESTAMP` value occurring after the statement finishes, not when it was received.

Example: `TIMESTAMP="2019-10-03T14:25:32 UTC"`

The following attributes are optional in `<AUDIT_RECORD>` elements. Many of them occur only for elements with specific values of the `NAME` attribute.

- `COMMAND_CLASS`

A string that indicates the type of action performed.

Example: `COMMAND_CLASS="drop_table"`

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `CONNECTION_ID`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example: `CONNECTION_ID="127"`

- `CONNECTION_TYPE`

The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

Example: `CONNECTION_TYPE="SSL/TLS"`

- `DB`

A string representing the default database name.

Example: `DB="test"`

- `HOST`

A string representing the client host name.

Example: `HOST="localhost"`

- `IP`

A string representing the client IP address.

Example: `IP="127.0.0.1"`

- `MYSQL_VERSION`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example: `MYSQL_VERSION="5.7.21-log"`

- `OS_LOGIN`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see [Section 6.2.18, “Proxy Users”](#)).

Example: `OS_LOGIN="jeffrey"`

- `OS_VERSION`

A string representing the operating system on which the server was built or is running.

Example: `OS_VERSION="x86_64-Linux"`

- `PRIV_USER`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.

Example: `PRIV_USER="jeffrey"`

- `PROXY_USER`

A string representing the proxy user (see [Section 6.2.18, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example: `PROXY_USER="developer"`

- `SERVER_ID`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example: `SERVER_ID="1"`

- `SQLTEXT`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- [STARTUP_OPTIONS](#)

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- [STATUS](#)

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for [STATUS_CODE](#) for information about how it differs from [STATUS](#).

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example: `STATUS="1051"`

- [STATUS_CODE](#)

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The [STATUS_CODE](#) value differs from the [STATUS](#) value: [STATUS_CODE](#) is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. [STATUS](#) is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: `STATUS_CODE="0"`

- [TABLE](#)

A string representing a table name.

Example: `TABLE="t3"`

- [USER](#)

A string representing the user name sent by the client. This may differ from the [PRIV_USER](#) value.

- [VERSION](#)

An unsigned integer representing the version of the audit log file format.

Example: `VERSION="1"`

JSON Audit Log File Format

For JSON-format audit logging (`audit_log_format=JSON`), the log file contents form a [JSON](#) array with each array element representing an audited event as a [JSON](#) hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```
[
  {
    "timestamp": "2019-10-03 13:50:01",
    "id": 0,
    "class": "audit",
    "event": "startup",
    ...
  },
  {
    "timestamp": "2019-10-03 15:02:32",
    "id": 0,
    "class": "connection",
```

```

    "event": "connect",
    ...
  },
  ...
  {
    "timestamp": "2019-10-03 17:37:26",
    "id": 0,
    "class": "table_access",
    "event": "insert",
    ...
  }
  ...
]

```

The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening `[` array marker. When the plugin closes a log file, it writes the closing `]` array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

- Some items appear in every audit record. Others are optional and may appear depending on the audit record type.
- Order of items within an audit record is not guaranteed.
- Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.
- The `"` and `\` characters are encoded as `\"` and `\\`, respectively.

The following examples show the JSON object formats for different event types (as indicated by the `class` and `event` items), reformatted slightly for readability:

Auditing startup event:

```

{ "timestamp": "2019-10-03 14:21:56",
  "id": 0,
  "class": "audit",
  "event": "startup",
  "connection_id": 0,
  "startup_data": { "server_id": 1,
                    "os_version": "i686-Linux",
                    "mysql_version": "5.7.21-log",
                    "args": [ "/usr/local/mysql/bin/mysqld",
                              "--loose-audit-log-format=JSON",
                              "--log-error=log.err",
                              "--pid-file=mysqld.pid",
                              "--port=3306" ] } }

```

When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Auditing shutdown event:

```

{ "timestamp": "2019-10-03 14:28:20",
  "id": 3,
  "class": "audit",
  "event": "shutdown",
  "connection_id": 0,
  "shutdown_data": { "server_id": 1 } }

```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Connect or change-user event:

```

{ "timestamp": "2019-10-03 14:23:18",
  "id": 1,
  "class": "connection",
  "event": "connect",

```

```

"connection_id": 5,
"account": { "user": "root", "host": "localhost" },
"login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
"connection_data": { "connection_type": "ssl",
                     "status": 0,
                     "db": "test",
                     "connection_attributes": {
                       "_pid": "43236",
                       ...
                       "program_name": "mysqldadmin"
                     }
                   }
}

```

Disconnect event:

```

{ "timestamp": "2019-10-03 14:24:45",
  "id": 3,
  "class": "connection",
  "event": "disconnect",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
  "connection_data": { "connection_type": "ssl" } }

```

Query event:

```

{ "timestamp": "2019-10-03 14:23:35",
  "id": 2,
  "class": "general",
  "event": "status",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
  "general_data": { "command": "Query",
                    "sql_command": "show_variables",
                    "query": "SHOW VARIABLES",
                    "status": 0 } }

```

Table access event (read, delete, insert, update):

```

{ "timestamp": "2019-10-03 14:23:41",
  "id": 0,
  "class": "table_access",
  "event": "insert",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "127.0.0.1", "proxy": "" },
  "table_access_data": { "db": "test",
                        "table": "t1",
                        "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
                        "sql_command": "insert" } }

```

The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a [JSON](#) hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- [account](#)

The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the [CURRENT_USER\(\)](#) function within the section: [user](#), [host](#).

Example:

```

"account": { "user": "root", "host": "localhost" }

```

- [class](#)

A string representing the event class. The class defines the type of event, when taken together with the [event](#) item that specifies the event subclass.

Example:

```
"class": "connection"
```

The following table shows the permitted combinations of `class` and `event` values.

Table 6.28 Audit Log Class and Event Combinations

Class Value	Permitted Event Values
<code>audit</code>	<code>startup</code> , <code>shutdown</code>
<code>connection</code>	<code>connect</code> , <code>change_user</code> , <code>disconnect</code>
<code>general</code>	<code>status</code>
<code>table_access_data</code>	<code>read</code> , <code>delete</code> , <code>insert</code> , <code>update</code>

- `connection_data`

Information about a client connection. The value is a hash containing these items: `connection_type`, `status`, `db`, and possibly `connection_attributes`. This item occurs only for audit records with a `class` value of `connection`.

Example:

```
"connection_data": { "connection_type": "ssl",
                    "status": 0,
                    "db": "test" }
```

As of MySQL 8.0.19, events with a `class` value of `connection` and `event` value of `connect` may include a `connection_attributes` item to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see [Section 26.12.9, “Performance Schema Connection Attribute Tables”](#).)

The `connection_attributes` value is a hash that represents each attribute by its name and value.

Example:

```
"connection_attributes": {
  "_pid": "43236",
  "_os": "osx10.14",
  "_platform": "x86_64",
  "_client_version": "8.0.19",
  "_client_name": "libmysql",
  "program_name": "mysqladmin"
}
```

If no connection attributes are present in the event, none are logged and no `connection_attributes` item appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- `connection_id`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
"connection_id": 5
```

- `event`

A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the `class` item that specifies the event class. For more information, see the `class` item description.

Example:

```
"event": "connect"
```

- `general_data`

Information about an executed statement or command. The value is a hash containing these items: `command`, `sql_command`, `query`, `status`. This item occurs only for audit records with a `class` value of `general`.

Example:

```
"general_data": { "command": "Query",  
                  "sql_command": "show_variables",  
                  "query": "SHOW VARIABLES",  
                  "status": 0 }
```

- `id`

An unsigned integer representing an event ID.

Example:

```
"id": 2
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

- `login`

Information indicating how a client connected to the server. The value is a hash containing these items: `user`, `os`, `ip`, `proxy`.

Example:

```
"login": { "user": "root", "os": "", "ip": "::1", "proxy": "" }
```

- `shutdown_data`

Information pertaining to audit log plugin termination. The value is a hash containing these items: `server_id`. This item occurs only for audit records with `class` and `event` values of `audit` and `shutdown`, respectively.

Example:

```
"shutdown_data": { "server_id": 1 }
```

- `startup_data`

Information pertaining to audit log plugin initialization. The value is a hash containing these items: `server_id`, `os_version`, `mysql_version`, `args`. This item occurs only for audit records with `class` and `event` values of `audit` and `startup`, respectively.

Example:

```
"startup_data": { "server_id": 1,  
                  "os_version": "i686-Linux",  
                  "mysql_version": "5.7.21-log",
```

```
"args": [ "/usr/local/mysql/bin/mysqld",
          "--loose-audit-log-format=JSON",
          "--log-error=log.err",
          "--pid-file=mysqld.pid",
          "--port=3306" ] }
```

- `table_access_data`

Information about an access to a table. The value is a hash containing these items: `db`, `table`, `query`, `sql_command`. This item occurs only for audit records with a `class` value of `table_access`.

Example:

```
"table_access_data": { "db": "test",
                      "table": "t1",
                      "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
                      "sql_command": "insert" }
```

- `timestamp`

A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

Example:

```
"timestamp": "2019-10-03 13:50:01"
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

These items appear within hash values associated with top-level items of JSON-format audit records:

- `args`

An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
"args": [ "/usr/local/mysql/bin/mysqld",
          "--loose-audit-log-format=JSON",
          "--log-error=log.err",
          "--pid-file=mysqld.pid",
          "--port=3306" ]
```

- `command`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
"command": "Query"
```

- `connection_type`

The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

Example:

```
"connection_type": "tcp/tcp"
```

- `db`

A string representing a database name. For `connection_data`, it is the default database. For `table_access_data`, it is the table database.

Example:

```
"db": "test"
```

- `host`

A string representing the client host name.

Example:

```
"host": "localhost"
```

- `ip`

A string representing the client IP address.

Example:

```
"ip": "::1"
```

- `mysql_version`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```
"mysql_version": "5.7.21-log"
```

- `os`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See [Section 6.2.18, “Proxy Users”](#).

Example:

```
"os": "jeffrey"
```

- `os_version`

A string representing the operating system on which the server was built or is running.

Example:

```
"os_version": "i686-Linux"
```

- `proxy`

A string representing the proxy user (see [Section 6.2.18, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example:

```
"proxy": "developer"
```

- `query`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
"query": "DELETE FROM t1"
```

- `server_id`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
"server_id": 1
```

- `sql_command`

A string that indicates the SQL statement type.

Example:

```
"sql_command": "insert"
```

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `status`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example:

```
"status": 1051
```

- `table`

A string representing a table name.

Example:

```
"table": "t1"
```

- `user`

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

- Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.
- Within `login` items, `user` is a string representing the user name sent by the client.

Example:

```
"user": "root"
```

6.4.5.5 Configuring Audit Logging Characteristics

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, and whether to enable log file compression and encryption.

- [Naming Conventions for Audit Log Files](#)
- [Selecting Audit Log File Format](#)
- [Compressing Audit Log Files](#)
- [Encrypting Audit Log Files](#)
- [Manually Uncompressing and Decrypting Audit Log Files](#)
- [Audit Log File Encryption Prior to MySQL 8.0.17](#)
- [Space Management and Name Rotation of Audit Log Files](#)
- [Write Strategies for Audit Logging](#)

Note

Encryption capabilities described here apply as of MySQL 8.0.17, with the exception of the section that compares current encryption capabilities to the previous more-limited capabilities; see [Audit Log File Encryption Prior to MySQL 8.0.17](#).

For additional information about the user-defined functions and system variables that affect audit logging, see [Audit Log Functions](#), and [Audit Log Options and Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See [Section 6.4.5.7, “Audit Log Filtering”](#).

Naming Conventions for Audit Log Files

To configure the audit log file name, set the `audit_log_file` system variable at server startup. The default name is `audit.log` in the server data directory. For best security, write the audit log to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

The plugin interprets the `audit_log_file` value as composed of an optional leading directory name, a base name, and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:

- If compression is enabled, the plugin adds a suffix of `.gz`.

- If encryption is enabled, the plugin adds a suffix of `.pwd_id.enc`, where `pwd_id` indicates which encryption password to use for log file operations. The audit log plugin stores encryption passwords in the keyring; see [Encrypting Audit Log Files](#).

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured `audit_log_file` value is `audit.log`, the effective file name is one of the values shown in the following table.

Enabled Features	Effective File Name
No compression or encryption	<code>audit.log</code>
Compression	<code>audit.log.gz</code>
Encryption	<code>audit.log.pwd_id.enc</code>
Compression, encryption	<code>audit.log.gz.pwd_id.enc</code>

`pwd_id` indicates the ID of the password used to encrypt or decrypt a file. `pwd_id` format is `pwd_timestamp-seq`, where:

- `pwd_timestamp` is a UTC value in `YYYYMMDDThhmmss` format indicating when the password was created.
- `seq` is a sequence number. Sequence numbers start at 1 and increase for passwords that have the same `pwd_timestamp` value.

Here are some example `pwd_id` password ID values:

```
20190403T142359-1
20190403T142400-1
20190403T142400-2
```

To construct the corresponding keyring IDs for storing passwords in the keyring, the audit log plugin adds a prefix of `audit_log-` to the `pwd_id` values. For the example password IDs just shown, the corresponding keyring IDs are:

```
audit_log-20190403T142359-1
audit_log-20190403T142400-1
audit_log-20190403T142400-2
```

The ID of the password currently used for encryption by the audit log plugin is the one having the largest `pwd_timestamp` value. If multiple passwords have that `pwd_timestamp` value, the current password ID is the one with the largest sequence number. For example, in the preceding set of password IDs, two of them have the largest timestamp, `20190403T142400`, so the current password ID is the one with the largest sequence number (2).

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

- During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- During termination, the plugin renames the audit log file.
- File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic log file rotation; see [Automatic Audit Log File Rotation](#).

Selecting Audit Log File Format

To configure the audit log file format, set the `audit_log_format` system variable at server startup. By default, the format is `NEW` (new-style XML format). For details about each format, see [Section 6.4.5.4, "Audit Log File Formats"](#).

If you change `audit_log_format`, it is recommended that you also change `audit_log_file`. Otherwise, there will be two sets of log files with the same base name but different formats.

Compressing Audit Log Files

Audit log file compression can be enabled for any logging format.

To configure audit log file compression, set the `audit_log_compression` system variable at server startup. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See [Manually Uncompressing and Decrypting Audit Log Files](#).

Encrypting Audit Log Files

Audit log file encryption can be enabled for any logging format. Encryption is based on user-defined passwords (with the exception of the initial password that the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring plugin can be used; for instructions, see [Section 6.4.4, “The MySQL Keyring”](#).

To configure audit log file encryption, set the `audit_log_encryption` system variable at server startup. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption).

To set or get an encryption password at runtime, use these user-defined functions (UDFs):

- To set the current encryption password, invoke `audit_log_encryption_password_set()`. This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic log file rotation; see [Automatic Audit Log File Rotation](#).

If the `audit_log_password_history_keep_days` system variable is nonzero, invoking `audit_log_encryption_password_set()` also causes expiration of old archived audit log encryption passwords. See the description of that variable for information about audit log password history, including password archiving and expiration.

- To get the current encryption password, invoke `audit_log_encryption_password_get()` with no argument. To get a password by ID, pass an argument specifying the keyring ID of the current password or an archived password.

To determine which audit log keyring IDs exist, query the Performance Schema `keyring_keys` table:

```
mysql> SELECT KEY_ID FROM performance_schema.keyring_keys
      WHERE KEY_ID LIKE 'audit_log%'
      ORDER BY KEY_ID;
+-----+
| KEY_ID |
+-----+
| audit_log-20190415T152248-1 |
| audit_log-20190415T153507-1 |
| audit_log-20190416T125122-1 |
| audit_log-20190416T141608-1 |
+-----+
```

For additional information about audit log encryption UDFs, see [Audit Log Functions](#).

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See [Manually Uncompressing and Decrypting Audit Log Files](#).

Manually Uncompressing and Decrypting Audit Log Files

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that `audit_log_file` is set to `audit.log`. In that case, an archived audit log file has one of the names shown in the following table.

Enabled Features	Archived File Name
No compression or encryption	<code>audit.timestamp.log</code>
Compression	<code>audit.timestamp.log.gz</code>
Encryption	<code>audit.timestamp.log.pwd_id.enc</code>
Compression, encryption	<code>audit.timestamp.log.gz.pwd_id.enc</code>

As discussed in [Naming Conventions for Audit Log Files](#), `pwd_id` format is `pwd_timestamp-seq`. Thus, the names of archived encrypted log files actually contain two timestamps. The first indicates file rotation time, and the second indicates when the encryption password was created.

Consider the following set of archived encrypted log file names:

```
audit.20190410T205827.log.20190403T185337-1.enc
audit.20190410T210243.log.20190403T185337-1.enc
audit.20190415T145309.log.20190414T223342-1.enc
audit.20190415T151322.log.20190414T223342-2.enc
```

Each file name has a unique rotation-time timestamp. By contrast, the password timestamps are not unique:

- The first two files have the same password ID and sequence number (`20190403T185337-1`). They have the same encryption password.
- The second two files have the same password ID (`20190414T223342`) but different sequence numbers (`1`, `2`). These files have different encryption passwords.

To uncompress a compressed log file manually, use `gunzip`, `gzip -d`, or equivalent command. For example:

```
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the `openssl` command. For example:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
-in audit.timestamp.log.pwd_id.enc
-out audit.timestamp.log
```

To execute that command, you must obtain `password`, the encryption password. To do this, use `audit_log_encryption_password_get()`. For example, if the audit log file name is `audit.20190415T151322.log.20190414T223342-2.enc`, the password ID is `20190414T223342-2` and the keyring ID is `audit-log-20190414T223342-2`. Retrieve the keyring password like this:

```
SELECT audit_log_encryption_password_get('audit-log-20190414T223342-2');
```

If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.pwd_id.enc` suffixes added, corresponding to the order in which those operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
-in audit.timestamp.log.gz.pwd_id.enc
-out audit.timestamp.log.gz
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

Audit Log File Encryption Prior to MySQL 8.0.17

This section covers the differences in audit log file encryption capabilities prior to and as of MySQL 8.0.17, which is when password history was implemented (which includes password archiving and expiration). It also indicates how the audit log plugin handles upgrades to MySQL 8.0.17 or higher from versions lower than 8.0.17.

Feature	Prior to MySQL 8.0.17	As of MySQL 8.0.17
Number of passwords	Single password only	Multiple passwords permitted
Encrypted log file names	.enc suffix	.pwd_id.enc suffix
Password keyring ID	audit_log	audit_log-pwd_id
Password history	No	Yes

Prior to MySQL 8.0.17, there is no password history, so setting a new password makes the old password inaccessible, rendering MySQL Enterprise Audit unable to read log files encrypted with the old password. Should you anticipate a need to decrypt those files manually, you must maintain a record of previous passwords.

If audit log file encryption is enabled when you upgrade to MySQL 8.0.17 or higher from a lower version, the audit log plugin performs these upgrade actions:

- During plugin initialization, the plugin checks for an encryption password with a keyring ID of `audit_log`. If it finds one, the plugin duplicates the password using a keyring ID in `audit_log-pwd_id` format and uses it as the current encryption password. (For details about `pwd_id` syntax, see [Naming Conventions for Audit Log Files](#).)
- Existing encrypted log files have a suffix of `.enc`. The plugin does not rename these to have a suffix of `.pwd_id.enc`, but can read them as long as the key with the ID of `audit_log` remains in the keyring.
- When password cleanup occurs, if the plugin expires any password with a keyring ID in `audit_log-pwd_id` format, it also expires the password with a keyring ID of `audit_log`, if it exists. (At this point, encrypted log files that have a suffix of `.enc` rather than `.pwd_id.enc` become unreadable by the plugin, so it is assumed that you no longer need them.)

Space Management and Name Rotation of Audit Log Files

The audit log file has the potential to grow very large and consume a lot of disk space. To enable management of the space used by its log files, the audit log plugin provides for log file rotation, either manually or automatically. Rotation capabilities use the `audit_log_flush` and `audit_log_rotate_on_size` system variables:

- By default, `audit_log_rotate_on_size=0` and no log rotation occurs unless performed manually. In this case, use `audit_log_flush` to close and reopen the current log file after manually renaming it.
- If `audit_log_rotate_on_size` is greater than 0, automatic rotation occurs when a write to the current log file causes its size to exceed this value. The audit log plugin closes the file, renames it, and opens a new log file. With automatic rotation enabled, `audit_log_flush` has no effect.
- Automatic rotation also occurs under several other conditions, described later.

Note

Renamed log files are not removed automatically. For example, with size-based log file rotation, renamed log files do not rotate off the end of the name

sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary. If backed-up log files are encrypted, also back up the corresponding encryption passwords to a safe place, should you need to decrypt the files later.

The following discussion describes log file rotation methods in greater detail.

- [Manual Audit Log File Rotation](#)
- [Automatic Audit Log File Rotation](#)

Manual Audit Log File Rotation

If `audit_log_rotate_on_size=0` (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
mv audit.log.2 audit.log.3
mv audit.log.1 audit.log.2
mv audit.log audit.log.1
```

This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
SET GLOBAL audit_log_flush = ON;
```

`audit_log_flush` is special in that its value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.

Note

If compression or encryption are enabled, log file names include suffixes that signify the enabled features, as well as a password ID if encryption is enabled. If file names include a password ID, be sure to retain the ID in the name of any files you rename manually so that the password to use for decryption operations can be determined.

Note

For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin no longer can determine that they are part of the log file sequence (see [Section 6.4.5.6, “Reading Audit Log Files”](#)). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

Automatic Audit Log File Rotation

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the file, renames it, and opens a new log file.

Automatic rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see [Naming Conventions for Audit Log Files](#)).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password, if encryption is enabled. (Rotation does not occur if encryption is disabled.)

The plugin renames the original file by inserting a timestamp just after its base name. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20190115T140633.log`. The timestamp is a UTC value in `YYYYMMDDThhmmss` format. The timestamp indicates rotation time for XML logging, and the timestamp of the last event written to the file for JSON logging.

Write Strategies for Audit Logging

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

6.4.5.6 Reading Audit Log Files

The audit log plugin supports user-defined functions that provide an SQL interface for reading JSON-format audit log files. (This capability does not apply to log files written in other formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the current audit log file as the location to search for readable audit log files. The plugin determines the file location, base name, and suffix from the value of the `audit_log_file` system variable, then looks for files with names that match the following pattern, where `[...]` indicates optional file name parts:

```
basename[.timestamp].suffix[.gz][[.pwd_id].enc]
```

If a file name ends with `.enc`, the file is encrypted and reading its unencrypted contents requires a decryption password obtained from the keyring. The audit log plugin determines the keyring ID of the decryption password as follows:

- If `.enc` is preceded by `pwd_id`, the keyring ID is `audit_log-pwd_id`.
- If `.enc` is not preceded by `pwd_id`, the file has an old name from before audit log encryption password history was implemented. The keyring ID is `audit_log`.

For more information about encrypted audit log files, see [Encrypting Audit Log Files](#).

The plugin ignores files that have been renamed manually and do not match the pattern, and files that were encrypted with a password no longer available in the keyring. The plugin opens each remaining candidate file, verifies that the file actually contains `JSON` audit events, and sorts the files using the timestamps from the first event of each file. The result is a sequence of files that are subject to access using the log-reading user-defined functions (UDFs):

- `audit_log_read()` reads events from the audit log or closes the reading process.
- `audit_log_read_bookmark()` returns a bookmark for the most recently written audit log event. This bookmark is suitable for passing to `audit_log_read()` to indicate where to begin reading.

`audit_log_read()` takes an optional `JSON` string argument, and the result returned from a successful call to either function is a `JSON` string.

To use the functions to read the audit log, follow these principles:

- Call `audit_log_read()` to read events beginning from a given position or the current position, or to close reading:
 - To initialize an audit log read sequence, pass an argument that indicates the position at which to begin. One way to do so is to pass the bookmark returned by `audit_log_read_bookmark()`:

```
SELECT audit_log_read(audit_log_read_bookmark());
```

- To continue reading from the current position in the sequence, call `audit_log_read()` with no position specified:

```
SELECT audit_log_read();
```

- To explicitly close the read sequence, pass a `JSON null` argument:

```
SELECT audit_log_read('null');
```

It is unnecessary to close reading explicitly. Reading is closed implicitly when the session ends or a new read sequence is initialized by calling `audit_log_read()` with an argument that indicates the position at which to begin.

- A successful call to `audit_log_read()` to read events returns a `JSON` string containing an array of audit events:
 - If the final value of the returned array is not a `JSON null` value, there are more events following those just read and `audit_log_read()` can be called again to read more of them.
 - If the final value of the returned array is a `JSON null` value, there are no more events left to be read in the current read sequence.

Each non-`null` array element is an event represented as a `JSON` hash. For example:

```
[
  {
    "timestamp": "2020-05-18 13:39:33", "id": 0,
    "class": "connection", "event": "connect",
    ...
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 1,
    "class": "general", "event": "status",
    ...
  }
]
```

```

    ...
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 2,
    "class": "connection", "event": "disconnect",
    ...
  },
  null
]

```

For more information about the content of JSON-format audit events, see [JSON Audit Log File Format](#).

- An `audit_log_read()` call to read events that does not specify a position produces an error under any of these conditions:
 - A read sequence has not yet been initialized by passing a position to `audit_log_read()`.
 - There are no more events left to be read in the current read sequence; that is, `audit_log_read()` previously returned an array ending with a JSON `null` value.
 - The most recent read sequence has been closed by passing a JSON `null` value to `audit_log_read()`.

To read events under those conditions, it is necessary to first initialize a read sequence by calling `audit_log_read()` with an argument that specifies a position.

To specify a position to `audit_log_read()`, pass a bookmark, which is a JSON hash containing `timestamp` and `id` elements that uniquely identify a particular event. Here is an example bookmark, obtained by calling the `audit_log_read_bookmark()` function:

```

mysql> SELECT audit_log_read_bookmark();
+-----+
| audit_log_read_bookmark() |
+-----+
| { "timestamp": "2020-05-18 21:03:44", "id": 0 } |
+-----+

```

Passing the current bookmark to `audit_log_read()` initializes event reading beginning at the bookmark position:

```

mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----+
| audit_log_read(audit_log_read_bookmark()) |
+-----+
| [ { "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", ... } |
+-----+

```

The argument to `audit_log_read()` is optional. If present, it can be a JSON `null` value to close the read sequence, or a JSON hash.

Within a hash argument to `audit_log_read()`, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- `timestamp`, `id`: The position within the audit log of the first event to read. If the position is omitted from the argument, reading continues from the current position. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.
- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

Example arguments accepted by `audit_log_read()`:

- Read events starting with the event that has the exact timestamp and event ID:

```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0 }')
```

- Like the previous example, but read at most 3 events:

```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0, "max_array_length": 3 }')
```

- Read events from the current position in the read sequence:

```
audit_log_read()
```

- Read at most 5 events beginning at the current position in the read sequence:

```
audit_log_read('{ "max_array_length": 5 }')
```

- Close the current read sequence:

```
audit_log_read('null')
```

A [JSON](#) string returned from either log-reading function can be manipulated as necessary. Suppose that a call to obtain a bookmark produces this value:

```
mysql> SET @mark := audit_log_read_bookmark();
mysql> SELECT @mark;
+-----+
| @mark |
+-----+
| { "timestamp": "2020-05-18 16:10:28", "id": 2 } |
+-----+
```

Calling `audit_log_read()` with that argument can return multiple events. To limit `audit_log_read()` to reading at most *N* events, add to the string a `max_array_length` item with that value. For example, to read a single event, modify the string as follows:

```
mysql> SET @mark := JSON_SET(@mark, '$.max_array_length', 1);
mysql> SELECT @mark;
+-----+
| @mark |
+-----+
| { "id": 2, "timestamp": "2020-05-18 16:10:28", "max_array_length": 1 } |
+-----+
```

The modified string, when passed to `audit_log_read()`, produces a result containing at most one event, no matter how many are available.

To read a specific number of events beginning at the current position, pass a [JSON](#) hash that includes a `max_array_length` value but no position. This statement invoked repeatedly returns five events each time until no more events are available:

```
SELECT audit_log_read('{ "max_array_length": 5 }');
```

Prior to MySQL 8.0.19, string return values from audit log UDFs are binary strings. To use a binary string with functions that require a nonbinary string (such as functions that manipulate [JSON](#) values), convert it to a nonbinary string. For example, before passing a bookmark to `JSON_SET()`, convert it to `utf8mb4` as follows:

```
SET @mark = CONVERT(@mark USING utf8mb4);
```

That statement can be used even for MySQL 8.0.19 and higher; for those versions, it is essentially a no-op and is harmless.

To set a limit on the number of bytes that `audit_log_read()` reads, set the `audit_log_read_buffer_size` system variable. As of MySQL 8.0.12, this variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`.

Each call to `audit_log_read()` returns as many available events as fit within the buffer size. Events that do not fit within the buffer size are skipped and generate warnings. Given this behavior, consider these factors when assessing the proper buffer size for an application:

- There is a tradeoff between number of calls to `audit_log_read()` and events returned per call:
 - With a smaller buffer size, calls return fewer events, so more calls are needed.
 - With a larger buffer size, calls return more events, so fewer calls are needed.
- With a smaller buffer size, such as the default size of 32KB, there is a greater chance that events will exceed the buffer size and be skipped.

Prior to MySQL 8.0.12, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

For additional information about audit log-reading functions, see [Audit Log Functions](#).

6.4.5.7 Audit Log Filtering

Note

This section describes how audit log filtering works if the audit log plugin and the accompanying audit tables and UDFs are installed. If the plugin is installed but not the accompanying audit tables and UDFs, the plugin operates in legacy filtering mode, described in [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#). Legacy mode is filtering behavior as it was prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

The audit log plugin has the capability of controlling logging of audited events by filtering them:

- Audited events can be filtered using these characteristics:
 - User account
 - Audit event class
 - Audit event subclass
 - Value of event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
 - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
 - Filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.
 - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
 - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.
- Audit filters can be defined, displayed, and modified using an SQL interface based on user-defined functions (UDFs).
- Audit filter definitions are stored in the tables in the `mysql` system database.
- Within a given session, the value of the read-only `audit_log_filter_id` system variable indicates whether a filter has been assigned to the session.

**Note**

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to % is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

The following list briefly summarizes the UDFs that implement the SQL interface for audit filtering control:

- `audit_log_filter_set_filter()`: Define a filter
- `audit_log_filter_remove_filter()`: Remove a filter
- `audit_log_filter_set_user()`: Start filtering a user account
- `audit_log_filter_remove_user()`: Stop filtering a user account
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see [Using Audit Log Filtering Functions](#), and [Audit Log Functions](#).

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the `audit_log` plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the `audit_log` plugin and its accompanying UDFs and tables, see [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).
- To use any filtering function, a user must possess the `SUPER` privilege or an error occurs. To grant the `SUPER` privilege to a user account, use this statement:

```
GRANT SUPER ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the `SUPER` privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring UDFs in [Using General-Purpose Keyring Functions](#); it can be adapted for use with filtering UDFs.

- The `audit_log` plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering,
which has not been installed yet. Audit Log plugin will run in the legacy
mode, which will be disabled in the next release.'
```

In legacy mode, filtering can be done based only on event account or status. For details, see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#).

- [Using Audit Log Filtering Functions](#)

Using Audit Log Filtering Functions

Before using the audit log user-defined functions (UDFs), install them according to the instructions provided in [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). The `SUPER` privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are [JSON](#) values. For information about using [JSON](#) data in MySQL, see [Section 11.5, “The JSON Data Type”](#). This section shows some simple filter definitions. For more information about filter definitions, see [Section 6.4.5.8, “Writing Audit Log Filter Definitions”](#).

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, the audit log uses that filter.
- Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (`%`), the audit log uses the default filter.
- Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see [mysql_change_user\(\)](#)), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that instead you want the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');
```

Now full logging is enabled for `user1@localhost` and `user2@localhost`. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- To unassign the filter from the user account:

```
SELECT audit_log_filter_remove_user('user1@localhost');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.

- To assign a different filter to the user account:

```
SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.

To remove a filter, do this:

```
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it has been assigned, including any current sessions for those users.

The filtering UDFs just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see [Audit Log Tables](#)). It is also possible to modify the audit log tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```
SELECT audit_log_filter_flush();
```

Warning

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

To determine whether a filter has been assigned to the current session, check the session value of the read-only `audit_log_filter_id` system variable. If the value is 0, no filter is assigned. A nonzero value indicates the internally maintained ID of the assigned filter:

```
mysql> SELECT @@audit_log_filter_id;
+-----+
| @@audit_log_filter_id |
+-----+
| 2 |
+-----+
```

6.4.5.8 Writing Audit Log Filter Definitions

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 11.5, “The JSON Data Type”](#).

Filter definitions have this form, where *actions* indicates how filtering takes place:

```
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

- [Logging All Events](#)
- [Logging Specific Event Classes](#)
- [Logging Specific Event Subclasses](#)
- [Inclusive and Exclusive Logging](#)
- [Testing Event Field Values](#)
- [Blocking Execution of Specific Events](#)
- [Logical Operators](#)
- [Referencing Predefined Variables](#)
- [Referencing Predefined Functions](#)
- [Replacing a User Filter](#)

Logging All Events

To explicitly enable or disable logging of all events, use a `log` element in the filter:

```
{
  "filter": { "log": true }
}
```

The `log` value can be either `true` or `false`.

The preceding filter enables logging of all events. It is equivalent to:

```
{
  "filter": { }
}
```

Logging behavior depends on the `log` value and whether `class` or `event` items are specified:

- With `log` specified, its given value is used.
- Without `log` specified, logging is `true` if no `class` or `event` item is specified, and `false` otherwise (in which case, `class` or `event` can include their own `log` item).

Logging Specific Event Classes

To log events of a specific class, use a `class` element in the filter, with its `name` field denoting the name of the class to log:

```
{
  "filter": {
    "class": { "name": "connection" }
  }
}
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```
{
  "filter": {
    "log": false,
    "class": { "log": true,
              "name": "connection" }
  }
}
```

To enable logging of multiple classes, define the `class` value as a `JSON` array element that names the classes:

```
{
  "filter": {
    "class": [
      { "name": "connection" },
      { "name": "general" },
      { "name": "table_access" }
    ]
  }
}
```

Note

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```
{
  "filter": {
```

```

    "class": [
      { "name": [ "connection", "general", "table_access" ] }
    ]
  }
}

```

Logging Specific Event Subclasses

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```

{
  "filter": {
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect" },
          { "name": "disconnect" }
        ]
      },
      { "name": "general" },
      {
        "name": "table_access",
        "event": [
          { "name": "insert" },
          { "name": "delete" },
          { "name": "update" }
        ]
      }
    ]
  }
}

```

The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```

"event": [
  { "name": "read", "log": false },
  { "name": "insert", "log": true },
  { "name": "delete", "log": true },
  { "name": "update", "log": true }
]

```

The `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see [Blocking Execution of Specific Events](#).

[Table 6.29, “Event Class and Subclass Combinations”](#) describes the permitted subclass values for each event class.

Table 6.29 Event Class and Subclass Combinations

Event Class	Event Subclass	Description
<code>connection</code>	<code>connect</code>	Connection initiation (successful or unsuccessful)
<code>connection</code>	<code>change_user</code>	User re-authentication with different user/password during session
<code>connection</code>	<code>disconnect</code>	Connection termination
<code>general</code>	<code>status</code>	General operation information
<code>message</code>	<code>internal</code>	Internally generated message
<code>message</code>	<code>user</code>	Message generated by <code>audit_api_message_emit_udf()</code>
<code>table_access</code>	<code>read</code>	Table read statements, such as <code>SELECT</code> or <code>INSERT INTO ... SELECT</code>

Event Class	Event Subclass	Description
table_access	delete	Table delete statements, such as <code>DELETE</code> or <code>TRUNCATE TABLE</code>
table_access	insert	Table insert statements, such as <code>INSERT</code> or <code>REPLACE</code>
table_access	update	Table update statements, such as <code>UPDATE</code>

Table 6.30, “Log and Abort Characteristics Per Event Class and Subclass Combination” describes for each event subclass whether it can be logged or aborted.

Table 6.30 Log and Abort Characteristics Per Event Class and Subclass Combination

Event Class	Event Subclass	Can be Logged	Can be Aborted
connection	connect	Yes	No
connection	change_user	Yes	No
connection	disconnect	Yes	No
general	status	Yes	No
message	internal	Yes	Yes
message	user	Yes	Yes
table_access	read	Yes	Yes
table_access	delete	Yes	Yes
table_access	insert	Yes	Yes
table_access	update	Yes	Yes

Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- Inclusive mode logs only explicitly specified items.
- Exclusive mode logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```
{
  "filter": {
    "log": false,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": true },
          { "name": "disconnect", "log": true }
        ]
      },
      { "name": "general", "log": true }
    ]
  }
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```
{
  "filter": {
    "log": true,
    "class": [
      { "name": "general", "log": false }
    ]
  }
}
```

This filter logs `change_user` events in the `connection` class, `message` events, and `table_access` events, by virtue of *not* logging everything else:

```
{
  "filter": {
    "log": true,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": false },
          { "name": "disconnect", "log": false }
        ]
      },
      { "name": "general", "log": false }
    ]
  }
}
```

Testing Event Field Values

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "field": { "name": "general_command.str", "value": "Query" }
        }
      }
    }
  }
}
```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

A connection event indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. [Table 6.31, “Connection Event Fields”](#) indicates the permitted fields for connection events.

Table 6.31 Connection Event Fields

Field Name	Field Type	Description
<code>status</code>	integer	Event status: 0: OK Otherwise: Failed
<code>connection_id</code>	unsigned integer	Connection ID
<code>user.str</code>	string	User name specified during authentication
<code>user.length</code>	unsigned integer	User name length
<code>priv_user.str</code>	string	Authenticated user name (account user name)
<code>priv_user.length</code>	unsigned integer	Authenticated user name length
<code>external_user.str</code>	string	External user name (provided by third-party authentication plugin)
<code>external_user.length</code>	unsigned integer	External user name length

Field Name	Field Type	Description
<code>proxy_user.str</code>	string	Proxy user name
<code>proxy_user.length</code>	unsigned integer	Proxy user name length
<code>host.str</code>	string	Connected user host
<code>host.length</code>	unsigned integer	Connected user host length
<code>ip.str</code>	string	Connected user IP address
<code>ip.length</code>	unsigned integer	Connected user IP address length
<code>database.str</code>	string	Database name specified at connect time
<code>database.length</code>	unsigned integer	Database name length
<code>connection_type</code>	integer	Connection type: or <code>:::undefined</code> : Undefined or <code>:::tcp/ip</code> : TCP/IP or <code>:::socket</code> : Socket or <code>:::named_pipe</code> : Named pipe or <code>:::ssl</code> : TCP/IP with encryption or <code>:::shared_memory</code> : Shared memory

The `:::xxx` values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

A general event indicates the status code of an operation and its details. [Table 6.32, “General Event Fields”](#) indicates the permitted fields for general events.

Table 6.32 General Event Fields

Field Name	Field Type	Description
<code>general_error_code</code>	integer	Event status: 0: OK Otherwise: Failed
<code>general_thread_id</code>	unsigned integer	Connection/thread ID
<code>general_user.str</code>	string	User name specified during authentication
<code>general_user.length</code>	unsigned integer	User name length
<code>general_command.str</code>	string	Command name
<code>general_command.length</code>	unsigned integer	Command name length
<code>general_query.str</code>	string	SQL statement text
<code>general_query.length</code>	unsigned integer	SQL statement text length
<code>general_host.str</code>	string	Host name
<code>general_host.length</code>	unsigned integer	Host name length
<code>general_sql_command.str</code>	string	SQL command type name
<code>general_sql_command.length</code>	unsigned integer	SQL command type name length
<code>general_external_user.str</code>	string	External user name (provided by third-party authentication plugin)
<code>general_external_user.length</code>	unsigned integer	External user name length

Field Name	Field Type	Description
<code>general_ip.str</code>	string	Connected user IP address
<code>general_ip.length</code>	unsigned integer	Connection user IP address length

`general_command.str` indicates a command name: `Query`, `Execute`, `Quit`, or `Change user`.

A general event with the `general_command.str` field set to `Query` or `Execute` contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. These values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```
mysql> SELECT NAME FROM performance_schema.setup_instruments
        WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
+-----+
| NAME                                     |
+-----+
| statement/sql/alter_db                  |
| statement/sql/alter_db_upgrade          |
| statement/sql/alter_event               |
| statement/sql/alter_function            |
| statement/sql/alter_instance            |
| statement/sql/alter_procedure           |
| statement/sql/alter_server              |
| ...                                     |
```

A table-access event provides information about specific table accesses. [Table 6.33, “Table-Access Event Fields”](#) indicates the permitted fields for table-access events.

Table 6.33 Table-Access Event Fields

Field Name	Field Type	Description
<code>connection_id</code>	unsigned integer	Event connection ID
<code>sql_command_id</code>	integer	SQL command ID
<code>query.str</code>	string	SQL statement text
<code>query.length</code>	unsigned integer	SQL statement text length
<code>table_database.str</code>	string	Database name associated with event
<code>table_database.length</code>	unsigned integer	Database name length
<code>table_name.str</code>	string	Table name associated with event
<code>table_name.length</code>	unsigned integer	Table name length

The following list shows which statements produce which table-access events:

- `read` event:
 - `SELECT`
 - `INSERT ... SELECT` (for tables referenced in `SELECT` clause)
 - `REPLACE ... SELECT` (for tables referenced in `SELECT` clause)
 - `UPDATE ... WHERE` (for tables referenced in `WHERE` clause)
 - `HANDLER ... READ`
- `delete` event:
 - `DELETE`
 - `TRUNCATE TABLE`

- `insert` event:
 - `INSERT`
 - `INSERT ... SELECT` (for table referenced in `INSERT` clause)
 - `REPLACE`
 - `REPLACE ... SELECT` (for table referenced in `REPLACE` clause)
 - `LOAD DATA`
 - `LOAD XML`
- `update` event:
 - `UPDATE`
 - `UPDATE ... WHERE` (for tables referenced in `UPDATE` clause)

Blocking Execution of Specific Events

`event` items can include an `abort` item that indicates whether to prevent qualifying events from executing. For example, `abort` enables rules to be written that block execution of specific SQL statements.

The `abort` item must appear within an `event` item. For example:

```
"event": {
  "name": qualifying event subclass names
  "abort": condition
}
```

For event subclasses selected by the `name` item, the `abort` action is true or false, depending on `condition` evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The `condition` specification can be as simple as `true` or `false`, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks `INSERT`, `UPDATE`, and `DELETE` statements:

```
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "insert", "update", "delete" ],
        "abort": true
      }
    }
  }
}
```

This more complex filter blocks the same statements, but only for a specific table (`finances.bank_account`):

```
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "insert", "update", "delete" ],
        "abort": {
          "and": [
            { "field": { "name": "table_database.str", "value": "finances" } },
            { "field": { "name": "table_name.str", "value": "bank_account" } }
          ]
        }
      }
    }
  }
}
```

```

    }
  }
}

```

Statements matched and blocked by the filter return an error to the client:

```
ERROR 1045 (28000): Statement was aborted by an audit log filter
```

Not all events can be blocked (see [Table 6.30, “Log and Abort Characteristics Per Event Class and Subclass Combination”](#)). For an event that cannot, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the `abort` item appears elsewhere than in an `event` item, an error occurs.

Logical Operators

Logical operators (`and`, `or`, `not`) can be used in `log` items. This permits construction of more advanced filtering configurations:

```

{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "or": [
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Query" } },
                { "field": { "name": "general_command.length", "value": 5 } }
              ]
            },
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Execute" } },
                { "field": { "name": "general_command.length", "value": 7 } }
              ]
            }
          ]
        }
      }
    }
  }
}

```

Referencing Predefined Variables

To refer to a predefined variable in a `log` condition, use a `variable` item, which tests equality against a given value:

```

{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "variable": {
            "name": "audit_log_connection_policy_value", "value": "::none"
          }
        }
      }
    }
  }
}

```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the `audit_log_connection_policy_value` predefined variable, you can modify filter operation by changing the value of the `audit_log_connection_policy` system variable.

The `audit_log_XXX_policy` system variables are used for the legacy mode audit log (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)). With rule-based audit log filtering, those variables remain visible (for example, using `SHOW VARIABLES`), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for `variable` items:

- `audit_log_connection_policy_value`

This variable corresponds to the value of the `audit_log_connection_policy` system variable. The value is an unsigned integer. [Table 6.34, “audit_log_connection_policy_value Values”](#) shows the permitted values and the corresponding `audit_log_connection_policy` values.

Table 6.34 audit_log_connection_policy_value Values

Value	Corresponding audit_log_connection_policy Value
0 or ":: <none"< td=""><td>NONE</td></none"<>	NONE
1 or ":: <errors"< td=""><td>ERRORS</td></errors"<>	ERRORS
2 or ":: <all"< td=""><td>ALL</td></all"<>	ALL

The "::

- `audit_log_policy_value`

This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. [Table 6.35, “audit_log_policy_value Values”](#) shows the permitted values and the corresponding `audit_log_policy` values.

Table 6.35 audit_log_policy_value Values

Value	Corresponding audit_log_policy Value
0 or ":: <none"< td=""><td>NONE</td></none"<>	NONE
1 or ":: <logins"< td=""><td>LOGINS</td></logins"<>	LOGINS
2 or ":: <all"< td=""><td>ALL</td></all"<>	ALL
3 or ":: <queries"< td=""><td>QUERIES</td></queries"<>	QUERIES

The "::

- `audit_log_statement_policy_value`

This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. [Table 6.36, “audit_log_statement_policy_value Values”](#) shows the permitted values and the corresponding `audit_log_statement_policy` values.

Table 6.36 audit_log_statement_policy_value Values

Value	Corresponding audit_log_statement_policy Value
0 or ":: <none"< td=""><td>NONE</td></none"<>	NONE
1 or ":: <errors"< td=""><td>ERRORS</td></errors"<>	ERRORS

Value	Corresponding audit_log_statement_policy Value
2 or "::all"	ALL

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

Referencing Predefined Functions

To refer to a predefined function in a `log` condition, use a `function` item, which takes `name` and `args` values to specify the function name and its arguments, respectively:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "function": {
            "name": "find_in_include_list",
            "args": [ { "string": [ { "field": "user.str" },
                                { "string": "@",
                                { "field": "host.str" } ] } ]
          }
        }
      }
    }
  }
}
```

The function as specified in the `name` item should be the function name only, without parentheses or the argument list. Arguments in the `args` item, if there is one, must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for `function` items:

- `audit_log_exclude_accounts_is_null()`

Checks whether the `audit_log_exclude_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `audit_log_include_accounts_is_null()`

Checks whether the `audit_log_include_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `debug_sleep(millisec)`

Sleeps for the given number of milliseconds. This function is used during performance measurement.

`debug_sleep()` is available for debug builds only.

Arguments:

- `millisec`: An unsigned integer that specifies the number of milliseconds to sleep.
- `find_in_exclude_list(account)`

Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).

Arguments:

- `account`: A string that specifies the user account name.
- `find_in_include_list(account)`

Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).

Arguments:

- `account`: A string that specifies the user account name.
- `string_find(text, substr)`

Checks whether the `substr` value is contained in the `text` value. This search is case-sensitive.

Arguments:

- `text`: The text string to search.
- `substr`: The substring to search for in `text`.

Replacing a User Filter

In some cases, the filter definition can be changed dynamically. To do this, define a `filter` configuration within an existing `filter`. For example:

```
{
  "filter": {
    "id": "main",
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "update", "delete" ],
        "log": false,
        "filter": {
          "class": {
            "name": "general",
            "event": { "name": "status",
                      "filter": { "ref": "main" } }
          },
          "activate": {
            "or": [
              { "field": { "name": "table_name.str", "value": "temp_1" } },
              { "field": { "name": "table_name.str", "value": "temp_2" } }
            ]
          }
        }
      }
    }
  }
}
```

A new filter is activated when the `activate` element within a subfilter evaluates to `true`. Using `activate` in a top-level `filter` is not permitted.

A new filter can be replaced with the original one by using a `ref` item inside the subfilter to refer to the original filter `id`.

The filter shown operates like this:

- The `main` filter waits for `table_access` events, either `update` or `delete`.
- If the `update` or `delete table_access` event occurs on the `temp_1` or `temp_2` table, the filter is replaced with the internal one (without an `id`, since there is no need to refer to it explicitly).
- If the end of the command is signalled (`general` / `status` event), an entry is written to the audit log file and the filter is replaced with the `main` filter.

The filter is useful to log statements that update or delete anything from the `temp_1` or `temp_2` tables, such as this one:

```
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```

The statement generates multiple `table_access` events, but the audit log file will contain only `general` / `status` entries.

Note

Any `id` values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the `audit_log_filter_id` system variable.

6.4.5.9 Legacy Mode Audit Log Filtering

Note

This section describes legacy audit log filtering, which applies if the `audit_log` plugin is installed but not the accompanying audit tables and UDFs needed for rule-based filtering.

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

- [Event Filtering by Account](#)
- [Event Filtering by Status](#)

Event Filtering by Account

To filter audited events based on the originating account, set one of these system variables at server startup or runtime:

- `audit_log_include_accounts`: The accounts to include in audit logging. If this variable is set, only these accounts are audited.
- `audit_log_exclude_accounts`: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host account accounts, set the `audit_log_include_accounts` system variable like this:

```
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-`NULL` at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;

-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;

-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To avoid this, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| audit_log_include_accounts |      |
+-----+-----+
mysql> SELECT @@audit_log_include_accounts;
+-----+
| @@audit_log_include_accounts |
+-----+
| NULL |
+-----+
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:

```
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = ''root''@''localhost'';
SET GLOBAL audit_log_include_accounts = '\root\'@\localhost\';
SET GLOBAL audit_log_include_accounts = "root'@localhost";
```

The last statement will not work if the `ANSI_QUOTES` SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

Event Filtering by Status

To filter audited events based on status, set the following system variables at server startup or runtime. These variables apply only for legacy audit log filtering. For JSON audit log filtering, different status variables apply; see [Audit Log Options and Variables](#).

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events

Each variable takes a value of `ALL` (log all associated events; this is the default), `ERRORS` (log only failed events), or `NONE` (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```
SET GLOBAL audit_log_statement_policy = ALL;
```

```
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup. At runtime, it is a read-only variable. It takes a value of `ALL` (log all events; this is the default), `LOGINS` (log connection events), `QUERIES` (log statement events), or `NONE` (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of `ALL`, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to `ALL`.
- If you set `audit_log_policy` to a non-`ALL` value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of `ALL`, the server writes a message to the error log to indicate that their values are being overridden.

Startup <code>audit_log_policy</code> Value	Resulting <code>audit_log_connection_policy</code> Value	Resulting <code>audit_log_statement_policy</code> Value
<code>LOGINS</code>	<code>ALL</code>	<code>NONE</code>
<code>QUERIES</code>	<code>NONE</code>	<code>ALL</code>
<code>NONE</code>	<code>NONE</code>	<code>NONE</code>

6.4.5.10 Audit Log Reference

The following sections provide a reference to MySQL Enterprise Audit elements:

- [Audit Log Tables](#)
- [Audit Log Functions](#)
- [Audit Log Option and Variable Reference](#)
- [Audit Log Options and Variables](#)
- [Audit Log Status Variables](#)

To install the audit log tables and functions, use the instructions provided in [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). Unless those objects are installed, the `audit_log` plugin operates in legacy mode. See [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#).

Audit Log Tables

MySQL Enterprise Audit uses tables in the `mysql` system database for persistent storage of filter and user account data. The tables can be accessed only by users who have privileges for that database. The tables use the `InnoDB` storage engine.

If these tables are missing, the `audit_log` plugin operates in legacy mode. See [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#).

The `audit_log_filter` table stores filter definitions. The table has these columns:

- `NAME`

The filter name.

- `FILTER`

The filter definition associated with the filter name. Definitions are stored as `JSON` values.

The `audit_log_user` table stores user account information. The table has these columns:

- `USER`

The user name part of an account. For an account `user1@localhost`, the `USER` part is `user1`.

- `HOST`

The host name part of an account. For an account `user1@localhost`, the `HOST` part is `localhost`.

- `FILTERNAME`

The name of the filter assigned to the account. The filter name associates the account with a filter defined in the `audit_log_filter` table.

Audit Log Functions

This section describes, for each audit log user-defined function (UDF), its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see [Section 6.4.5.7, “Audit Log Filtering”](#).

Each audit log UDF returns a string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

As of MySQL 8.0.19, audit log UDFs convert string arguments to `utf8mb4` and string return values are `utf8mb4` strings. Prior to MySQL 8.0.19, audit log UDFs treat string arguments as binary strings (which means they do not distinguish lettercase), and string return values are binary strings.

These audit log UDFs are available:

- `audit_log_encryption_password_get([keyring_id])`

This function fetches an audit log encryption password from the MySQL keyring, which must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see [Section 6.4.4, “The MySQL Keyring”](#).

With no argument, the function retrieves the current encryption password as a binary string. An argument may be given to specify which audit log encryption password to retrieve. The argument must be the keyring ID of the current password or an archived password.

For additional information about audit log encryption, see [Encrypting Audit Log Files](#).

Arguments:

`keyring_id`: As of MySQL 8.0.17, this optional argument indicates the keyring ID of the password to retrieve. The maximum permitted length is 766 bytes. If omitted, the function retrieves the current password.

Prior to MySQL 8.0.17, no argument is permitted. The function always retrieves the current password.

Return value:

The password string for success (up to 766 bytes), or `NULL` and an error for failure.

Example:

Retrieve the current password:

```
mysql> SELECT audit_log_encryption_password_get();
+-----+
| audit_log_encryption_password_get() |
+-----+
```

```
| secret |
+-----+
```

To retrieve a password by ID, you can determine which audit log keyring IDs exist by querying the Performance Schema `keyring_keys` table:

```
mysql> SELECT KEY_ID FROM performance_schema.keyring_keys
      WHERE KEY_ID LIKE 'audit_log%'
      ORDER BY KEY_ID;
+-----+
| KEY_ID |
+-----+
| audit_log-20190415T152248-1 |
| audit_log-20190415T153507-1 |
| audit_log-20190416T125122-1 |
| audit_log-20190416T141608-1 |
+-----+
mysql> SELECT audit_log_encryption_password_get('audit_log-20190416T125122-1');
+-----+
| audit_log_encryption_password_get('audit_log-20190416T125122-1') |
+-----+
| segreto |
+-----+
```

- `audit_log_encryption_password_set(password)`

Sets the current audit log encryption password to the argument and stores the password in the MySQL keyring. As of MySQL 8.0.19, the password is stored as a `utf8mb4` string. Prior to MySQL 8.0.19, the password is stored in binary form.

If encryption is enabled, this function performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. The keyring must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see [Section 6.4.4, “The MySQL Keyring”](#).

For additional information about audit log encryption, see [Encrypting Audit Log Files](#).

Arguments:

password: The password string. The maximum permitted length is 766 bytes.

Return value:

1 for success, 0 for failure.

Example:

```
mysql> SELECT audit_log_encryption_password_set(password);
+-----+
| audit_log_encryption_password_set(password) |
+-----+
| 1 |
+-----+
```

- `audit_log_filter_flush()`

Calling any of the other filtering UDFs affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, the changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`.

Warning

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and

reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to `audit_log_filter_flush()`.

Arguments:

None.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_flush();
+-----+
| audit_log_filter_flush() |
+-----+
| OK                       |
+-----+
```

- `audit_log_filter_remove_filter(filter_name)`

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Arguments:

- `filter_name`: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+-----+
| audit_log_filter_remove_filter('SomeFilter') |
+-----+
| OK                                           |
+-----+
```

- `audit_log_filter_remove_user(user_name)`

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected. New connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is `%`, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Arguments:

- *user_name*: The user account name as a string in *user_name@host_name* format, or % to represent the default account.

Return value:

A string that indicates whether the operation succeeded. *OK* indicates success. *ERROR: message* indicates failure.

Example:

```
mysql> SELECT audit_log_filter_remove_user('user1@localhost');
+-----+
| audit_log_filter_remove_user('user1@localhost') |
+-----+
| OK                                             |
+-----+
```

- *audit_log_filter_set_filter(filter_name, definition)*

Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

Arguments:

- *filter_name*: A string that specifies the filter name.
- *definition*: A *JSON* value that specifies the filter definition.

Return value:

A string that indicates whether the operation succeeded. *OK* indicates success. *ERROR: message* indicates failure.

Example:

```
mysql> SET @f = '{ "filter": { "log": false } }';
mysql> SELECT audit_log_filter_set_filter('SomeFilter', @f);
+-----+
| audit_log_filter_set_filter('SomeFilter', @f) |
+-----+
| OK                                             |
+-----+
```

- `audit_log_filter_set_user(user_name, filter_name)`

Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

As a special case, the name `%` represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.

Arguments:

- `user_name`: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.
- `filter_name`: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+-----+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+-----+
| OK |
+-----+
```

- `audit_log_read([arg])`

Reads the audit log and returns a `JSON` string result. If the audit log format is not `JSON`, an error occurs.

With no argument or a `JSON` hash argument, `audit_log_read()` reads events from the audit log and returns a `JSON` string containing an array of audit events. Items in the hash argument influence how reading occurs, as described later. Each element in the returned array is an event represented as a `JSON` hash, with the exception that the last element may be a `JSON null` value to indicate no following events are available to read.

With an argument consisting of a `JSON null` value, `audit_log_read()` closes the current read sequence.

For additional details about the audit log-reading process, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

Arguments:

`arg`: The argument is optional. If omitted, the function reads events from the current position. If present, the argument can be a `JSON null` value to close the read sequence, or a `JSON` hash. Within a hash argument, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- `timestamp`, `id`: The position within the audit log of the first event to read. If the position is omitted from the argument, reading continues from the current position. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()`

argument includes either item, it must include both to completely specify a position or an error occurs.

To obtain a bookmark for the most recently written event, call `audit_log_read_bookmark()`.

- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

Return value:

If the call succeeds, the return value is a `JSON` string containing an array of audit events, or a `JSON null` value if that was passed as the argument to close the read sequence. If the call fails, the return value is `NULL` and an error occurs.

Example:

```
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----+
| audit_log_read(audit_log_read_bookmark()) |
+-----+
| [ { "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", ... } |
+-----+
mysql> SELECT audit_log_read('null');
+-----+
| audit_log_read('null') |
+-----+
| null |
+-----+
```

Notes:

Prior to MySQL 8.0.19, string return values are binary `JSON` strings. For information about converting such values to nonbinary strings, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

- `audit_log_read_bookmark()`

Returns a `JSON` string representing a bookmark for the most recently written audit log event. If the audit log format is not `JSON`, an error occurs.

The bookmark is a `JSON` hash with `timestamp` and `id` items that uniquely identify the position of an event within the audit log. It is suitable for passing to `audit_log_read()` to indicate to that function the position at which to begin reading.

For additional details about the audit log-reading process, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

Arguments:

None.

Return value:

A `JSON` string containing a bookmark for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT audit_log_read_bookmark();
+-----+
| audit_log_read_bookmark() |
+-----+
| { "timestamp": "2019-10-03 21:03:44", "id": 0 } |
+-----+
```

Notes:

Prior to MySQL 8.0.19, string return values are binary [JSON](#) strings. For information about converting such values to nonbinary strings, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

Audit Log Option and Variable Reference

Table 6.37 Audit Log Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
audit-log	Yes	Yes				
audit_log_buffer_size	Yes	Yes	Yes		Global	No
audit_log_compression	Yes	Yes	Yes		Global	No

audit_log_strategy	Yes	Yes	Yes		Global	No
Audit_log_total_size				Yes	Global	No
Audit_log_write_waits				Yes	Global	No

Audit Log Options and Variables

This section describes the command options and system variables that configure operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the [audit_log](#) plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To configure activation of the audit log plugin, use this option:

- `--audit-log[=value]`

Command-Line Format	<code>--audit-log[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON OFF FORCE FORCE_PLUS_PERMANENT

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 5.6.1, “Installing and Uninstalling Plugins”](#). For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
```

Variable_name	Value
audit_log_buffer_size	1048576
audit_log_connection_policy	ALL
audit_log_current_session	OFF
audit_log_exclude_accounts	
audit_log_file	audit.log
audit_log_filter_id	0
audit_log_flush	OFF
audit_log_format	NEW
audit_log_include_accounts	
audit_log_policy	ALL
audit_log_rotate_on_size	0
audit_log_statement_policy	ALL
audit_log_strategy	ASYNCHRONOUS

You can set any of these variables at server startup, and some of them at runtime. Those that are available only for legacy mode audit log filtering are so noted.

- `audit_log_buffer_size`

Command-Line Format	<code>--audit-log-buffer-size=#</code>
System Variable	<code>audit_log_buffer_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1048576
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520

Maximum Value (32-bit platforms)	4294967295
----------------------------------	------------

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- [audit_log_compression](#)

Command-Line Format	<code>--audit-log-compression=value</code>
System Variable	audit_log_compression
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	NONE
Valid Values	NONE GZIP

The type of compression for the audit log file. Permitted values are [NONE](#) (no compression; the default) and [GZIP](#) (GNU Zip compression). For more information, see [Compressing Audit Log Files](#).

- [audit_log_connection_policy](#)

Command-Line Format	<code>--audit-log-connection-policy=value</code>
System Variable	audit_log_connection_policy
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	ALL
Valid Values	ALL ERRORS NONE

Note

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

Value	Description
ALL	Log all connection events
ERRORS	Log only failed connection events

Value	Description
NONE	Do not log connection events

**Note**

At server startup, any explicit value given for [audit_log_connection_policy](#) may be overridden if [audit_log_policy](#) is also specified, as described in [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- [audit_log_current_session](#)

System Variable	audit_log_current_session
Scope	Global, Session
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	depends on filtering policy

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the [audit_log_include_accounts](#) and [audit_log_exclude_accounts](#) system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- [audit_log_encryption](#)

Command-Line Format	--audit-log-encryption=value
System Variable	audit_log_encryption
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	NONE
Valid Values	NONE AES

The type of encryption for the audit log file. Permitted values are [NONE](#) (no encryption; the default) and [AES](#) (AES-256-CBC cipher encryption). For more information, see [Encrypting Audit Log Files](#).

- [audit_log_exclude_accounts](#)

Command-Line Format	--audit-log-exclude-accounts=value
System Variable	audit_log_exclude_accounts
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Default Value	NULL
---------------	------

**Note**

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)).

The accounts for which events should not be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 6.4.5.7, “Audit Log Filtering”](#).

Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_file`

Command-Line Format	<code>--audit-log-file=file_name</code>
System Variable	<code>audit_log_file</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>audit.log</code>

The base name and suffix of the file to which the audit log plugin writes events. The default value is `audit.log`, regardless of logging format. To have the name suffix correspond to the format, set the name explicitly, choosing a different suffix (for example, `audit.xml` for XML format, `audit.json` for JSON format).

If the value of `audit_log_file` is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

For details about how the audit log plugin interprets the `audit_log_file` value and the rules for file renaming that occurs at plugin initialization and termination, see [Naming Conventions for Audit Log Files](#).

The audit log plugin uses the directory containing the audit log file (determined from the `audit_log_file` value) as the location to search for readable audit log files. From these log files and the current file, the plugin constructs a list of the ones that are subject to use with the audit log bookmarking and reading functions. See [Section 6.4.5.6, “Reading Audit Log Files”](#).

- `audit_log_filter_id`

System Variable	<code>audit_log_filter_id</code>
Scope	Global, Session
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer

The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- `audit_log_flush`

System Variable	<code>audit_log_flush</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0. For more information, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_format`

Command-Line Format	<code>--audit-log-format=value</code>
System Variable	<code>audit_log_format</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NEW</code>
Valid Values	<code>OLD</code> <code>NEW</code> <code>JSON</code>

The audit log file format. Permitted values are `OLD` (old-style XML), `NEW` (new-style XML; the default), and `JSON`. For details about each format, see [Section 6.4.5.4, “Audit Log File Formats”](#).

Note

For information about issues to consider when changing the log format, see [Selecting Audit Log File Format](#).

- `audit_log_include_accounts`

Command-Line Format	<code>--audit-log-include-accounts=value</code>
System Variable	<code>audit_log_include_accounts</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

**Note**

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)).

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 6.4.5.7, “Audit Log Filtering”](#).

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_password_history_keep_days`

Command-Line Format	<code>--audit-log-password-history-keep-days=#</code>
Introduced	8.0.17
System Variable	<code>audit_log_password_history_keep_days</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

The audit log plugin implements log file encryption using encryption passwords stored in the MySQL keyring (see [Encrypting Audit Log Files](#)). The plugin also implements password history, which includes password archiving and expiration (removal).

When the audit log plugin creates a new encryption password, it archives the previous password, if one exists, for later use. The `audit_log_password_history_keep_days` variable controls automatic removal of expired archived passwords. Its value indicates the number of days after which archived audit log encryption passwords are removed. The default of 0 disables password expiration: the password retention period is forever.

New audit log encryption passwords are created under these circumstances:

- During plugin initialization, if the plugin finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password.
- When the `audit_log_encryption_password_set()` function is called to set a specific password.

In each case, the plugin stores the new password in the key ring and uses it to encrypt new log files.

Removal of expired audit log encryption passwords occurs under these circumstances:

- During plugin initialization.
- When the `audit_log_encryption_password_set()` function is called.
- When the runtime value of `audit_log_password_history_keep_days` is changed from its current value to a value greater than 0. Runtime value changes occur for `SET` statements that use

the `GLOBAL` or `PERSIST` keyword, but not the `PERSIST_ONLY` keyword. `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`, but has no effect on the runtime value.

When password removal occurs, the current value of `audit_log_password_history_keep_days` determines which passwords to remove:

- If the value is 0, the plugin removes no passwords.
- If the value is `N > 0`, the plugin removes passwords more than `N` days old.

Note

Take care not to expire old passwords that are still needed to read archived encrypted log files.

If you normally leave password expiration disabled (that is, `audit_log_password_history_keep_days` has a value of 0), it is possible to perform an on-demand cleanup operation by temporarily assigning the variable a value greater than zero. For example, to expire passwords older than 365 days, do this:

```
SET GLOBAL audit_log_password_history_keep_days = 365;
SET GLOBAL audit_log_password_history_keep_days = 0;
```

Setting the runtime value of `audit_log_password_history_keep_days` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

- `audit_log_policy`

Command-Line Format	<code>--audit-log-policy=value</code>
System Variable	<code>audit_log_policy</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ALL</code>
Valid Values	<code>ALL</code> <code>LOGINS</code> <code>QUERIES</code> <code>NONE</code>

Note

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

Value	Description
<code>ALL</code>	Log all events
<code>LOGINS</code>	Log only login events
<code>QUERIES</code>	Log only query events

Value	Description
NONE	Log nothing (disable the audit stream)

`audit_log_policy` can be set only at server startup. At runtime, it is a read-only variable. Two other system variables, `audit_log_connection_policy` and `audit_log_statement_policy`, provide finer control over logging policy and can be set either at startup or at runtime. If you use `audit_log_policy` at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_read_buffer_size`

Command-Line Format	<code>--audit-log-read-buffer-size=#</code>
System Variable	<code>audit_log_read_buffer_size</code>
Scope (≥ 8.0.12)	Global, Session
Scope (8.0.11)	Global
Dynamic (≥ 8.0.12)	Yes
Dynamic (8.0.11)	No
SET_VAR Hint Applies	No
Type	Integer
Default Value (≥ 8.0.12)	32768
Default Value (8.0.11)	1048576
Minimum Value (≥ 8.0.12)	32768
Minimum Value (8.0.11)	1024
Maximum Value	4194304

The buffer size for reading from the audit log file, in bytes. The `audit_log_read()` function reads no more than this many bytes. Log file reading is supported only for JSON log format. For more information, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

As of MySQL 8.0.12, this variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`. Prior to MySQL 8.0.12, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

- `audit_log_rotate_on_size`

Command-Line Format	<code>--audit-log-rotate-on-size=#</code>
System Variable	<code>audit_log_rotate_on_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0

If the `audit_log_rotate_on_size` value is 0, the audit log plugin does not perform automatic log file rotation. Instead, use `audit_log_flush` to close and reopen the log on demand. In this case, manually rename the file externally to the server before flushing it.

If the `audit_log_rotate_on_size` value is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the

`audit_log_rotate_on_size` value, the audit log plugin closes the current log file, renames it, and opens a new log file.

For more information about audit log file rotation, see [Space Management and Name Rotation of Audit Log Files](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs, except manually.)

- `audit_log_statement_policy`

Command-Line Format	<code>--audit-log-statement-policy=value</code>
System Variable	<code>audit_log_statement_policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ALL</code>
Valid Values	<code>ALL</code> <code>ERRORS</code> <code>NONE</code>

Note

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

Value	Description
<code>ALL</code>	Log all statement events
<code>ERRORS</code>	Log only failed statement events
<code>NONE</code>	Do not log statement events

Note

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_strategy`

Command-Line Format	<code>--audit-log-strategy=value</code>
System Variable	<code>audit_log_strategy</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration

Default Value	ASYNCHRONOUS
Valid Values	ASYNCHRONOUS PERFORMANCE SEMISYNCHRONOUS SYNCHRONOUS

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

Audit Log Status Variables

If the audit log plugin is enabled, it exposes several status variables that provide operational information. These variables are available for legacy mode audit filtering and JSON mode audit filtering.

- **Audit_log_current_size**

The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

- **Audit_log_event_max_drop_size**

The size of the largest dropped event in performance logging mode. For a description of logging modes, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- **Audit_log_events**

The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#)).

- **Audit_log_events_filtered**

The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#)).

- **Audit_log_events_lost**

The number of events lost in performance logging mode because an event was larger than than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

- **Audit_log_events_written**

The number of events written to the audit log.

- **Audit_log_total_size**

The total size of events written to all audit log files. Unlike `Audit_log_current_size`, the value of `Audit_log_total_size` increases even when the log is rotated.

- **Audit_log_write_waits**

The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see [Section 6.4.5.5, “Configuring Audit Logging Characteristics”](#).

6.4.5.11 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.
- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA` are not logged.

NDB Cluster. It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.
- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.
- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

6.4.6 The Audit Message Component

As of MySQL 8.0.14, the `audit_api_message_emit` component enables applications to add their own message events to the audit log, using the `audit_api_message_emit_udf()` user-defined function.

The `audit_api_message_emit` component cooperates with all plugins of audit type. For concreteness, examples use the `audit_log` plugin described in [Section 6.4.5, “MySQL Enterprise Audit”](#).

- [Installing or Uninstalling the Audit Message Component](#)
- [Audit Message Function](#)

Installing or Uninstalling the Audit Message Component

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `audit_api_message_emit` component, use this statement:

```
INSTALL COMPONENT "file://component_audit_api_message_emit";
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `audit_api_message_emit` component, use this statement:

```
UNINSTALL COMPONENT "file://component_audit_api_message_emit";
```

`UNINSTALL COMPONENT` unloads the component, and deregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

Installing or uninstalling the `audit_api_message_emit` component installs or uninstalls the `audit_api_message_emit_udf()` function that the component implements. It is not necessary to use `CREATE FUNCTION` or `DROP FUNCTION` to do so.

Audit Message Function

This section describes the `audit_api_message_emit_udf()` user-defined function (UDF) implemented by the `audit_api_message_emit` component.

Before using the audit message function, install the audit message component according to the instructions provided at [Installing or Uninstalling the Audit Message Component](#).

- `audit_api_message_emit_udf(component, producer, message[, key, value] ...)`

Adds a message event to the audit log. Message events include component, producer, and message strings of the caller's choosing, and optionally a set of key-value pairs.

An event posted by this UDF is sent to all enabled plugins of audit type, each of which handles the event according to its own rules. If no plugin of audit type is enabled, posting the event has no effect.

Arguments:

- `component`: A string that specifies a component name.
- `producer`: A string that specifies a producer name.
- `message`: A string that specifies the event message.
- `key, value`: Events may include 0 or more key-value pairs that specify an arbitrary application-provided data map. Each `key` argument is a string that specifies a name for its immediately following `value` argument. Each `value` argument specifies a value for its immediately following `key` argument. Each `value` can be a string or numeric value, or `NULL`.

Return value:

The string `OK` to indicate success. An error occurs if the function fails.

Example:

```
mysql> SELECT audit_api_message_emit_udf('component_text',
                                         'producer_text',
                                         'message_text',
                                         'key1', 'value1',
                                         'key2', 123,
                                         'key3', NULL) AS 'Message';
+-----+
| Message |
+-----+
| OK      |
+-----+
```

Additional information:

Each audit plugin that receives an event posted by `audit_api_message_emit_udf()` logs the event in plugin-specific format. For example, the `audit_log` plugin (see [Section 6.4.5, "MySQL Enterprise Audit"](#)) logs message values as follows, depending on the log format configured by the `audit_log_format` system variable:

- JSON format (`audit_log_format=JSON`):

```
{
  ...
  "class": "message",
  "event": "user",
  ...
}
```

```
"message_data": {
  "component": "component_text",
  "producer": "producer_text",
  "message": "message_text",
  "map": {
    "key1": "value1",
    "key2": 123,
    "key3": null
  }
}
```

- New-style XML format (`audit_log_format=NEW`):

```
<AUDIT_RECORD>
...
<NAME>Message</NAME>
...
<COMMAND_CLASS>user</COMMAND_CLASS>
<COMPONENT>component_text</COMPONENT>
<PRODUCER>producer_text</PRODUCER>
<MESSAGE>message_text</MESSAGE>
<MAP>
  <ELEMENT>
    <KEY>key1</KEY>
    <VALUE>value1</VALUE>
  </ELEMENT>
  <ELEMENT>
    <KEY>key2</KEY>
    <VALUE>123</VALUE>
  </ELEMENT>
  <ELEMENT>
    <KEY>key3</KEY>
    <VALUE/>
  </ELEMENT>
</MAP>
</AUDIT_RECORD>
```

- Old-style XML format (`audit_log_format=OLD`):

```
<AUDIT_RECORD
...
NAME="Message"
...
COMMAND_CLASS="user"
COMPONENT="component_text"
PRODUCER="producer_text"
MESSAGE="message_text" />
```

Note

Message events logged in old-style XML format do not include the key-value map due to representational constraints imposed by this format.

Messages posted by `audit_api_message_emit_udf()` have an event class of `MYSQL_AUDIT_MESSAGE_CLASS` and a subclass of `MYSQL_AUDIT_MESSAGE_USER`. (Internally generated audit messages have the same class and a subclass of `MYSQL_AUDIT_MESSAGE_INTERNAL`; this subclass currently is unused.) To refer to such events in `audit_log` filtering rules, use a `class` element with a `name` value of `message`. For example:

```
{
  "filter": {
    "class": {
      "name": "message"
    }
  }
}
```

}

Should it be necessary to distinguish user-generated and internally generated message events, test the `subclass` value against `user` or `internal`.

Filtering based on the contents of the key-value map is not supported.

For information about writing filtering rules, see [Section 6.4.5.7, “Audit Log Filtering”](#).

6.4.7 MySQL Enterprise Firewall

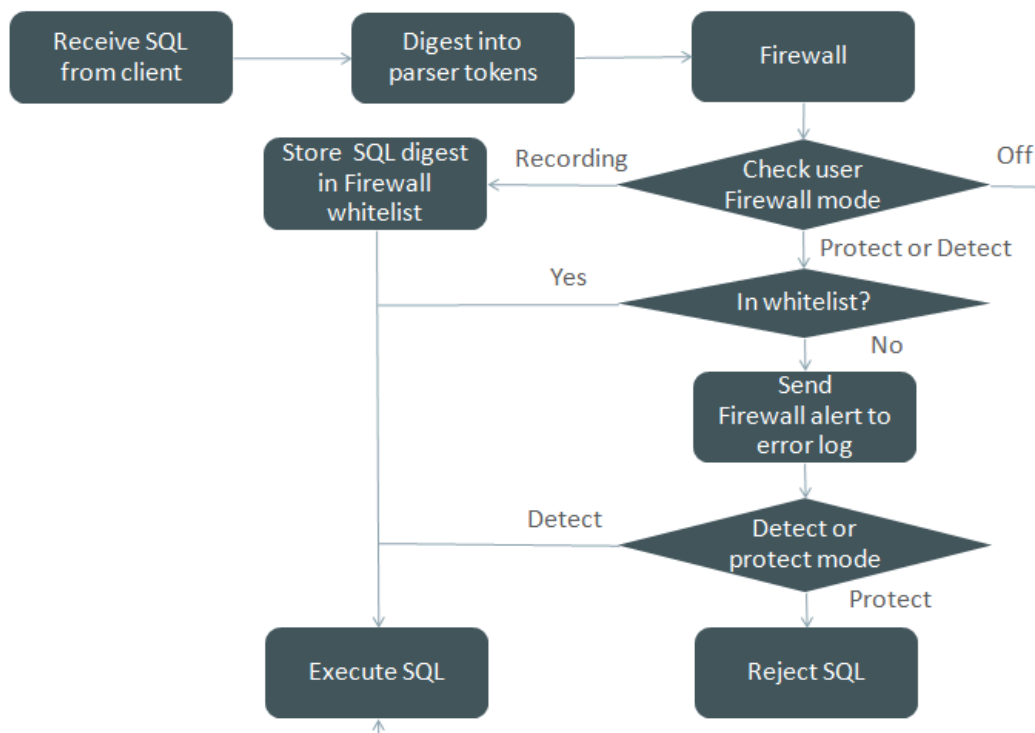

Note

MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.

Figure 6.1 MySQL Enterprise Firewall Operation

The following sections describe the elements of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its elements.

6.4.7.1 Elements of MySQL Enterprise Firewall

MySQL Enterprise Firewall is based on a plugin library that includes these elements:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on its in-memory data cache, renders a decision whether to execute or reject each statement.
- Server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement `INFORMATION_SCHEMA` tables that provide views into the in-memory firewall cache.
- Tables in the `mysql` system database provide persistent backing storage of firewall data.
- Stored procedures perform tasks such as registering firewall subjects (entities to which the firewall applies), establishing their operational mode, and managing transfer of firewall data between the in-memory cache and persistent storage.
- User-defined functions provide an SQL-level API for lower-level tasks such as synchronizing the cache with persistent storage.
- System variables enable firewall configuration and status variables provide runtime operational information.
- The `FIREWALL_ADMIN` and `FIREWALL_USER` privileges enable users to administer firewall rules for any user, and their own firewall rules, respectively.

6.4.7.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the elements described in [Section 6.4.7.1, “Elements of MySQL Enterprise Firewall”](#). Installation can be performed using a graphical interface or manually:

- On Windows, MySQL Installer includes an option to enable MySQL Enterprise Firewall for you.
- MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.
- Manual MySQL Enterprise Firewall installation involves running a script located in the `share` directory of your MySQL installation.

Important

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

Note

If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

For usage instructions, see [Section 6.4.7.3, “Using MySQL Enterprise Firewall”](#). For reference information, see [Section 6.4.7.4, “MySQL Enterprise Firewall Reference”](#).

- [Installing MySQL Enterprise Firewall](#)
- [Uninstalling MySQL Enterprise Firewall](#)

Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use MySQL Installer to install MySQL Enterprise Firewall, as shown in [Figure 6.2, “MySQL Enterprise Firewall Installation on Windows”](#). Check the **Enable MySQL**

Enterprise Firewall check box. (**Open Firewall port for network access** has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)

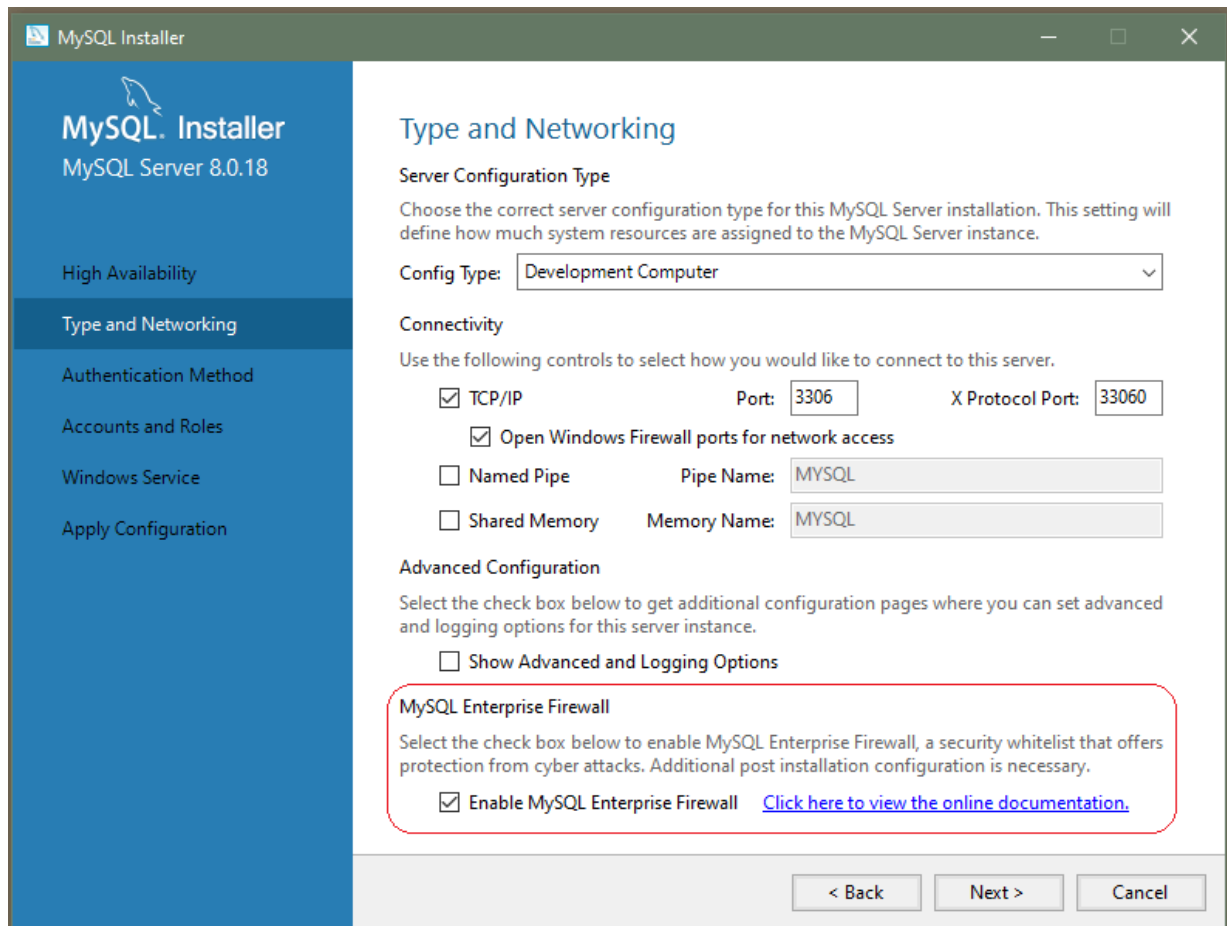

Important

There is an issue for MySQL 8.0.19 installed using MySQL Installer that prevents the server from starting if MySQL Enterprise Firewall is selected during the server configuration steps. If the server startup operation fails, click **Cancel** to end the configuration process and return to the dashboard. You must uninstall the server.

The workaround is to run MySQL Installer without MySQL Enterprise Firewall selected. (That is, do not select the **Enable MySQL Enterprise Firewall** check box.) Then install MySQL Enterprise Firewall afterward using the instructions for manual installation later in this section. This problem is corrected in MySQL 8.0.20.

Figure 6.2 MySQL Enterprise Firewall Installation on Windows

To install MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see [MySQL Enterprise Firewall Interface](#).

To install MySQL Enterprise Firewall manually, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `win_install_firewall.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.

- `linux_install_firewall.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

The installation script creates stored procedures in the default database, so choose a database to use. Then run the script as follows, naming the chosen database on the command line. The example here uses the `mysql` system database and the Linux installation script. Make the appropriate substitutions for your system.

```
shell> mysql -u root -p mysql < linux_install_firewall.sql
Enter password: (enter root password here)
```

Note

To use MySQL Enterprise Firewall in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statements in the script are not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statements from the installation script and execute them manually.
2. On the source node, run the installation script as described previously.

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| mysql_firewall_mode | ON    |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see [MySQL Enterprise Firewall Interface](#).

To uninstall MySQL Enterprise Firewall manually, execute the following statements. Statements use `IF EXISTS` because, depending on the previously installed firewall version, some objects might not exist.

```
DROP TABLE IF EXISTS mysql.firewall_users;
DROP TABLE IF EXISTS mysql.firewall_whitelist;

UNINSTALL PLUGIN MYSQL_FIREWALL;
UNINSTALL PLUGIN MYSQL_FIREWALL_USERS;
UNINSTALL PLUGIN MYSQL_FIREWALL_WHITELIST;

DROP FUNCTION IF EXISTS mysql_firewall_flush_status;
DROP FUNCTION IF EXISTS normalize_statement;
DROP FUNCTION IF EXISTS read_firewall_users;

6.4.7.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in [Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#).

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See [MySQL Enterprise Firewall Interface](#).

- [Enabling or Disabling the Firewall](#)
- [Assigning Firewall Privileges](#)
- [Firewall Operational Concepts](#)
- [Registering Firewall Account Subjects](#)
- [Monitoring the Firewall](#)

Enabling or Disabling the Firewall

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

After modifying `my.cnf`, restart the server to cause the new setting to take effect.

Alternatively, to set and persist the firewall setting at runtime:

```
SET PERSIST mysql_firewall_mode = OFF;
SET PERSIST mysql_firewall_mode = ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

Assigning Firewall Privileges

With the firewall installed, grant the appropriate privileges to the MySQL account or accounts that will administer it. The privileges depend on which firewall operations an account should be permitted to perform:

- Grant the `FIREWALL_ADMIN` privilege to any account that should have full administrative firewall access. (Some user-defined procedures can be invoked by accounts that have `FIREWALL_ADMIN` or the deprecated `SUPER` privilege, as indicated in individual UDF descriptions.)
- Grant the `FIREWALL_USER` privilege to any account that should have administrative access only for its own firewall rules.
- Grant the `EXECUTE` privilege for the firewall stored procedures in the `mysql` system database. These may invoke UDFs, so stored procedure access also requires the privileges indicated earlier that are needed for those UDFs.

Note

The `FIREWALL_ADMIN` and `FIREWALL_USER` privileges can be granted only while the firewall is installed because the firewall component defines those privileges.

Firewall Operational Concepts

The MySQL server permits clients to connect and receives from them SQL statements to be executed. The server passes to the firewall each incoming statement that does not immediately fail with a syntax error. Based on whether the firewall accepts the statement, the server executes it or returns an error to the client.

Firewall statement evaluation proceeds according to these principles:

- A subject registry lists the entities to which firewall protection can be applied. A given subject corresponds to a client account.
- Each subject has rules that define which statements are acceptable to it. This set of rules forms the subject allowlist.
- For each client connection, the firewall determines which subject allowlist applies, and accepts only statements the allowlist permits. (If the client matches no subject, the firewall ignores it and accepts all statements.)
- Each subject has a current operational mode. Modes enable the allowlist to be trained, used for restricting statement execution or intrusion detection, or disabled.

The firewall supports account-based subjects such that each subject matches a particular client account (client user name and host name combination). For example, you can register one account subject for which the allowlist applies to connections originating from `admin@localhost` and another account subject for which the allowlist applies to connections originating from `myapp@apphost.example.com`.

By default, the firewall accepts all statements and has no effect on which statements MySQL accounts can execute. To apply firewall protective capabilities, you must take explicit action:

- Register one or more subjects with the firewall. (Required because the firewall ignores clients that match no subject.)
- Train the firewall to establish the allowlist for each subject; that is, the types of statements the subject permits clients to execute.
- Tell the firewall to protect each subject for which it has been trained; that is, to match incoming statements against the appropriate allowlist when clients connect.

Statement matching performed by the firewall does not use SQL statements as received from clients. Instead, the server converts incoming statements to normalized digest form and firewall operation uses these digests. The benefit of statement normalization is that it enables similar statements to be grouped and recognized using a single pattern. For example, these statements are distinct from each other:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
select first_name, last_name from customer where customer_id = 99;
SELECT first_name, last_name FROM customer WHERE customer_id = 143;
```

But all of them have the same normalized digest form:

```
SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?
```

By using normalization, the firewall can store digests in allowlists that each match many different statements received from clients. For more information about normalization and digests, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

Each subject registered with the firewall has its own operational mode, chosen from these values:

- **OFF**: This mode disables the subject. The firewall considers it inactive and ignores it.
- **RECORDING**: This is the firewall training mode. In **RECORDING** mode, incoming statements received from a client that matches the subject are considered acceptable for the subject and become part of its “fingerprint.” The firewall records the normalized digest form of each statement to learn the acceptable statement patterns for the subject. Each pattern is a rule, and the union of the rules is the subject allowlist.
- **PROTECTING**: This mode protects the subject by matching incoming statements against its allowlist, accepting only statements that match and rejecting those that do not. After training the

subject in **RECORDING** mode, switch it to **PROTECTING** mode to harden MySQL against access by statements that deviate from the allowlist.

- **DETECTING**: This mode detects but does not block intrusions (statements that are suspicious because they match nothing in the subject allowlist). In **DETECTING** mode, the firewall writes suspicious statements to the error log but accepts them without denying access.

When any of the preceding mode values is assigned to a subject, the firewall stores the mode as part of the current subject information. Firewall mode-setting operations also permit a mode value of **RESET**, but this value is not stored. Setting a subject to **RESET** mode causes the firewall to delete all rules for the subject and set its mode to **OFF**.

Registering Firewall Account Subjects

MySQL Enterprise Firewall enables subjects to be registered and protected that correspond to individual accounts.

MySQL authenticates each client session for a specific user name and host name combination. This combination is the *session account*. The firewall matches the session account against registered account subjects to determine which subject applies to handling incoming statements from the session:

- The firewall ignores inactive subjects (subjects with a mode of **OFF**).
- The session account matches the active account subject having the same user and host, if there is one. There is at most one such account subject.

In other words, at most one active account subject is applicable to a given session, for which the firewall handles each incoming statement as follows:

- If there is no applicable subject, there are no restrictions. The firewall accepts the statement.
- If there is an applicable subject, its mode determines statement handling:
 - In **RECORDING** mode, the firewall adds the statement to the subject allowlist rules and accepts it.
 - In **PROTECTING** mode, the firewall compares the statement to the rules in the subject allowlist. The firewall accepts the statement if there is a match, and rejects it otherwise. If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log.
 - In **DETECTING** mode, the firewall detects intrusions without denying access. The firewall accepts the statement, but also matches it to the subject allowlist, as in **PROTECTING** mode. If the statement is suspicious (nonmatching), the firewall writes it to the error log.

To protect a MySQL account using a firewall account subject, follow these steps:

1. Register the account subject and put it in **RECORDING** mode.
2. Connect to the MySQL server using the account and execute statements to be learned. This trains the corresponding firewall account subject and establishes the rules that form the subject allowlist.
3. Switch the account subject to **PROTECTING** mode. When a client connects to the server using the account, the account subject allowlist restricts statement execution.
4. Should additional training be necessary, switch the account subject to **RECORDING** mode again, update its allowlist with new statement patterns, then switch it back to **PROTECTING** mode.

By maintaining an allowlist per registered account subject, the firewall enables implementation of protection strategies such as these:

- If an application has unique protection requirements, configure it to use an account not used for any other purpose and set up a corresponding firewall account subject.

- If related applications share protection requirements, configure them all to use the same account (and thus the same account subject).

When referring to accounts for use with the firewall, observe these guidelines:

- Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string (`'user_name@host_name'`). This differs from the usual MySQL convention for statements such as `CREATE USER` and `GRANT`, for which you quote the user and host parts of an account name separately (`'user_name'@'host_name'`).

The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded `@` characters in the user name.

- The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering account subjects, do not use wildcard characters or netmasks:
 - Suppose that an account named `me@%.example.org` exists and a client uses it to connect to the server from the host `abc.example.org`.
 - The account name contains a `%` wildcard character, but the server authenticates the client as having a user name of `me` and host name of `abc.example.com`, and that is what the firewall sees.
 - Consequently, the account to use for firewall operations is `me@abc.example.org`, not `me@%.example.org`.

The following example shows how to register an account subject with the firewall, teach the firewall the acceptable statements for that subject, and use the subject to protect the account against execution of unacceptable statements. The example account, `fwuser@localhost`, is suitable for use by an application that accesses tables in the `sakila` database (available at <https://dev.mysql.com/doc/index-other.html>).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by the `fwuser@localhost` account corresponding to the account subject registered with the firewall. The default database for statements executed using the account should be `sakila`. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the account to be protected (choose an appropriate password) and grant it privileges for the `sakila` database:

```
CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
```

2. Register an account subject with the firewall and place it in `RECORDING` (training) mode using the `sp_set_firewall_mode()` stored procedure:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
```

During the course of its execution, the stored procedure invokes firewall user-defined functions, which may produce output of their own.

3. To use the registered account subject, connect to the server as `fwuser` from the server host so that the firewall sees a session account of `fwuser@localhost`. Then use the account to execute some statements that are legitimate for the account:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
SELECT get_customer_balance(1, NOW());
```

Because the account subject is in `RECORDING` mode, the firewall records the normalized digest form of the statements as rules in the subject allowlist.

**Note**

Until the `fwuser@localhost` account subject receives statements in `RECORDING` mode, its allowlist is empty, which is equivalent to “deny all.” No statement can match an empty allowlist, which has these implications:

- The account subject cannot be switched to `PROTECTING` mode because the firewall would reject every statement, effectively prohibiting the account from executing any statement.
- The account subject can be switched to `DETECTING` mode and the firewall will accept every statement but log it as suspicious.

4. At this point, the account subject and allowlist information is cached and can be seen in the firewall `INFORMATION_SCHEMA` tables:

```
mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
      WHERE USERHOST = 'fwuser@localhost';
+-----+
| MODE |
+-----+
| RECORDING |
+-----+
mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
      WHERE USERHOST = 'fwuser@localhost';
+-----+
| RULE |
+-----+
| SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ? |
| SELECT `get_customer_balance` ( ? , NOW ( ) ) |
| UPDATE `rental` SET `return_date` = NOW ( ) WHERE `rental_id` = ? |
| SELECT @@`version_comment` LIMIT ? |
+-----+
```

**Note**

The `@@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server using the account corresponding to the account subject.

**Important**

Train the firewall under conditions matching application use. For example, a given MySQL connector might send statements to the server at the beginning of a connection to determine server characteristics and capabilities. If an application normally is used through that connector, train the firewall that way, too. That enables those initial statements to become part of the allowlist for the account subject associated with the application.

5. Invoke `sp_set_firewall_mode()` again, this time switching the account subject to `PROTECTING` mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

**Important**

Switching the account subject out of `RECORDING` mode synchronizes its firewall cache data to the `mysql` system database tables that provide persistent underlying storage. If you do not switch the mode for a subject that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted.

6. Test the account against the firewall by using it to execute some acceptable and unacceptable statements. The firewall matches each statement against the account subject allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+-----+-----+
| first_name | last_name |
+-----+-----+
| ANN       | EVANS     |
+-----+-----+
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

- If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in whitelist.
Statement: TRUNCATE TABLE `mysql`.`slow_log` '
```

You can use these log messages in your efforts to identify the source of attacks.

The firewall account subject now is trained for the `fwuser@localhost` account and is protecting it against statements not matched by the subject allowlist.

It is also possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the account subject in `DETECTING` mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

Then, using the account, execute a statement that does not match the account subject allowlist. In `DETECTING` mode, the firewall permits the nonmatching statement to execute:

```
mysql> SHOW TABLES LIKE 'customer%';
+-----+-----+
| Tables_in_sakila (customer%) |
+-----+-----+
| customer                     |
| customer_list                |
+-----+-----+
```

In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in whitelist.
Statement: SHOW TABLES LIKE ? '
```

Note

`DETECTING` mode writes messages as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that error-logging verbosity is sufficient to log information messages. For example, if you are using priority-based log filtering, as described in [Section 5.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#), set the `log_error_verbosity` system variable to a value of 3.

To stop protecting an account, change its subject mode to `OFF`:

```
CALL mysql.sp_set_firewall_mode(user, 'OFF');
```

To forget all training for a subject and disable firewall protection for it, reset it:

```
CALL mysql.sp_set_firewall_mode(user, 'RESET');
```

A reset operation causes the firewall to delete all rules for the subject and set its mode to `OFF`.

Monitoring the Firewall

To assess firewall activity, examine its status variables. For example, after performing the procedure shown earlier to train and protect the `fwuser@localhost` account, the variables look like this:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Firewall_access_denied | 3 |
| Firewall_access_granted | 4 |
| Firewall_access_suspicious | 1 |
| Firewall_cached_entries | 4 |
+-----+-----+
```

The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three times you connected using the registered account, plus the `SHOW TABLES` statement that was not blocked in `DETECTING` mode.

6.4.7.4 MySQL Enterprise Firewall Reference

The following sections provide a reference to MySQL Enterprise Firewall elements:

- [MySQL Enterprise Firewall Tables](#)
- [MySQL Enterprise Firewall Stored Procedures](#)
- [MySQL Enterprise Firewall User-Defined Functions](#)
- [MySQL Enterprise Firewall System Variables](#)
- [MySQL Enterprise Firewall Status Variables](#)

MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains per-account allowlist information using tables in the `mysql` system database for persistent storage and `INFORMATION_SCHEMA` tables to provide views into in-memory cached data. When enabled, the firewall bases operational decisions on the cached data.

Each `mysql` system database table is accessible only by accounts that have the `SELECT` privilege for it. The `INFORMATION_SCHEMA` tables are accessible by anyone.

The `mysql.firewall_users` table lists registered firewall accounts and their operational modes. The table has the following columns (with the corresponding `INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS` table having similar but not necessarily identical columns):

- `USERHOST`

An account registered with the firewall. Each account has the format `user_name@host_name`.

- `MODE`

The current firewall operational mode for the account. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see [Firewall Operational Concepts](#).

The `mysql.firewall_whitelist` table associates registered firewall accounts and their allowlist rules. The table has the following columns (with the corresponding `INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST` table having similar but not necessarily identical columns):

- `USERHOST`

An account registered with the firewall. Each account has the format `user_name@host_name`.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the account. An account allowlist is the union of its rules.

- `ID`

An integer column that is a primary key for the table. This column was added in MySQL 8.0.12.

MySQL Enterprise Firewall Stored Procedures

MySQL Enterprise Firewall stored procedures perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage. These procedures invoke user-defined functions (UDFs) that provide an SQL-level API for lower-level tasks.

To invoke a firewall stored procedure when the default database is not the `mysql` system database that contains the procedure, qualify the procedure name with the database name. For example:

```
CALL mysql.sp_set_firewall_mode(user, mode);
```

The following list describes each firewall stored procedure:

- `sp_reload_firewall_rules(user)`

This stored procedure provides control over firewall operation for individual accounts. The procedure uses firewall UDFs to reload the in-memory rules for an account from the rules stored in the `mysql.firewall_whitelist` table.

Arguments:

- `user`: The affected account, as a string in `user_name@host_name` format.

Example:

```
CALL mysql.sp_reload_firewall_rules('fwuser@localhost');
```

Warning

This procedure clears the account in-memory allowlist rules before reloading them from persistent storage, and sets the account mode to `OFF`. If the account mode was not `OFF` prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the account was in `PROTECTING` mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to `PROTECTING` again explicitly.

- `sp_set_firewall_mode(user, mode)`

This stored procedure establishes the operational mode for a firewall account, after registering the account with the firewall if it was not already registered. The procedure also invokes firewall UDFs as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the `mysql_firewall_mode` system variable is `OFF`, although setting the mode for an account has no operational effect until the firewall is enabled.

Arguments:

- `user`: The affected account, as a string in `user_name@host_name` format.
- `mode`: The operational mode for the account, as a string. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see [Firewall Operational Concepts](#).

Switching an account to any mode but `RECORDING` synchronizes its firewall cache data to the `mysql` system database tables that provide persistent underlying storage. Switching the mode from `OFF` to `RECORDING` reloads the allowlist from the `mysql.firewall_whitelist` table into the cache.

If an account has an empty allowlist, its mode cannot be set to `PROTECTING` because the firewall would reject every statement, effectively prohibiting the account from executing statements. In response to such a mode-setting attempt, the firewall produces a diagnostic message that is returned as a result set rather than as an SQL error:

```
mysql> CALL mysql.sp_set_firewall_mode('a@b','PROTECTING');
+-----+
| set_firewall_mode(arg_userhost, arg_mode) |
+-----+
| ERROR: PROTECTING mode requested for a@b but the whitelist is empty. |
+-----+
```

MySQL Enterprise Firewall User-Defined Functions

MySQL Enterprise Firewall user-defined functions (UDFs) provide an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables. Under normal operation, these UDFs are invoked by the stored procedures, not directly by users.

- [Firewall Account-Management User-Defined Functions](#)
- [Firewall Miscellaneous User-Defined Functions](#)

Firewall Account-Management User-Defined Functions

These UDFs perform per-account firewall-management operations:

- `read_firewall_users(user, mode)`

This aggregate UDF updates the firewall account cache through a `SELECT` statement on the `mysql.firewall_users` table. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
FROM mysql.firewall_users;
```

- `read_firewall_whitelist(user, rule)`

This aggregate UDF updates the recorded-statement cache for the named account through a `SELECT` statement on the `mysql.firewall_whitelist` table. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT read_firewall_whitelist('fwuser@localhost', fw.rule)
FROM mysql.firewall_whitelist AS fw
WHERE USERHOST = 'fwuser@localhost';
```

- `set_firewall_mode(user, mode)`

This UDF manages the account cache and establishes the account operational mode. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
```

Firewall Miscellaneous User-Defined Functions

These UDFs perform miscellaneous firewall operations:

- `mysql_firewall_flush_status()`

This UDF resets several firewall status variables to 0:

- `Firewall_access_denied`
- `Firewall_access_granted`
- `Firewall_access_suspicious`

This UDF requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT mysql_firewall_flush_status();
```

- `normalize_statement(stmt)`

This UDF normalizes an SQL statement into the digest form used for allowlist rules. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
```

MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see [Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)).

- `mysql_firewall_mode`

Command-Line Format	<code>--mysql-firewall-mode[={OFF ON}]</code>
System Variable	<code>mysql_firewall_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- `mysql_firewall_trace`

Command-Line Format	<code>--mysql-firewall-trace[={OFF ON}]</code>
System Variable	<code>mysql_firewall_trace</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the MySQL Enterprise Firewall trace is enabled or disabled (the default). When `mysql_firewall_trace` is enabled, for `PROTECTING` mode, the firewall writes rejected statements to the error log.

MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see [Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)). Firewall status variables are set to 0 whenever the `MYSQLE_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` UDF (see [MySQL Enterprise Firewall User-Defined Functions](#)).

- `Firewall_access_denied`

The number of statements rejected by MySQL Enterprise Firewall.

- `Firewall_access_granted`

The number of statements accepted by MySQL Enterprise Firewall.

- `Firewall_access_suspicious`

The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in `DETECTING` mode.

- `Firewall_cached_entries`

The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

6.5 MySQL Enterprise Data Masking and De-Identification

Note

MySQL Enterprise Data Masking and De-Identification is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

As of MySQL 8.0.13, MySQL Enterprise Edition provides data masking and de-identification capabilities:

- Transformation of existing data to mask it and remove identifying characteristics, such as changing all digits of a credit card number but the last four to 'X' characters.
- Generation of random data, such as email addresses and payment card numbers.

The way that applications use these capabilities depends on the purpose for which the data will be used and who will access it:

- Applications that use sensitive data may protect it by performing data masking and permitting use of partially masked data for client identification. Example: A call center may ask for clients to provide their last four Social Security number digits.
- Applications that require properly formatted data, but not necessarily the original data, can synthesize sample data. Example: An application developer who is testing data validators but has no access to original data may synthesize random data with the same format.

Example 1:

Medical research facilities can hold patient data that comprises a mix of personal and medical data. This may include genetic sequences (long strings), test results stored in JSON format, and other data types. Although the data may be used mostly by automated analysis software, access to genome data or test results of particular patients is still possible. In such cases, data masking should be used to render this information not personally identifiable.

Example 2:

A credit card processor company provides a set of services using sensitive data, such as:

- Processing a large number of financial transactions per second.
- Storing a large amount of transaction-related data.
- Protecting transaction-related data with strict requirements for personal data.
- Handling client complaints about transactions using reversible or partially masked data.

A typical transaction may include many types of sensitive information, including:

- Credit card number.
- Transaction type and amount.
- Merchant type.
- Transaction cryptogram (to confirm transaction legitimacy).
- Geolocation of GPS-equipped terminal (for fraud detection).

Those types of information may then be joined within a bank or other card-issuing financial institution with client personal data, such as:

- Full client name (either person or company).
- Address.
- Date of birth.
- Social Security number.
- Email address.
- Phone number.

Various employee roles within both the card processing company and the financial institution require access to that data. Some of these roles may require access only to masked data. Other roles may require access to the original data on a case-to-case basis, which is recorded in audit logs.

Masking and de-identification are core to regulatory compliance, so MySQL Enterprise Data Masking and De-Identification can help application developers satisfy privacy requirements:

- PCI – DSS: Payment Card Data.

- HIPAA: Privacy of Health Data, Health Information Technology for Economic and Clinical Health Act (HITECH Act).
- EU General Data Protection Directive (GDPR): Protection of Personal Data.
- Data Protection Act (UK): Protection of Personal Data.
- Sarbanes Oxley, GLBA, The USA Patriot Act, Identity Theft and Assumption Deterrence Act of 1998.
- FERPA – Student Data, NASD, CA SB1386 and AB 1950, State Data Protection Laws, Basel II.

The following sections describe the elements of MySQL Enterprise Data Masking and De-Identification, discuss how to install and use it, and provide reference information for its elements.

6.5.1 MySQL Enterprise Data Masking and De-Identification Elements

MySQL Enterprise Data Masking and De-Identification is based on a plugin library that implements these elements:

- A server-side plugin named `data_masking`.
- A set of user-defined functions (UDFs) provides an SQL-level API for performing masking and de-identification operations. Some of these functions require the `SUPER` privilege.

6.5.2 Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification

This section describes how to install or uninstall MySQL Enterprise Data Masking and De-Identification, which is implemented as a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#), and [Section 5.7.1, “Installing and Uninstalling User-Defined Functions”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `data_masking`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the MySQL Enterprise Data Masking and De-Identification plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN data_masking SONAME 'data_masking.so';
CREATE FUNCTION gen_blacklist RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_drop RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_load RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_range RETURNS INTEGER
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_email RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_ssn RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_us_phone RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_inner RETURNS STRING
```

```
SONAME 'data_masking.so';
CREATE FUNCTION mask_outer RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan_relaxed RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_ssn RETURNS STRING
  SONAME 'data_masking.so';
```

If the plugin and UDFs are used on a source replication server, install them on all replica servers as well to avoid replication issues.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN data_masking;
DROP FUNCTION gen_blacklist;
DROP FUNCTION gen_dictionary;
DROP FUNCTION gen_dictionary_drop;
DROP FUNCTION gen_dictionary_load;
DROP FUNCTION gen_range;
DROP FUNCTION gen_rnd_email;
DROP FUNCTION gen_rnd_pan;
DROP FUNCTION gen_rnd_ssn;
DROP FUNCTION gen_rnd_us_phone;
DROP FUNCTION mask_inner;
DROP FUNCTION mask_outer;
DROP FUNCTION mask_pan;
DROP FUNCTION mask_pan_relaxed;
DROP FUNCTION mask_ssn;
```

6.5.3 Using MySQL Enterprise Data Masking and De-Identification

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at [Section 6.5.2, “Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification”](#).

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see [Section 6.5.5, “MySQL Enterprise Data Masking and De-Identification User-Defined Function Descriptions”](#). This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:

- [Masking Data to Remove Identifying Characteristics](#)
- [Generating Random Data with Specific Characteristics](#)
- [Generating Random Data Using Dictionaries](#)
- [Using Masked Data for Customer Identification](#)
- [Creating Views that Display Masked Data](#)

Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

General-Purpose Masking Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```
mysql> SELECT mask_inner('This is a string', 5, 1);
+-----+
| mask_inner('This is a string', 5, 1) |
+-----+
| This XXXXXXXXXXg                     |
+-----+
mysql> SELECT mask_inner('This is a string', 1, 5);
+-----+
| mask_inner('This is a string', 1, 5) |
+-----+
| TXXXXXXXXXXtring                     |
+-----+
```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

```
mysql> SELECT mask_outer('This is a string', 5, 1);
+-----+
| mask_outer('This is a string', 5, 1) |
+-----+
| XXXXXis a strinX                     |
+-----+
mysql> SELECT mask_outer('This is a string', 1, 5);
+-----+
| mask_outer('This is a string', 1, 5) |
+-----+
| Xhis is a sXXXXX                     |
+-----+
```

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

```
mysql> SELECT mask_inner('This is a string', 5, 1, '*');
+-----+
| mask_inner('This is a string', 5, 1, '*') |
+-----+
| This *****g                         |
+-----+
mysql> SELECT mask_outer('This is a string', 5, 1, '#');
+-----+
| mask_outer('This is a string', 5, 1, '#') |
+-----+
| #####is a strin#                     |
+-----+
```

Special-Purpose Masking Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

Note

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see [Generating Random Data with Specific Characteristics](#).

Payment card Primary Account Number masking. Masking functions provide strict and relaxed masking of Primary Account Numbers.

- `mask_pan()` masks all but the last four digits of the number:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
```

```
+-----+
| XXXXXXXXXXXX2461 |
+-----+
```

- `mask_pan_relaxed()` is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

```
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 770630XXXXXX0807 |
+-----+
```

US Social Security number masking. `mask_ssn()` masks all but the last four digits of the number:

```
mysql> SELECT mask_ssn(gen_rnd_ssn());
+-----+
| mask_ssn(gen_rnd_ssn()) |
+-----+
| XXX-XX-1723 |
+-----+
```

Generating Random Data with Specific Characteristics

Several functions generate random values. These values can be used for testing, simulation, and so forth.

`gen_range()` returns a random integer selected from a given range:

```
mysql> SELECT gen_range(1, 10);
+-----+
| gen_range(1, 10) |
+-----+
| 6 |
+-----+
```

`gen_rnd_email()` returns a random email address in the `example.com` domain:

```
mysql> SELECT gen_rnd_email();
+-----+
| gen_rnd_email() |
+-----+
| ayxnq.xmkpvvy@example.com |
+-----+
```

`gen_rnd_pan()` returns a random payment card Primary Account Number:

```
mysql> SELECT gen_rnd_pan();
```

(The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)

`gen_rnd_ssn()` returns a random US Social Security number with the first and second parts each chosen from a range not used for legitimate numbers:

```
mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 912-45-1615 |
+-----+
```

`gen_rnd_us_phone()` returns a random US phone number in the 555 area code not used for legitimate numbers:

```
mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+
| 1-555-747-5627     |
+-----+
```

Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values. To use a dictionary, it must first be loaded from a file and given a name. Each loaded dictionary becomes part of the dictionary registry. Items then can be selected from registered dictionaries and used as random values or as replacements for other values.

A valid dictionary file has these characteristics:

- The file contents are plain text, one term per line.
- Empty lines are ignored.
- The file must contain at least one term.

Suppose that a file named `de_cities.txt` contains these city names in Germany:

```
Berlin
Munich
Bremen
```

Also suppose that a file named `us_cities.txt` contains these city names in the United States:

```
Chicago
Houston
Phoenix
El Paso
Detroit
```

Assume that the `secure_file_priv` system variable is set to `/usr/local/mysql/mysql-files`. In that case, copy the dictionary files to that directory so that the MySQL server can access them. Then use `gen_dictionary_load()` to load the dictionaries into the dictionary registry and assign them names:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities') |
+-----+
| Dictionary load success                                                         |
+-----+
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities') |
+-----+
| Dictionary load success                                                         |
+-----+
```

To select a random term from a dictionary, use `gen_dictionary()`:

```
mysql> SELECT gen_dictionary('DE_Cities');
+-----+
| gen_dictionary('DE_Cities') |
+-----+
| Berlin                      |
+-----+
mysql> SELECT gen_dictionary('US_Cities');
+-----+
| gen_dictionary('US_Cities') |
+-----+
```

```
| Phoenix |
+-----+
```

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Detroit |
+-----+
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Bremen |
+-----+
```

The `gen_blacklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_blacklist()` like this:

```
mysql> SELECT gen_blacklist('Munich', 'DE_Cities', 'US_Cities');
+-----+
| gen_blacklist('Munich', 'DE_Cities', 'US_Cities') |
+-----+
| Houston |
+-----+
mysql> SELECT gen_blacklist('El Paso', 'US_Cities', 'DE_Cities');
+-----+
| gen_blacklist('El Paso', 'US_Cities', 'DE_Cities') |
+-----+
| Bremen |
+-----+
```

If the term to replace is not in the first dictionary, `gen_blacklist()` returns it unchanged:

```
mysql> SELECT gen_blacklist('Moscow', 'DE_Cities', 'US_Cities');
+-----+
| gen_blacklist('Moscow', 'DE_Cities', 'US_Cities') |
+-----+
| Moscow |
+-----+
```

Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.

Suppose that a `customer` table containing customer records has these columns:

- `id`: Customer ID number.
- `first_name`: Customer first name.
- `last_name`: Customer last name.
- `ssn`: Customer Social Security number.

For example, the table might be defined as follows:

```
CREATE TABLE customer
(
```

```

id          BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
first_name  VARCHAR(40),
last_name   VARCHAR(40),
ssn         VARCHAR(11)
);

```

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```

mysql> SELECT id, ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | ssn          |
+-----+-----+
| 786 | 906-39-0007 |
+-----+-----+

```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```

mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | masked_ssn    |
+-----+-----+
| 786 | XXX-XX-0007 |
+-----+-----+

```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a UDF, and an error occurs. Converting the value to a binary string ensures that the UDF sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```

CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;

```

Then the query to look up a customer becomes simpler but still returns masked data:

```

mysql> SELECT id, masked_ssn
mysql> FROM masked_customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | masked_ssn    |
+-----+-----+
| 786 | XXX-XX-0007 |
+-----+-----+

```

6.5.4 MySQL Enterprise Data Masking and De-Identification User-Defined Function Reference

MySQL Enterprise Data Masking and De-Identification User-Defined Functions A reference that lists MySQL Enterprise Data Masking and De-Identification user-defined functions.

6.5.5 MySQL Enterprise Data Masking and De-Identification User-Defined Function Descriptions

The MySQL Enterprise Data Masking and De-Identification plugin library includes several user-defined functions (UDFs), which may be grouped into these categories:

- [Data Masking Functions](#)
- [Random Data Generation Functions](#)
- [Random Data Dictionary-Based Functions](#)

As of MySQL 8.0.19, these UDFs support the single-byte `latin1` character set for string arguments and return values. Prior to MySQL 8.0.19, the UDFs treat string arguments as binary strings (which means they do not distinguish lettercase), and string return values are binary strings. You can see the difference in return value character set as follows:

MySQL 8.0.19 and higher:

```
mysql> SELECT CHARSET(gen_rnd_email());
+-----+
| CHARSET(gen_rnd_email()) |
+-----+
| latin1                    |
+-----+
```

Prior to MySQL 8.0.19:

```
mysql> SELECT CHARSET(gen_rnd_email());
+-----+
| CHARSET(gen_rnd_email()) |
+-----+
| binary                    |
+-----+
```

For any version, if a string return value should be in a different character set, convert it. The following example shows how to convert the result of `gen_rnd_email()` to the `utf8mb4` character set:

```
SET @email = CONVERT(gen_rnd_email() USING utf8mb4);
```

It may also be necessary to convert string arguments, as illustrated in [Using Masked Data for Customer Identification](#).

Data Masking Functions

Each function in this section performs a masking operation on its string argument and returns the masked result.

- `mask_inner(str, margin1, margin2 [, mask_char])`

Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

Arguments:

- `str`: The string to mask.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.

- *margin2*: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
- *mask_char*: (Optional) The single character to use for masking. The default is 'X' if *mask_char* is not given.

The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or `NULL` if either margin is negative.

If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

Example:

```
mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
+-----+-----+
| mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
+-----+-----+
| aXXef                    | Xbcdef                    |
+-----+-----+
mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
+-----+-----+
| mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
+-----+-----+
| a***ef                        | #bcdef                      |
+-----+-----+
```

- `mask_outer(str, margin1, margin2 [, mask_char])`

Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

Arguments:

- *str*: The string to mask.
- *margin1*: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
- *margin2*: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.
- *mask_char*: (Optional) The single character to use for masking. The default is 'X' if *mask_char* is not given.

The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or `NULL` if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

Example:

```
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef',0, 5);
+-----+-----+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef',0, 5) |
+-----+-----+
```

```

| XbcdXX | aXXXXX |
+-----+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef',0, 5, '#');
+-----+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef',0, 5, '#') |
+-----+
| *bcd** | a##### |
+-----+

```

- `mask_pan(str)`

Masks a payment card Primary Account Number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

- `str`: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```

mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXXX9102 |
+-----+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+-----+
| mask_pan(gen_rnd_pan(19)) |
+-----+
| XXXXXXXXXXXXXXX8268 |
+-----+
mysql> SELECT mask_pan('a*Z');
+-----+
| mask_pan('a*Z') |
+-----+
| a*Z |
+-----+

```

- `mask_pan_relaxed(str)`

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer.

Arguments:

- `str`: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```

mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 551279XXXXXX3108 |
+-----+

```

```

+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 462634XXXXXXXXX6739 |
+-----+
mysql> SELECT mask_pan_relaxed('a*Z');
+-----+
| mask_pan_relaxed('a*Z') |
+-----+
| a*Z |
+-----+

```

- `mask_ssn(str)`

Masks a US Social Security number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

- `str`: The string to mask. The string must be 11 characters long, but is not otherwise checked.

Return value:

The masked Social Security number as a string, or `NULL` if the argument is not the correct length.

Example:

```

mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('abcdefghijk');
+-----+
| mask_ssn('909-63-6922') | mask_ssn('abcdefghijk') |
+-----+
| XXX-XX-6922 | XXX-XX-hijk |
+-----+
mysql> SELECT mask_ssn('909');
+-----+
| mask_ssn('909') |
+-----+
| NULL |
+-----+

```

Random Data Generation Functions

The functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

- `gen_range(lower, upper)`

Generates a random number chosen from a specified range.

Arguments:

- `lower`: An integer that specifies the lower boundary of the range.
- `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

Return value:

A random integer in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`.

Example:

```
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+-----+-----+
| gen_range(100, 200) | gen_range(-1000, -800) |
+-----+-----+
| 177 | -917 |
+-----+-----+
mysql> SELECT gen_range(1, 0);
+-----+
| gen_range(1, 0) |
+-----+
| NULL |
+-----+
```

- `gen_rnd_email()`

Generates a random email address in the `example.com` domain.

Arguments:

None.

Return value:

A random email address as a string.

Example:

```
mysql> SELECT gen_rnd_email();
+-----+
| gen_rnd_email() |
+-----+
| ijocv.mwvhhuf@example.com |
+-----+
```

- `gen_rnd_pan([size])`

Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

Warning

Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

Arguments:

- `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

Return value:

A random payment number as a string, or `NULL` if a `size` argument outside the permitted range is given.

Example:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
```

```

| XXXXXXXXXXXXX5805 |
+-----+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+-----+
| mask_pan(gen_rnd_pan(19)) |
+-----+
| XXXXXXXXXXXXXXX5067 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 398403XXXXXX9547 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 578416XXXXXXXXXX6509 |
+-----+
mysql> SELECT gen_rnd_pan(11), gen_rnd_pan(20);
+-----+
| gen_rnd_pan(11) | gen_rnd_pan(20) |
+-----+
| NULL | NULL |
+-----+

```

- `gen_rnd_ssn()`

Generates a random US Social Security number in `AAA-BB-CCCC` format. The `AAA` part is greater than 900 and the `BB` part is less than 70, which are characteristics not used for legitimate Social Security numbers.

Arguments:

None.

Return value:

A random Social Security number as a string.

Example:

```

mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 951-26-0058 |
+-----+

```

- `gen_rnd_us_phone()`

Generates a random US phone number in `1-555-AAA-BBBB` format. The 555 area code is not used for legitimate phone numbers.

Arguments:

None.

Return value:

A random US phone number as a string.

Example:

```

mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+

```

```
+-----+
| 1-555-682-5423 |
+-----+
```

Random Data Dictionary-Based Functions

The functions in this section manipulate dictionaries of terms and perform generation and masking operations based on them. Some of these functions require the [SUPER](#) privilege.

When a dictionary is loaded, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions. Dictionaries are loaded from plain text files containing one term per line. Empty lines are ignored. To be valid, a dictionary file must contain at least one nonempty line.

- `gen_blacklist(str, dictionary_name, replacement_dictionary_name)`

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution.

Arguments:

- `str`: A string that indicates the term to replace.
- `dictionary_name`: A string that names the dictionary containing the term to replace.
- `replacement_dictionary_name`: A string that names the dictionary from which to choose the replacement term.

Return value:

A string randomly chosen from `replacement_dictionary_name` as a replacement for `str`, or `str` if it does not appear in `dictionary_name`, or `NULL` if either dictionary name is not in the dictionary registry.

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```
mysql> SELECT gen_blacklist('Berlin', 'DE_Cities', 'US_Cities');
+-----+
| gen_blacklist('Berlin', 'DE_Cities', 'US_Cities') |
+-----+
| Phoenix                                           |
+-----+
```

- `gen_dictionary(dictionary_name)`

Returns a random term from a dictionary.

Arguments:

- `dictionary_name`: A string that names the dictionary from which to choose the term.

Return value:

A random term from the dictionary as a string, or `NULL` if the dictionary name is not in the dictionary registry.

Example:

```
mysql> SELECT gen_dictionary('mydict');
+-----+
| gen_dictionary('mydict') |
+-----+
| My term                  |
+-----+
```

```
+-----+
mysql> SELECT gen_dictionary('no-such-dict');
+-----+
| gen_dictionary('no-such-dict') |
+-----+
| NULL                           |
+-----+
```

- `gen_dictionary_drop(dictionary_name)`

Removes a dictionary from the dictionary registry.

This function requires the `SUPER` privilege.

Arguments:

- `dictionary_name`: A string that names the dictionary to remove from the dictionary registry.

Return value:

A string that indicates whether the drop operation succeeded. `Dictionary removed` indicates success. `Dictionary removal error` indicates failure.

Example:

```
mysql> SELECT gen_dictionary_drop('mydict');
+-----+
| gen_dictionary_drop('mydict') |
+-----+
| Dictionary removed            |
+-----+
mysql> SELECT gen_dictionary_drop('no-such-dict');
+-----+
| gen_dictionary_drop('no-such-dict') |
+-----+
| Dictionary removal error          |
+-----+
```

- `gen_dictionary_load(dictionary_path, dictionary_name)`

Loads a file into the dictionary registry and assigns the dictionary a name to be used with other functions that require a dictionary name argument.

This function requires the `SUPER` privilege.

Important

Dictionaries are not persistent. Any dictionary used by applications must be loaded for each server startup.

Once loaded into the registry, a dictionary is used as is, even if the underlying dictionary file changes. To reload a dictionary, first drop it with `gen_dictionary_drop()`, then load it again with `gen_dictionary_load()`.

Arguments:

- `dictionary_path`: A string that specifies the path name of the dictionary file.
- `dictionary_name`: A string that provides a name for the dictionary.

Return value:

A string that indicates whether the load operation succeeded. `Dictionary load success` indicates success. `Dictionary load error` indicates failure. Dictionary load failure can occur for several reasons, including:

- A dictionary with the given name is already loaded.
- The dictionary file is not found.
- The dictionary file contains no terms.
- The `secure_file_priv` system variable is set and the dictionary file is not located in the directory named by the variable.

Example:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict') |
+-----+
| Dictionary load success                                             |
+-----+
mysql> SELECT gen_dictionary_load('/dev/null','null');
+-----+
| gen_dictionary_load('/dev/null','null') |
+-----+
| Dictionary load error                                             |
+-----+
```

6.6 MySQL Enterprise Encryption

Note

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

MySQL Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

MySQL Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

6.6.1 MySQL Enterprise Encryption Installation

MySQL Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements, adjusting the file name suffix as necessary:

```
CREATE FUNCTION asymmetric_decrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING
  SONAME 'openssl_udf.so';
```

Once installed, UDFs remain installed across server restarts. To unload the UDFs, use the `DROP FUNCTION` statement:

```
DROP FUNCTION asymmetric_decrypt;
DROP FUNCTION asymmetric_derive;
DROP FUNCTION asymmetric_encrypt;
DROP FUNCTION asymmetric_sign;
DROP FUNCTION asymmetric_verify;
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
DROP FUNCTION create_dh_parameters;
DROP FUNCTION create_digest;
```

In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

6.6.2 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks:

- [Create a private/public key pair using RSA encryption](#)

- [Use the private key to encrypt data and the public key to decrypt it](#)
- [Generate a digest from a string](#)
- [Use the digest with a key pair](#)
- [Create a symmetric key](#)
- [Limit CPU usage by key-generation operations](#)

Create a private/public key pair using RSA encryption

```
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = create_asymmetric_priv_key(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = create_asymmetric_pub_key(@algo, @priv);
```

Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

Use the private key to encrypt data and the public key to decrypt it

This requires that the members of the key pair be RSA keys.

```
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @priv);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @pub);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

Generate a digest from a string

```
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';

-- Generate digest string
SET @dig = create_digest(@dig_type, 'My text to digest');
```

Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest.

```
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

Create a symmetric key

This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `create_dh_parameters()`, then pass the secret as the “key length” to `create_asymmetric_priv_key()`.

```
-- Generate DH shared symmetric secret
SET @dhp = create_dh_parameters(1024);
```

```
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub1 = create_asymmetric_pub_key(@algo, @priv1);
SET @priv2 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub2 = create_asymmetric_pub_key(@algo, @priv2);

-- Generate symmetric key using public key of first party,
-- private key of second party
SET @sym1 = asymmetric_derive(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = asymmetric_derive(@pub2, @priv1);
```

Key string values can be created at runtime and stored into a variable or table using [SET](#), [SELECT](#), or [INSERT](#):

```
SET @priv1 = create_asymmetric_priv_key('RSA', 1024);
SELECT create_asymmetric_priv_key('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(create_asymmetric_priv_key('RSA', 1024));
```

Key string values stored in files can be read using the [LOAD_FILE\(\)](#) function by users who have the [FILE](#) privilege.

Digest and signature strings can be handled similarly.

Limit CPU usage by key-generation operations

The [create_asymmetric_priv_key\(\)](#) and [create_dh_parameters\(\)](#) encryption functions take a key-length parameter, and the amount of CPU resources required by these functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL imposes a minimum key length of 1,024 bits for all keys. OpenSSL also imposes a maximum key length of 10,000 bits and 16,384 bits for DSA and RSA keys, respectively, for [create_asymmetric_priv_key\(\)](#), and a maximum key length of 10,000 bits for [create_dh_parameters\(\)](#). If those maximum values are too high, three environment variables are available to enable MySQL server administrators to set lower maximum lengths for key generation, and thereby to limit CPU usage:

- [MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD](#): Maximum DSA key length in bits for [create_asymmetric_priv_key\(\)](#). The minimum and maximum values for this variable are 1,024 and 10,000.
- [MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD](#): Maximum RSA key length in bits for [create_asymmetric_priv_key\(\)](#). The minimum and maximum values for this variable are 1,024 and 16,384.
- [MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD](#): Maximum key length in bits for [create_dh_parameters\(\)](#). The minimum and maximum values for this variable are 1,024 and 10,000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4,096 bits for DSA and RSA keys for [create_asymmetric_priv_key\(\)](#), set these variables:

```
export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096
```

The example uses Bourne shell syntax. The syntax for other shells may differ.

6.6.3 MySQL Enterprise Encryption User-Defined Function Reference

MySQL Enterprise Encryption User-Defined Functions A reference that lists MySQL Enterprise Encryption user-defined functions.

6.6.4 MySQL Enterprise Encryption User-Defined Function Descriptions

MySQL Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.
- If the arguments are not suitable to permit a function to perform the requested operation, it returns `NULL` or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key. (OpenSSL imposes its own key-length limits, and server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”](#).)
- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

Table 6.38 Supported Algorithms by Function

Function	Supported Algorithms
<code>asymmetric_decrypt()</code>	RSA
<code>asymmetric_derive()</code>	DH
<code>asymmetric_encrypt()</code>	RSA
<code>asymmetric_sign()</code>	RSA, DSA
<code>asymmetric_verify()</code>	RSA, DSA
<code>create_asymmetric_priv_key()</code>	RSA, DSA, DH
<code>create_asymmetric_pub_key()</code>	RSA, DSA, DH
<code>create_dh_parameters()</code>	DH

Note

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, `asymmetric_encrypt()` and `asymmetric_decrypt()` accept only RSA keys.

The following descriptions describe the calling sequences for MySQL Enterprise Encryption functions. For additional examples and discussion, see [Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”](#).

- `asymmetric_decrypt(algorithm, crypt_str, key_str)`

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting plaintext as a binary string. If decryption fails, the result is `NULL`.

key_str must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with `asymmetric_encrypt()` to produce the encrypted string. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA'

For a usage example, see the description of `asymmetric_encrypt()`.

- `asymmetric_derive(pub_key_str, priv_key_str)`

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is `NULL`.

`pub_key_str` and `priv_key_str` must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```
SET @dhp = create_dh_parameters(1024);
SET @priv1 = create_asymmetric_priv_key('DH', @dhp);
SET @pub1 = create_asymmetric_pub_key('DH', @priv1);
SET @priv2 = create_asymmetric_priv_key('DH', @dhp);
SET @pub2 = create_asymmetric_pub_key('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```
asymmetric_derive(@pub1, @priv2) = asymmetric_derive(@pub2, @priv1)
```

- `asymmetric_encrypt(algorithm, str, key_str)`

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

The `str` length cannot be greater than the `key_str` length – 11, in bytes

`key_str` must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA'

To encrypt a string, pass a private or public key string to `asymmetric_encrypt()`. To recover the original unencrypted string, pass the encrypted string to `asymmetric_decrypt()`, along with the public or private key string corresponding to the private or public key string used for encryption.

```
-- Generate private/public key pair
SET @priv = create_asymmetric_priv_key('RSA', 1024);
SET @pub = create_asymmetric_pub_key('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @priv);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @pub);

-- Encrypt using public key, decrypt using private key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @pub);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @priv), @pub) = @s
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @pub), @priv) = @s
```

- `asymmetric_sign(algorithm, digest_str, priv_key_str, digest_type)`

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is `NULL`.

`digest_str` is the digest string. It can be generated by calling `create_digest()`. `digest_type` indicates the digest algorithm used to generate the digest string.

`priv_key_str` is the private key string to use for signing the digest string. It must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA', 'DSA'

Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

For a usage example, see the description of `asymmetric_verify()`.

- `asymmetric_verify(algorithm, digest_str, sig_str, pub_key_str, digest_type)`

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

`digest_str` is the digest string. It can be generated by calling `create_digest()`. `digest_type` indicates the digest algorithm used to generate the digest string.

`sig_str` is the signature string. It can be generated by calling `asymmetric_sign()`.

`pub_key_str` is the public key string of the signer. It corresponds to the private key passed to `asymmetric_sign()` to generate the signature string and must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA', 'DSA'

Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';

-- Create private/public key pair
SET @priv = create_asymmetric_priv_key(@algo, 1024);
SET @pub = create_asymmetric_pub_key(@algo, @priv);

-- Generate digest from string
SET @dig = create_digest(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

- `create_asymmetric_priv_key(algorithm, {key_len|dh_secret})`

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is `NULL`.

Supported `algorithm` values: 'RSA', 'DSA', 'DH'

Supported `key_len` values: The minimum key length in bits is 1,024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”](#).

For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to `create_dh_parameters()`.

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

```
SET @priv = create_asymmetric_priv_key('DSA', 2048);
```

```
SET @pub = create_asymmetric_pub_key('DSA', @priv);
```

For an example showing DH key generation, see the description of [asymmetric_derive\(\)](#).

Some general considerations in choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.
- Generation of DH keys takes much longer than RSA or RSA keys.
- Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using [AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#).
- [create_asymmetric_pub_key\(algorithm, priv_key_str\)](#)

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is [NULL](#).

[priv_key_str](#) must be a valid key string in PEM format. [algorithm](#) indicates the encryption algorithm used to create the key.

Supported [algorithm](#) values: 'RSA', 'DSA', 'DH'

For a usage example, see the description of [create_asymmetric_priv_key\(\)](#).

- [create_dh_parameters\(key_len\)](#)

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to [create_asymmetric_priv_key\(\)](#). If secret generation fails, the result is null.

Supported [key_len](#) values: The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”](#).

For an example showing how to use the return value for generating symmetric keys, see the description of [asymmetric_derive\(\)](#).

```
SET @dhp = create_dh_parameters(1024);
```

- [create_digest\(digest_type, str\)](#)

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is [NULL](#).

Supported [digest_type](#) values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
SET @dig = create_digest('SHA512', 'The quick brown fox');
```

The resulting digest string is suitable for use with [asymmetric_sign\(\)](#) and [asymmetric_verify\(\)](#).

6.7 SELinux

Security-Enhanced Linux (SELinux) is a mandatory access control (MAC) system that implements access rights by applying a security label referred to as an *SELinux context* to each system object. SELinux policy modules use SELinux contexts to define rules for how processes, files, ports, and other system objects interact with each other. Interaction between system objects is only permitted if a policy rule allows it.

An SELinux context (the label applied to a system object) has the following fields: `user`, `role`, `type`, and `security level`. Type information rather than the entire SELinux context is used most commonly to define rules for how processes interact with other system objects. MySQL SELinux policy modules, for example, define policy rules using `type` information.

You can view SELinux contexts using operating system commands such as `ls` and `ps` with the `-Z` option. Assuming that SELinux is enabled and a MySQL Server is running, the following commands show the SELinux context for the `mysqld` process and MySQL data directory:

`mysqld` process:

```
shell> ps -eZ | grep mysqld
system_u:system_r:mysqld_t:s0      5924 ?          00:00:03 mysqld
```

MySQL data directory:

```
shell> cd /var/lib
shell> ls -Z | grep mysql
system_u:object_r:mysqld_db_t:s0 mysql
```

where:

- `system_u` is an SELinux user identity for system processes and objects.
- `system_r` is an SELinux role used for system processes.
- `objects_r` is an SELinux role used for system objects.
- `mysqld_t` is the type associated with the `mysqld` process.
- `mysqld_db_t` is the type associated with the MySQL data directory and its files.
- `s0` is the security level.

For more information about interpreting SELinux contexts, refer to your distribution's SELinux documentation.

6.7.1 Check if SELinux is Enabled

SELinux is enabled by default on some Linux distributions including Oracle Linux, RHEL, CentOS, and Fedora. Use the `sestatus` command to determine if SELinux is enabled on your distribution:

```
shell> sestatus
SELinux status:                enabled
SELinuxfs mount:              /sys/fs/selinux
SELinux root directory:       /etc/selinux
Loaded policy name:            targeted
Current mode:                  enforcing
Mode from config file:        enforcing
Policy MLS status:             enabled
Policy deny_unknown status:    allowed
Memory protection checking:    actual (secure)
Max kernel policy version:     31
```

If SELinux is disabled or the `sestatus` command is not found, refer to your distribution's SELinux documentation for guidance before enabling SELinux.

6.7.2 Changing the SELinux Mode

SELinux supports enforcing, permissive, and disabled modes. Enforcing mode is the default. Permissive mode allows operations that are not permitted in enforcing mode and logs those operations to the SELinux audit log. Permissive mode is typically used when developing policies or troubleshooting. In disabled mode, policies are not enforced, and contexts are not applied to system objects, which makes it difficult to enable SELinux later.

To view the current SELinux mode, use the `sestatus` command mentioned previously or the `getenforce` utility.

```
shell> getenforce
Enforcing
```

To change the SELinux mode, use the `setenforce` utility:

```
shell> setenforce 0
shell> getenforce
Permissive
```

```
shell> setenforce 1
shell> getenforce
Enforcing
```

Changes made with `setenforce` are lost when you restart the system. To permanently change the SELinux mode, edit the `/etc/selinux/config` file and restart the system.

6.7.3 MySQL Server SELinux Policies

MySQL Server SELinux policy modules are typically installed by default. You can view installed modules using the `semodule -l` command. MySQL Server SELinux policy modules include:

- `mysqld_selinux`
- `mysqld_safe_selinux`

For information about MySQL Server SELinux policy modules, refer to the SELinux manual pages. The manual pages provide information about types and Booleans associated with the MySQL service. Manual pages are named in the `service-name_selinux` format.

```
man mysqld_selinux
```

If SELinux manual pages are not available, refer to your distribution's SELinux documentation for information about how to generate manual pages using the `sepolicy manpage` utility.

6.7.4 SELinux File Context

The MySQL Server reads from and writes to many files. If the SELinux context is not set correctly for these files, access to the files could be denied.

The instructions that follow use the `semanage` binary to manage file context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list MySQL file contexts using `semanage` with the `fcontext` option.

```
semanage fcontext -l | grep -i mysql
```

Setting the MySQL Data Directory Context

The default data directory location is `/var/lib/mysql/`; and the SELinux context used is `mysqld_db_t`.

If you edit the configuration file to use a different location for the data directory, or for any of the files normally in the data directory (such as the binary logs), you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/datadir(/.*)"
restorecon -Rv /path/to/my/custom/datadir
```

```
semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/logdir(/.*)?"
restorecon -Rv /path/to/my/custom/logdir
```

Setting the MySQL Error Log File Context

The default location for RedHat RPMs is `/var/log/mysqld.log`; and the SELinux context type used is `mysqld_log_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_log_t "/path/to/my/custom/error.log"
restorecon -Rv /path/to/my/custom/error.log
```

Setting the PID File Context

The default location for the PID file is `/var/run/mysqld/mysqld.pid`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/pidfile/directory/.*)"
restorecon -Rv /path/to/my/custom/pidfile/directory
```

Setting the Unix Domain Socket Context

The default location for the Unix domain socket is `/var/lib/mysql/mysql.sock`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/mysql\*.sock"
restorecon -Rv /path/to/my/custom/mysql.sock
```

Setting the `secure_file_priv` Directory Context

For MySQL versions since 5.6.34, 5.7.16, and 8.0.11.

Installing the MySQL Server RPM creates a `/var/lib/mysql-files/` directory but does not set the SELinux context for it. The `/var/lib/mysql-files/` directory is intended to be used for operations such as `SELECT ... INTO OUTFILE`.

If you enabled the use of this directory by setting `secure_file_priv`, you may need to set the context like so:

```
semanage fcontext -a -t mysqld_db_t "/var/lib/mysql-files(/.*)?"
restorecon -Rv /var/lib/mysql-files
```

Edit this path if you used a different location. For security purposes, this directory should never be within the data directory.

For more information about this variable, see the `secure_file_priv` documentation.

6.7.5 SELinux TCP Port Context

The instructions that follow use the `semanage` binary to manage port context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list ports defined with the `mysqld_port_t` context using `semanage` with the `port` option.

```
shell> semanage port -l | grep mysqld
mysqld_port_t                tcp                1186, 3306, 63132-63164
```

6.7.5.1 Setting the TCP Port Context for mysqld

The default TCP port for `mysqld` is `3306`; and the SELinux context type used is `mysqld_port_t`.

If you configure `mysqld` to use a different TCP `port`, you may need to set the context for the new port. For example to define the SELinux context for a non-default port such as port 3307:

```
semanage port -a -t mysqld_port_t -p tcp 3307
```

To confirm that the port is added:

```
shell> semanage port -l | grep mysqld
mysqld_port_t                tcp                3307, 1186, 3306, 63132-63164
```

6.7.5.2 Setting the TCP Port Context for MySQL Features

If you enable certain MySQL features, you might need to set the SELinux TCP port context for additional ports used by those features. If ports used by MySQL features do not have the correct SELinux context, the features might not function correctly.

The following sections describe how to set port contexts for MySQL features. Generally, the same method can be used to set the port context for any MySQL features. For information about ports used by MySQL features, refer to the [MySQL Port Reference](#).

From MySQL 8.0.14 to MySQL 8.0.17, the `mysql_connect_any` SELinux boolean must be set to `ON`. As of MySQL 8.0.18, enabling `mysql_connect_any` is not required or recommended.

```
setsebool -P mysql_connect_any=ON
```

Setting the TCP Port Context for Group Replication

If SELinux is enabled, you must set the port context for the Group Replication communication port, which is defined by the `group_replication_local_address` variable. `mysqld` must be able to bind to the Group Replication communication port and listen there. InnoDB Cluster relies on Group Replication so this applies equally to instances used in a cluster. To view ports currently used by MySQL, issue:

```
semanage port -l | grep mysqld
```

Assuming the Group Replication communication port is 33061, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33061
```

Setting the TCP Port Context for Document Store

If SELinux is enabled, you must set the port context for the communication port used by X Plugin, which is defined by the `mysqlx_port` variable. `mysqld` must be able to bind to the X Plugin communication port and listen there.

Assuming the X Plugin communication port is 33060, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33060
```

Setting the TCP Port Context for MySQL Router

If SELinux is enabled, you must set the port context for the communication ports used by MySQL Router. Assuming the additional communication ports used by MySQL Router are the default 6446, 6447, 64460 and 64470, on each instance set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 6446
semanage port -a -t mysqld_port_t -p tcp 6447
```

```
semanage port -a -t mysqld_port_t -p tcp 64460
semanage port -a -t mysqld_port_t -p tcp 64470
```

6.7.6 Troubleshooting SELinux

Troubleshooting SELinux typically involves placing SELinux into permissive mode, rerunning problematic operations, checking for access denial messages in the SELinux audit log, and placing SELinux back into enforcing mode after problems are resolved.

To avoid placing the entire system into permissive mode using `setenforce`, you can permit only the MySQL service to run permissively by placing its SELinux domain (`mysqld_t`) into permissive mode using the `semanage` command:

```
semanage permissive -a mysqld_t
```

When you are finished troubleshooting, use this command to place the `mysqld_t` domain back into enforcing mode:

```
semanage permissive -d mysqld_t
```

SELinux writes logs for denied operations to `/var/log/audit/audit.log`. You can check for denials by searching for “denied” messages.

```
grep "denied" /var/log/audit/audit.log
```

The following sections describes a few common areas where SELinux-related issues may be encountered.

File Contexts

If a MySQL directory or file has an incorrect SELinux context, access may be denied. This issue can occur if MySQL is configured to read from or write to a non-default directory or file. For example, if you configure MySQL to use a non-default data directory, the directory may not have the expected SELinux context.

Attempting to start the MySQL service on a non-default data directory with an invalid SELinux context causes the following startup failure.

```
shell> systemctl start mysql.service
Job for mysqld.service failed because the control process exited with error code.
See "systemctl status mysqld.service" and "journalctl -xe" for details.
```

In this case, a “denial” message is logged to `/var/log/audit/audit.log`:

```
shell> grep "denied" /var/log/audit/audit.log
type=AVC msg=audit(1587133719.786:194): avc: denied { write } for pid=7133 comm="mysqld"
name="mysql" dev="dm-0" ino=51347078 scontext=system_u:system_r:mysqld_t:s0
tcontext=unconfined_u:object_r:default_t:s0 tclass=dir permissive=0
```

For information about setting the proper SELinux context for MySQL directories and files, see [Section 6.7.4, “SELinux File Context”](#).

Port Access

SELinux expects services such as MySQL Server to use specific ports. Changing ports without updating the SELinux policies may cause a service failure.

The `mysqld_port_t` port type defines the ports that the MySQL listens on. If you configure the MySQL Server to use a non-default port, such as port 3307, and do not update the policy to reflect the change, the MySQL service fails to start:

```
shell> systemctl start mysql.service
Job for mysqld.service failed because the control process exited with error code.
See "systemctl status mysqld.service" and "journalctl -xe" for details.
```

In this case, a denial message is logged to `/var/log/audit/audit.log`:

```
shell> grep "denied" /var/log/audit/audit.log
type=AVC msg=audit(1587134375.845:198): avc: denied { name_bind } for pid=7340
comm="mysqld" src=3307 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:object_r:unreserved_port_t:s0 tclass=tcp_socket permissive=0
```

For information about setting the proper SELinux port context for MySQL, see [Section 6.7.5, “SELinux TCP Port Context”](#). Similar port access issues can occur when enabling MySQL features that use ports that are not defined with the required context. For more information, see [Section 6.7.5.2, “Setting the TCP Port Context for MySQL Features”](#).

Application Changes

SELinux may not be aware of application changes. For example, a new release, an application extension, or a new feature may access system resources in a way that is not permitted by SELinux, resulting in access denials. In such cases, you can use the `audit2allow` utility to create custom policies to permit access where it is required. The typical method for creating custom policies is to change the SELinux mode to permissive, identify access denial messages in the SELinux audit log, and use the `audit2allow` utility to create custom policies to permit access.

For information about using the `audit2allow` utility, refer to your distribution's SELinux documentation.

If you encounter access issues for MySQL that you believe should be handled by standard MySQL SELinux policy modules, please open a bug report in your distribution's bug tracking system.

6.8 FIPS Support

MySQL supports FIPS mode, if compiled using OpenSSL 1.0.2, and an OpenSSL library and FIPS Object Module are available at runtime.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (source/replica and Group Replication) and X Plugin, which run within the server. FIPS mode also applies to attempts by clients to connect to the server.

The following sections describe FIPS mode and how to take advantage of it within MySQL:

- [FIPS Overview](#)
- [System Requirements for FIPS Mode in MySQL](#)
- [Configuring FIPS Mode in MySQL](#)

FIPS Overview

Federal Information Processing Standards 140-2 (FIPS 140-2) describes a security standard that can be required by Federal (US Government) agencies for cryptographic modules used to protect sensitive or valuable information. To be considered acceptable for such Federal use, a cryptographic module must be certified for FIPS 140-2. If a system intended to protect sensitive data lacks the proper FIPS 140-2 certificate, Federal agencies cannot purchase it.

Products such as OpenSSL can be used in FIPS mode, although the OpenSSL library itself is not validated for FIPS. Instead, the OpenSSL library is used with the OpenSSL FIPS Object Module to enable OpenSSL-based applications to operate in FIPS mode.

For general information about FIPS and its implementation in OpenSSL, these references may be helpful:

- [National Institute of Standards and Technology FIPS PUB 140-2](#)
- [OpenSSL FIPS 140-2 Security Policy](#)

- [User Guide for the OpenSSL FIPS Object Module v2.0](#)

**Important**

FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. For OpenSSL, the exact FIPS behavior depends on the OpenSSL version. For details, refer to the OpenSSL FIPS User Guide.

System Requirements for FIPS Mode in MySQL

For MySQL to support FIPS mode, these system requirements must be satisfied:

- At build time, MySQL must be compiled using OpenSSL. FIPS mode cannot be used in MySQL if compilation uses an SSL library different from OpenSSL.

In addition, MySQL must be compiled with an OpenSSL version that is certified for use with FIPS. OpenSSL 1.0.2 is certified, but OpenSSL 1.1.1 is not. Binary distributions for recent versions of MySQL are compiled using OpenSSL 1.1.1 on some platforms, which means they are not certified for FIPS. This leads to tradeoffs in available MySQL features, depending on system and MySQL configuration:

- Use a system that has OpenSSL 1.0.2 and the required FIPS Object Module. In this case, you can enable FIPS mode for MySQL if you use a binary distribution compiled using OpenSSL 1.0.2, or compile MySQL from source using OpenSSL 1.0.2. However, in this case, you cannot use the TLSv1.3 protocol or ciphersuites (which require OpenSSL 1.1.1). In addition, you are using an OpenSSL version that reached End of Life status at the end of 2019.
- Use a system that has OpenSSL 1.1.1 or higher. In this case, you can install MySQL using binary packages, and you can use the TLSv1.3 protocol and ciphersuites, in addition to other already supported TLS protocols. However, you cannot enable FIPS mode for MySQL.
- At runtime, the OpenSSL library and OpenSSL FIPS Object Module must be available as shared (dynamically linked) objects. It is possible to build statically linked OpenSSL objects, but MySQL will not use them.

FIPS mode has been tested for MySQL on EL7, but may work on other systems.

If your platform or operating system provides the OpenSSL FIPS Object Module, you can use it. Otherwise, you can build the OpenSSL library and FIPS Object Module from source. Use the instructions in the OpenSSL FIPS User Guide (see [FIPS Overview](#)).

Configuring FIPS Mode in MySQL

MySQL enables control of FIPS mode on the server side and the client side:

- The `ssl_fips_mode` system variable controls whether the server operates in FIPS mode.
- The `--ssl-fips-mode` client option controls whether a given MySQL client operates in FIPS mode.

The `ssl_fips_mode` system variable and `--ssl-fips-mode` client option permit these values:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

On the server side, numeric `ssl_fips_mode` values of 0, 1, and 2 are equivalent to `OFF`, `ON`, and `STRICT`, respectively.

**Important**

In general, [STRICT](#) imposes more restrictions than [ON](#), but MySQL itself has no FIPS-specific code other than to specify to OpenSSL the FIPS mode value. The exact behavior of FIPS mode for [ON](#) or [STRICT](#) depends on the OpenSSL version. For details, refer to the OpenSSL FIPS User Guide (see [FIPS Overview](#)).

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for [ssl_fips_mode](#) and [--ssl-fips-mode](#) is [OFF](#). An error occurs for attempts to set the FIPS mode to a different value.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (source/replica and Group Replication) and X Plugin, which run within the server.

FIPS mode also applies to attempts by clients to connect to the server. When enabled, on either the client or server side, it restricts which of the supported encryption ciphers can be chosen. However, enabling FIPS mode does not require that an encrypted connection must be used, or that user credentials must be encrypted. For example, if FIPS mode is enabled, stronger cryptographic algorithms are required. In particular, MD5 is restricted, so trying to establish an encrypted connection using an encryption cipher such as [RC4-MD5](#) does not work. But there is nothing about FIPS mode that prevents establishing an unencrypted connection. (To do that, you can use the [REQUIRE](#) clause for [CREATE USER](#) or [ALTER USER](#) for specific user accounts, or set the [require_secure_transport](#) system variable to affect all accounts.)

Chapter 7 Backup and Recovery

Table of Contents

7.1 Backup and Recovery Types	1416
7.2 Database Backup Methods	1419
7.3 Example Backup and Recovery Strategy	1421
7.3.1 Establishing a Backup Policy	1421

7.6 MyISAM Table Maintenance and Crash Recovery	1433
7.6.1 Using myisamchk for Crash Recovery	1433
7.6.2 How to Check MyISAM Tables for Errors	1434
7.6.3 How to Repair MyISAM Tables	1435
7.6.4 MyISAM Table Optimization	1437
7.6.5 Setting Up a MyISAM Table Maintenance Schedule	1437

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replica servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).
- A forum dedicated to backup issues is available at <https://forums.mysql.com/list.php?28>.
- Details for `mysqldump` can be found in [Chapter 4, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 13, SQL Statements](#).

- For additional information about [InnoDB](#) backup procedures, see [Section 15.18.1, “InnoDB Backup”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the source by using a replica. See [Chapter 17, Replication](#).
- MySQL InnoDB Cluster is a collection of products that work together to provide a high availability solution. A group of MySQL servers can be configured to create a cluster using MySQL Shell. The cluster of servers has a single source, called the primary, which acts as the read-write source. Multiple secondary servers are replicas of the source. A minimum of three servers are required to create a high availability cluster. A client application is connected to the primary via MySQL Router. If the primary fails, a secondary is automatically promoted to the role of primary, and MySQL Router routes requests to the new primary.
- NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 22, MySQL NDB Cluster 8.0](#), which provides information about MySQL NDB Cluster 8.0.

7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure ([CREATE DATABASE](#), [CREATE TABLE](#) statements) and content ([INSERT](#) statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, [InnoDB](#) tables can each be in a separate file, or share file storage with other [InnoDB](#) tables; each [MyISAM](#) table corresponds uniquely to a set of files.
- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from [MEMORY](#) tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from [MEMORY](#) tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.

- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.
- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for `InnoDB` or any other tables, or file system-level commands (such as `cp`, `scp`, `tar`, `rsync`) for `MyISAM` tables.
- For restore:
 - MySQL Enterprise Backup restores `InnoDB` and other tables that it backed up.
 - `ndb_restore` restores `NDB` tables.
 - Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA` statement or the `mysqlimport` client.

Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replica that can be taken offline without harming availability.

- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server. host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

Table Maintenance

Data integrity can be compromised if tables become corrupt. For `InnoDB` tables, this is not a typical issue. For programs to check `MyISAM` tables and repair them if problems are found, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

7.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the `mysqldump` command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).

Making Backups with `mysqldump`

The `mysqldump` program can make backups. It can back up all kinds of tables. (See [Section 7.4, “Using `mysqldump` for Backups”](#).)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` option to `mysqldump`. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Making Backups by Copying Table Files

MyISAM tables can be backed up by copying table files (`*.MYD`, `*.MYI` files, and associated `*.sdi` files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See [Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Statements”](#), and [Section 13.7.8.3, “FLUSH Statement”](#).

You can also create a binary backup simply by copying the table files, as long as the server isn't updating anything. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. Also, even if the server is not actively updating data, [InnoDB](#) may still have modified data cached in memory and not flushed to disk.)

For an example of this backup method, refer to the export and import example in [Section 13.2.5, “IMPORT TABLE Statement”](#).

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See [Section 13.2.10, “SELECT Statement”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See [Section 7.4.3, “Dumping Data in Delimited-Text Format with `mysqldump`”](#).

To reload a delimited-text data file, use `LOAD DATA` or `mysqlimport`.

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups using the binary log. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 8.0 ; see [Section 5.4.4, “The Binary Log”](#).

At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS` or `mysqldump --flush-logs`. See [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#).

Making Backups Using Replicas

If you have performance problems with a server while making backups, one strategy that can help is to set up replication and perform backups on the replica rather than on the source. See [Section 17.4.1, “Using Replication for Backups”](#).

If you are backing up a replica, you should back up its connection metadata repository and applier metadata repository (see [Section 17.2.4, “Relay Log and Replication Metadata Repositories”](#)) when you back up the replica's databases, regardless of the backup method you choose. This information is always needed to resume replication after you restore the replica's data. If your replica is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `slave_load_tmpdir` system variable. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption

when backing up InnoDB data files; `mysqldump` provides online [logical backup](#). This discussion uses `mysqldump`.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --all-databases --master-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to InnoDB tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem      4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem    79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem   508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem  998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem   361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-`

`data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication source server, because replicas might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#).

7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic unexpected exit on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any

subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#).

7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always tun the MySQL server with binary logging enabled (that is the default setting for MySQL 8.0). If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 7.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

7.4 Using mysqldump for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replicas.
- As a source of data for experimentation:
 - To make a copy of a database that you can use without changing the original data.
 - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

7.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 7.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

By default, if GTIDs are in use on the server where you create the dump file (`gtid_mode=ON`), `mysqldump` includes a `SET @@GLOBAL.gtid_purged` statement in the output to add the GTIDs from the `gtid_executed` set on the source server to the `gtid_purged` set on the target server. If you are dumping only specific databases or tables, it is important to note that the value that is included by `mysqldump` includes the GTIDs of all transactions in the `gtid_executed` set on the source server, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. If you only replay one partial dump file on the target server, the extra GTIDs do not cause any problems with the future operation of that server. However, if you replay a second dump file on the target server that contains the same GTIDs (for example, another partial dump from the same source server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. To avoid this issue, either set the `mysqldump` option `--set-gtid-purged` to `OFF` or `COMMENTED` to output the second dump file without an active `SET @@GLOBAL.gtid_purged` statement, or remove the statement manually before replaying the dump file.

7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--`

`databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

Note

For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes `cmd.exe /c "mysql < dump.sql"`.

7.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 7.4.4, "Reloading Delimited-Text Format Backups"](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=`*str*

The string for separating column values (default: tab).

- `--fields-enclosed-by=`*char*

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=`*char*

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=`*char*

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=`*str*

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='\"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
--fields-enclosed-by='\"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
```

```
--fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
        FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
        LINES TERMINATED BY '\r\n';
```

7.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

7.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

7.4.5.5 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

7.5 Point-in-Time (Incremental) Recovery

Point-in-time recovery refers to recovery of data changes up to a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 7.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

7.5.1 Point-in-Time Recovery Using Binary Log

This section explains the general idea of using the binary log to perform a point-in-time-recovery. The next section, [Section 7.5.2, “Point-in-Time Recovery Using Event Positions”](#), explains the operation in details with an example.

Note

Many of the examples in this and the next section use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains `\0` (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

The source of information for point-in-time recovery is the set of binary log files generated subsequent to the full backup operation. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 8.0 (see [Section 5.4.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be viewed or applied. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

Applying events from the binary log causes the data modifications they represent to be reexecuted. This enables recovery of data changes for a given span of time. To apply events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

If binary log files have been encrypted, which can be done from MySQL 8.0.14 onwards, `mysqlbinlog` cannot read them directly as in the above example, but can read them from the server using the `--read-from-remote-server` (`-R`) option. For example:

```
shell> mysqlbinlog --read-from-remote-server --host=host_name --port=3306 --user=root --password --ssl-mode=required
```

Here, the option `--ssl-mode=required` has been used to ensure that the data from the binary log files is protected in transit, because it is sent to `mysqlbinlog` in an unencrypted format.

Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
```

```
shell> ... edit tmpfile ...
```

Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP TABLE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, apply the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to apply on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to apply the contents of all binary log files that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write the whole log to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

When writing to a dump file while reading back from a binary log containing GTIDs (see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#)), use the `--skip-gtids` option with `mysqlbinlog`, like this:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

7.5.2 Point-in-Time Recovery Using Event Positions

The last section, [Section 7.5.1, “Point-in-Time Recovery Using Binary Log”](#), explains the general idea of using the binary log to perform a point-in-time-recovery. The section explains the operation in details with an example.

As an example, suppose that around 20:06:00 on March 11, 2020, an SQL statement was executed that deleted a table. You can perform a point-in-time recovery to restore the server up to its state right before the table deletion. These are some sample steps to achieve that:

1. Restore the last full backup created before the point-in-time of interest (call it t_p , which is 20:06:00 on March 11, 2020 in our example). When finished, note the binary log position up to which you have restored the server—you will need that information later—and restart the server.

Note

While the last binary log position recovered is also displayed by InnoDB after the restore and server restart, that is *not* a reliable means for obtaining the ending log position of your restore, as there could be DDL events and non-InnoDB changes that have taken place after the time reflected by the displayed position. Your backup and restore tool should provide you with the last binary log position for your recovery: for example, if you are using `mysqlbinlog` for the task, check the stop position of the binary log replay;

if you are using MySQL Enterprise Backup, the last binary log position has been saved in your backup. See [Point-in-Time Recovery](#).

- Find the precise binary log event position corresponding to the point in time up to which you want to restore your database. In our example, given that we know the rough time where the table deletion took place (t_p), we can find the log position by checking the log contents around that time using the `mysqlbinlog` utility. Use the `--start-datetime` and `--stop-datetime` options to specify a short time period around t_p , and then look for the event in the output. For example:

```
shell> mysqlbinlog --start-datetime="2020-03-11 20:05:00" \
               --stop-datetime="2020-03-11 20:08:00" --verbose \
               /var/lib/mysql/bin.123456 | grep -C 15 "DROP TABLE"

use `pets`/*!*/;
SET TIMESTAMP=1583971668/*!*/;
/*!80013 SET @@session.sql_require_primary_key=0*//*!*/;
CREATE TABLE dogs
```

From the output of `mysqlbinlog`, the `DROP TABLE `pets`.`cats`` statement can be found in the segment of the binary log between the line `# at 232` and `# at 355`, which means the statement takes place *after* the log position 232, and the log is at position 355 after the `DROP TABLE` statement.

Note

Only use the `--start-datetime` and `--stop-datetime` options to help you find the actual event positions of interest. Using the two options to specify the range of binary log segment to apply is not recommended: there is a higher risk of missing binary log events when using the options. Use `--start-position` and `--stop-position` instead.

- Apply the events in binary log file to the server, starting with the log position your found in step 1 (assume it is 155) and ending at the position you have found in step 2 that is *before* your point-in-time of interest (which is 232):

```
shell> mysqlbinlog --start-position=155 --stop-position=232 /var/lib/mysql/bin.123456 \
               | mysql -u root -p
```

The command recovers all the transactions from the starting position until just before the stop position. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each

SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

Your database has now been restored to the point-in-time of interest, t_p , right before the table `pets.cats` was dropped.

4. Beyond the point-in-time recovery that has been finished, if you also want to reexecute all the statements *after* your point-in-time of interest, use `mysqlbinlog` again to apply all the events after t_p to the server. We noted in step 2 that after the statement we wanted to skip, the log is at position 355; we can use it for the `--start-position` option, so that any statements after the position are included:

```
shell> mysqlbinlog --start-position=355 /var/lib/mysql/bin.123456 \  
      | mysql -u root -p
```

Your database has been restored the latest statement recorded in the binary log file, but with the selected event skipped.

7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.11.13, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 4.6.4.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause `MyISAM FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 4.6.4.1, “myisamchk General Options”](#).

`MyISAM` table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check `MyISAM` tables, use `CHECK TABLE`.
- To repair `MyISAM` tables, use `REPAIR TABLE`.
- To optimize `MyISAM` tables, use `OPTIMIZE TABLE`.
- To analyze `MyISAM` tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 13.7.3, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how **MyISAM** tables can become corrupted, see [Section 16.2.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each **MyISAM** table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

7.6.2 How to Check MyISAM Tables for Errors

To check a **MyISAM** table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a

long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.3.2, “CHECK TABLE Statement”](#), and [Section 13.7.3.5, “REPAIR TABLE Statement”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to three stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 7.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 4.6.4.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
```

```
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 13.7.3.5, “REPAIR TABLE Statement”](#).

7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 13.7.3.4, “OPTIMIZE TABLE Statement”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 13.7.3, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have

been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check **MyISAM** tables automatically, start it with the `myisam_recover_options` system variable set. See [Section 5.1.8, “Server System Variables”](#).

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to **MyISAM** tables with dynamic-sized rows (tables with **VARCHAR**, **BLOB**, or **TEXT** columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M */*.MYI
```

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

- [Optimizing at the Database Level](#)
- [Optimizing at the Hardware Level](#)
- [Balancing Portability and Performance](#)

Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.
- Are the right [indexes](#) in place to make queries efficient?
- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as [InnoDB](#) or a nontransactional one such as [MyISAM](#) can be very important for performance and scalability.

Note

[InnoDB](#) is the default storage engine for new tables. In practice, the advanced [InnoDB](#) performance features mean that [InnoDB](#) tables often outperform the simpler [MyISAM](#) tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with [InnoDB](#) tables, and for read-only [MyISAM](#) tables.
- Does the application use an appropriate [locking strategy](#)? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The [InnoDB](#) storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.
- Are all [memory areas used for caching](#) sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the [InnoDB](#) buffer pool and the [MyISAM](#) key cache.

Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these [bottlenecks](#), or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/* ! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see [Section 9.6, “Comment Syntax”](#).

8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

8.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

NDB Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see [Conditions for NDB pushdown joins](#).

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an [index](#). Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as [joins](#) and [foreign keys](#). You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 8.3.1, “How MySQL Uses Indexes”](#) and [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.
- Minimize the number of [full table scans](#) in your queries, particularly for big tables.
- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.

- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both [InnoDB](#) and [MyISAM](#) have sets of guidelines for enabling and sustaining high performance in queries. For details, see [Section 8.5.6, “Optimizing InnoDB Queries”](#) and [Section 8.6.1, “Optimizing MyISAM Queries”](#).
- You can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#).
- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.
- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the [EXPLAIN](#) plan and adjusting your indexes, [WHERE](#) clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the [EXPLAIN](#) plan might be your first step for every query.)
- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the [InnoDB buffer pool](#), [MyISAM](#) key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.
- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.
- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

8.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing [WHERE](#) clauses. The examples use [SELECT](#) statements, but the same optimizations apply for [WHERE](#) clauses in [DELETE](#) and [UPDATE](#) statements.

Note

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal:

```
(b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6)
-> b=5 OR b=6
```

In MySQL 8.0.14 and later, this takes place during preparation rather than during the optimization phase, which helps in simplification of joins. See [Section 8.2.1.9, “Outer Join Optimization”](#), for further information and examples.

- Constant expressions used by indexes are evaluated only once.
- Beginning with MySQL 8.0.16, comparisons of columns of numeric types with constant values are checked and folded or removed for invalid or out-of-range values:

```
# CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
SELECT * FROM t WHERE c << 256;
->> SELECT * FROM t WHERE 1;
```

See [Section 8.2.1.14, “Constant-Folding Optimization”](#), for more information.

- `COUNT(*)` on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `MEMORY` tables. This is also done for any `NOT NULL` expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT` statements are impossible and returns no rows.
- `HAVING` is merged with `WHERE` if you do not use `GROUP BY` or aggregate functions (`COUNT()`, `MIN()`, and so on).
- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
 - An empty table or a table with one row.
 - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;
```

```

SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;

```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```

SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;

```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... ;

```

8.2.1.2 Range Optimization

The [range](#) access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections describe conditions under which the optimizer uses range access.

- [Range Access Method for Single-Part Indexes](#)
- [Range Access Method for Multiple-Part Indexes](#)
- [Equality Range Optimization of Many-Valued Comparisons](#)
- [Skip Scan Range Access Method](#)
- [Range Optimization of Row Constructor Expressions](#)
- [Limiting Memory Use for Range Optimization](#)

Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the [WHERE](#) clause, denoted as *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both [BTREE](#) and [HASH](#) indexes, comparison of a key part with a constant value is a range condition when using the [=](#), [<=>](#), [IN\(\)](#), [IS NULL](#), or [IS NOT NULL](#) operators.
- Additionally, for [BTREE](#) indexes, comparison of a key part with a constant value is a range condition when using the [>](#), [<](#), [>=](#), [<=](#), [BETWEEN](#), [!=](#), or [<>](#) operators, or [LIKE](#) comparisons if the argument to [LIKE](#) is a constant string that does not start with a wildcard character.
- For all index types, multiple range conditions combined with [OR](#) or [AND](#) form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a [const](#) or [system](#) table from the same join

- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```
SELECT * FROM t1
  WHERE key_col > 1
     AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
     OR key_col IN (15,18,20);

SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
     OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Replacing them with `TRUE` yields:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants yields:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants yields:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<code>key_part1</code>	<code>key_part2</code>	<code>key_part3</code>
NULL	1	'abc'
NULL	1	'xyz'
NULL	2	'foo'
1	1	'abc'
1	1	'xyz'
1	2	'abc'
2	1	'aaa'

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For `HASH` indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1`, `const2`, ... are constants, `cmp` is one of the `=`, `<=>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part `HASH` index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Range Access Method for Single-Part Indexes](#).

- For a `BTREE` index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<=>`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=`, `<=>`, or `IS NULL`. If the operator is `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE`, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR`, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND`, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see [Range Access Method for Single-Part Indexes](#). Analogous steps are performed for range conditions on multiple-part indexes.

Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where `col_name` is an indexed column:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

Each expression is true if `col_name` is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

- If there is a unique index on `col_name`, the row estimate for each range is 1 because at most one row can have the given value.
- Otherwise, any index on `col_name` is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression `col_name IN (10, 20, 30)` has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The `eq_range_index_dive_limit` system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to N equality ranges, set `eq_range_index_dive_limit` to $N + 1$. To disable use of statistics and always use index dives regardless of N , set `eq_range_index_dive_limit` to 0.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

Prior to MySQL 8.0, there is no way of skipping the use of index dives to estimate index usefulness, except by using the `eq_range_index_dive_limit` system variable. In MySQL 8.0, index dive skipping is possible for queries that satisfy all these conditions:

- The query is for a single table, not a join on multiple tables.
- A single-index `FORCE INDEX` index hint is present. The idea is that if index use is forced, there is nothing to be gained from the additional overhead of performing dives into the index.
- The index is nonunique and not a `FULLTEXT` index.
- No subquery is present.
- No `DISTINCT`, `GROUP BY`, or `ORDER BY` clause is present.

For `EXPLAIN FOR CONNECTION`, the output changes as follows if index dives are skipped:

- For traditional output, the `rows` and `filtered` values are `NULL`.
- For JSON output, `rows_examined_per_scan` and `rows_produced_per_join` do not appear, `skip_index_dive_due_to_force` is `true`, and cost calculations are not accurate.

Without `FOR CONNECTION`, `EXPLAIN` output does not change when index dives are skipped.

After execution of a query for which index dives are skipped, the corresponding row in the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table contains an `index_dives_for_range_access` value of `skipped_due_to_force_index`.

Skip Scan Range Access Method

Consider the following scenario:

```
CREATE TABLE t1 (f1 INT NOT NULL, f2 INT NOT NULL, PRIMARY KEY(f1, f2));
INSERT INTO t1 VALUES
  (1,1), (1,2), (1,3), (1,4), (1,5),
  (2,1), (2,2), (2,3), (2,4), (2,5);
INSERT INTO t1 SELECT f1, f2 + 5 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 10 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 20 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 40 FROM t1;
ANALYZE TABLE t1;

EXPLAIN SELECT f1, f2 FROM t1 WHERE f2 > 40;
```

To execute this query, MySQL can choose an index scan to fetch all rows (the index includes all columns to be selected), then apply the `f2 > 40` condition from the `WHERE` clause to produce the final result set.

A range scan is more efficient than a full index scan, but cannot be used in this case because there is no condition on `f1`, the first index column. However, as of MySQL 8.0.13, the optimizer can perform multiple range scans, one for each value of `f1`, using a method called Skip Scan that is similar to Loose Index Scan (see [Section 8.2.1.17, "GROUP BY Optimization"](#)):

1. Skip between distinct values of the first index part, `f1` (the index prefix).
2. Perform a subrange scan on each distinct prefix value for the `f2 > 40` condition on the remaining index part.

For the data set shown earlier, the algorithm operates like this:

1. Get the first distinct value of the first key part (`f1 = 1`).
2. Construct the range based on the first and second key parts (`f1 = 1 AND f2 > 40`).
3. Perform a range scan.
4. Get the next distinct value of the first key part (`f1 = 2`).
5. Construct the range based on the first and second key parts (`f1 = 2 AND f2 > 40`).
6. Perform a range scan.

Using this strategy decreases the number of accessed rows because MySQL skips the rows that do not qualify for each constructed range. This Skip Scan access method is applicable under the following conditions:

- Table T has at least one compound index with key parts of the form `([A_1, ..., A_k], B_1, ..., B_m, C [, D_1, ..., D_n])`. Key parts A and D may be empty, but B and C must be nonempty.
- The query references only one table.
- The query does not use `GROUP BY` or `DISTINCT`.
- The query references only columns in the index.
- The predicates on `A_1, ..., A_k` must be equality predicates and they must be constants. This includes the `IN()` operator.
- The query must be a conjunctive query; that is, an `AND` of `OR` conditions: `(cond1(key_part1) OR cond2(key_part1)) AND (cond1(key_part2) OR ...) AND ...`
- There must be a range condition on C.
- Conditions on D columns are permitted. Conditions on D must be in conjunction with the range condition on C.

Use of Skip Scan is indicated in `EXPLAIN` output as follows:

- `Using index for skip scan` in the `Extra` column indicates that the loose index Skip Scan access method is used.
- If the index can be used for Skip Scan, the index should be visible in the `possible_keys` column.

Use of Skip Scan is indicated in optimizer trace output by a `"skip_scan"` element of this form:

```
"skip_scan_range": {
  "type": "skip_scan",
  "index": index_used_for_skip_scan,
  "key_parts_used_for_access": [key_parts_used_for_access],
  "range": [range]
}
```

You may also see a `"best_skip_scan_summary"` element. If Skip Scan is chosen as the best range access variant, a `"chosen_range_access_summary"` is written. If Skip Scan is chosen as the overall best access method, a `"best_access_path"` element is present.

Use of Skip Scan is subject to the value of the `skip_scan` flag of the `optimizer_switch` system variable. See [Section 8.9.2, “Switchable Optimizations”](#). By default, this flag is `on`. To disable it, set `skip_scan` to `off`.

In addition to using the `optimizer_switch` system variable to control optimizer use of Skip Scan session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 8.9.3, “Optimizer Hints”](#).

Range Optimization of Row Constructor Expressions

The optimizer is able to apply the range scan access method to queries of this form:

```
SELECT ... FROM t1 WHERE ( col_1, col_2 ) IN ( ( 'a', 'b' ), ( 'c', 'd' ) );
```

Previously, for range scans to be used, it was necessary to write the query as:

```
SELECT ... FROM t1 WHERE ( col_1 = 'a' AND col_2 = 'b' )
OR ( col_1 = 'c' AND col_2 = 'd' );
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only `IN()` predicates are used, not `NOT IN()`.
- On the left side of the `IN()` predicate, the row constructor contains only column references.
- On the right side of the `IN()` predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.
- On the right side of the `IN()` predicate, there is more than one row constructor.

For more information about the optimizer and row constructors, see [Section 8.2.1.22, “Row Constructor Expression Optimization”](#)

Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the `range_optimizer_max_mem_size` system variable:

- A value of 0 means “no limit.”
- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this happens, the following warning occurs (where *N* is the current `range_optimizer_max_mem_size` value):

```
Warning      3170      Memory capacity of N bytes for
                  'range_optimizer_max_mem_size' exceeded. Range
                  optimization was not done for this query.
```

- For `UPDATE` and `DELETE` statements, if the optimizer falls back to a full table scan and the `sql_safe_updates` system variable is enabled, an error occurs rather than a warning because, in effect, no key is used to determine which rows to modify. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with `OR` uses approximately 230 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 OR a=2 OR a=3 OR ... a=N;
```

- Similarly for a query such as the following, each predicate combined with `AND` uses approximately 125 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 AND b=1 AND c=1 ... N;
```

- For a query with `IN()` predicates:

```
SELECT COUNT(*) FROM t
WHERE a IN (1,2, ..., M) AND b IN (1,2, ..., N);
```

Each literal value in an `IN()` list counts as a predicate combined with `OR`. If there are two `IN()` lists, the number of predicates combined with `OR` is the product of the number of literal values in each list. Thus, the number of predicates combined with `OR` in the preceding case is $M \times N$.

8.2.1.3 Index Merge Optimization

The *Index Merge* access method retrieves rows with multiple `range` scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;

SELECT * FROM t1, t2
WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
AND t2.key1 = t1.some_col;

SELECT * FROM t1, t2
WHERE t1.key1 = 1
AND (t2.key1 = t1.some_col OR t2.key2 = t1.some_col2);
```

Note

The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

```
(x AND y) OR z => (x OR z) AND (y OR z)
(x OR y) AND z => (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the `Extra` field of `EXPLAIN` output:

- Using `intersect(...)`

- `Using union(...)`
- `Using sort_union(...)`

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

- [Index Merge Intersection Access Algorithm](#)
- [Index Merge Union Access Algorithm](#)
- [Index Merge Sort-Union Access Algorithm](#)
- [Influencing Index Merge Optimization](#)

Index Merge Intersection Access Algorithm

This access algorithm is applicable when a `WHERE` clause is converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- An *N*-part expression of this form, where the index has exactly *N* parts (that is, all index parts are covered):

```
key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN
```

- Any range condition over the primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table
  WHERE primary_key < 10 AND key_coll = 20;

SELECT * FROM tbl_name
  WHERE key1_part1 = 1 AND key1_part2 = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an `InnoDB` table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

Index Merge Union Access Algorithm

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table's `WHERE` clause is converted to several range conditions on different keys combined with `OR`, and each condition is one of the following:

- An *N*-part expression of this form, where the index has exactly *N* parts (that is, all index parts are covered):

```
key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN
```

- Any range condition over a primary key of an `InnoDB` table.
- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1
WHERE key1 = 1 OR key2 = 2 OR key3 = 3;

SELECT * FROM innodb_table
WHERE (key1 = 1 AND key2 = 2)
OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;
```

Index Merge Sort-Union Access Algorithm

This access algorithm is applicable when the `WHERE` clause is converted to several range conditions combined by `OR`, but the Index Merge union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name
WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

Influencing Index Merge Optimization

Use of Index Merge is subject to the value of the `index_merge`, `index_merge_intersection`, `index_merge_union`, and `index_merge_sort_union` flags of the `optimizer_switch` system variable. See [Section 8.9.2, “Switchable Optimizations”](#). By default, all those flags are `on`. To enable only certain algorithms, set `index_merge` to `off`, and enable only such of the others as should be permitted.

In addition to using the `optimizer_switch` system variable to control optimizer use of the Index Merge algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 8.9.3, “Optimizer Hints”](#).

8.2.1.4 Hash Join Optimization

Beginning with MySQL 8.0.18, MySQL employs a hash join for any query for which each join has an equi-join condition and uses no indexes, such as this one:

```
SELECT *
FROM t1
JOIN t2
ON t1.c1=t2.c1;
```

A hash join is usually faster than and is intended to be used in such cases instead of the block nested loop algorithm (see [Block Nested-Loop Join Algorithm](#)) employed in previous versions of MySQL. Beginning with MySQL 8.0.20, support for block nested loop is removed, and the server employs a hash join wherever a block nested loop would have been used previously.

In the example just shown and the remaining examples in this section, we assume that the three tables `t1`, `t2`, and `t3` have been created using the following statements:

```
CREATE TABLE t1 (c1 INT, c2 INT);
CREATE TABLE t2 (c1 INT, c2 INT);
CREATE TABLE t3 (c1 INT, c2 INT);
```

You can see that a hash join is being employed by using `EXPLAIN`, like this:

```
mysql> EXPLAIN
-> SELECT * FROM t1
-> JOIN t2 ON t1.c1=t2.c1\G
***** 1. row *****
id: 1
```

```

select_type: SIMPLE
table: t1
partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: NULL
***** 2. row *****
id: 1
select_type: SIMPLE
table: t2
partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: Using where; Using join buffer (hash join)
    
```

(Prior to MySQL 8.0.20, it was necessary to include the `FORMAT=TREE` option to see whether hash joins were being used for a given join.)

`EXPLAIN ANALYZE` also displays information about hash joins used.

The hash join is used for queries involving multiple joins as well, as long as at least one join condition for each pair of tables is an equi-join, like the query shown here:

```

SELECT * FROM t1
  JOIN t2 ON (t1.c1 = t2.c1 AND t1.c2 < t2.c2)
  JOIN t3 ON (t2.c1 = t3.c1);
    
```

In cases like the one just shown, which makes use of an inner join, any extra conditions which are not equi-joins are applied as filters after the join is executed. (For outer joins, such as left joins, semijoins, and antijoins, they are printed as part of the join.) This can be seen here in the output of `EXPLAIN`:

```

mysql> EXPLAIN FORMAT=TREE
-> SELECT *
->   FROM t1
->   JOIN t2
->     ON (t1.c1 = t2.c1 AND t1.c2 < t2.c2)
->   JOIN t3
->     ON (t2.c1 = t3.c1)\G
***** 1. row *****
EXPLAIN: -> Inner hash join (t3.c1 = t1.c1) (cost=1.05 rows=1)
-> Table scan on t3 (cost=0.35 rows=1)
-> Hash
->   Filter: (t1.c2 < t2.c2) (cost=0.70 rows=1)
->     Inner hash join (t2.c1 = t1.c1) (cost=0.70 rows=1)
->       Table scan on t2 (cost=0.35 rows=1)
->       Hash
->         Table scan on t1 (cost=0.35 rows=1)
    
```

As also can be seen from the output just shown, multiple hash joins can be (and are) used for joins having multiple equi-join conditions.

Prior to MySQL 8.0.20, a hash join could not be used if any pair of joined tables did not have at least one equi-join condition, and the slower block nested loop algorithm was employed. In MySQL 8.0.20 and later, the hash join is used in such cases, as shown here:

```

mysql> EXPLAIN FORMAT=TREE
-> SELECT * FROM t1
->   JOIN t2 ON (t1.c1 = t2.c1)
    
```

```

-> JOIN t3 ON (t2.c1 < t3.c1)\G
***** 1. row *****
EXPLAIN: -> Filter: (t1.c1 < t3.c1) (cost=1.05 rows=1)
-> Inner hash join (no condition) (cost=1.05 rows=1)
-> Table scan on t3 (cost=0.35 rows=1)
-> Hash
-> Inner hash join (t2.c1 = t1.c1) (cost=0.70 rows=1)
-> Table scan on t2 (cost=0.35 rows=1)
-> Hash
-> Table scan on t1 (cost=0.35 rows=1)
    
```

(Additional examples are provided later in this section.)

A hash join is also applied for a Cartesian product—that is, when no join condition is specified, as shown here:

```

mysql> EXPLAIN FORMAT=TREE
-> SELECT *
-> FROM t1
-> JOIN t2
-> WHERE t1.c2 > 50\G
***** 1. row *****
EXPLAIN: -> Inner hash join (cost=0.70 rows=1)
-> Table scan on t2 (cost=0.35 rows=1)
-> Hash
-> Filter: (t1.c2 > 50) (cost=0.35 rows=1)
-> Table scan on t1 (cost=0.35 rows=1)
    
```

In MySQL 8.0.20 and later, it is no longer necessary for the join to contain at least one equi-join condition in order for a hash join to be used. This means that the types of queries which can be optimized using hash joins include those in the following list (with examples):

- *Inner non-equi-join:*

```

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 JOIN t2 ON t1.c1 < t2.c1\G
***** 1. row *****
EXPLAIN: -> Filter: (t1.c1 < t2.c1) (cost=4.70 rows=12)
-> Inner hash join (no condition) (cost=4.70 rows=12)
-> Table scan on t2 (cost=0.08 rows=6)
-> Hash
-> Table scan on t1 (cost=0.85 rows=6)
    
```

- *Semijoin:*

```

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1
-> WHERE t1.c1 IN (SELECT t2.c2 FROM t2)\G
***** 1. row *****
EXPLAIN: -> Nested loop inner join
-> Filter: (t1.c1 is not null) (cost=0.85 rows=6)
-> Table scan on t1 (cost=0.85 rows=6)
-> Single-row index lookup on <subquery2> using <auto_distinct_key> (c2=t1.c1)
-> Materialize with deduplication
-> Filter: (t2.c2 is not null) (cost=0.85 rows=6)
-> Table scan on t2 (cost=0.85 rows=6)
    
```

- *Antijoin:*

```

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t2
-> WHERE NOT EXISTS (SELECT * FROM t1 WHERE t1.c1 = t2.c1)\G
***** 1. row *****
EXPLAIN: -> Nested loop antijoin
-> Table scan on t2 (cost=0.85 rows=6)
-> Single-row index lookup on <subquery2> using <auto_distinct_key> (c1=t2.c1)
-> Materialize with deduplication
-> Filter: (t1.c1 is not null) (cost=0.85 rows=6)
-> Table scan on t1 (cost=0.85 rows=6)
    
```

- *Left outer join:*

```

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 LEFT JOIN t2 ON t1.c1 = t2.c1\G
    
```

```
***** 1. row *****
EXPLAIN: -> Left hash join (t2.c1 = t1.c1) (cost=3.99 rows=36)
-> Table scan on t1 (cost=0.85 rows=6)
-> Hash
-> Table scan on t2 (cost=0.14 rows=6)
```

- *Right outer join* (observe that MySQL rewrites all right outer joins as left outer joins):

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 RIGHT JOIN t2 ON t1.c1 = t2.c1\G
***** 1. row *****
EXPLAIN: -> Left hash join (t1.c1 = t2.c1) (cost=3.99 rows=36)
-> Table scan on t2 (cost=0.85 rows=6)
-> Hash
-> Table scan on t1 (cost=0.14 rows=6)
```

By default, MySQL 8.0.18 and later employs hash joins whenever possible. It is possible to control whether hash joins are employed using one of the [BNL](#) and [NO_BNL](#) optimizer hints.

(MySQL 8.0.18 supported [hash_join=on](#) or [hash_join=off](#) as part of the setting for the [optimizer_switch](#) server system variable as well as the optimizer hints [HASH_JOIN](#) or [NO_HASH_JOIN](#). In MySQL 8.0.19 and later, these no longer have any effect.)

Memory usage by hash joins can be controlled using the [join_buffer_size](#) system variable; a hash join cannot use more memory than this amount. When the memory required for a hash join exceeds the amount available, MySQL handles this by using files on disk. If this happens, you should be aware that the join may not succeed if a hash join cannot fit into memory and it creates more files than set for [open_files_limit](#). To avoid such problems, make either of the following changes:

- Increase [join_buffer_size](#) so that the hash join does not spill over to disk.
- Increase [open_files_limit](#).

Beginning with MySQL 8.0.18, join buffers for hash joins are allocated incrementally; thus, you can set [join_buffer_size](#) higher without small queries allocating very large amounts of RAM, but outer joins allocate the entire buffer. In MySQL 8.0.20 and later, hash joins are used for outer joins (including antijoins and semijoins) as well, so this is no longer an issue.

8.2.1.5 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the [NDB](#) storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

```
CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDB;
```

Engine condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of engine condition pushdown can be seen in the output of [EXPLAIN](#):

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
```

```
***** 1. row *****
  id: 1
  select_type: SIMPLE
  table: t1
  type: ALL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 10
  Extra: Using where with pushed condition
```

However, engine condition pushdown *cannot* be used with the following query:

```
SELECT a,b FROM t1 WHERE a = 10;
```

Engine condition pushdown is not applicable here because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.)

Engine condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
  id: 1
  select_type: SIMPLE
  table: t1
  type: range
possible_keys: a
  key: a
  key_len: 5
  ref: NULL
  rows: 2
  Extra: Using where with pushed condition
```

Other supported comparisons for engine condition pushdown include the following:

- `column [NOT] LIKE pattern`

`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 12.8.1, “String Comparison Functions and Operators”](#).

- `column IS [NOT] NULL`
- `column IN (value_list)`

Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable's `engine_condition_pushdown` flag to `off`. For example, in a `my.cnf` file, use these lines:

```
[mysqld]
optimizer_switch=engine_condition_pushdown=off
```

At runtime, disable condition pushdown like this:

```
SET optimizer_switch='engine_condition_pushdown=off';
```

Limitations. Engine condition pushdown is subject to the following limitations:

- Engine condition pushdown is supported only by the [NDB](#) storage engine.
- Prior to NDB 8.0.18, columns could be compared with constants or expressions which evaluate to constant values only. In NDB 8.0.18 and later, columns can be compared with one another as long as they are of exactly the same type, including the same signedness, length, character set, precision, and scale, where these are applicable.
- Columns used in comparisons cannot be of any of the [BLOB](#) or [TEXT](#) types. This exclusion extends to [JSON](#), [BIT](#), and [ENUM](#) columns as well.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended [EXPLAIN](#) output to determine which conditions are actually pushed down. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

Previously, engine condition pushdown was limited to terms referring to column values from the same table to which the condition was being pushed. Beginning with NDB 8.0.16, column values from tables earlier in the query plan can also be referred to from pushed conditions. This reduces the number of rows which must be handled by the SQL node during join processing. Filtering can be also performed in parallel in the LDM threads, rather than in a single `mysqld` process. This has the potential to improve performance of queries by a significant margin.

Beginning with NDB 8.0.20, an outer join using a scan can be pushed if there are no unpushable conditions on any table used in the same join nest, or on any table in join nmests above it on which it depends. This is also true for a semijoin, provided the optimization strategy employed is [firstMatch](#) (see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)).

Join algorithms cannot be combined with referring columns from previous tables in the following two situations:

1. When any of the referred previous tables are in a join buffer. In this case, each row retrieved from the scan-filtered table is matched against every row in the buffer. This means that there is no single specific row from which column values can be fetched from when generating the scan filter.
2. When the column originates from a child operation in a pushed join. This is because rows referenced from ancestor operations in the join have not yet been retrieved when the scan filter is generated.

8.2.1.6 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the [WHERE](#) condition for the rows. With ICP enabled, and if parts of the [WHERE](#) condition can be evaluated by using only columns from the index, the MySQL server pushes this part of the [WHERE](#) condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Applicability of the Index Condition Pushdown optimization is subject to these conditions:

- ICP is used for the [range](#), [ref](#), [eq_ref](#), and [ref_or_null](#) access methods when there is a need to access full table rows.
- ICP can be used for [InnoDB](#) and [MyISAM](#) tables, including partitioned [InnoDB](#) and [MyISAM](#) tables.
- For [InnoDB](#) tables, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-row reads and thereby reduce I/O operations. For [InnoDB](#) clustered indexes, the complete record is already read into the [InnoDB](#) buffer. Using ICP in this case does not reduce I/O.

- ICP is not supported with secondary indexes created on virtual generated columns. [InnoDB](#) supports secondary indexes on virtual generated columns.
- Conditions that refer to subqueries cannot be pushed down.
- Conditions that refer to stored functions cannot be pushed down. Storage engines cannot invoke stored functions.
- Triggered conditions cannot be pushed down. (For information about triggered conditions, see [Section 8.2.2.3, “Optimizing Subqueries with the EXISTS Strategy”](#).)

To understand how this optimization works, first consider how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.
2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

Using Index Condition Pushdown, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).
2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.
3. If the condition is satisfied, use the index tuple to locate and read the full table row.
4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

`EXPLAIN` output shows `Using index condition` in the `Extra` column when Index Condition Pushdown is used. It does not show `Using index` because that does not apply when full table rows must be read.

Suppose that a table contains information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL checks the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to index tuples that match the `zipcode` condition but not the `lastname` condition.

Index Condition Pushdown is enabled by default. It can be controlled with the `optimizer_switch` system variable by setting the `index_condition_pushdown` flag:

```
SET optimizer_switch = 'index_condition_pushdown=off';
SET optimizer_switch = 'index_condition_pushdown=on';
```

See [Section 8.9.2, “Switchable Optimizations”](#).

8.2.1.7 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- [Nested-Loop Join Algorithm](#)
- [Block Nested-Loop Join Algorithm](#)

Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

Table	Join Type
<code>t1</code>	<code>range</code>
<code>t2</code>	<code>ref</code>
<code>t3</code>	<code>ALL</code>

If a simple NLJ algorithm is used, the join is processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions, send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces by an order of magnitude the number of times the inner table must be read.

Prior to MySQL 8.0.18, this algorithm was applied for equi-joins when no indexes could be used; in MySQL 8.0.18 and later, the hash join optimization is employed in such cases. Starting with MySQL 8.0.20, the block nested loop is no longer used by MySQL, and a hash join is employed for in all cases where the block nested loop was used previously. See [Section 8.2.1.4, “Hash Join Optimization”](#).

MySQL join buffering has these characteristics:

- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`. Use of buffering is also applicable to outer joins, as described in [Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#).
- A join buffer is never allocated for the first nonconstant table, even if it would be of type `ALL` or `index`.
- Only columns of interest to a join are stored in its join buffer, not whole rows.
- The `join_buffer_size` system variable determines the size of each join buffer used to process a query.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.

- A join buffer is allocated prior to executing the join and freed after the query is done.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions, send to client
        }
      }
      empty join buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions, send to client
    }
  }
}
```

If S is the size of each stored $t1$, $t2$ combination in the join buffer and C is the number of combinations in the buffer, the number of times table $t3$ is scanned is:

$$(S * C) / \text{join_buffer_size} + 1$$

The number of $t3$ scans decreases as the value of `join_buffer_size` increases, up to the point when `join_buffer_size` is large enough to hold all previous row combinations. At that point, no speed is gained by making it larger.

8.2.1.8 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in [Section 13.2.10.2, “JOIN Clause”](#).

The syntax of *table_factor* is extended in comparison with the SQL Standard. The latter accepts only *table_reference*, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of *table_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is syntactically equivalent to `INNER JOIN`; they can replace each other. In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
      ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows (1), (2)
- Table `t2` contains row (1,101)
- Table `t3` contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
      FROM t1
      LEFT JOIN
      (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
      ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
      FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
      LEFT JOIN t3
      ON t2.b=t3.b OR t2.b IS NULL;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
      FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
      FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

Is equivalent to this expression for any tables `t1,t2,t3` and any condition `P` over attributes `t2.b` and `t3.b`:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

Whenever the order of execution of join operations in a join expression (*joined_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1
```

```
SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` play the role of the left and right delimiters for the expression `(t2,t3)`.

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see [Section 8.2.1.7, “Nested-Loop Join Algorithms”](#)). Suppose that a join query over 3 tables `T1,T2,T3` has this form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
          INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3)
```

Here, `P1(T1,T2)` and `P2(T2,T3)` are some join conditions (on expressions), whereas `P(T1,T2,T3)` is a condition over columns of tables `T1,T2,T3`.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
```

```

FOR each row t2 in T2 such that P1(t1,t2) {
  FOR each row t3 in T3 such that P2(t2,t3) {
    IF P(t1,t2,t3) {
      t:=t1||t2||t3; OUTPUT t;
    }
  }
}

```

The notation `t1 || t2 || t3` indicates a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`. In some of the following examples, `NULL` where a table name appears means a row in which `NULL` is used for each column of that table. For example, `t1 || t2 || NULL` indicates a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`. Such a row is said to be `NULL`-complemented.

Now consider a query with nested outer joins:

```

SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON P2(T2,T3))
      ON P1(T1,T2)
WHERE P(T1,T2,T3)

```

For this query, modify the nested-loop pattern to obtain:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

```

(T2 LEFT JOIN T3 ON P2(T2,T3))

```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```

FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {

```

```

        t:=t1||t2||t3; OUTPUT t;
    }
}
}

```

For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, **T1** must be processed in the outer loop because it is used in an outer join. **T2** and **T3** are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, **T2** and **T3** can be processed in either order.

```

SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)

```

One nesting evaluates **T2**, then **T3**:

```

FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) {
        FOR each row t3 in T3 such that P2(t1,t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}

```

The other nesting evaluates **T3**, then **T2**:

```

FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t3 in T3 such that P2(t1,t3) {
        FOR each row t2 in T2 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}

```

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our **WHERE** condition **P(T1,T2,T3)** can be represented by a conjunctive formula:

```

P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).

```

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

```

FOR each row t1 in T1 such that C1(t1) {
    FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
        FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}

```

```

    }
  }
}

```

You see that each of the conjuncts `C1(T1)`, `C2(T2)`, `C3(T3)` are pushed out of the most inner loop to the most outer loop where it can be evaluated. If `C1(T1)` is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table `T1` passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

```

FOR each row t1 in T1 such that C1(t1) {
  BOOL f1:=FALSE;
  FOR each row t2 in T2
    such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
      BOOL f2:=FALSE;
      FOR each row t3 in T3
        such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
          IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
            t:=t1||t2||t3; OUTPUT t;
          }
          f2=TRUE;
        }
        f1=TRUE;
      }
      IF (!f2) {
        IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
          t:=t1||t2||NULL; OUTPUT t;
        }
        f1=TRUE;
      }
    }
  }
  IF (!f1 && P(t1,NULL,NULL)) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}

```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition.

8.2.1.9 Outer Join Optimization

Outer joins include `LEFT JOIN` and `RIGHT JOIN`.

MySQL implements an `A LEFT JOIN B join_specification` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)

- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The `RIGHT JOIN` implementation is analogous to that of `LEFT JOIN` with the table roles reversed. Right joins are converted to equivalent left joins, as described in [Section 8.2.1.10, “Outer Join Simplification”](#).

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to an inner join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to an inner join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

In MySQL 8.0.14 and later, trivial `WHERE` conditions arising from constant literal expressions are removed during preparation, rather than at a later stage in optimization, by which time joins have already been simplified. Earlier removal of trivial conditions allows the optimizer to convert outer joins to inner joins; this can result in improved plans for queries with outer joins containing trivial conditions in the `WHERE` clause, such as this one:

```
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2 OR 0 = 1
```

The optimizer now sees during preparation that `0 = 1` is always false, making `OR 0 = 1` redundant, and removes it, leaving this:

```
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 where condition_2
```

Now the optimizer can rewrite the query as an inner join, like this:

```
SELECT * FROM t1 JOIN t2 WHERE condition_1 AND condition_2
```

Now the optimizer can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use optimizer hints; see [Section 8.9.3, “Optimizer Hints”](#). Alternatively, use `STRAIGHT_JOIN`; see [Section 13.2.10, “SELECT Statement”](#). However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations; see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).

8.2.1.10 Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```

Becomes this equivalent left join:

```
(T2, ...) LEFT JOIN (T1, ...) ON P(T1, ..., T2, ...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2,P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where `R(T2)` greatly narrows the number of matching rows from table `T2`:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
WHERE P(T1,T2) AND R(T2)
```

If the query is executed as written, the optimizer has no choice but to access the less-restricted table `T1` before the more-restricted table `T2`, which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the `WHERE` condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an outer join operation if it evaluates to `FALSE` or `UNKNOWN` for any `NULL`-complemented row generated for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected because they cannot be true for any `NULL`-complemented row (with `T2` columns set to `NULL`):

```
T2.B IS NOT NULL
T2.B > 3
T2.C <= T1.C
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected because they might be true for a `NULL`-complemented row:

```
T2.B IS NULL
T1.B < 3 OR T2.B IS NOT NULL
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

If the **WHERE** condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
              INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer evaluates only plans compatible with the single table-access order **T1, T2, T3**. For the rewritten query, it additionally considers the access order **T3, T1, T2**.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
              LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Is first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
              INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

The remaining outer join operation can also be replaced by an inner join because the condition **T3.B=T2.B** is null-rejected. This results in a query with no outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
WHERE T3.C > 0
```

Is converted to:

```
SELECT * FROM T1 LEFT JOIN
              (T2 INNER JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
WHERE T3.C > 0
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
              (T2,T3)
              ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0
```

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the **WHERE** condition. In this query, the **WHERE** condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join **T2.A=T1.A AND T3.C=T1.C** is null-rejected:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

Consequently, the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2, T3)
      ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

8.2.1.11 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.
- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on virtual generated columns. [InnoDB](#) supports secondary indexes on virtual generated columns.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for [InnoDB](#) and [MyISAM](#) tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for [NDB](#) tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the [Extra](#) column in [EXPLAIN](#) output shows [Using MRR](#).

[InnoDB](#) and [MyISAM](#) do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a [covering index](#)); MRR provides no benefit.

Two `optimizer_switch` system variable flags provide an interface to the use of MRR optimization. The `mrr` flag controls whether MRR is enabled. If `mrr` is enabled (`on`), the `mrr_cost_based` flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR (`on`) or uses MRR whenever possible (`off`). By default, `mrr` is `on` and `mrr_cost_based` is `on`. See [Section 8.9.2, “Switchable Optimizations”](#).

For MRR, a storage engine uses the value of the `read_rnd_buffer_size` system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to `read_rnd_buffer_size` bytes and determines the number of ranges to process in a single pass.

8.2.1.12 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semijoin operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semijoin operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semijoin strategies, see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)

- [Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms](#)
- [Block Nested-Loop Algorithm for Outer Joins and Semijoins](#)
- [Batched Key Access Joins](#)
- [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#)

Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semijoins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the `VARCHAR` type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer `B1` is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer `B2`:

- A regular join buffer contains columns from each join operand. If `B2` is a regular join buffer, each row `r` put into `B2` is composed of the columns of a row `r1` from `B1` and the interesting columns of a matching row `r2` from table `t3`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If `B2` is an incremental join buffer, it contains the interesting columns of the row `r2` together with a link to the row `r1` from `B1`.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer `B1` used to join tables `t1` and `t2` must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the

incremental buffer can refer to the same row *r* whose columns are stored in the previous join buffers insofar as all these rows match row *r*.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

In MySQL 8.0, the `block_nested_loop` flag of the `optimizer_switch` system variable works as follows:

- Prior to MySQL 8.0.20, it controls how the optimizer uses the Block Nested Loop join algorithm.
- In MySQL 8.0.18 and later, it also controls the use of hash joins (see [Section 8.2.1.4, “Hash Join Optimization”](#)).
- Beginning with MySQL 8.0.20, the flag controls hash joins only, and the block nested loop algorithm is no longer supported.

The `batched_key_access` flag controls how the optimizer uses the Batched Key Access join algorithms.

By default, `block_nested_loop` is `on` and `batched_key_access` is `off`. See [Section 8.9.2, “Switchable Optimizations”](#). Optimizer hints may also be applied; see [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#).

For information about semijoin strategies, see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)

Block Nested-Loop Algorithm for Outer Joins and Semijoins

The original implementation of the MySQL BNL algorithm was extended to support outer join and semijoin operations (and was later superseded by the hash join algorithm; see [Section 8.2.1.4, “Hash Join Optimization”](#)).

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by `NULL` complements (`NULL` values for each column in the second operand) and sent for further extensions by the remaining join operations.

In MySQL 8.0, the `block_nested_loop` flag of the `optimizer_switch` system variable works as follows:

- Prior to MySQL 8.0.20, it controls how the optimizer uses the Block Nested Loop join algorithm.
- In MySQL 8.0.18 and later, it also controls the use of hash joins (see [Section 8.2.1.4, “Hash Join Optimization”](#)).
- Beginning with MySQL 8.0.20, the flag controls hash joins only, and the block nested loop algorithm is no longer supported.

See [Section 8.9.2, “Switchable Optimizations”](#), for more information. Optimizer hints may also be applied; see [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#).

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer (Block Nested Loop)` and the `type` value is `ALL`, `index`, or `range`.

For information about semijoin strategies, see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)

Batched Key Access Joins

MySQL implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see [Section 8.2.1.11, “Multi-Range Read Optimization”](#)). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as [InnoDB](#) and [MyISAM](#). For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.
- The second scenario is used for remote storage engines such as [NDB](#). A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In `EXPLAIN` output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer (Batched Key Access)` and the `type` value is `ref` or `eq_ref`.

Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

In addition to using the `optimizer_switch` system variable to control optimizer use of the BNL and BKA algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 8.9.3, “Optimizer Hints”](#).

To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

8.2.1.13 Condition Filtering

In join processing, prefix rows are those rows passed from one table in a join to the next. In general, the optimizer attempts to put tables with low prefix counts early in the join order to keep the number of row combinations from increasing rapidly. To the extent that the optimizer can use information about conditions on rows selected from one table and passed to the next, the more accurately it can compute row estimates and choose the best execution plan.

Without condition filtering, the prefix row count for a table is based on the estimated number of rows selected by the `WHERE` clause according to whichever access method the optimizer chooses. Condition filtering enables the optimizer to use other relevant conditions in the `WHERE` clause not taken into account by the access method, and thus improve its prefix row count estimates. For example, even though there might be an index-based access method that can be used to select rows from the current table in a join, there might also be additional conditions for the table in the `WHERE` clause that can filter (further restrict) the estimate for qualifying rows passed to the next table.

A condition contributes to the filtering estimate only if:

- It refers to the current table.
- It depends on a constant value or values from earlier tables in the join sequence.
- It was not already taken into account by the access method.

In `EXPLAIN` output, the `rows` column indicates the row estimate for the chosen access method, and the `filtered` column reflects the effect of condition filtering. `filtered` values are expressed as percentages. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering.

The prefix row count (the number of rows estimated to be passed from the current table in a join to the next) is the product of the `rows` and `filtered` values. That is, the prefix row count is the estimated row count, reduced by the estimated filtering effect. For example, if `rows` is 1000 and `filtered` is 20%, condition filtering reduces the estimated row count of 1000 to a prefix row count of $1000 \times 20\% = 1000 \times .2 = 200$.

Consider the following query:

```
SELECT *
FROM employee JOIN department ON employee.dept_no = department.dept_no
WHERE employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01';
```

Suppose that the data set has these characteristics:

- The `employee` table has 1024 rows.
- The `department` table has 12 rows.
- Both tables have an index on `dept_no`.
- The `employee` table has an index on `first_name`.
- 8 rows satisfy this condition on `employee.first_name`:

```
employee.first_name = 'John'
```

- 150 rows satisfy this condition on `employee.hire_date`:

```
employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
```

- 1 row satisfies both conditions:

```
employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
```

Without condition filtering, `EXPLAIN` produces output like this:

id	table	type	possible_keys	key	ref	rows	filtered
1	employee	ref	name,h_date,dept	name	const	8	100.00
1	department	eq_ref	PRIMARY	PRIMARY	dept_no	1	100.00

For `employee`, the access method on the `name` index picks up the 8 rows that match a name of 'John'. No filtering is done (`filtered` is 100%), so all rows are prefix rows for the next table: The prefix row count is $\text{rows} \times \text{filtered} = 8 \times 100\% = 8$.

With condition filtering, the optimizer additionally takes into account conditions from the `WHERE` clause not taken into account by the access method. In this case, the optimizer uses heuristics to estimate a filtering effect of 16.31% for the `BETWEEN` condition on `employee.hire_date`. As a result, `EXPLAIN` produces output like this:

id	table	type	possible_keys	key	ref	rows	filtered
1	employee	ref	name,h_date,dept	name	const	8	16.31
1	department	eq_ref	PRIMARY	PRIMARY	dept_no	1	100.00

Now the prefix row count is $\text{rows} \times \text{filtered} = 8 \times 16.31\% = 1.3$, which more closely reflects actual data set.

Normally, the optimizer does not calculate the condition filtering effect (prefix row count reduction) for the last joined table because there is no next table to pass rows to. An exception occurs for `EXPLAIN`: To provide more information, the filtering effect is calculated for all joined tables, including the last one.

To control whether the optimizer considers additional filtering conditions, use the `condition_fanout_filter` flag of the `optimizer_switch` system variable (see [Section 8.9.2, "Switchable Optimizations"](#)). This flag is enabled by default but can be disabled to suppress condition filtering (for example, if a particular query is found to yield better performance without it).

If the optimizer overestimates the effect of condition filtering, performance may be worse than if condition filtering is not used. In such cases, these techniques may help:

- If a column is not indexed, index it so that the optimizer has some information about the distribution of column values and can improve its row estimates.
- Similarly, if no column histogram information is available, generate a histogram (see [Section 8.9.6, "Optimizer Statistics"](#)).
- Change the join order. Ways to accomplish this include join-order optimizer hints (see [Section 8.9.3, "Optimizer Hints"](#)), `STRAIGHT_JOIN` immediately following the `SELECT`, and the `STRAIGHT_JOIN` join operator.
- Disable condition filtering for the session:

```
SET optimizer_switch = 'condition_fanout_filter=off';
```

Or, for a given query, using an optimizer hint:

```
SELECT /*+ SET_VAR(optimizer_switch = 'condition_fanout_filter=off') */ ...
```

8.2.1.14 Constant-Folding Optimization

Comparisons between constants and column values in which the constant value is out of range or of the wrong type with respect to the column type are now handled once during query optimization rather row-by-row than during execution. The comparisons that can be treated in this manner are `>`, `>=`, `<`, `<=`, `<>`, `!=`, `=`, and `<=>`.

Consider the table created by the following statement:

```
CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
```

The `WHERE` condition in the query `SELECT * FROM t WHERE c < 256` contains the integral constant 256 which is out of range for a `TINYINT UNSIGNED` column. Previously, this was handled by treating both operands as the larger type, but now, since any allowed value for `c` is less than the constant, the `WHERE` expression can instead be folded as `WHERE 1`, so that the query is rewritten as `SELECT * FROM t WHERE 1`.

This makes it possible for the optimizer to remove the `WHERE` expression altogether. If the column `c` were nullable (that is, defined only as `TINYINT UNSIGNED`) the query would be rewritten like this:

```
SELECT * FROM t WHERE ti IS NOT NULL
```

Folding is performed for constants compared to supported MySQL column types as follows:

- **Integer column type.** Integer types are compared with constants of the following types as described here:
- **Integer value.** If the constant is out of range for the column type, the comparison is folded to `1` or `IS NOT NULL`, as already shown.

If the constant is a range boundary, the comparison is folded to `=`. For example (using the same table as already defined):

```
mysql> EXPLAIN SELECT * FROM t WHERE c >= 255;
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t
    partitions: NULL
       type: ALL
possible_keys: NULL
        key: NULL
       key_len: NULL
         ref: NULL
        rows: 5
   filtered: 20.00
    Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
***** 1. row *****
    Level: Note
     Code: 1003
 Message: /* select#1 */ select `test`.`t`.`ti` AS `ti` from `test`.`t` where (`test`.`t`.`ti` = 255)
1 row in set (0.00 sec)
```

- **Floating- or fixed-point value.** If the constant is one of the decimal types (such as `DECIMAL`, `REAL`, `DOUBLE`, or `FLOAT`) and has a nonzero decimal portion, it cannot be equal; fold accordingly. For other comparisons, round up or down to an integer value according to the sign, then perform a range check and handle as already described for integer-integer comparisons.

A **REAL** value that is too small to be represented as **DECIMAL** is rounded to .01 or -.01 depending on the sign, then handled as a **DECIMAL**.

- **String types.** Try to interpret the string value as an integer type, then handle the comparison as between integer values. If this fails, attempt to handle the value as a **REAL**.
- **DECIMAL or REAL column.** Decimal types are compared with constants of the following types as described here:
 - **Integer value.** Perform a range check against the column value's integer part. If no folding results, convert the constant to **DECIMAL** with the same number of decimal places as the column value, then check it as a **DECIMAL** (see next).
 - **DECIMAL or REAL value.** Check for overflow (that is, whether the constant has more digits in its integer part than allowed for the column's decimal type). If so, fold.

If the constant has more significant fractional digits than column's type, truncate the constant. If the comparison operator is = or <>, fold. If the operator is >= or <=, adjust the operator due to truncation. For example, if column's type is **DECIMAL(3,1)**, **SELECT * FROM t WHERE f >= 10.13** becomes **SELECT * FROM t WHERE f > 10.1**.

If the constant has fewer decimal digits than the column's type, convert it to a constant with same number of digits. For underflow of a **REAL** value (that is, too few fractional digits to represent it), convert the constant to decimal 0.

- **String value.** If the value can be interpreted as an integer type, handle it as such. Otherwise, try to handle it as **REAL**.
- **FLOAT or DOUBLE column.** **FLOAT(m,n)** or **DOUBLE(m,n)** values compared with constants are handled as follows:

If the value overflows the range of the column, fold.

If the value has more than *n* decimals, truncate, compensating during folding. For = and <> comparisons, fold to **TRUE**, **FALSE**, or **IS [NOT] NULL** as described previously; for other operators, adjust the operator.

If the value has more than *m* integer digits, fold.

Limitations. This optimization cannot be used in the following cases:

1. With comparisons using **BETWEEN** or **IN**.
2. With **BIT** columns or columns using date or time types.
3. During the preparation phase for a prepared statement, although it can be applied during the optimization phase when the prepared statement is actually executed. This due to the fact that, during statement preparation, the value of the constant is not yet known.

8.2.1.15 IS NULL Optimization

MySQL can perform the same optimization on **col_name IS NULL** that it can use for **col_name = constant_value**. For example, MySQL can use indexes and ranges to search for **NULL** with **IS NULL**.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;
```

```
SELECT * FROM tbl_name
WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
  OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL)
  OR (t1.b=t2.b AND t2.b IS NULL);
```

8.2.1.16 ORDER BY Optimization

This section describes when MySQL can use an index to satisfy an `ORDER BY` clause, the `filesort` operation used when an index cannot be used, and execution plan information available from the optimizer about `ORDER BY`.

An `ORDER BY` with and without `LIMIT` may return rows in different orders, as discussed in [Section 8.2.1.19, “LIMIT Query Optimization”](#).

- [Use of Indexes to Satisfy ORDER BY](#)
- [Use of filesort to Satisfy ORDER BY](#)
- [Influencing ORDER BY Optimization](#)
- [ORDER BY Execution Plan Information Available](#)

Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an `ORDER BY` clause and avoid the extra sorting involved in performing a `filesort` operation.

The index may also be used even if the `ORDER BY` does not match the index exactly, as long as all unused portions of the index and all extra `ORDER BY` columns are constants in the `WHERE` clause. If

the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on `(key_part1, key_part2)`, the following queries may use the index to resolve the `ORDER BY` part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on `(key_part1, key_part2)` enables the optimizer to avoid sorting:

```
SELECT * FROM t1
ORDER BY key_part1, key_part2;
```

However, the query uses `SELECT *`, which may select more columns than `key_part1` and `key_part2`. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer probably will not use the index. If `SELECT *` selects only the index columns, the index will be used and sorting avoided.

If `t1` is an `InnoDB` table, the table primary key is implicitly part of the index, and the index can be used to resolve the `ORDER BY` for this query:

```
SELECT pk, key_part1, key_part2 FROM t1
ORDER BY key_part1, key_part2;
```

- In this query, `key_part1` is constant, so all rows accessed through the index are in `key_part2` order, and an index on `(key_part1, key_part2)` avoids sorting if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

- In the next two queries, whether the index is used is similar to the same queries without `DESC` shown previously:

```
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2 DESC;
```

- Two columns in an `ORDER BY` can sort in the same direction (both `ASC`, or both `DESC`) or in opposite directions (one `ASC`, one `DESC`). A condition for index use is that the index must have the same homogeneity, but need not have the same actual direction.

If a query mixes `ASC` and `DESC`, the optimizer can use an index on the columns if the index also uses corresponding mixed ascending and descending columns:

```
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 ASC;
```

The optimizer can use an index on `(key_part1, key_part2)` if `key_part1` is descending and `key_part2` is ascending. It can also use an index on those columns (with a backward scan) if `key_part1` is ascending and `key_part2` is descending. See [Section 8.3.13, “Descending Indexes”](#)

- In the next two queries, `key_part1` is compared to a constant. The index will be used if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;

SELECT * FROM t1
WHERE key_part1 < constant
```

```
ORDER BY key_part1 DESC;
```

- In the next query, the `ORDER BY` does not name *key_part1*, but all rows selected have a constant *key_part1* value, so the index can still be used:

```
SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it may still use indexes to find the rows that match the `WHERE` clause. Examples:

- The query uses `ORDER BY` on different indexes:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- The query uses `ORDER BY` on nonconsecutive parts of an index:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1_part1, key1_part3;
```

- The index used to fetch the rows differs from the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- The query uses `ORDER BY` with an expression that includes terms other than the index column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- The query joins many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- The query has different `ORDER BY` and `GROUP BY` expressions.
- There is an index on only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a `CHAR(20)` column are indexed, the index cannot distinguish values past the 10th byte and a `filesort` is needed.
- The index does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` refers to `t1.a` and the index on `t1.a` can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

Previously (MySQL 5.7 and lower), `GROUP BY` sorted implicitly under certain conditions. In MySQL 8.0, that no longer occurs, so specifying `ORDER BY NULL` at the end to suppress implicit sorting (as was done previously) is no longer necessary. However, query results may differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

Use of filesort to Satisfy ORDER BY

If an index cannot be used to satisfy an `ORDER BY` clause, MySQL performs a `filesort` operation that reads table rows and sorts them. A `filesort` constitutes an extra sorting phase in query execution.

To obtain memory for `filesort` operations, as of MySQL 8.0.12, the optimizer allocates memory buffers incrementally as needed, up to the size indicated by the `sort_buffer_size` system variable, rather than allocating a fixed amount of `sort_buffer_size` bytes up front, as was done prior to MySQL 8.0.12. This enables users to set `sort_buffer_size` to larger values to speed up larger sorts, without concern for excessive memory use for small sorts. (This benefit may not occur for multiple concurrent sorts on Windows, which has a weak multithreaded `malloc`.)

A `filesort` operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory `filesort` operations. For example, the optimizer can use `filesort` to efficiently handle in memory, without temporary files, the `ORDER BY` operation for queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

Influencing ORDER BY Optimization

For slow `ORDER BY` queries for which `filesort` is not used, try lowering the `max_length_for_sort_data` system variable to a value that is appropriate to trigger a `filesort`. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.) This technique applies only before MySQL 8.0.20. As of 8.0.20, `max_length_for_sort_data` is deprecated due to optimizer changes that make it obsolete and of no effect.

To increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the `sort_buffer_size` variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes).

Take into account that the size of column values stored in the sort buffer is affected by the `max_sort_length` system variable value. For example, if tuples store values of long string columns and you increase the value of `max_sort_length`, the size of sort buffer tuples increases as well and may require you to increase `sort_buffer_size`.

To monitor the number of merge passes (to merge temporary files), check the `Sort_merge_passes` status variable.

- Increase the `read_rnd_buffer_size` variable value so that more rows are read at a time.
- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different *physical* disks, not different partitions on the same disk.

ORDER BY Execution Plan Information Available

With `EXPLAIN` (see [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)), you can check whether MySQL can use indexes to resolve an `ORDER BY` clause:

- If the `Extra` column of `EXPLAIN` output does not contain `Using filesort`, the index is used and a `filesort` is not performed.
- If the `Extra` column of `EXPLAIN` output contains `Using filesort`, the index is not used and a `filesort` is performed.

In addition, if a `filesort` is performed, optimizer trace output includes a `filesort_summary` block. For example:

```
"filesort_summary": {
  "rows": 100,
  "examined_rows": 100,
  "number_of_tmp_files": 0,
  "peak_memory_used": 25192,
  "sort_mode": "<sort_key, packed_additional_fields>"
}
```

`peak_memory_used` indicates the maximum memory used at any one time during the sort. This is a value up to but not necessarily as large as the value of the `sort_buffer_size` system variable. Prior to MySQL 8.0.12, the output shows `sort_buffer_size` instead, indicating the value of `sort_buffer_size`. (Prior to MySQL 8.0.12, the optimizer always allocates `sort_buffer_size` bytes for the sort buffer. As of 8.0.12, the optimizer allocates sort-buffer memory incrementally, beginning with a small amount and adding more as necessary, up to `sort_buffer_size` bytes.)

The `sort_mode` value provides information about the contents of tuples in the sort buffer:

- `<sort_key, rowid>`: This indicates that sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.
- `<sort_key, additional_fields>`: This indicates that sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.
- `<sort_key, packed_additional_fields>`: Like the previous variant, but the additional columns are packed tightly together instead of using a fixed-length encoding.

`EXPLAIN` does not distinguish whether the optimizer does or does not perform a `filesort` in memory. Use of an in-memory `filesort` can be seen in optimizer trace output. Look for `filesort_priority_queue_optimization`. For information about the optimizer trace, see [MySQL Internals: Tracing the Optimizer](#).

8.2.1.17 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a `BTREE` index, but not for a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

- [Loose Index Scan](#)
- [Tight Index Scan](#)

Loose Index Scan can also be used in the absence of `GROUP BY` under some conditions. See [Skip Scan Range Access Method](#).

Loose Index Scan

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *Loose Index Scan*. When there is no `WHERE` clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range` join type in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` names only columns that form a leftmost prefix of the index and no other columns. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table `t1` has an index on `(c1,c2,c3)`, Loose Index Scan is applicable if the query has `GROUP BY c1, c2`. It is not applicable if the query has `GROUP BY c2, c3` (the columns are not a leftmost prefix) or `GROUP BY c1, c2, c4` (`c4` is not in the index).
- The only aggregate functions used in the select list (if any) are `MIN()` and `MAX()`, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the `GROUP BY`.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with `c1 VARCHAR(20)`, `INDEX (c1(10))`, the index uses only a prefix of `c1` values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the `EXPLAIN` output shows `Using index for group-by` in the `Extra` column.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

```
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.
- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

Tight Index Scan

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a *Tight Index Scan*. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

8.2.1.18 DISTINCT Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see [Section 8.2.1.17, “GROUP BY Optimization”](#).

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

8.2.1.19 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a `LIMIT` clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a `LIMIT row_count` clause and no `HAVING` clause:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you combine `LIMIT row_count` with `ORDER BY`, MySQL stops sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause are selected, and most or all of them are sorted, before the first `row_count` are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an `ORDER BY` query with and without `LIMIT` may return rows in different order, as described later in this section.

- If you combine `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`. In that case, the number of rows can be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.16, “Information Functions”](#).
- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL API that makes result set metadata available. With the `mysql` client program, you can use the `--column-type-info` option to display result column types.
- If the server uses temporary tables to resolve a query, it uses the `LIMIT row_count` clause to calculate how much space is required.
- If an index is not used for `ORDER BY` but a `LIMIT` clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory using an in-memory `filesort` operation.

If multiple rows have identical values in the `ORDER BY` columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is `LIMIT`, so an `ORDER BY` query with and without `LIMIT` may return rows in different orders. Consider this query, which is sorted by the `category` column but nondeterministic with respect to the `id` and `rating` columns:

```
mysql> SELECT * FROM ratings ORDER BY category;
```

id	category	rating
1	1	4.5
5	1	3.2
3	2	3.7
4	2	3.5
6	2	3.5
2	3	5.0
7	3	2.7

Including `LIMIT` may affect order of rows within each `category` value. For example, this is a valid query result:

```
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
```

id	category	rating
1	1	4.5
5	1	3.2
4	2	3.5
3	2	3.7
6	2	3.5

In each case, the rows are sorted by the `ORDER BY` column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without `LIMIT`, include additional columns in the `ORDER BY` clause to make the order deterministic. For example, if `id` values are unique, you can make rows for a given `category` value appear in `id` order by sorting like this:

```
mysql> SELECT * FROM ratings ORDER BY category, id;
```

id	category	rating
1	1	4.5
5	1	3.2
3	2	3.7
4	2	3.5
6	2	3.5
2	3	5.0
7	3	2.7

```
mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
```

id	category	rating
1	1	4.5
5	1	3.2
3	2	3.7
4	2	3.5
6	2	3.5

For a query with an `ORDER BY` or `GROUP BY` and a `LIMIT` clause, the optimizer tries to choose an ordered index by default when it appears doing so would speed up query execution. Prior to MySQL 8.0.21, there was no way to override this behavior, even in cases where using some other optimization

might be faster. Beginning with MySQL 8.0.21, it is possible to turn off this optimization by setting the `optimizer_switch` system variable's `prefer_ordering_index` flag to `off`.

Example: First we create and populate a table `t` as shown here:

```
# Create and populate a table t:

mysql> CREATE TABLE t (
->     id1 BIGINT NOT NULL,
->     id2 BIGINT NOT NULL,
->     c1 VARCHAR(50) NOT NULL,
->     c2 VARCHAR(50) NOT NULL,
->     PRIMARY KEY (id1),
->     INDEX i (id2, c1)
-> );

# [Insert some rows into table t - not shown]
```

Verify that the `prefer_ordering_index` flag is enabled:

```
mysql> SELECT @@optimizer_switch LIKE '%prefer_ordering_index=on%';
+-----+
| @@optimizer_switch LIKE '%prefer_ordering_index=on%' |
+-----+
| 1 |
+-----+
```

Since the following query has a `LIMIT` clause, we expect it to use an ordered index, if possible. In this case, as we can see from the `EXPLAIN` output, it uses the table's primary key.

```
mysql> EXPLAIN SELECT c2 FROM t
->     WHERE id2 > 3
->     ORDER BY id1 ASC LIMIT 2\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: index
possible_keys: i
key: PRIMARY
key_len: 8
ref: NULL
rows: 2
filtered: 70.00
Extra: Using where
```

Now we disable the `prefer_ordering_index` flag, and re-run the same query; this time it uses the index `i` (which includes the `id2` column used in the `WHERE` clause), and a filesort:

```
mysql> SET optimizer_switch = "prefer_ordering_index=off";

mysql> EXPLAIN SELECT c2 FROM t
->     WHERE id2 > 3
->     ORDER BY id1 ASC LIMIT 2\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 8
ref: NULL
rows: 14
filtered: 100.00
Extra: Using index condition; Using filesort
```

See also [Section 8.9.2, “Switchable Optimizations”](#).

8.2.1.20 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: `RAND()`, `UUID()`.

If a function is tagged nondeterministic, a reference to it in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses `RAND()` but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because `POW()` with constant arguments is a constant value and is used for index lookup.
- The second query contains an expression that uses the nondeterministic function `RAND()`, which is not constant in the query but in fact has a new value for every row of table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The effects of nondeterminism are not limited to `SELECT` statements. This `UPDATE` statement uses a nondeterministic function to select rows to be modified:

```
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- `InnoDB` might escalate to a range-key lock rather than taking a single row lock for one matching row.
- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

```
SET @keyval = FLOOR(1 + RAND() * 49);
```

```
UPDATE t SET col_a = some_expr WHERE id = @keyval;
```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:

```
UPDATE /*+ NO_MERGE(dt) */ t, (SELECT FLOOR(1 + RAND() * 49) AS r) AS dt
SET col_a = some_expr WHERE id = dt.r;
```

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the `WHERE` clause if other expressions are deterministic. For example:

```
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

8.2.1.21 Window Function Optimization

Window functions affect the strategies the optimizer considers:

- Derived table merging for a subquery is disabled if the subquery has window functions. The subquery is always materialized.
- Semijoins are not applicable to window function optimization because semijoins apply to subqueries in `WHERE` and `JOIN ... ON`, which cannot contain window functions.
- The optimizer processes multiple windows that have the same ordering requirements in sequence, so sorting can be skipped for windows following the first one.
- The optimizer makes no attempt to merge windows that could be evaluated in a single step (for example, when multiple `OVER` clauses contain identical window definitions). The workaround is to define the window in a `WINDOW` clause and refer to the window name in the `OVER` clauses.

An aggregate function not used as a window function is aggregated in the outermost possible query. For example, in this query, MySQL sees that `COUNT(t1.b)` is something that cannot exist in the outer query because of its placement in the `WHERE` clause:

```
SELECT * FROM t1 WHERE t1.a = (SELECT COUNT(t1.b) FROM t2);
```

Consequently, MySQL aggregates inside the subquery, treating `t1.b` as a constant and returning the count of rows of `t2`.

Replacing `WHERE` with `HAVING` results in an error:

```
mysql> SELECT * FROM t1 HAVING t1.a = (SELECT COUNT(t1.b) FROM t2);
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1
of SELECT list contains nonaggregated column 'test.t1.a'; this is
incompatible with sql_mode=only_full_group_by
```

The error occurs because `COUNT(t1.b)` can exist in the `HAVING`, and so makes the outer query aggregated.

Window functions (including aggregate functions used as window functions) do not have the preceding complexity. They always aggregate in the subquery where they are written, never in the outer query.

Window function evaluation may be affected by the value of the `windowing_use_high_precision` system variable, which determines whether to compute window operations without loss of precision. By default, `windowing_use_high_precision` is enabled.

For some moving frame aggregates, the inverse aggregate function can be applied to remove values from the aggregate. This can improve performance but possibly with a loss of precision. For example, adding a very small floating-point value to a very large value causes the very small value to be “hidden” by the large value. When inverting the large value later, the effect of the small value is lost.

Loss of precision due to inverse aggregation is a factor only for operations on floating-point (approximate-value) data types. For other types, inverse aggregation is safe; this includes `DECIMAL`, which permits a fractional part but is an exact-value type.

For faster execution, MySQL always uses inverse aggregation when it is safe:

- For floating-point values, inverse aggregation is not always safe and might result in loss of precision. The default is to avoid inverse aggregation, which is slower but preserves precision. If it is permissible to sacrifice safety for speed, `windowing_use_high_precision` can be disabled to permit inverse aggregation.
- For nonfloating-point data types, inverse aggregation is always safe and is used regardless of the `windowing_use_high_precision` value.
- `windowing_use_high_precision` has no effect on `MIN()` and `MAX()`, which do not use inverse aggregation in any case.

For evaluation of the variance functions `STDDEV_POP()`, `STDDEV_SAMP()`, `VAR_POP()`, `VAR_SAMP()`, and their synonyms, evaluation can occur in optimized mode or default mode. Optimized mode may produce slightly different results in the last significant digits. If such differences are permissible, `windowing_use_high_precision` can be disabled to permit optimized mode.

For `EXPLAIN`, windowing execution plan information is too extensive to display in traditional output format. To see windowing information, use `EXPLAIN FORMAT=JSON` and look for the `windowing` element.

8.2.1.22 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on `(c1, c2, c3)`:

```
CREATE TABLE t1 (
  c1 INT, c2 INT, c3 INT, c4 CHAR(100),
  PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only `c1` (`key_len=4`, the size of `c1`):

```
mysql> EXPLAIN SELECT * FROM t1
      WHERE c1=1 AND (c2,c3) > (1,1)\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
    partitions: NULL
       type: ref
possible_keys: PRIMARY
         key: PRIMARY
      key_len: 4
         ref: const
        rows: 3
   filtered: 100.00
      Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

```
(c2,c3) > (1,1)
c2 > 1 OR ((c2 = 1) AND (c3 > 1))
```

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (`key_len=12`):

```
mysql> EXPLAIN SELECT * FROM t1
        WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: t1
   partitions: NULL
         type: range
possible_keys: PRIMARY
          key: PRIMARY
       key_len: 12
         ref: NULL
        rows: 3
   filtered: 100.00
      Extra: Using where
```

Thus, for better results, avoid mixing row constructors with `AND/OR` expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to `IN()` expressions that have row constructor arguments. See [Range Optimization of Row Constructor Expressions](#).

8.2.1.23 Avoiding Full Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a [full table scan](#) to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See [Section 8.2.1.1, “WHERE Clause Optimization”](#).
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 13.7.3.1, “ANALYZE TABLE Statement”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
        WHERE t1.col_name=t2.col_name;
```

See [Section 8.9.4, “Index Hints”](#).

- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 5.1.8, “Server System Variables”](#).

8.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

The MySQL query optimizer has different strategies available to evaluate subqueries:

- For a subquery used with an `IN`, `= ANY`, or `EXISTS` predicate, the optimizer has these choices:
 - Semijoin
 - Materialization
 - `EXISTS` strategy
- For a subquery used with a `NOT IN`, `<> ALL` or `NOT EXISTS` predicate, the optimizer has these choices:
 - Materialization
 - `EXISTS` strategy

For a derived table, the optimizer has these choices (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

The following discussion provides more information about the preceding optimization strategies.

Note

A limitation on `UPDATE` and `DELETE` statements that use a subquery to modify a single table is that the optimizer does not use semijoin or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table `UPDATE` and `DELETE` statements that use a join rather than a subquery.

8.2.2.1 Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations

A semijoin is a preparation-time transformation that enables multiple execution strategies such as table pullout, duplicate weedout, first match, loose scan, and materialization. The optimizer uses semijoin strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named `class` and `roster` that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```
SELECT class.class_num, class.class_name
FROM class
INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that `class_num` is a primary key in the `class` table, duplicate suppression is possible by using `SELECT DISTINCT`, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```
SELECT class_num, class_name
FROM class
WHERE class_num IN
  (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the `IN` clause requires the subquery to return only one instance of each class number from the `roster` table. In this case, the query can use a *semijoin*; that is, an operation that returns only one instance of each row in `class` that is matched by rows in `roster`.

The following statement, which contains an `EXISTS` subquery predicate, is equivalent to the previous statement containing an `IN` subquery predicate:

```
SELECT class_num, class_name
  FROM class
 WHERE EXISTS
    (SELECT * FROM roster WHERE class.class_num = roster.class_num);
```

In MySQL 8.0.16 and later, any statement with an `EXISTS` subquery predicate is subject to the same semijoin transforms as a statement with an equivalent `IN` subquery predicate.

Beginning with MySQL 8.0.17, the following subqueries are transformed into antijoins:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`.
- `IN (SELECT ... FROM ...) IS NOT TRUE`
- `EXISTS (SELECT ... FROM ...) IS NOT TRUE.`
- `IN (SELECT ... FROM ...) IS FALSE`
- `EXISTS (SELECT ... FROM ...) IS FALSE.`

In short, any negation of a subquery of the form `IN (SELECT ... FROM ...)` or `EXISTS (SELECT ... FROM ...)` is transformed into an antijoin.

An antijoin is an operation that returns only rows for which there is no match. Consider the query shown here:

```
SELECT class_num, class_name
  FROM class
 WHERE class_num NOT IN
    (SELECT class_num FROM roster);
```

This query is rewritten internally as the antijoin `SELECT class_num, class_name FROM class ANTIJOIN roster ON class_num`, which returns one instance of each row in `class` that is *not* matched by any rows in `roster`. This means that, for each row in `class`, as soon as a match is found in `roster`, the row in `class` can be discarded.

Antijoin transformations cannot in most cases be applied if the expressions being compared are nullable. An exception to this rule is that `(... NOT IN (SELECT ...)) IS NOT FALSE` and its equivalent `(... IN (SELECT ...)) IS NOT TRUE` can be transformed into antijoins.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables, derived tables, view references, or common table expressions.

In MySQL, a subquery must satisfy these criteria to be handled as a semijoin (or, in MySQL 8.0.17 and later, an antijoin if `NOT` modifies the subquery):

- It must be part of an `IN`, `= ANY`, or `EXISTS` predicate that appears at the top level of the `WHERE` or `ON` clause, possibly as a term in an `AND` expression. For example:

```
SELECT ...
  FROM ot1, ...
 WHERE (oe1, ...) IN
    (SELECT ie1, ... FROM it1, ... WHERE ...);
```

Here, `ot_i` and `it_i` represent tables in the outer and inner parts of the query, and `oe_i` and `ie_i` represent expressions that refer to columns in the outer and inner tables.

In MySQL 8.0.17 and later, the subquery can also be the argument to an expression modified by `NOT`, `IS [NOT] TRUE`, or `IS [NOT] FALSE`.

- It must be a single `SELECT` without `UNION` constructs.
- It must not contain a `HAVING` clause.
- It must not contain any aggregate functions (whether it is explicitly or implicitly grouped).
- It must not have a `LIMIT` clause.
- The statement must not use the `STRAIGHT_JOIN` join type in the outer query.
- The `STRAIGHT_JOIN` modifier must not be present.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.
- The subquery may be correlated or uncorrelated. In MySQL 8.0.16 and later, decorrelation looks at trivially correlated predicates in the `WHERE` clause of a subquery used as the argument to `EXISTS`, and makes it possible to optimize it as if it was used within `IN (SELECT b FROM ...)`. The term *trivially correlated* means that the predicate is an equality predicate, that it is the sole predicate in the `WHERE` clause (or is combined with `AND`), and that one operand is from a table referenced in the subquery and the other operand is from the outer query block.
- The `DISTINCT` keyword is permitted but ignored. Semijoin strategies automatically handle duplicate removal.
- A `GROUP BY` clause is permitted but ignored, unless the subquery also contains one or more aggregate functions.
- An `ORDER BY` clause is permitted but ignored, since ordering is irrelevant to the evaluation of semijoin strategies.

If a subquery meets the preceding criteria, MySQL converts it to a semijoin (or, in MySQL 8.0.17 or later, an antijoin if applicable) and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- *Duplicate Weedout*: Run the semijoin as if it was a join and remove duplicate records using a temporary table.
- *FirstMatch*: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- *LooseScan*: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into an indexed temporary table that is used to perform a join, where the index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned. For more information about materialization, see [Section 8.2.2.2, "Optimizing Subqueries with Materialization"](#).

Each of these strategies can be enabled or disabled using the following `optimizer_switch` system variable flags:

- The `semi_join` flag controls whether semijoins are used. Starting with MySQL 8.0.17, this also applies to antijoins.

- If `semijoin` is enabled, the `firstmatch`, `loosescan`, `duplicateweedout`, and `materialization` flags enable finer control over the permitted semijoin strategies.
- If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.
- If `duplicateweedout` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

These flags are enabled by default. See [Section 8.9.2, “Switchable Optimizations”](#).

The optimizer minimizes differences in handling of views and derived tables. This affects queries that use the `STRAIGHT_JOIN` modifier and a view with an `IN` subquery that can be converted to a semijoin. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```
CREATE VIEW v AS
SELECT *
FROM t1
WHERE a IN (SELECT b
            FROM t2);

SELECT STRAIGHT_JOIN *
FROM t3 JOIN v ON t3.x = v.a;
```

The optimizer first looks at the view and converts the `IN` subquery to a semijoin, then checks whether it is possible to merge the view into the outer query. Because the `STRAIGHT_JOIN` modifier in the outer query prevents semijoin, the optimizer refuses the merge, causing derived table evaluation using a materialized table.

`EXPLAIN` output indicates the use of semijoin strategies as follows:

- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` shows the rewritten query, which displays the semijoin structure. (See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).) From this you can get an idea about which tables were pulled out of the semijoin. If a subquery was converted to a semijoin, you will see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.
- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` have their `rowid` in the temporary table.
- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.
- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.
- Temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

In MySQL 8.0.21 and later, a semijoin transformation can also be applied to a single-table `UPDATE` or `DELETE` statement that uses a `[NOT] IN` or `[NOT] EXISTS` subquery predicate, provided that the statement does not use `ORDER BY` or `LIMIT`, and that semijoin transformations are allowed by an optimizer hint or by the `optimizer_switch` setting.

8.2.2.2 Optimizing Subqueries with Materialization

The optimizer uses materialization to enable more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The optimizer may

index the table with a hash index to make lookups fast and inexpensive. The index contains unique values to eliminate duplicates and make the table smaller.

Subquery materialization uses an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following `IN` subquery is noncorrelated (*where_condition* involves only columns from `t2` and not `t1`):

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an `EXISTS` correlated subquery:

```
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the `optimizer_switch` system variable `materialization` flag must be enabled. (See [Section 8.9.2, “Switchable Optimizations”](#).) With the `materialization` flag enabled, materialization applies to subquery predicates that appear anywhere (in the select list, `WHERE`, `ON`, `GROUP BY`, `HAVING`, or `ORDER BY`), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression `oe_i` or inner expression `ie_i` is nullable. `N` is 1 or larger.

```
(oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, ie_2, ..., ie_N ...)
```

- The predicate has this form, when there is a single outer expression `oe` and inner expression `ie`. The expressions can be nullable.

```
oe [NOT] IN (SELECT ie ...)
```

- The predicate is `IN` or `NOT IN` and a result of `UNKNOWN` (`NULL`) has the same meaning as a result of `FALSE`.

The following examples illustrate how the requirement for equivalence of `UNKNOWN` and `FALSE` predicate evaluation affects whether subquery materialization can be used. Assume that *where_condition* involves columns only from `t2` and not `t1` so that the subquery is noncorrelated.

This query is subject to materialization:

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

Here, it does not matter whether the `IN` predicate returns `UNKNOWN` or `FALSE`. Either way, the row from `t1` is not included in the query result.

An example where subquery materialization is not used is the following query, where `t2.b` is a nullable column:

```
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
                        WHERE where_condition);
```

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal, but cannot if one expression is integer and the other is decimal.

- The inner expression cannot be a `BLOB`.

Use of `EXPLAIN` with a query provides some indication of whether the optimizer uses subquery materialization:

- Compared to query execution that does not use materialization, `select_type` may change from `DEPENDENT SUBQUERY` to `SUBQUERY`. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once.
- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` includes `materialize` and `materialized-subquery`.

In MySQL 8.0.21 and later, MySQL can also apply subquery materialization to a single-table `UPDATE` or `DELETE` statement that uses a `[NOT] IN` or `[NOT] EXISTS` subquery predicate, provided that the statement does not use `ORDER BY` or `LIMIT`, and that subquery materialization is allowed by an optimizer hint or by the `optimizer_switch` setting.

8.2.2.3 Optimizing Subqueries with the EXISTS Strategy

Certain optimizations are applicable to comparisons that use the `IN` (or `=ANY`) operator to test subquery results. This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery's `WHERE` clause to make it more restrictive. The converted comparison looks like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN  
(SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where  
      AND oe_1 = ie_1  
      AND ...  
      AND oe_N = ie_N)
```

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The “pushdown” strategy just described works if either of these conditions is true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You need not distinguish `NULL` from `FALSE` subquery results. If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you do not care. Another instance where the optimizer notices that `NULL` and `FALSE` subquery results need not be distinguished is this construct:

```
... WHERE outer_expr IN (subquery)
```

In this case, the `WHERE` clause rejects the row whether `IN (subquery)` returns `NULL` or `FALSE`.

Suppose that *outer_expr* is known to be a non-`NULL` value but the subquery does not produce a row such that *outer_expr* = *inner_expr*. Then *outer_expr* `IN` (`SELECT ...`) evaluates as follows:

- `NULL`, if the `SELECT` produces any row where *inner_expr* is `NULL`
- `FALSE`, if the `SELECT` produces only non-`NULL` values or produces nothing

In this situation, the approach of looking for rows with *outer_expr* = *inner_expr* is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where *inner_expr* is `NULL`. Roughly speaking, the subquery can be converted to something like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
        (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` condition is why MySQL has the `ref_or_null` access method:

```
mysql> EXPLAIN
        SELECT outer_expr IN (SELECT t2.maybe_null_key
                               FROM t2, t3 WHERE ...)
        FROM t1;
***** 1. row *****
      id: 1
  select_type: PRIMARY
      table: t1
  ...
***** 2. row *****
      id: 2
  select_type: DEPENDENT SUBQUERY
      table: t2
        type: ref_or_null
possible_keys: maybe_null_key
         key: maybe_null_key
      key_len: 5
         ref: func
        rows: 2
      Extra: Using where; Using index
  ...
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or `NULL`” variants.

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when *outer_expr* can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- `NULL`, if the `SELECT` produces any rows
- `FALSE`, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so *outer_expr* = *inner_expr* cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of *outer_expr*.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that *outer_expr* might be `NULL`:

- If `outer_expr` is `NULL`, to evaluate the following expression, it is necessary to execute the `SELECT` to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to execute the original `SELECT` here, without any pushed-down equalities of the kind mentioned previously.

- On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

And converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(oe_1=ie_1)
      AND ...
      AND trigcond(oe_N=ie_N)
    )
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression `oe_i` is not `NULL`
- `TRUE` when the “linked” outer expression `oe_i` is `NULL`

Note

Trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped within `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as `Full scan on NULL key` in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1,
      t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: key1
      key: key1
      key_len: 5
      ref: func
      rows: 2
      Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
***** 1. row *****
      Level: Note
      Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
      <in_optimizer>(`test`.`t1`.`col1`,
      <exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
      on key1 checking NULL
      where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
      trigcond(<is_not_null_test>(`test`.`t2`.`key1`)))) AS
      `t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
      from `test`.`t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` is particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as `NOT NULL` if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.
- If you need not distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr [NOT] IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr [NOT] IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

Another possible rewrite:

```
[NOT] EXISTS (SELECT inner_expr FROM ...  
              WHERE inner_expr=outer_expr)
```

The `subquery_materialization_cost_based` flag of the `optimizer_switch` system variable enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See [Section 8.9.2, “Switchable Optimizations”](#).

8.2.2.4 Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization

The optimizer can handle derived table references using two strategies (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

Example 1:

```
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging of the derived table `derived_t1`, that query is executed similar to:

```
SELECT * FROM t1;
```

Example 2:

```
SELECT *  
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1  
WHERE t1.f1 > 0;
```

With merging of the derived table `derived_t2`, that query is executed similar to:

```
SELECT t1.*, t2.f1  
FROM t1 JOIN t2 ON t1.f2=t2.f1  
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are each treated as a separate table within their respective queries.

The optimizer handles derived tables, view references, and common table expressions the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see [Section 8.2.2.2, “Optimizing Subqueries with Materialization”](#).)

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

The optimizer propagates an `ORDER BY` clause in a derived table or view reference to the outer query block if these conditions are all true:

- The outer query is not grouped or aggregated.
- The outer query does not specify `DISTINCT`, `HAVING`, or `ORDER BY`.
- The outer query has this derived table or view reference as the only source in the `FROM` clause.

Otherwise, the optimizer ignores the `ORDER BY` clause.

The following means are available to influence whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block:

- The `MERGE` and `NO_MERGE` optimizer hints can be used. They apply assuming that no other rule prevents merging. See [Section 8.9.3, “Optimizer Hints”](#).

- Similarly, you can use the `derived_merge` flag of the `optimizer_switch` system variable. See [Section 8.9.2, “Switchable Optimizations”](#). By default, the flag is enabled to permit merging. Disabling the flag prevents merging and avoids `ER_UPDATE_TABLE_USED` errors.

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an `ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes precedence over the `derived_merge` value.

- It is possible to disable merging by using in the subquery any constructs that prevent merging, although these are not as explicit in their effect on materialization. Constructs that prevent merging are the same for derived tables, common table expressions, and view references:
 - Aggregate functions or window functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
 - `DISTINCT`
 - `GROUP BY`
 - `HAVING`
 - `LIMIT`
 - `UNION` or `UNION ALL`
 - Subqueries in the select list
 - Assignments to user variables
 - References only to literal values (in this case, there is no underlying table)

If the optimizer chooses the materialization strategy rather than merging for a derived table, it handles the query as follows:

- The optimizer postpones derived table materialization until its contents are needed during query execution. This improves performance because delaying materialization may result in not having to do it at all. Consider a query that joins the result of a derived table to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the derived table.
- During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following `EXPLAIN` statement, for a `SELECT` query that contains a derived table:

```
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the derived table by delaying it until the result is needed during `SELECT` execution. In this case, the query is not executed (because it occurs in an `EXPLAIN` statement), so the result is never needed.

Even for queries that are executed, delay of derived table materialization may enable the optimizer to avoid materialization entirely. When this happens, query execution is quicker by the time needed to perform materialization. Consider the following query, which joins the result of a derived table to another table:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the derived table need not be materialized.

For cases when a derived table requires materialization, the optimizer may add an index to the materialized table to speed up access to it. If such an index enables [ref](#) access to the table, it can greatly reduce amount of data read during query execution. Consider the following query:

```
SELECT *
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2
ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column [f1](#) from [derived_t2](#) if doing so would enable use of [ref](#) access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If [ref](#) access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

For optimizer trace output, a merged derived table or view reference is not shown as a node. Only its underlying tables appear in the top query's plan.

What is true for materialization of derived tables is also true for common table expressions (CTEs). In addition, the following considerations pertain specifically to CTEs.

If a CTE is materialized by a query, it is materialized once for the query, even if the query references it several times.

A recursive CTE is always materialized.

If a CTE is materialized, the optimizer automatically adds relevant indexes if it estimates that indexing will speed up access by the top-level statement to the CTE. This is similar to automatic indexing of derived tables, except that if the CTE is referenced multiple times, the optimizer may create multiple indexes, to speed up access by each reference in the most appropriate way.

The [MERGE](#) and [NO_MERGE](#) optimizer hints can be applied to CTEs. Each CTE reference in the top-level statement can have its own hint, permitting CTE references to be selectively merged or materialized. The following statement uses hints to indicate that [cte1](#) should be merged and [cte2](#) should be materialized:

```
WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT /*+ MERGE(cte1) NO_MERGE(cte2) */ cte1.b, cte2.d
FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

The [ALGORITHM](#) clause for [CREATE VIEW](#) does not affect materialization for any [WITH](#) clause preceding the [SELECT](#) statement in the view definition. Consider this statement:

```
CREATE ALGORITHM={TEMPTABLE|MERGE} VIEW v1 AS WITH ... SELECT ...
```

The [ALGORITHM](#) value affects materialization only of the [SELECT](#), not the [WITH](#) clause.

Prior to MySQL 8.0.16, if [internal_tmp_disk_storage_engine=MYISAM](#), an error occurred for any attempt to materialize a CTE using an on-disk temporary table, since for CTEs, the storage engine used for on-disk internal temporary tables could not be [MyISAM](#). Beginning with MySQL 8.0.16, this is no longer an issue, since [TempTable](#) now always uses [InnoDB](#) for on-disk internal temporary tables.

As mentioned previously, a CTE, if materialized, is materialized once, even if referenced multiple times. To indicate one-time materialization, optimizer trace output contains an occurrence of [creating_tmp_table](#) plus one or more occurrences of [reusing_tmp_table](#).

CTEs are similar to derived tables, for which the [materialized_from_subquery](#) node follows the reference. This is true for a CTE that is referenced multiple times, so there is no duplication of [materialized_from_subquery](#) nodes (which would give the impression that the subquery is executed multiple times, and produce unnecessarily verbose output). Only one reference to the CTE has a complete [materialized_from_subquery](#) node with the description of its subquery plan.

Other references have a reduced `materialized_from_subquery` node. The same idea applies to `EXPLAIN` output in `TRADITIONAL` format: Subqueries for other references are not shown.

8.2.2.5 Derived Condition Pushdown Optimization

MySQL 8.0.22 and later supports derived condition pushdown for eligible subqueries. For a query such as `SELECT * FROM (SELECT i, j FROM t1) AS dt WHERE i > constant`, it is possible in many cases to push the the outer `WHERE` condition down to the derived table, in this case resulting in `SELECT * FROM (SELECT i, j FROM t1 WHERE i > constant) AS dt`. When a derived table cannot be merged into the outer query (for example, if the derived table uses aggregation), pushing the outer `WHERE` condition down to the derived table should decrease the number of rows that need to be processed and thus speed up execution of the query.

Note

Prior to MySQL 8.0.22, if a derived table was materialized but not merged, MySQL materialized the entire table, then qualified all of the resulting rows with the `WHERE` condition. This is still the case if derived condition pushdown is not enabled, or cannot be employed for some other reason.

Outer `WHERE` conditions can be pushed down to derived materialized tables under the following circumstances:

- When the derived table uses no aggregate or window functions, the outer `WHERE` condition can be pushed down to it directly. This includes `WHERE` conditions having multiple predicates joined with `AND`, `OR`, or both.

For example, the query `SELECT * FROM (SELECT f1, f2 FROM t1) AS dt WHERE f1 < 3 AND f2 > 11` is rewritten as `SELECT f1, f2 FROM (SELECT f1, f2 FROM t1 WHERE f1 < 3 AND f2 > 11) AS dt`.

- When the derived table has a `GROUP BY` and uses no window functions, an outer `WHERE` condition referencing one or more columns which are not part of the `GROUP BY` can be pushed down to the derived table as a `HAVING` condition.

For example, `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE sum > 100` is rewritten following derived condition pushdown as `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j HAVING sum > 100) AS dt`.

- When the derived table uses a `GROUP BY` and the columns in the outer `WHERE` condition are `GROUP BY` columns, the `WHERE` conditions referencing those columns can be pushed down directly to the derived table.

For example, the query `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE i > 10` is rewritten as `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 WHERE i > 10 GROUP BY i, j) AS dt`.

In the event that the outer `WHERE` condition has predicates referencing columns which are part of the `GROUP BY` as well as predicates referencing columns which are not, predicates of the former sort are pushed down as `WHERE` conditions, while those of the latter type are pushed down as `HAVING` conditions. For example, in the query `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE i > 10 AND sum > 100`, the predicate `i > 10` in the outer `WHERE` clause references a `GROUP BY` column, whereas the predicate `sum > 100` does not reference any `GROUP BY` column. Thus the derived table pushdown optimization causes the query to be rewritten in a manner similar to what is shown here:

```
SELECT * FROM (
  SELECT i, j, SUM(k) AS sum FROM t1
    WHERE i > 10
    GROUP BY i, j
    HAVING sum > 100
) AS dt;
```

- If the derived table uses a window function and the outer `WHERE` references columns used in the window function's `PARTITION` clause, the `WHERE` condition can be pushed down to a `HAVING` condition if there is a `GROUP BY`; otherwise, it can be pushed to the `WHERE` condition in the derived table. For example, the query `SELECT * FROM (SELECT i, j, SUM(k) OVER (PARTITION BY j) AS sum FROM t1) AS dt WHERE j > 10` can be rewritten as `SELECT * FROM (SELECT i, j, SUM(k) OVER (PARTITION BY j) AS sum FROM t1 WHERE j > 10) AS dt`.

In cases in which the derived table uses a window function, predicates in the outer `WHERE` clause can sometimes be pushed down separately according to the rules already given. In the query `SELECT * FROM (SELECT i, j, MIN(k) AS min, SUM(k) OVER (PARTITION BY i) AS sum FROM t1 GROUP BY i, j) AS dt WHERE i > 10 AND min < 3`, the predicate `i > 10` references the column used in `PARTITION BY`, and so can be pushed down directly; `min < 3` does not reference any columns in either of the `PARTITION BY` or `GROUP BY` clauses but can be pushed down as a `HAVING` condition. This means that the query can be rewritten like this:

```
SELECT * FROM (
  SELECT i, j, MIN(k) AS min, SUM(k) OVER (PARTITION BY i) AS sum
  FROM t1
  WHERE i > 10
  GROUP BY i, j
  HAVING MIN < 3
) AS dt;
```

To enable derived condition pushdown, the `optimizer_switch` system variable's `derived_condition_pushdown` flag (added in this release) must be set to `on`, which is the default setting. If this optimization is disabled by `optimizer_switch`, you can enable it for a specific query using the `DERIVED_CONDITION_PUSHDOWN` optimizer hint. To disable the optimization for a given query, use the `NO_DERIVED_CONDITION_PUSHDOWN` optimizer hint.

The following restrictions and limitations apply to the derived table condition pushdown optimization:

- The optimization cannot be used if the derived table contains `UNION`.
- The derived table cannot use a `LIMIT` clause.
- Conditions containing subqueries cannot be pushed down.
- The optimization cannot be used if the derived table is an inner table of an outer join.
- If a materialized derived table is a common table expression, conditions are not pushed down to it if it is referenced multiple times.
- Conditions using parameters can be pushed down if the condition is of the form `derived_column > ?`. If a derived column in an outer `WHERE` condition is an expression having a `?` in the underlying derived table, this condition cannot be pushed down.

8.2.3 Optimizing INFORMATION_SCHEMA Queries

Applications that monitor databases may make frequent use of `INFORMATION_SCHEMA` tables. To write queries for these tables most efficiently, use the following general guidelines:

- Try to query only `INFORMATION_SCHEMA` tables that are views on data dictionary tables.
- Try to query only for static metadata. Selecting columns or using retrieval conditions for dynamic metadata along with static metadata adds overhead to process the dynamic metadata.

Note

Comparison behavior for database and table names in `INFORMATION_SCHEMA` queries might differ from what you expect. For details, see [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

These [INFORMATION_SCHEMA](#) tables are implemented as views on data dictionary tables, so queries on them retrieve information from the data dictionary:

Some types of values, even for a non-view [INFORMATION_SCHEMA](#) table, are retrieved by lookups from the data dictionary. This includes values such as database and table names, table types, and storage engines.

Some [INFORMATION_SCHEMA](#) tables contain columns that provide table statistics:

```
STATISTICS.CARDINALITY
TABLES.AUTO_INCREMENT
TABLES.AVG_ROW_LENGTH
TABLES.CHECKSUM
TABLES.CHECK_TIME
TABLES.CREATE_TIME
TABLES.DATA_FREE
TABLES.DATA_LENGTH
TABLES.INDEX_LENGTH
TABLES.MAX_DATA_LENGTH
TABLES.TABLE_ROWS
TABLES.UPDATE_TIME
```

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the `mysql.index_stats` and `mysql.table_stats` dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the `mysql.index_stats` and `mysql.table_stats` dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire.

The `information_schema_stats_expiry` session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use `ANALYZE TABLE`.
